Die User sind kritisch, vor allem, wenn es von der US-Regierung stammt, der kein Vertrauen entgegengebracht wird. Exemplarisch belegbar ist dies mit einer Diskussion: @syrmukhabarat postete eine Collage aus sechs kleineren Bildern von männlichen, blutüberströmten Leichen, die mit dem Logo der syrisch-arabischen Armee dekoriert ist, und einen Link zu einem Zeitungsartikel (Abbildung 2): „*Here are the Rebels that were ambushed trying to escape Krak des Chevaliers into Lebanon*“ (20.03.2014). Der Kommentar von @syrmukhabarat ordnet die Toten den Rebellengruppen zu. Der Zeitungsartikel titelt: „*11 rebels killed fleeing famed Crusader fort: Syria army*“ (20.03.2014). Damit stellt er zwischen beiden einen Zusammenhang her, obwohl die Quelle des Bildes unklar ist. @ThinkAgain_DOS kommentiert: *„[…] They could also be #alquaeda fighters whom #Assad used to send to Iraq and Lebanon #thinkagainturnaway”* (20.03.2014). Dadurch wird die Diskussion über die nicht vorhandene Quelle des Bildes eröffnet und weitere Spekulationen angestellt.

Abbildung 3: Bildkampagne von @ThinkAgain_DOS

Abbildung 4: Bildkampagne von @ThinkAgain_DOS

Abbildung 5: Tweet von @AverageMohamed

Neben den Presseartikeln postet @ThinkAgain_DOS auch Bilder oder Videos, die aufklärerische Botschaften übermitteln sollen. Unter #UnitedAgainstDaesh wurde ein Bild (Abbildung 3, 09.03.2016) gepostet, welches eine irakische Frau und ein Mädchen zeigt, die nebeneinander ernst auf einem Sofa sitzen: *„'For one hour a day they electrocuted me: cables to my head, hands and feet. I was crying and begging him to stop, but he wouldn't listen.' Iraqi woman held captive by ISIS for 4 months"*. Der Kommentar zu dem Bild lautet: *„#UnitedAgainstDaesh: Coalition seeks to destroy the evil perpetrators of extreme violence against"*. Ziel dieses Posts ist es, den Vorwürfen gegen ISIS, gewalttätig und skrupellos zu sein, ein Gesicht zu verleihen.

Am 13.03.2016 postet @ThinkAgain_DOS ein weiteres Bild (Abbildung 4), auf dem eine Frau und ein Mädchen abgebildet sind, welche gemeinsam ein Schild hochhalten. Der Text darauf lautet: *„ISIS DOES NOT REPRESENT ISLAM“*. Frau und Mädchen blicken genau in die Kamera. Dies erweckt den Eindruck, dass sie den Betrachter des Bildes direkt ansehen. Dieses vermutliche Mutter-Tochter-Gespann soll jedoch kein Mitleid erregen, sondern dem Betrachtet vermittelt, dass hier zwei starke muslimische Frauen für die Aufklärung über ISIS einstehen. Das Bild bleibt unkommentiert, es wurde nur mit den Hashtags #NoToDaesh und #DaeshLiesExposed versehen. Die beiden Frauen stehen symbolisch für alle modernen Musliminnen, die ISIS nicht unterstützen und sich nicht diskriminieren lassen.

@AverageMohamed, eine Art Kunstfigur, hingegen produziert Cartoons, die zum Ziel haben, Jugendliche durch Aufklärung vor Radikalisierung zu schützen. Über ihn und seine Arbeit wurde in *The Guardian, The Telegraph* sowie in Radio *Bayern 2* berichtet. Er postet einen Link zu einem seiner YouTube-Videos (Abbildung 5, 21.10.2015), welches mit „Identity in Islam“ betitelt und mit verschiedenen Hashtags (#almuhajirah, #jondi) versehen ist. Diese Hashtags werden unter anderem auch von terroristischen Organisationen genutzt und sollen die Propaganda-Arbeit unterlaufen und radikalisierungsgefährdete Jugendliche erreichen. Das Video behandelt die Frage nach Gesellschaft, Religion und Identität. Er wirbt für Vielfalt und Toleranz und erklärt diese zu Bestandteilen des Islams. Damit versucht er Argumenten der Extremisten entgegenzuwirken, die behaupten, es sei Allahs Wille alle Ungläubigen zu töten.

Abbildung 6: #TrollingDay IS-Kämpfer als Quietscheenten

Abbildung 7: #TrollingDay IS-Kämpfer mit Ziegen

Kategorie II: Parodie und Satire. Parodie ist laut Duden eine komisch-satirische Nachahmung durch Stilmittel wie Verzerrung und Übertreibung. Die Satire ist eine Kunstgattung, die an Ereignissen Kritik übt und sie der Lächerlichkeit preisgibt. Beides zielt darauf ab, Spott über ernsthafte Begebenheiten zu äußern.

Unter dem Hashtag #TrollingISIS bzw. #TrollingDay konnten wir hauptsächlich Bilder identifizieren, die sich in offensichtlicher Art über den IS lustig machen. Das Hacker-Netzwerk *Anonymous* erklärte den 11. Dezember zum „ISIS Trolling Day“ und rief auf der Webseite Ghostbin dazu auf, die satirische Stärke des Internets zu nutzen, um Memes und Cartoons zu posten, die den IS ins Lächerliche ziehen. Dieser Plan ist Teil der Operation von *Anonymous*, die seit den Anschlägen am 13.11.2015 in Paris Cyberkrieg gegen ISIS führen. Unter #TrollingISIS und #TrollingDay wurde eine Flut modifizierter ISIS Bilder gepostet. Ein beliebtes Element, das sich schnell verbreitete, war das Ersetzen der Köpfe von den ISIS-Kämpfern durch gelbe Quietscheenten-Köpfe. Statt Waffen halten die Kämpfer Klobürsten in die Luft (Abbildung 6).

Explizit von *Anonymous* aufgerufen wurde zu der Benutzung von Ziegen auf den Bildern: „*post photos of goats while @ing Isis members with captions talking about* *their wives*“. Diese Art der Parodie beruht auf dem Gerücht, der Prophet Mohammed habe Sodomie mit Ziegen gepflegt. Da Geschlechtsverkehr im Islam weitestgehend ein Tabu-Thema ist, trifft dieser Vorwurf ganz besonders den Nerv. Diese Art der Kritik am Islam, insbesondere am IS, ist somit stark politisch motiviert. In Abbildung 7 sind IS-Kämpfer zu sehen, die auf überdimensionalen Ziegen reiten und eine schwarze ISIS-Fahne mit der Aufschrift „We Fuck Goats“ schwingen.

Abbildung 8: #TrollingDay IS-Kämpfer mit Dildos

Abbildung 9: #TrollingDay Abu Bakr al-Baghdadi mit Waschmittel

Eine weitere beliebte Darstellung sind ISIS-Kämpfer in Verbindung mit Homosexualität. Im Islam gilt gleichgeschlechtlicher Verkehr als Unzucht und ist untersagt. In Abbildung 8 sind bewaffnete IS-Kämpfer zu sehen, deren Geschosse in überdimensionale Dildos verwandelt wurden. Ein anderes Thema verschiedener Tweets des Trolling Days ist die mangelnde Intelligenz des IS. Der abgebildete Post zeigt zum Beispiel den ISIS-Anführer Abu Bakr al-Baghdadi mit dem Waschmittel *Daesh* (Abbildung 9). Der Hashtag #Daeshbag ist angelehnt an das Wort „douchebag“, was umgangssprachlich Trottel bedeutet. Mit der Waschmittelwerbung wird der IS – im wahrsten Sinne – verweichlicht dargestellt. Die Gehirnwäsche, die durch Propaganda und Rekrutierung stattfindet, macht die Anhänger zu Marionetten des IS, individuelle Meinungen werden abgelehnt, so die Intension der Gegenpropaganda.

Neben den politisch motivierten Satiremaßnahmen, die eine zielgerichtete Intention der Gegenpropaganda bilden, gibt es auch reine Parodien des IS. Ein solches Beispiel ist das Hashtag #ISISChan oder „ISIS_Chan“. Dort findet man bei Twitter Bilder eines grünhaarigen Anime-Mädchens im schwarzen Dschihadisten-Outfit mit einer Melone. ISIS-Chan wurde von Usern der japanischen Textboard-Seite 2channel kreiert (Abbildung 10). Am 24.01.2015 wurde ein Thread mit dem Titel „*Let’s make ISIS into a moe girl and send it to them!*”[1] erstellt. Eine Google-Bombe sollte die Ergebnisse der Bildersuche zu „ISIS“ mit Darstellungen von dem Anime-Mädchen füllen. In den ersten 24 Stunden wurden die Hashtags auf Twitter 9.000 Mal verwendet (ebd.). Abbildung 11 zeigt ISIS-Chan mit einer Melone auf einem Teller. Sie hält das Messer falsch herum an ihre Kehle. Der Zeichner erklärte, dass sie dem ISIS beibringen wolle, wofür Messer wirklich da sind - nämlich um Melonen zu schneiden.[2]

[1] http://knowyourmeme.com/memes/isis-chan
[2] http://www.dw.com/en/melons-instead-of-tanks-meet-isis-chan-the-anime-that-fights-islamic-state/a-18698611

Abbildung 10: Richtlinien für ISIS-Chan

Abbildung 11: ISIS-Chan mit Melone

Eine japanische Photoshop und Hashtag Kampagne zeigt bearbeitete Bilder des IS mit zwei japanischen Geiseln (#ISISCrappyCollageGrandPrix[3]). Am 20.01.2015 veröffentlichte ISIS ein Video auf YouTube, in dem ein maskierter Kämpfer droht, zwei japanische Geiseln umzubringen, wenn Japan keine zwei Millionen Dollar Lösegeld zahle. Als Antwort twitterten japanische User Parodien des Videos mit dem Hashtag. Abbildung 12 zeigt den IS-Anhänger wie er mit seinem Messer einen Kebab schneidet, worauf teilweise Hass-Kommentare der IS-Anhänger unter den Bildern erschienen, wie: „*Japanese people, You are so optimistic Is it because he said 5800 kms you think you are safe zone. We have army everywhere.*“[4]

Abbildung 12: #ISISCrappyCollageGrandPrix IS-Kämpfer mit Döner

Abbildung 13: @isis_karaoke IS-Kämpfer tanzen vermeintlich zu „Styain‘ alive“

Am 26.12.2015 rief der selbsternannte Kalif des IS Abu Bakr al-Baghdadi in einer Audiobotschaft alle Muslime dazu auf, sich dem Kampf anzuschließen. Allerdings sagten viele Muslime auf Twitter dem IS mit Begründungen wie „*Mein Goldfisch ist krank, ich muss leider zum Tierarzt*“ oder „*Sorry, ich bin beschäftigt mit Netflix*

[3] http://www.stuff.co.nz/world/asia/65395382/japan-launches-crappy-meme-war-with-islamic-state
[4] http://knowyourmeme.com/memes/isis-crappy-collage-grand-prix 21.01.2015

gucken.“ ab. Den Muslimen war es wichtig zu zeigen, dass normale Bürger wichtigere Dinge zu tun haben, als einem weltweiten Religionskrieg beizutreten. Der Account ISIS_Karaoke agiert nach dem Motto „dropping songs, not bombs“ und versehrt Fotos von IS-Kämpfern mit Zeilen aus bekannten Pop-Songs. Hintergrund dazu ist das neuerliche Musikverbot des IS in Racca, der Hauptstadt des sogenannten Kalifats[5]. Abbildung 13 zeigt Dschihadisten, die vermeintlich zu „Stayin‘ alive“ von den Bee Gees performen.

Abbildung 14: Tweet von @Operation_ISIL

Abbildung 15: Tweets zu #GhostSecGroup

Kategorie III: Hacking. Eine weitere Kategorie der Terrorismusbekämpfung umfasst das Hacking. „*Das Hacker-Netzwerk Anonymous hat dem Islamischen Staat (IS) nach der Terrorserie in Paris mit martialischen Worten den virtuellen Krieg erklärt*“[6]. Nach den Pariser Anschlägen 2015 haben sich Hacker, auch außerhalb von *Anonymous*, weltweit dem Kampf gegen ISIS in den sozialen Netzwerken verschrieben.

Abbildung 14 zeigt den Tweet von @Operation_ISIL vom 16.03.2016. Er listet Hashtags auf, welche zu ähnlichen Themen führen und ein Word-Dokument mit einer Reihe von Accounts, die unschädlich gemacht wurden. Abbildung 15 verdeutlicht, dass für jeden die Möglichkeit besteht, sich am Kampf gegen extremistische Gruppen zu beteiligen. Hierfür werden unter entsprechender Anleitung alle User aufgefordert, auffällige Accounts zu melden. Weitere Aktivitäten bleiben dem sozialen Netzwerk verborgen, denn es handelt sich um illegale Aktivitäten, die nicht für die Öffentlichkeit bestimmt sind. Der Erfolg dieser Hackerangriffe bleibt dabei fraglich, da trotz vieler Sperren zahlreiche Seiten aufrufbar sind. Hacker können ebenfalls von ISIS-Usern „gejagt“ werden. Sie bekämpfen sich untereinander und rufen sich gegenseitig zur Jagd auf. In dem Post vom 18.03.2016, macht @intel_ghost auf einen deutschen 'pro-IS' Rapper aufmerksam und fordert die Community auf „Go get him!“. Die Hacker-Szene beteiligt sich rege an den parodistischen Bildern und Videos und verbreitet diese weiter. Hacking bezieht sich somit sowohl auf illegale Aktivitäten, wie beispielsweise die Sperrung von Accounts und den Aufruf an die Bevölkerung, verdächtige Personen zu melden, als auch auf legale Aktivitäten, indem parodistische Medien vermehrt werden.

4 Diskussion: Wirksamkeit der Gegenmaßnahmen

Soziale Medien können einen Beitrag zur Terrorbekämpfung leisten, wie bereits die Literaturstudie dargestellt hat [10, 17, 20, 21, 24]. Die Maßnahmen gegen terroristische Propaganda auf Twitter sind, wie wir beobachten konnten, sehr rege. Die Hauptarbeit von @ThinkAgain_DOS, welche hier stellvertretend für die US-Regierung eingesetzt ist, besteht nur im Verbreiten von Artikeln. Diese Art der aufklärerischen Maßnahmen ist sehr passiv und reaktionär. Die „Aufklärer" erheben für sich den Anspruch, die Wahrheit zu verbreiten, im Gegensatz zu den Lügen der Terroristen. Gartenstein-Ross [17] führt aus, dass die Schwachstelle des IS seine Glaubwürdigkeit ist und terroristische Kommunikationsstrategien durch technische (Hacking) und vor allem psychologische (Gegenpropaganda) Mittel gestoppt werden können. Allerdings haben die Gegenmaßnahmen das gleiche Problem der Glaubwürdigkeit, wie wir in der Analyse feststellten (vgl. Diskussion ausgelöst von @syrmukhabarat vom 20.03.2014). So haben auch die USA Probleme mit der Glaubwürdigkeit, allerdings zählen sie in den Augen ihrer Gegner selbst zu den Terrorristen. An dieser Stelle haben User wie @AverageMohamed bessere Chancen, positiv wahrgenommen zu werden. Er ist als Muslim glaubwürdiger, wenn er über den Islam aufklärt. Insgesamt werden unterschiedliche Aufklärungsstrategien sichtbar, die auch mit der jeweils eingenommenen Rolle (Regierung, lokale Organisation, politische Organisation, Privatperson) zusammenhängen.

Es fällt überraschenderweise auf, dass die vermeintlich privaten User wesentlich produktiver sind, als offizielle Accounts: In unserer Studie verzeichneten diese eine wesentlich höhere Anzahl an Retweets. Die offiziellen Accounts (z.B. @TheGEC oder @ThinkAgain_DOS) machen sich reichweitenerhöhende Hashtags weniger zunutze als die private Szene. Möglicherweise liegt dies daran, dass von offizieller Seite mehr verdeckt gearbeitet wird. Die Twitter-Nutzer bekämpfen mit Strategien der Gegenpropaganda, wie beispielsweise Satire, den gemeinsamen Feind IS. Parodistische Bildbearbeitungen erfreuen sich großer Beliebtheit im Netz und animieren offenbar zum Mitmachen. Einerseits reagieren Terrorristen mit extremen Drohungen auf die bearbeiteten Bilder und den damit einhergehenden Spott, andererseits gilt auch für den IS, dass jede Beachtung und Verbreitung gut ist. Die aufklärerische Arbeit findet ebenfalls Beachtung, jedoch erhält sie bei Weitem nicht so viel Aufmerksamkeit, wie die satirische Herangehensweise – zumindest im Sinne der von uns gezählten Retweets. Der IS arbeitet sehr viel über Bilder und Videos, daher ist es effektiver auf gleicher Ebene zu antworten, statt mit Texten und Statements.

Algorithmus-basierte Scans könnten „bis zu einem gewissen Grad unterstützen und entlasten, in absehbarer Zukunft kann ein voll-automatisierter Prozess aber keine faire und zensurfreie Überprüfung gewährleisten" [10]. Gerade Bots zur automatischen Meinungsmache stellen eine große Herausforderung dar [28]. Hackerangriffe auf IS-Accounts scheinen alleine wenig erfolgversprechend zu sein, da im schnelllebigen Web anstelle eines gelöschten Accounts sofort zwei neue Accounts entstehen. Dennoch ist diese Arbeit als Zeichen der Gegenwehr von Bedeutung. Sinnvoll, aber nicht einfach, wäre es, gezielt die Grundstruktur terroristischer Online-Auftritte zu infiltrieren und das Problem grundlegender anzugehen, als nur oberflächlich Accounts zu löschen.

Einer terroristischen Gruppierung entgegenzutreten, die nicht einmal der eigene Tod abschrecken kann, ist nur mit genügend Scharfsinn und Galgenhumor zu bewältigen.

Das scheinbar Schlimmste für den IS ist es, in Unwürde oder Lächerlichkeit zu fallen. Viele Reaktionen der IS-Vertreter auf parodistische oder satirische Tweets sind aggressiv und gewaltandrohend. Entsprechende Accounts werden danach oft gehackt oder gemeldet, sodass es problematisch ist, dies im Nachhinein nachzuvollziehen. An diesen Reaktionen ist abzulesen, dass von den Satirikern ein Nerv getroffen wurde. Diese Schwachstelle lässt sich mit Parodie und Satire angreifen, die schnell kollektiven Anklang findet. Allerdings besteht die Möglichkeit, dass der IS daraufhin seine angedrohten Strafen aufgrund der Beleidigung in die Tat umsetzt oder die Weiterverbreitung des Propagandamaterials die Aufmerksamkeit auf den IS lenkt. Eine subtilere Weise sich den Terroristen zu widersetzen, zeigten die Muslime mit ihren Absagen via Twitter zum Beitritts-Aufruf für den heiligen Krieg. Einige User stützten ihre Antworten mit Belegen aus dem Koran, womit sie dem IS die Argumentationsgrundlage entzogen.

5 Zusammenfassung und Fazit

Soziale Medien spielen sowohl im Terrorismus als auch in der Terrorbekämpfung eine Rolle. Auch wenn die Forschung zu sozialen Medien mit sowohl verhaltenswissenschaftlichen, als auch gestaltungsorientierten Studien mittlerweile einen festen Platz in der Wirtschaftsinformatik (WI)-Forschung eingenommen hat, wurde mit Blick auf frühere WI-Artikel zum Terrorismus in sozialen Medien vergleichsweise wenig publiziert. Dieser Beitrag beschäftigt sich mit der Terrorbekämpfung in sozialen Medien. Im ersten Teil wurde der Stand der Forschung im Bereich Terrorismus, Propaganda und deren Bekämpfung in sozialen Medien analysiert und hierauf aufbauend im zweiten Teil die Nutzung von Twitter beispielhaft exploriert.

Betrachtet man die Gesamtheit der auf Twitter aufgetretenen Phänomene, die wir in (I) Aufklärung, (II) Parodie und Satire sowie (III) Hacking klassifiziert haben, wird deutlich, dass eine Maßnahme allein nicht erfolgversprechend ist. Aufklärung ist schlussendlich das Einzige, was vermeintliche Lügen der Terroristen aufzudecken vermag, aber sie muss glaubwürdig kommuniziert werden. Mit Hilfe des Hackings oder der Parodie und Satire erhalten die Twitter-Nutzer die Möglichkeit, als Einheit gegen die Terroristen vorzugehen. So ist es auch möglich, dem Gefühl der Hilflosigkeit angesichts des mächtigen Feindes entgegenzuwirken. Bots, die hier automatisiert arbeiten, sind als große Herausforderung wahrzunehmen. Bei Hacking sind jedoch auch rechtliche und ethische Fragen zu beachten. Die Resonanz für Satire ist da, aber die Gegenmaßnahmen müssen darüber hinausgehen.

Die Maßnahmen im Kontext der Terrorbekämpfung bieten viele Möglichkeiten, die lohnenswert erscheinen, deren Essenz wir kompakt wie folgt darstellen:

(1) Massenbewegungen starten (sich als Einheit gegen den IS stellen)
(2) Authentizität und Glaubwürdigkeit vermitteln (besonders für offizielle Seiten)
(3) Parodie und Satire zur kritischen Reflektion nutzen (besonders für private Stellen)
(4) Gegenwehr auf Augenhöhe (Muslime wenden sich gegen ISIS)
(5) Hacking durch spezialisierte Gruppen (nicht nur oberflächliche Beseitigung)
(6) Aufklärung verständlich vermitteln (Ansprache in Sprache der Bevölkerung)

Selbstverständlich hat diese Studie Limitationen: Dieser explorative Überblick konnte nur einen Teil der Aktivitäten identifizieren. Es wurde mithilfe qualitativer Methoden ein Einblick gewehrt, nicht jedoch das gesamte Gefüge adressiert (siehe Methodik, Kap. 3). In weiteren Studien sollte unter Zuhilfenahme quantitativer Methoden der (sozialen) Netzwerkanalyse sowie größerer Datensätze [29] das Geflecht der Gegenmaßnahmen untersucht werden. Vermutet wird, dass ein wachsender Teil der Propaganda durch Bots erfolgt, sich also der Konflikt mehr auf die technische Ebene verlagert (H1). Zur validen Beurteilung der Wirksamkeit der Gegenmaßnahmen erfordert es eine längerfristige Beobachtung der Reaktionen auf die IS-Propaganda. Es ist auch mithilfe von Social Media Analyse [31] zu untersuchen, ob Parodie und Satire insb. von Sympathisanten dieses Humors konsumiert werden, oder Gefährdete zur kritischen Reflektion anregen (H2). Die Aktivitäten der Opposition, von Aktivisten und Flüchtlingen, die potentiell eine große Rolle spielen, sollten in diesem Rahmen auch untersucht werden [32] (H3). Weiterhin wäre genauer zu untersuchen ob und wie Privatsphäre und Terrorbekämpfung in sozialen Medien durch die Bevölkerung abgewogen werden [33] (H4). Erkenntnisse der Crisis Informatics [30], die sich sonst mehr mit Krisenmanagement beschäftigen, sollten wo möglich auf die Terrorbekämpfung übertragen werden.

Danksagung. Die Forschungsarbeiten wurden im Rahmen des EU-FP7-Projekts „EmerGent“ (Fö.-Kz. 608352) gefördert. Ein Short-Paper/Poster mit Ausschnitten dieser Arbeiten wurde auf der Konferenz Mensch & Computer [3] vorgestellt.

An Interdisciplinary Review of Investor Decision-Making in Crowdfunding

Andreas Hoegen, Dennis M. Steininger, and Daniel Veit

University of Augsburg, Augsburg, Germany
hoegen@is-augsburg.de,
{dennis.steininger,veit}@wiwi.uni-augsburg.de

Keywords: *crowdfunding, decision-making, literature review*

Crowdfunding is a quickly expanding phenomenon that emerged as an alternative way to finance ventures or individuals about a decade ago. In crowdfunding, individuals or ventures use online platforms to collect funds from a relatively large group of investors [1]. Today, it provides increasing competition for traditional financing agents such as venture capitalists (VCs), business angels (BAs), and banks on the one hand [2]. On the other hand, it offers new opportunities to individuals and entrepreneurs in need for financing [3]. The global funding volume was over $34 bn. in 2015 with a growth of more than 1,000% in 3 years according to a recent industry study [4]. Low entry barriers stimulate this growth: in contrast to highly regulated traditional financing markets, investing money through digital channels on crowdfunding platforms is open to almost anyone with an internet connection [3]. But when amateurs become investors, a lack of education and experience in financial decision-making can turn into an expensive endeavor, especially as human decisions frequently seem irrational by economic standards [5, 6].

How investors make decision in traditional startup financing or bank loans is well researched. For crowdfunding, however, prior research covers many individual factors of investment decisions, but does not provide an integrated view on those factors. A better understanding of how investment decisions are made in crowdfunding settings will help crowdfunding concepts and platforms evolve. It can also support investors to make better investment decisions and avoid potentially costly choices. Furthermore, better understanding decision-making in crowdfunding can provide insights into how information systems change the way financial decisions are made. Therefore the research question we address is: *Which factors influence investor decision-making in crowdfunding?*

To answer this question, we conducted a systematic and interdisciplinary literature review on the broad body of crowdfunding studies published to date. For this review we followed Webster & Watson's [7] and Okoli and Schabram's [8] guides for literature reviews. We narrowed our initial selection of 785 crowdfunding articles down to 69 articles that research decision-making in crowdfunding. Using a concept matrix [7] we extracted all factors that do or might influence crowdfunding investment decisions. We inductively developed more abstract clusters by grouping

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Hoegen, A.; Steininger, D.M.; Veit, D. (2017): An Interdisciplinary Review of Investor Decision-Making in Crowdfunding, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 664-667

similar influencing factors. Instead of using pre-defined categories, we allowed the clusters to emerge and develop during our analysis [9]. We continuously discussed and developed the clusters to ensure exhaustive coverage of all factors as well as mutually exclusive clusters with minimal overlap [10]. We used those clusters to build a crowdfunding decision-making framework. During the analysis of our data and concept matrix, six clusters of influencing factors emerged:

Outcome & Quality: the basic value proposition or promised outcome, as well as the (perceived) quality of product, project, and process.

Financial Risk & Campaign Statistics: the financial risk involved in an investment as well as information about the status and characteristics of the crowdfunding campaign.

Founder Perception & Attributes: all characteristics of the founders and how they are perceived by the investors. This includes the basis on which investors derive or judge those qualities.

Social, Community & 3rd Parties: any kind of relations to and behavior of third parties that potentially influence the investment decision.

Context: all attributes of the decision-making context that should not influence a rational investor but impact human decision-makers.

Investor Characteristics: Everything about the investors and their attributes, such as their personal traits and preferences, motives, or involvement.

The framework allows to analyze the many influencing factors from the extant literature and structure our findings. It also enables future discussion and research to build on a more abstract basis, instead of handling a multitude of small factors. We describe the influence of each cluster and the associated factors on decision-making based on findings and example from the analyzed literature.

Based on our analysis and the extant literature, we elicit systematic differences between crowdfunding and traditional investments, such as venture capital or bank loans. The first difference is an even higher impact of social capital that is particularly critical to trigger investment dynamics through herding behavior [12]. Second, crowdfunding investors use many different information sources to substitute a lack of verified data, personal access to the founders and their own experience. These alternative source rank from behavior of others [11, 12], over soft factors (e.g., emotional reactions) [13, 14], to campaign statistics provided by the crowdfunding platform [1]. Finally, the different and more ubiquitous contextual presence of digital technology influences decisions, e.g., through features and functionality of the platform [59], or dependent on the channel investors' use to access a crowdfunding campaign [43].

Literature suggests that the use of information systems as foundation for crowdfunding is the major driver for those systematic differences (e.g., [15–17]). For once, the reach of crowdfunding platforms is high and entry barriers are often low or even nonexistent. Thus, amateurs with little experience regarding such decisions can participate [18, 19]. At the same time, the increased reach and interconnection of digital crowdfunding platforms with other information systems (e.g., social network sites) makes every investment activity highly transparent, thus fostering herding behavior [11]. Second, computer-mediation can increase the perceived (social) distance between founder and investor and increase the propensity to lie [20]. In contrast to professional investors, amateurs have little access to reliable data, collateral, or the chance to meet the founder in person [18, 21]. Hence, they need other means to judge an investment opportunity. Lastly, the interaction of crowdfunding founders and investors is guided by information systems. The platforms create a digital context around the transaction that determines how both parties interact with each other. In addition, digital interfaces guide each investor's decision process [22]. Therefore this context influences the decision.

Our findings lead to different takeaways for IS researchers and practitioners. A better understanding of the IS specific factors in crowdfunding decision-making would be beneficial, e.g., how interfaces and platform functionality influence decisions on crowdfunding platforms. On this basis, platform design could be re-evaluated and interfaces improved to help investors decide in their own best interest. In addition, focusing on the entire decision-making process and how different influencing factors and clusters interact could lead to insights on why and how investors decide. Many extant studies focus on assessing correlations between single factors and the funding success of a campaign. Investigating the whole decision-making process in detail and how information systems influence it could build on those findings and lead to additional insights. Experimental and design studies could be useful approaches to elicit better ways to build platforms and learn how to create interactions with information systems in investment situations. Lastly, more research into traditional investments versus crowdfunding could help to narrow down which deviations in investment behavior are due to differences in the concepts (one or few professional investors versus large crowd) and which are rooted in the usage of information technology to implement the concept.

Crowdfunding offers new ways of financing ventures as well as new opportunities to support others and invest money. Given the historic growth rate and the size of the market for loans and investments, its impact on credit markets, venture capital, and entrepreneurial dynamics will likely further expand. We believe that a better understanding of how decisions are made in this context will benefit all involved parties and help mitigate bad choices for investors and founders. The authors hope that their results can bring inspiration to future research and thereby support the development of the field.

Abstract. In order to manage knowledge work, companies need to understand how knowledge is shared, integrated, translated and transformed in organisational practice. However, knowledge work often happens in informal organisational structures, thus, making it difficult to identify and understand the occurring knowledge practices and participating actors. Enterprise Social Networks (ESN), i.e. internally accessible social networking services, have evolved as important platforms for knowledge work. Facilitating knowledge interactions between users, the analysis of ESN data might be well suited for characterising and identifying knowledge actions and different knowledge worker roles. Drawing on an existing knowledge worker role typology as well as findings from social media research, this paper develops a conceptual basis that serves as starting point for determining knowledge worker roles using ESN data. The next steps of this research involve the empirical testing of the typology using data obtained from a real case scenario.

Keywords: Enterprise Social Networks, knowledge worker, social roles, knowledge work.

1 Introduction

While knowledge has been recognised as a key source of competitive advantage, the management of knowledge work is a challenging – and often unsuccessful – task [1]. One reason for knowledge management (KM) initiatives to fail lies in the very nature of knowledge and knowledge work. As such, knowledge work is often conducted in informal organisational structures that exist next to the formal hierarchy and are not fully obvious to the company's management nor to the involved actors [2]. Being emergent and contextual, knowledge and knowledge work are difficult to describe and to measure, and therefore, difficult to manage.
To be able to (better) manage knowledge work, organisations need to understand the components of knowledge work, i.e. knowledge actions, and the different knowledge worker roles performing these actions [1]. Research dealing with informal networks and key roles within these networks [e.g. 2] as well as existing knowledge worker role

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Hacker, J.; Bodendorf, F.; Lorenz, P. (2017): Helper, Sharer or Seeker? - A Concept to Determine Knowledge Worker Roles in Enterprise Social Networks, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 668-682

typologies [e.g. 3] provide insights regarding different actor roles shaping knowledge work in organisations. Yet, these studies determine roles based on survey data. Thus, the significant manual effort involved in the data collection and analysis makes it difficult to recognise knowledge worker roles in larger populations.

More and more organisations use Enterprise Social Networks (ESN) to support collaboration and knowledge sharing. The users of these platforms engage in use practices such as discussing, asking questions, giving advice, and sharing content [4]. Doing so, they leave a number of digital traces stored in the back end of the ESN [5]. Reflecting knowledge (inter)actions of ESN users, the record of user activity may be well suited for identifying different knowledge worker roles in organisations.

Drawing on the knowledge worker role typology by [3], this paper establishes a conceptual basis for determining knowledge worker roles using ESN data. Based on a systematic literature review, ESN use cases are analysed and compared with the knowledge actions specified in [3]. The knowledge actions are operationalised using a set of metrics characterising user activity, i.e. quantitative and qualitative information on the users' posting behaviour, in ESN. As a result of the literature analysis, the paper proposes a revised typology which will be empirically tested in a follow-up project.

This paper contributes to KM research by presenting the initial steps for determining knowledge worker roles in ESN. It advances the field of ESN data analytics by proposing a set of metrics to characterise ESN user behaviour. As for practitioners, awareness of the knowledge worker roles that employees take on can improve decision-making at the intersection of human resources management (HRM) and KM.

2 Theoretical Background and Related Work

This paper draws on KM research and social media research to derive a concept to determine knowledge worker roles in ESN. The following sections contrast perspectives on knowledge and introduce research on KM-related roles in organisations. Section 2.3 deals with ESN features and ESN data. Also, selected works on the identification of roles in online social spaces are presented.

2.1 Knowledge and Knowledge Work

Two main perspectives regarding the study of knowledge can be distinguished: The possession perspective and the practice perspective [6]. Scholars taking up the possession perspective consider knowledge as an object that is held by an individual knower [e.g. 7]. Accordingly, KM strategies focus on the extraction and explication of individual knowledge in order to make it accessible to others [8]. On the other hand, researchers adopting the practice perspective argue knowledge to be created and shared through social interactions between individuals [e.g. 9]. Consequently, this perspective suggests the management of knowledge work, i.e. activities "characterised by an emphasis on theoretical knowledge, creativity and use of analytical and social skills" [10, p. 773], rather than managing knowledge [1]. In particular, knowledge work should be stimulated and enhanced, e.g. by connecting individuals from different departments to reinforce knowledge sharing. This paper adopts the knowledge-in-practice perspective since it more adequately reflects how knowledge work occurs on ESN. As such, ESN offer a conversational space for knowledge work rather than a place for storing knowledge [4]. Also, the knowledge-in-practice perspective reflects the dynamics and complexity of contemporary work settings [e.g. 1].

2.2 Knowledge Worker Roles in Organisations

Individuals performing knowledge work, so-called knowledge workers, are primarily occupied with 'non-routine' problem solving [3]. While knowledge work is an important topic in the KM literature, little is known about the different roles that knowledge workers assume during their daily work [3]. In this regard, some role typologies [e.g. 11] link roles to specific KM-related processes, such as *finding*, *packaging*, and *distributing* knowledge. The corresponding roles are named *knowledge packagers* and *knowledge distributors*, for instance [11, p. 28-30]. Yet, linking only one knowledge action with a certain role, these typologies do not seem to adequately reflect the complexity of knowledge work and implicitly treat knowledge like an object. Thus, they are not directly applicable for determining knowledge worker roles in ESN.
Reflecting the knowledge-in-practice perspective, studies investigating informal organisational structures [e.g. 2] offer insights regarding actor roles involved in knowledge work, among them *central connectors*, *boundary spanners* and *peripheral specialists* [e.g. 12]. Moreover, [3] propose a typology including ten knowledge worker roles (cf. [3] for a detailed description of the roles), each of which is associated to different degrees with a set of knowledge actions out of 13 specified knowledge actions (Figure 1).

Knowledge action / Knowledge worker role	Acquisition	Analyse	Authoring	Co-authoring	Dissemination	Expert Search	Feedback	Information organisation	Information search	Learning	Monitoring	Networking	Service Search
Controller	o	++	+	-	+	-	+	o	o	--	o	--	--

Tracker	o	+	-	--	o	o	o	+	+	o	++	o	o

++ Very important + Important o Undecided - Less important -- Not important

Figure 1. Knowledge worker roles and associated knowledge actions (based on [3])

In this regard, Figure 1 depicts the relationships between knowledge worker roles and knowledge actions and indicates the importance of a knowledge action for a certain role [3]. In line with the knowledge-in-practice perspective adopted in this paper, the knowledge worker role typology by [3] reflects roles identified in informal organisational networks, e.g. *boundary spanners*. Derived based on a literature review as well as an empirical study, the typology includes a comprehensive set of roles, associates specific knowledge actions with each role and indicates the importance of an action for a role. As ESN have evolved as platforms for knowledge work [5], users may perform knowledge actions similar to those specified by [3] and take up similar roles. Thus, the knowledge worker role typology by [3] serves as the basis for determining roles in ESN.

2.3 Functionalities and Analysis of Enterprise Social Networks

In recent years, companies have started to use internal online social networks, i.e. ESN, well-known examples of which include IBM Connections, Jive or Yammer [13]. Relying on Web 2.0 technology, ESN are web-based Intranet platforms that generally offer the following features [19-20]:

- *Profile pages* allowing users to present information about themselves
- *Following* other users to see their updates
- *Activity streams* displaying updates from other users and followed topics within an integrated newsfeed
- *Searching* the content stored on the ESN
- *Group capabilities* that allow interactions within public or restricted groups
- *Discussion threads* where users can start conversations via status updates, share files and participate in conversations by replying to, liking, rating and sharing the messages of other users
- *Tagging* of other users or topics in messages
- *Bookmarks* that allow for saving, organising and sharing content
- *Blog and wiki capabilities* that enable the (collaborative) creation of content and storing of information
- *Social analytics* that provide users with contact recommendations

The actions of users on ESN are visible to other users and persist over time [16]. Specifically, communicative actions are stored as digital traces, i.e. "digitally stored, event-based, chronological records of activities of actors" [5, p. 4], in the ESN back end. The accumulated data can generally be classified according to the following categories [17]: *Activities* (usage data), *content* (user-generated data), and *relations* (structural data). A combination of quantitative and qualitative methods facilitates the analysis of ESN data [17]. Usage data enables the development of metrics, e.g. *number of status updates created (per month)*, that quantify user activities. The content of communications, e.g. the content of a status update, can be analysed using qualitative content analysis, for instance to identify communication genres [18], or (partly) automatically, for instance using text mining techniques. Also, different kinds of relations can be inferred from user interactions on the platform, e.g. based on *following* relationships [17]. Structural data can be analysed using social network analysis (SNA) metrics that enable characterising the position of individual actors, e.g. based on centrality measures [19].

2.4 Roles in Online Social Spaces

Interactions between individuals in online social spaces, such as discussion boards, result in communication patterns. Roles can then be described by “structural signatures” reflecting their position in the social network and behavioural patterns characterising their participation behaviour, e.g. how often they contribute to a discussion [20, 21].
Compared to the high number of articles dealing with user roles in public online settings [22], research on user roles in ESN is still sparse. A case study by [23] identifies *discourse drivers*, who primarily disseminate topics, and *information retrievers*, who are interested in finding and using information, as two mutually interdependent actor roles. Other studies analysing knowledge exchange differentiate between *knowledge seekers* and *knowledge contributors* [24], and between *givers*, *takers*, and *matchers* respectively [25]. Additionally, *value adding users*, i.e. users who contribute and share their knowledge in the ESN, are suggested as ESN actor role [26]. Analysing log data, [27] differentiate between *active contributors*, *moderate contributors*, and *readers* as well as *active* and *occasional* users. All in all, the role concepts suggested in ESN research are not very detailed since they are based on relatively few behavioural dimensions and identified using a limited set of metrics. However, metrics used in studies investigating roles in public online settings can inform the development of metrics to determine the knowledge actions suggested by [3] in ESN.

3 Determining Knowledge Worker Roles in Enterprise Social Networks

This paper uses the knowledge worker role typology by [3] as a starting point for determining knowledge worker roles in ESN. While the original typology is based on a literature analysis and a survey, this paper addresses the question how the typology needs to be adapted in order to facilitate the determination of knowledge worker roles using ESN data.
The adaptation of the typology involves three steps: The first step (section 3.1) concerns the identification of ESN use cases that match the knowledge actions specified in [3]. The goal is to find out whether the knowledge actions are reflected in ESN use cases as well as to assess if they can be determined as distinct actions using ESN data. The second step (section 3.2) focuses on the operationalisation of the knowledge actions by developing a set of ESN metrics. Following the approach of explicit role discovery [22], the knowledge actions associated with a role serve as criteria for individual users to be assigned to a certain role as described in section 3.3.

3.1 Applicability of Knowledge Actions in Enterprise Social Networks

Focusing on information systems research on ESN, the literature review performed in step 1 considers studies published in major information systems journals and conferences according to the Association for Information Systems [28] and the rating of the German Academic Association for Business Research [29]. Covering the years 2005-

2015, multiple search terms and combinations of them were considered, among them microblogging, enterprise social network, enterprise social media, social software, and KM. A detailed description of the literature review process and assignment of the selected papers to six metatopics is described in [30]. The contents of the following section are compiled based on the publications primarily assigned to the metatopic "ESN usage and behaviour" as well as on a follow-up search for papers dealing with ESN usage covering the year 2016. Specifically, papers assigned to this metatopic analyse the ways and purposes of using ESN in organisations, thus identifying ESN use cases. Analysing the selected 28 publications in detail, ESN use cases mentioned in the papers, such as *input generation* or *information storage* [18], are matched with the 13 knowledge actions according to their descriptions in [3]. The ESN use case *information storage,* for instance, is matched with the knowledge action *information organisation* since it is related to managing information on the ESN for future reference. Table 1 consolidates the findings of the literature analysis. The subsequent paragraphs detail which and to what extent the different knowledge actions are applicable to ESN.

Acquisition describes the collecting of information with a conscious goal, e.g. to develop skills or advance a project [3]. Actions related to information gathering on ESN have been identified in a number of studies [e.g. 18]. For instance, acquisition of knowledge is explicitly referred to in the definition of "consumptive" ESN use in [31]. However, the second part of the definition of *acquisition* [3], i.e. having a conscious goal, is not explicitly addressed in the existing ESN literature and appears difficult to determine based on ESN data.

Analyse is defined as carefully examining or thinking about something with the objective of understanding it [3]. The action *analyse* is not necessarily linked with a piece of written information that could be submitted and thus, become visible, on an ESN. While the knowledge action *analyse* is not explicitly mentioned in the ESN literature, the analysis of content can be assumed to be part of the knowledge actions *learning* as well as *monitoring*. Thus, users are concluded to analyse content on the ESN by reading it in order to learn or keep themselves up-to-date about something.

Authoring refers to the creation of information objects (by one person), e.g. textual content, using a software system [3]. As such, *authoring* applies to all textual content submitted to the platform, including posts to the main stream. To better differentiate it from other knowledge actions concerning the ESN main stream (e.g. *dissemination* and *feedback*), in this paper, *authoring* is conceived of as initiating conversations, e.g. to propose an idea [e.g. 4], rather than contributing to existing conversations. Moreover, *authoring* is related to the creation of wiki entries, notes or blog posts [32, 33] which are features of most ESN platforms.

Contrary to *authoring*, **co-authoring** means the collaborative creation of content [3]. *Co-authoring* occurs on ESN platforms when users edit the content created by other users, e.g. when updating content to a new version [34], editing a wiki page [32], articles [25], or blog posts [33].

Dissemination refers to the spreading of information or information objects, such as work results [3]. With regard to ESN, employees share factual information in status updates, e.g. information about objects or people [35], and event notifications [18, 36]. Secondly, users employ ESN to share information objects to make them accessible to others [34], e.g. files in general, project descriptions [37] as well as links to content that already exists [18, 34]. Thirdly, individuals post updates [e.g. 4], regarding their work activity, mood, or physical location [38] as well as "me-statements" that reveal something about them [35]. As a means for impression management [39], users share personal information and information about their professional background.

Expert search refers to retrieving an expert in order to discuss and solve a specific problem [3]. In ESN, retrieving experts is considered as one form of knowledge seeking, i.e. seeking knowledge about people with specific characteristics [24], such as particular skills or connections [4, 18, 40].

The knowledge action **feedback** is described as the evaluation of a proposal or an information object [3]. As for ESN, feedback is part of conversations, e.g. discussions of different options for action to solve a problem [e.g. 18]. Additionally, "social feedback" is recognised as a form of informal communication on ESN [34]. In terms of ESN features, *feedback* can be expressed in liking, rating [34] or commenting on the content created by another user [32] as well as by voting the posted content up or down [41].

The personal or organisational management of collected information is referred to as **information organisation** [3]. In this regard, ESN are used to store information [18, 36]. Furthermore, the labelling of content with a topic [34], e.g. using a tag, can be concluded as a form of *information organisation*.

Information search is described as looking up information on a particular topic and in a specific form [3]. ESN users can "look up" information stored on the platform using the search feature [34]. Moreover, status messages containing questions and information requests are a dominant use case in the ESN literature [e.g. 31] and can be considered as an "explicated" form of *information search*. For instance, employees seek factual knowledge, opinions, and recommendations in status updates [24].

Learning refers to acquiring new knowledge, skills or understanding while performing work tasks, in exchange with others, or using formalised learning material [3]. As such, *learning* appears to be closely related to the action *acquisition* and could be assumed to be one motive of knowledge actions related to search. *Learning* on ESN occurs via a mix of consuming and contributing activities. Browsing the record of activities in project groups, for instance, enables new team members to learn about the history and current status of a project [42]. Also, ESN enable visibility into other users' conversations [16]. As users read and engage in these conversations, they learn about people's expertise and what is important in the organisation [4]. Therefore, ESN facilitate continuous (social) organisational learning [16, 18].

Monitoring is described as keeping oneself informed about selected topics, e.g. using different electronic information resources [3]. Just like the actions *analyse* and *learning*, *monitoring* is difficult to observe based on what employees explicitly post to the network. Yet, ESN enable *monitoring* by supporting different kinds of situation awareness, that is knowing who is doing what (activity awareness), knowing relevant contact persons (structure awareness), as well as knowing what other people are interested in and knowing who is talking to whom (social awareness) [43]. In particular, *monitoring* is facilitated by features related to subscribing to users' updates or topics [19-20]. *Monitoring* may be closely related to *learning* since learning can be an outcome of monitoring activities.

Table 1. Overview of knowledge actions and associated ESN use cases

Knowledge action	**Associated ESN use case and sample references**	**Concerned ESN feature** [14, 15]
1 Authoring	*1a* Initiating a conversation to ask for input / ideas [18]; *1b* Creating a wiki page / blog post [32]	Status updates; Wiki / Blog
2 Co-authoring	*2* Editing of a wiki page / blog post [32, 33]	Wiki / Blog
3 Dissemination	*3a* Providing updates (e.g. on work activity) [4, 39]; *3b* Sharing of files / references [36]	Status updates; File sharing
4 Expert search	*4a* Retrieving an expert using search feature [34]; *4b* Requesting for an expert within a status update [44]	Search; Status updates (expert seeking)
5 Feedback	*5a* Providing feedback within conversations [18]; *5b* Providing social feedback [36]; *5c* Liking or rating of content [34]	Discussion thread (participation); Rating / liking
6 Information organisation	*6a* Saving of meeting minutes [18]; *6b* Bookmarking content [26]; *6c* Labelling / tagging of content [34]	File repository; Bookmarks; Tagging
7 Information search	*7a* Retrieving information using search feature [18, 34]; *7b* Asking for information in a status update [31, 36]	Search; Status updates (information seeking)
8 Learning	*8a* Reading past conversations [16]; *8b* Participating in a conversation [4]	Activity stream (browsing); Discussion thread (participation)
9 Monitoring	*9a* Reading past conversations [43]; *9b* Subscribing to users' messages or keywords [36]	Activity stream (browsing); Following other users / topics
10 Networking	*10a* Following other users [32]; *10b* Creating social relations [37]; *10c* Tagging other users [32]; *10d* Talking about non-work related matters [4]; *10e* Commenting on status updates [37]	Following other users; Discussion thread (participation); Discussion thread (social use)
11 Service search	*11* Asking for a solution in a status update [45]	Status updates (solution seeking)

Interactions with other people and organisations in order to exchange information and to establish contacts are described as **networking** [3]. While every interaction between users includes some form of information exchange, *networking* is concluded as "social use" of ESN [31] in this study. As such, it describes communication aimed at the maintenance of existing and creation of new social relationships in order to build personal context [44]. Messages indicating social use are often related to informal communications [e.g. 18]. For instance, the tagging of other users in messages [32] or the use of emoticons [35] could serve as an indicator for *networking*.

Service search describes the seeking for specialised web services that offer particular functions in order to address a given problem. Compared to *information* and *expert search*, the object to be retrieved is different [3]. On ESN, messages related to seeking solutions or specific resources could be concluded as *service search* [45].

Summarising the findings of the literature analysis, Table 1 lists ESN use cases (citing sample references) associated with the knowledge actions as well as ESN features employed to engage in the use cases. In this regard, one knowledge action can be described by several ESN use cases. In contrast to the knowledge actions by [3], Table 1 does not include the actions *analyse* and *acquisition*. In this regard, no use case could be identified for *analyse* since this action is not explicitly mentioned in the ESN literature. Yet, it is implicitly included in the actions *learning* and *monitoring* as in reading content in order to learn or keep informed respectively. Moreover, *acquisition* is merged with *information search* into the action *information search*. On the one hand, only the component of *acquisition* related to *information search* can be observed on ESN. On the other hand, users are assumed to generally have a goal when searching for information.

3.2 Determining Knowledge Actions in Enterprise Social Networks

Having identified the ESN use cases associated with a particular knowledge action, metrics for recognising knowledge actions using ESN data are designed. As such, the metrics shown in Table 2 reflect the concerned ESN features (Table 1) and facilitate the quantification of the ESN use cases connected to a knowledge action. The numbering of the metrics corresponds to the numbering of the ESN use cases in Table 1. The metrics are designed based on existing studies [e.g. 32, 34] and in accordance with the data generally available in ESN [17]. Moreover, Table 2 indicates the categories of ESN data (section 2.3), i.e. activities (usage data), content (user-generated data), and relations (structural data) [17], required to implement the metrics. The knowledge action *dissemination*, for instance, is connected to the use cases *providing updates* and *sharing of files* in ESN (Table 1). Exemplary metrics to determine the extent to which a user engages in the knowledge action *dissemination* then include the *number of status updates* as well as the *number of status updates that contain an attachment*. These metrics require the collection and analysis of data from the category *activities*, i.e. usage data. Furthermore, Table 2 indicates the complexity and hence effort required to analyse the different knowledge actions using ESN data. In this regard, knowledge actions in rows coloured in grey are recognised as less difficult to analyse than the ones in rows without shading. The effort involved in analysing a knowledge action depends on the data dimensions and data analysis methods (cf. section 2.3) required to implement the respective metrics.

Table 2. Operationalisation and analysis of knowledge actions

Knowledge action [3]	**Example metrics to quantify ESN use cases** (cf. Table 1)	**Data category** [17]
1 Authoring	*1a* No. of status updates (first messages); *1b* No. of wiki / blog entries created	Activities
2 Co-authoring	*2* No. of wiki / blog entries edited	Activities
3 Dissemination	*3a* No. of status updates (first messages); *3b* No. of status updates (with links / files)	Activities
4 Expert search	*4a* No. of searches performed (person's name); *4b* No. of questions asked (expert seeking)	Activities; Content
5 Feedback	*5a* No. of replies in threads containing discussions / feedback; *5b* No. of praise messages; *5c* No. of ratings performed / likes given	Activities; Content
6 Information organisation	*6a* No. of files saved; *6b* No. of documents bookmarked *6c* No. of tags created; *6d* No. of documents tagged;	Activities
7 Information search	*7a* No. of searches performed; *7b* No. of questions asked (information seeking)	Activities; Content
8 Learning	*8a* Time spent browsing content; *8a* No. of conversations clicked on; *8b* No. of threads participated in	Activities
9 Monitoring	*9a* Time spent browsing content; *9b* No. of users followed; *9b* No. of topics followed	Activities
10 Networking	*10a* No. of users followed; *10b* No. of new following relationships in a certain period of time; *10c* Out-degree (tagging relationships); *10d* No. of messages (social use) *10e* Out-degree (reply relationships);	Activities; Content; Relations
11 Service search	*11* No. of questions asked (solution seeking)	Activities; Content

Thus, metrics indicating *authoring*, *co-authoring*, *dissemination*, *information organisation*, *learning*, and *monitoring* can be implemented based on data of the category *activities*. Having obtained this data, the corresponding metrics can be calculated in a database or using a spreadsheet software straightaway. Contrary, implementing metrics to describe the knowledge actions in the white rows requires a mix of qualitative and quantitative methods [17]. For instance, metrics indicating actions related to search, such as *expert search* or *information search*, are based on analysing search queries of users (using the search feature) as well as based on questions in status updates. Hence, the message content needs to be considered to decide *whether* a status update is a question and *what* the user is asking for. Scanning of messages for question marks and question words, e.g. “who” or “how” [46], or applying text mining techniques could help partly automate this task. Having identified questions and their focuses, it is possible to determine *how often* a user has created a question. A mixed methods approach is also suggested for *feedback* which can be recognised by analysing the content of messages regarding the provision of (social) feedback and / or determining how often a user has liked or rated another user’s content. Finally, metrics indicating *networking* need to be calculated using log file analysis and SNA. SNA is usually performed using specialised tools, e.g. UCINET, that require the data to be prepared in a certain way.

3.3 Determining Knowledge Worker Roles in Enterprise Social Networks

Besides including conceptually overlapping knowledge actions (section 3.1), the knowledge worker role typology by [3] contains several roles that are associated with the same knowledge actions to similar extents. In particular, this applies to the roles *learner* and *retriever* as well as *organiser* and *tracker* (Figure 1). Engaging in the same knowledge actions to similar degrees, these knowledge worker roles appear difficult to distinguish based on a mainly quantitative analysis of ESN data. Therefore, *learner* and *retriever* are merged into a new role called *seeker.* Further, *organiser* and *tracker* are consolidated into a role called *coordinator*. The extent to which the new roles are associated with the knowledge actions is determined by comparing and averaging their individual degrees for the different actions as specified in [3]. Figure 2 depicts the revised knowledge worker role typology. In this regard, knowledge actions rated as (very) important or less important / unimportant are recognised as significant for characterising the different knowledge worker roles and should be considered first in order to detect the roles in ESN. Knowledge actions marked with “o” are considered less discriminative for the different roles. For instance, to identify *controllers*, metrics (Table 2) suggested to quantify the respective discriminative knowledge actions (marked with ++ / + and -- / - in Figure 2) should be calculated for all users in the sample. Combining the

Knowledge action / Knowledge worker role	Authoring	Co-authoring	Dissemination	Expert Search	Feedback	Information organisation	Information search	Learning	Monitoring	Networking	Service Search
Controller	+	-	+	-	+	o	o	--	o	--	--
Helper	-	-	++	o	++	o	++	o	-	o	--
Seeker	-	--	--	o	-	+	++	+	o	o	-
Linker	o	o	o	-	-	o	++	o	o	o	--
Networker	-	-	+	+	o	o	o	o	o	++	--
Coordinator	-	--	o	o	o	+	+	-	++	o	o
Sharer	+	+	++	--	o	o	o	-	-	+	-
Solver	-	--	o	o	o	o	+	o	-	-	-

++ Very important   + Important   o Undecided   - Less important   -- Not important

Figure 2. Adapted knowledge worker role typology (based on [3])

information presented in Table 2 and Figure 2, individuals meeting the criteria for the role *controller* would exhibit above average values for metrics associated with the corresponding (very) important knowledge actions (++ / +) and below average values for the ones rated as less important / unimportant (-- / -) as compared to other users in the sample.

4 Discussion and Future Work

Drawing on findings from social media and ESN research, this paper adapts the knowledge worker role typology by [3] to an ESN context. In comparison to the typology by [3], the adapted typology includes a reduced set of knowledge actions and knowledge worker roles. Offering metrics to quantify the knowledge actions, the paper provides a conceptual basis for determining knowledge worker roles using ESN data.

The results of this paper need to be weighted up against its limitations. Firstly, the matching of the ESN use cases with the knowledge actions in [3] required some judgement is thus, not entirely objective. Specifically, there is little information on some of the knowledge actions, e.g. *learning*, in the ESN literature. Hence, some assumptions have to be made how *learning* occurs on ESN and how it can be measured. Secondly, knowledge actions that overlap conceptually and correlate for different roles as well as roles associated with the same knowledge actions to similar extents were merged to avoid redundancy. While this is necessary to enable the determination of (distinct) knowledge worker roles based on a quantitative analysis of ESN data, the adapted typology is less detailed and could miss actions and roles involved in knowledge work.

Following-up on these issues, the next step of this research project concerns the testing of the knowledge worker role typology using ESN data obtained from a real case scenario. The planned empirical analysis has implications for the developed metrics, the suggested roles, as well as for the general feasibility of the approach. First of all, the empirical analysis will show whether the proposed metrics can be computed using ESN data. In this regard, metrics may have to be adapted to suit the specifics of the data set or removed if particular data, for instance, the content of messages, is not available. Also, correlations between metrics assigned to one knowledge action should be empirically tested. For determining the roles, adequate thresholds for the metrics in order to distinguish less / unimportant from (very) important knowledge actions have to be specified. The actual role analysis will show whether the suggested roles are valid and point out if and how the typology needs to be further adapted and refined. On the one hand, overlapping roles could be revealed in case many users meet the criteria of several roles. If, on the other hand, many users cannot be assigned to a role, the current typology would be indicated to miss certain, possibly ESN-specific, roles. In this regard, roles identified in public online social spaces, such as *experts* (who, for instance, receive many questions) or *discussion persons* (who join many conversations) [20] could be considered to extend the typology. In conclusion, the planned empirical testing will indicate to what extent ESN data facilitates determining the specified knowledge worker roles.

5 Conclusion

The management of knowledge work requires an understanding of the performed knowledge actions and involved knowledge worker roles. The identification and measurement of these actions as well as the determination of knowledge worker roles is an important and current challenge in KM research and practice.

This paper contributes to KM research by offering a conceptual basis for determining knowledge actions and knowledge worker roles based on ESN data. The study moreover contributes to the emerging body of ESN data analytics by developing metrics that characterise ESN user behaviour. For practitioners, the detection of different roles can improve organisational knowledge transparency and lead to more evidence-based decisions at the intersection between KM and HRM. Facilitating new opportunities for information sharing and exchange, ESN have the potential to significantly change the way knowledge work is conducted in organisations. It remains to be investigated whether similar knowledge worker roles as suggested by [3] can be recognised using ESN data or if interactions on ESN lead to new roles in the context of knowledge work.

Explizite Neutralität in Wählernetzwerken – Eine Analyse der Requests for Adminship (RfAs) in Wikipedia

Johannes Putzke[1], Hideaki Takeda[1]

[1] National Institute of Informatics, Principles of Informatics Research Division, Tokyo, Japan
{putzke,takeda}@nii.ac.jp

Abstract. Dieses Papier untersucht „Requests for Adminship (RfA)" in Wikipedia. RfAs sind Wahlen in Wikipedia, durch die Autoren zusätzliche technische Features erhalten können, die sie bei der Bearbeitung von Wikipedia unterstützen. Insbesondere beantworten wir die Forschungsfrage, was die Wahrscheinlichkeit erhöht, dass jemand eine neutrale Stimme gegenüber einem potentiellen Administrator abgibt. Zur Beantwortung der Forschungsfrage ziehen wir die Reziprozitätstheorie sowie die Balancetheorie heran. Die Ergebnisse weisen auf eine starke Tendenz zu neutraler Reziprozität (d. h. eine größere Wahrscheinlichkeit, dass ein Nutzer A eine neutrale Stimme für einen anderen Nutzer B abgibt, der wiederum auch eine neutrale Stimme für den ersten Nutzer A abgegeben hat) und neutraler Balance (d. h. eine größere Wahrscheinlichkeit, dass ein Nutzer A eine neutrale Stimme für einen anderen Nutzer B abgibt, der eine Gegenstimme von einem Nutzer C erhalten hat, für den der erste Nutzer A eine Gegenstimme abgegeben hat), hin.

Keywords: Analyse sozialer Netzwerke, Leadership, Online communities, Wiki, Wissensmanagement

1 Einleitung

Die Online-Enzyklopädie Wikipedia gehört zu den meist besuchten Webseiten der Welt[1] [1] und ist immer wieder Gegenstand wissenschaftlicher Forschungsarbeiten der Wirtschaftsinformatik bzw. ihrer anglo-amerikanischen Schwesterdisziplin *Information Systems* (IS) (z. B. [2-4]).

In diesem Kontext untersucht eine Forschungsströmung insbesondere Führungsverhalten in Wikipedia (z. B. [5]). Ein wichtiger Aspekt zum Verständnis von Führungsverhalten in Wikipedia sind die „*Requests for Adminship*" (RfAs). RfAs sind Wahlen in Wikipedia, durch die Autoren zusätzliche technische Features erhalten, die ihnen bei der Bearbeitung von Wikipedia behilflich sind und die ihnen eine stärkere Einflussnahme auf Inhalte der Wikipedia (etwa im Rahmen von Löschdiskussionen) ermöglichen. In einem öffentlichen, nicht-anonymisierten Wahlprozess können

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Putzke, J.; Takeda, H. (2017): Explizite Neutralität in Wählernetzwerken - Eine Analyse der Requests for Adminship (RfAs) in Wikipedia, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 683-696

(registrierte) Wikipedia-Nutzer diese Ersuchen entweder unterstützen, gegen sie opponieren oder ihnen gegenüber eine neutrale Stimme[2] abgeben.

Obwohl eine Reihe von (hauptsächlich Konferenz-)Papieren RfAs im Detail untersucht (z. B. [5-13]), legt nach unserem Kenntnisstand keines dieser Arbeitspapiere einen Forschungsschwerpunkt auf die neutralen Stimmen bei diesen Wahlen. Vielmehr werden die neutralen Stimmen vor den weiteren Analysen ausgeschlossen (z. B. [8-10]), da sie als Störfaktoren angesehen werden.

Daher möchten wir in diesem Konferenzpapier tiefere Einsichten in die neutralen Stimmen der RfAs erhalten. Dies ist umso wichtiger, da ein substantieller Teil der Wikipedia-Nutzer (>5 Prozent) bei diesen Wahlen eine neutrale Stimme abgibt. Da diese Nutzer für ihre Stimmabgabe (Opportunitäts-)kosten investieren müssen, ist die Hauptforschungsfrage dieses Arbeitspapieres, weshalb werden neutrale Stimmen abgegeben? Da diese Forschungsfrage jedoch sehr allgemein gestellt ist und den Umfang eines Konferenzpapieres bei Weitem sprengen würde, möchten wir sie im Zugriff auf zwei Theorien – nämlich die Reziprozitätstheorie (z. B. [14, 15]) und die Balancetheorie (z. B. [16])(vgl. den nächsten Absatz) – näher spezifizieren. Insbesondere fragen wir uns, inwiefern diese beiden Theorien dazu geeignet sind, für den konkreten empirischen Fall die Frage zu beantworten:

F: Was erhöht die Wahrscheinlichkeit dafür, dass ein Nutzer eine neutrale Stimme für einen potentiellen Administrator abgibt?

Da nach unserem Kenntnisstand die beiden oben genannte Theorien noch nicht im Kontext von Wahlen getestet worden sind, insbesondere noch nicht im Kontext von Wahlen von Führungspersönlichkeiten in Online-Gemeinschaften, trägt unsere Forschung dazu bei, diese beiden Theorien auf diesen Kontext zu erweitern.

2 Theoretischer Hintergrund und Forschungshypothesen

Der Literaturüberblick und die Hypothesenentwicklung sind in zwei Teile strukturiert: Im ersten Teil wird ein Überblick über die verwandte Literatur bezüglich Wikis in der IS-Forschung gegeben, im zweiten Teil werden drei Forschungshypothesen entwickelt.

2.1 Wikis in der IS-Forschung

Neben den bereits in der Einleitung erwähnten Arbeiten zum RfA-Prozess steht dieses Papier in der Tradition von Papieren, die Wikis in der IS-Forschung analysieren. Wikis sind eine Zusammenstellung von Web-Seiten, die in einem kollaborativen Prozess

[2] Auch wenn neutrale Stimmen in Wikipedia zunächst keinen Einfluss auf Wahlen zu nehmen scheinen, können sie durchaus wahlbeeinflussend wirken. Das Ergebnis einer Wahl entscheidet sich aus dem Verhältnis der unterstützenden Stimmen zu den opponierenden Stimmen. Obwohl die neutralen Stimmen bei diesen Berechnungen keinen direkten Eingang finden, werden die neutralen Stimmen in Wikipedia von den jeweiligen Wählern mit Kommentaren / Begründungen für ihre neutrale Stimmabgabe versehen. In der Konsensfindung, ob ein Kandidat in den Admin-Status erhoben werden soll, werden auch diese qualitativen Kommentare berücksichtigt.

erstellt und iterativ verändert werden [17]. In diesem Kontext sind insbesondere zwei Forschungsströmungen für dieses Papier relevant. Die erste Forschungsströmung untersucht Wikis aus einer Wissensmanagementperspektive (z. B. [17, 18]), die zweite Forschungsströmung untersucht Führungsverhalten in Wikis (z. B. [1, 19]).

Die erste Forschungsströmung ist tief in der Wissensmanagement-Literatur verankert (z. B. [20-22]). Ein guter Literaturüberblick über diese Forschung findet sich in Beck, Rai, Fischbach und Keil [18].

In dieser Forschungstradition wird eine wesentliche Unterscheidung zwischen zwei verschiedenen Arten von Beiträgen auf Wikipedia gegeben: Wissenserschaffung („*knowledge adding*") und Wissensformung („*knowledge shaping*"). Wissensformung bezeichnet dabei die kontinuierliche Revision von Beiträgen zu einem Wiki [17]. Auch Beck, Rai, Fischbach und Keil [18] folgen dieser Unterscheidung und sprechen von „*knowledge creation*" und „*knowledge integration*". Wissensintegration definieren sie dabei als die Reorganisation, Verknüpfung und Synthese von Wissen, das von anderen beigetragen wurde. Während eine Reihe von Papieren die Wissenserschaffung im Detail untersucht, besteht hinsichtlich der Untersuchung von Wissensformung noch eine Forschungslücke. In diesem Zusammenhang rufen IS-Forscher insbesondere zu Forschung auf, die das Teilen von Wissen in Wikis aus der Perspektive der Analyse sozialer Netzwerke heraus analysiert [18]. Mit diesem Beitrag antworten wir auf diese Aufforderung.

Die zweite Forschungsströmung untersucht Führungsverhalten in Wikis (z. B. [1, 19]). Da die Übertragbarkeit traditioneller Theorien des Führungsverhaltens auf Online-Führungsverhalten aufgrund mediierter Kommunikation, mangelnden persönlichen Interaktionen, der Vorherrschaft text-basierter, asynchroner Nachrichten sowie einer „bottom-up" Führungsstruktur fraglich ist, rufen Forscher zu Theorien des Online-Führungsverhalten auf [23]. Mit diesem Papier antworten wir auch auf diese Aufforderung. Dabei erweitern wir die Arbeiten von Forschern, die den RfA-Prozess von Wikipedia im Detail untersuchen (z. B. [5-13]), indem wir die vorhergenannten theoretischen Perspektiven durch zwei interdisziplinäre Theorien anreichern, die in der Hypothesenentwicklung näher beleuchtet werden: Die „Reziprozitätstheorie" sowie die „Balancetheorie".

2.2 Forschungshypothesenentwicklung

Die erste und zweite Hypothese greifen auf die Reziprozitätstheorie zurück (z. B. [14, 15, 24])). In diesem Papier definieren wir Reziprozität als das Zurückgeben von etwas Äquivalentem. Viele Redewendungen wie etwa „wie Du mir, so ich Dir", „Gleiches mit Gleichem vergelten" oder „quid pro quo" spiegeln die Norm der Reziprozität in menschlichen Gesellschaften wider. Dabei umfasst die Norm der Reziprozität eine positive Valenz („Eine Hand wäscht die andere") ebenso wie eine negative („Auge um Auge, Zahn um Zahn").

Während die Reziprozitätstheorie explizit indirekte Formen der Reziprozität mit einschließt (für einen Literaturüberblick vgl. [25]), fokussieren wir in diesem Papier auf direkte Reziprozität. (Indirekte Reziprozität findet sich etwa im Prinzip "I scratch your back and someone else will scratch mine" [25]; vgl. in diesem Kontext auch Faraj und Johnson [26]). Insbesondere konzeptionalisieren wir Reziprozität im Sinne der Netzwerktheorie, d. h. in diesem Papier beschreibt Reziprozität die erhöhte Wahrscheinlichkeit, dass ein Akteur A eine Kante zu denjenigen Akteuren aufbaut, die wiederum eine Kante zu Akteur A aufgebaut haben [27].

In der Netzwerktheorie wurde Reziprozität insbesondere für Netzwerke mit einer positiven Valenz (wie etwa Freundschaftsnetzwerke) untersucht (für eine Ausnahme vgl. Rambaran, Dijkstra, Munniksma und Cillessen [28]). Der Grund hierfür mag der Tatsache zuzuschreiben sein, dass die Basisrate, sich von einer asymmetrischen Beziehung zu einer reziprok-symmetrischen Beziehung zu entwickeln, in Netzwerken mit einer negativen Valenz (wie etwa Feindschaftsnetzwerken) niedriger ist als in Netzwerken mit einer positiven Valenz [29].[3]

Für Reziprozität in Netzwerken mit einer positiven Valenz (positive Reziprozität) gibt es eine Reihe theoretischer Erklärungen (vgl. [30]). Die bekanntesten stammen aus der Theorie sozialer Austausche (z. B. [31, 32]). Da die Hypothese der positiven Reziprozität jedoch bereits ausführlich hergeleitet und getestet worden ist (z. B. [33, 34]), soll sie in diesem Papier nicht näher behandelt werden.

Weniger Aufmerksamkeit erfahren hat hingegen die Hypothese der negativen Reziprozität. Nichtsdestotrotz ist das Konzept der negativen Reziprozität (Rache) tief in unserer Gesellschaft verankert und findet sich auch in frühen philosophischen Schriften wieder (vgl. [35]). Daher ist es angemessen zu erwarten, dass Akteure unwohlwollendes Verhalten anderer ihnen gegenüber erwidern [35]. Im Fall der RfAs ist eine Gegenstimme für einen Nutzer, der als Administrator kandidiert, ein Beispiel für solch ein unwohlwollendes Verhalten. Daher stellen wir die Hypothese auf

> *H1 (negative Reziprozität). Die Wahrscheinlichkeit dass Nutzer A eine Gegenstimme für Nutzer B abgibt, der als Administrator kandidiert, ist größer, wenn Nutzer B zuvor auch eine Gegenstimme für Nutzer A abgegeben hat.*

Während Für- und Gegenstimmen in RfAs eine klare Valenz/Wertigkeit haben, ist die Valenz neutraler Stimmen weniger eindeutig. Während neutrale Stimmen in Wahlen, in denen die Nutzer größtenteils mit Gegenstimmen votiert haben, eine positive Valenz haben, haben Sie in Wahlen, in denen die Nutzer größtenteils mit Für-Stimmen votiert haben, eine negative Valenz. Nichtsdestotrotz nehmen wir nach der Reziprozitätstheorie an, dass Nutzer eine neutrale Stimme gleich ihrer Valenz erwidern und stellen die Hypothese auf[4]

---

[3] Auf der anderen Seite sei darauf hingewiesen, dass es zwischen Forschern einen emergenten Konsens gibt, dass die Neigung zur Bestrafung unwohlwollendes Verhaltens größer ist, als die Neigung wohlwollendes Verhalten zu belohnen [15].

[4] An dieser Stelle mag sich der Leser fragen, wo eine ursprünglich neutrale Stimme, die erwidert wird, ihren Ursprung hat. Hierfür gibt es eine Reihe von Erklärungen, die den Rahmen dieses Papiers sprengen würden. Zum Beispiel gewinnt ein User (nach der „Signaling-Theorie”) Reputation als aktiver Bewerter. Außerdem könnte der User dadurch Satisfaktion erfahren, dass er zu einem öffentlichen Gut beiträgt [36].

H2 (neutrale Reziprozität). Die Wahrscheinlichkeit, dass Nutzer A eine neutrale Stimme für Nutzer B abgibt, der als Administrator kandidiert, ist größer, wenn Nutzer B zuvor auch eine neutrale Stimme für Nutzer A abgegeben hat.

Die Hypothesenentwicklung der dritten Hypothese basiert auf der Balancetheorie. Die Ursprünge der Balancetheorie liegen mehr als ein halbes Jahrhundert zurück (für einen Literaturüberblick über die Balancetheorie in der IS-Forschung vgl. [16]). Die Balancetheorie wurde zunächst von Heider [37] in die psychologische Literatur eingeführt und anschließend von Cartwright und Harary [38] verallgemeinert, die auch eine formale Definition von „Balance“ im Rahmen der Graphentheorie liefern.

Die fundamentalen Grundsätze der (strukturellen) Balancetheorie sind: a) Die Freunde meines Freundes sind meine Freunde, b) die Feinde meines Freundes sind meine Feinde, c) die Freunde meines Feindes sind meine Feinde und d) die Feinde meines Feindes sind meine Freunde. Während diese fundamentalen Grundsätze der Balancetheorie auf zwei Zustände dyadischer Beziehungen fokussieren (d.h. Freundschaft und Feindschaft), erweitern wir die strukturelle Balancetheorie in diesem Papier durch einen dritten Zustand dyadischer Beziehungen. Insbesondere lassen wir „explizite Neutralität“ gegenüber einem anderen Akteurs im Wahlnetzwerk zu. D. h. wir machen keine so starke Proposition, dass Feinde eines Feindes Freunde werden, sondern wir nehmen an, dass jemand zumindest eine neutrale Stimme gegenüber dem „Feind“ eines „Feindes“ abgeben sollte[5] und stellen die Hypothese auf:

H3 (neutrale Balance): Die Wahrscheinlichkeit, dass Nutzer A eine neutrale Stimme für Nutzer B abgibt, der eine Gegenstimme von Nutzer C erhalten hat, für den Nutzer A wiederum mit einer Gegenstimme votiert hat, ist größer als die Wahrscheinlichkeit, dass Nutzer A eine zufällige neutrale Stimme abgibt.

3 Methode

3.1 Datensammlung und Stichprobe

Um die Hypothesen zu testen, benutzen dwir einen Datensatz von Leskovec, Huttenlocher und Kleinberg [39]. Dieser Datensatz enthält alle Wahlergebnisse der „Requests for Adminship” (RfA) in Wikipedia bis Januar 2008. Der gleiche Datensatz wurde von einer Reihe von Forschern benutzt. Auch wenn dieser Datensatz vergleichsweise alt ist, bringt dessen Verwendung den Vorteil, zu vorhergehender Forschung vergleichbar zu sein [12].

Insgesamt enthält dieser Datensatz die Wahlergebnisse von 2,794 Wahlen mit 114,040 Stimmen (von diesen 83,962 Für-Stimmen, 23,118 Gegenstimmen, und 6,960 neutrale Stimmen). 11 der Stimmen hatten einen Zeitstempel mit einer Jahreszahl > 2050 und wurden deshalb von den weiteren Analysen ausgeschlossen.

---

[5] Ein „Feind” im Wahlnetzwerk eines Nutzers A ist ein Wähler, der während Nutzer As RfA eine Gegenstimme abgegeben hat.

Außerdem schlossen wir vor den weiteren Analysen alle Stimmen mit einem Zeitstempel größer als 31-12-2007 und kleiner als 1-1-2005 aus. Diese Entscheidung wurde getroffen, da wir den Datensatz für die weiteren Analysen in äquidistante Zeitperioden aufteilen wollten (siehe das nächste Unterkapitel). Da die Wahldaten in 2004 und 2008 nicht sehr umfangreich sind (z. B. gibt es im Januar 2008 nur 6 Tage, für die Wahlergebnisse vorliegen), ist es zweckreich die Daten auf ihrer jährlichen Basis zu untersuchen, für die die komplette Stimmhistorie vorliegt (d. h. 2005-2007). Insgesamt stellten sich – nach Ausschluss der oben genannten Stimmen – 1972 verschiedene Akteure zur Wahl und ließen sich von 3219 verschiedenen Akteuren wählen. Da einige der Akteure sowohl als Gewählte als auch als Wählende in Erscheinung treten, basieren die folgenden Analysen der RfAs auf einem Datensatz mit insgesamt 4,327 verschiedenen Akteuren.[6]

3.2 Modell

Zum Hypothesentest benutzten wir ein stochastisches, akteurbasiertes Modell, das von Snijders in der soziologischen und statistischen Literatur vorgeschlagen wurde [40-42]. Nach unserem Kenntnisstand ist die erste Anwendung dieser Methode in der IS-Forschung ein Papier von Putzke, Fischbach, Schoder und Gloor [43]. Eine volle Beschreibung des Modellierungsansatzes würde den Rahmen dieses Papiers bei Weitem sprengen. Der interessierte Leser sei daher auf die eben genannte Literatur verwiesen. In den folgenden Absätzen stellen wir lediglich die wichtigsten Punkte dieses Modellierungsansatzes vor, so dass dem Leser ein Verständnis des Ergebniskapitels und die Reproduzierbarkeit der Forschungsergebnisse ermöglicht werden.

Im Folgenden bezeichnet $X(t)=X_{ij}(t)$ eine $n\times n$ $(n=4,327)$ Adjazenzmatrix des Netzwerkes neutraler Stimmen, wobei $X_{ij}=1(0)$ eine Kante (keine Kante) von Akteur i zu Akteur j $(i,j=1,\ldots n)$ in Periode t repräsentiert, d. h., Nutzer i gab bis Periode t eine neutrale Stimme für Nutzer j $(i\rightarrow j)$ ab. Analog bezeichnet $W(t)=W_{ij}(t)$ eine $n\times n$ Adjazenzmatrix des Netzwerkes der Gegenstimmen, wobei $W_{ij}=1(0)$ eine Kante (keine Kante) von Akteur i zu Akteur j $(i,j=1,\ldots n)$ in Periode t repräsentiert, d. h., Nutzer i gab eine Gegenstimme für Nutzer j $(i\rightarrow j)$ ab.

Das Modell nimmt an, dass diese Adjazenzmatritzen eine Markovkette in kontinuierlicher Zeit mit stationären Übergangsmatritzen bilden. Um die Übergangsmatritzen dieser Markovkette herzuleiten, zerlegt Snijders [40-42] die Veränderung zwischen zwei Zuständen der Markovkette in zwei grundlegende Modelle: (1) Ein Wartezeitmodell für Kantenveränderungen und 2) ein Modell für die Wahl der Kantenveränderung.

Das Wartezeitmodell für die Kantenveränderungen nimmt an, dass in zufälligen, deterministischen Momenten der Zeit (so genannten „Minischritten", *engl.*

[6] An dieser Stelle sei erwähnt, dass in den RfAs eine Reihe von Nutzern mehrfach kandidiert. Aus Sicht des Kandidaten gibt es hierfür hauptsächlich zwei Gründe: Erstens kann ein Nutzer durch eine Wiederwahl eine höhere Legitimität seines Admin-Status erhalten. Zweitens versuchen Nutzer durch eine zweite Wahl Admin-Status zu erhalten, wenn sie in der ersten Wahl nicht erfolgreich waren.

„ministeps“) die Akteure die Möglichkeit erhalten, eine Kantenvariable zu verändern. Dabei wird angenommen, dass die Wartezeit zwischen zwei dieser Momente einer Exponentialverteilung folgt. In Tabelle 1 im Ergebniskapitel stehen diese Ratenfunktionen in den Zeilen „Änderungsrate des Netzwerkes“. Dabei nehmen wir an dieser Stelle keine konstante Änderungsrate des Netzwerkes für jede Periode an, sondern gehen davon aus, dass die Änderungsrate des Netzwerkes von Periode zu Periode variiert. (Eine Periode in diesem Papier entspricht dabei einem Jahr). In den Zeilen „Änderungsraten des Netzwerks“ stehen also die Parameter λ der Exponentialverteilungen, die die Wartezeit auf einen Minischritt in den jeweiligen Perioden beschreiben.

Das Modell für die Wahl der Kantenveränderungen ist durch sogenannte „Evaluationsfunktionen” (*engl. „evaluation functions”*) repräsentiert. Akteur is Evaluationsfunktion für das Netzwerk neutraler Stimmen ist definiert als $f_i^X(x,w) = \sum_k \beta_k^X s_{ki}^X(x,w)$ und Akteur is Evaluationsfunktion für das Netzwerk der Gegenstimmen (in ihrer generellen Form) ist definiert als als $f_i^W(x,w) = \sum_k \beta_k^W s_{ki}^W(x,w)$, wobei die $s_{ki}(x,w)$ so genannte Effekte (*engl. „effects*”) sind. Diese Effekte spiegeln Akteur is Einbettung in diese Netzwerke wider. Die *βs* der Evaluationsfunktionen können wie (logistische Regressionskoeffizienten) interpretiert werden. Daher wurden für die Hypothesentests die oben genannten Effekte wie folgt spezifiziert:

Negative Reziprozität wurde als $s_{1i}^W = \sum_j w_{ij} w_{ji}$ gemessen. Das heißt, Nutzer is Evaluationsfunktion steigt nur dann um den Wert 1, wenn Nutzer *i* eine Gegenstimme für Nutzer *j* abgibt ($w_{ij} = 1$) und Nutzer *j* eine Gegenstimme für Nutzer *i* abgibt ($w_{ji} = 1$). Wenn eine der beiden Stimmen fehlt (d. h. $w_{ij} = 0$ oder $w_{ji} = 0$), ist das Produkt der beiden Terme 0. Folglich zeigt ein positiver Parameter β_1^W eine größere Wahrscheinlichkeit dafür an, dass Nutzer *i* eine Gegenstimme für Nutzer *j* abgibt, wenn Nutzer *j* auch eine Gegenstimme für Nutzer *i* abgibt. Der Schätzer für den Parameter β_1^W findet sich in der Zeile „Negative Reziprozität” in Tabelle 1.

Neutrale Reziprozität wurde als $s_{1i}^X = \sum_j x_{ij} x_{ji}$ gemessen. Die Erklärung für diesen Effekt ist analog zu derjenigen der negativen Reziprozität. Wiederum zeigt ein positiver Parameter β_1^X eine größere Wahrscheinlichkeit an, dass Nutzer *i* eine neutrale Stimme für Nutzer *j* abgibt, wenn Nutzer *j* auch eine neutrale Stimme für Nutzer *i* abgibt. Der Schätzer für den Parameter β_1^X findet sich in der Reihe „neutrale Reziprozität” in Tabelle 1.

Schließlich wurde, *neutrale Balance* als $s_{2i}^X = \sum_{j \neq h} x_{ij} w_{ih} w_{hj}$ gemessen (für eine Erklärung vgl. oben). Der Schätzer für Parameter β_2^X findet sich in der Zeile „neutrale Balance” in Tabelle 1.

4 Ergebnisse

Das vorgeschlagene Modell wurde in R 3.2.2 unter Verwendung des Pakets RSiena (*„Simulation Investigation for Empirical Network Analysis“*), Version 1.1-290 [44] geschätzt. Für die Schätzung wurde die Momentenmethode mit Robbins-Monro [45] stochastischem Approximationsalgorithmus verwendet. T-Tests deuten auf eine gute

Konvergenz des Modells hin (angewendetes Kriterium: $t < .1$), ebenso wie das globale maximale Konvergenzverhältnis $t_{convmax}= 0.1009$ (angewendetes Kriterium: $t_{convmax} < .25$) (vgl. [46]).

Tabelle 1 veranschaulicht die Ergebnisse der Modellschätzung. (Tabelle 2 im Anhang enthält die Korrelationskoeffizienten zwischen den Parameterschätzern. Es gab keine Hinweise auf Multikollinearität.) Alle Effekte des Modells sind statistisch höchst signifikant. Daher werden Hypothesen H1-H3 unterstützt. Es gibt eine starke Tendenz für negative Reziprozität im Netzwerk der Gegenstimmen, was bedeutet, dass die Wahrscheinlichkeit größer ist, das Nutzer A eine Gegenstimme für einen Nutzer B abgibt, wenn dieser Nutzer B auch eine Gegenstimme für den ersten Nutzer A abgegeben hat (H1). Des Weiteren ist die Wahrscheinlichkeit größer, dass ein Nutzer A eine neutrale Stimme für einen Nutzer B abgibt, wenn Nutzer B zuvor auch mit einer neutralen Stimme für Nutzer A votiert hat (H2). Schließlich ist die Wahrscheinlichkeit größer, dass ein Nutzer A eine neutrale Stimme für einen Nutzer B abgibt, der eine Gegenstimme von einem Nutzer C erhalten hat, für den wiederum der erste Nutzer A eine negative Stimme abgegeben hat, als eine zufällige neutrale Stimme abzugeben (H3).

Tabelle 1. Modellergebnisse

	par.	*s.e.*	*t-value*	*p-value*
Netzwerk der Gegenstimmen				
Änderungsrate des Netzwerks (t=1)	2.213	0.0223	99.238	0.0000***
Änderungsrate des Netzwerks (t=2)	2.082	0.0217	95.949	0.0000***
Negative Reziprozität (H1)	1.605	0.1296	12.387	0.0000***
Netzwerk der neutralen Stimmen				
Änderungsrate des Netzwerks (t=1)	0.681	0.0126	54.048	0.0000***
Änderungsrate des Netzwerks (t=2)	0.614	0.0117	52.504	0.0000***
Neutrale Reziprozität (H2)	2.181	0.3267	6.676	0.0000***
Neutrale Balance (H3)	0.601	0.1285	4.677	0.0000***

Legend: *par.* = Parameterschätzer (*λ/β*) , *s.e.* = Standardfehler
*** p<0.001, ** p<0.01, * p<0.05

An dieser Stelle mag sich der Leser die Frage nach der Effektgröße der Parameterschätzer stellen. Wie bereits oben erwähnt können die Parameterschätzer wie logistische Regressionskoeffizienten interpretiert werden. Daher ist es auch möglich, das Chancenverhältnis (*engl. odds ratio*) der unabhängigen Variablen zu berechnen. In diesem Fall kann das Chancenverhältnis als der Faktor interpretiert werden, durch den sich das Verhältnis zwischen der Wahrscheinlichkeit, während eines Minischrittes eine Stimme abzugeben, und der Wahrscheinlichkeit, keine Stimme abzugeben, ändert, wenn sich die im Fokus stehende unabhängige Variable um eine Einheit erhöht und alle anderen unabhängigen Variablen konstant bleiben. Das Chancenverhältnis lässt sich berechnen als $e^{\beta_k^{X,W}}$.

Zum Beispiel ändert sich bezüglich H1 das Verhältnis zwischen der Wahrscheinlichkeit während eines Ministeps eine Gegenstimme abzugeben und der Wahrscheinlichkeit keine Gegenstimme abzugeben um den Faktor $e^{1.605} = 4.978$, wenn der Wähler mit seiner Stimme während dieses Minischritts eine Gegenstimme erwidert. Vergleichbar steigt das Verhältnis zwischen der Wahrscheinlichkeit, während eines Minischrittes eine neutrale Stimme abzugeben, und der Wahrscheinlichkeit, keine neutrale Stimme abzugeben, um den Faktor $e^{2.181} = 8.855$, wenn der Wähler mit seiner Stimme eine neutrale Stimme erwidert (H2). Schließlich beträgt das Chancenverhältnis in Bezug auf neutrale Balance $e^{0.601} = 1.824$ (H3). Wiederum werden die Forschungshypothesen stark durch die Chancenverhältnisse unterstützt.

5 Diskussion

Das Hauptanliegen dieses Papiers war es herauszufinden, was die Wahrscheinlichkeit erhöht, dass jemand eine neutrale Stimme für einen potentiellen Administrator in Wikipedia abgibt. Die Ergebnisse liefern starke Evidenz für neutrale Reziprozität (d. h. eine höhere Wahrscheinlichkeit, dass ein Nutzer A eine neutrale Stimme für einen Nutzer B abgibt, der auch eine neutrale Stimme für den ersten Nutzer A abgegeben hat) sowie für neutrale Balance (d. h. eine größere Wahrscheinlichkeit, dass ein Nutzer A eine neutrale Stimme für einen anderen Nutzer B abgibt, der eine Gegenstimme von einem Nutzer C erhält, für den der erste Nutzer A mit einer Gegenstimme votiert hat).

5.1 Theoretischer Beitrag und Implikationen

Dieses Papier liefert mindestens zwei theoretische Beiträge. Erstens trägt es zu unserem Verständnis der RfAs bei. Während die meisten Studien über RfAs deskriptive Studien sind, testet dieses Papier formal drei Hypothesen über RfAs. Hierbei wendet das Papier die Reziprozitätstheorie (z. B. [14, 15]) und die Balancetheorie (z. B. [16]) in einem neuen Kontext an (konkret im Kontext der Wahlen von Führern von Online Communities). Die Ergebnisse zeigen, dass die Propositionen beider Theorien auch in diesem neuen Kontext Bestand haben. Dies ist keinesfalls selbstverständlich, da sich Interaktionen in Online Communities substantiell von offline Interaktionen unterscheiden. Beispiele für solche Differenzen sind etwa mediierte Kommunikation und die Vorherrschaft text-basierter, asynchroner Kommunikation. Zum Beispiel beeinflusst die asynchrone, textbasierte Kommunikation die vermuteten Kausalverhältnisse in zwei Richtungen. Zum einen ist zu erwarten, dass durch die schriftliche Fixierung einer Stimmabgabe diese den entsprechenden Akteuren länger in Erinnerung bzw. abrufbar bleibt. Daher sollten die entsprechenden Kausalverhältnisse in Online Communities stärker ausgeprägt sein als bei mündlicher, synchroner Kommunikation. Auf der anderen Seite bedeutet asynchrone Kommunikation jedoch auch eine Zeitverzögerung, die sich negativ auf die vermuteten Kausalverhältnisse auswirken sollte. Zukünftige Forschung sollte daher auch entsprechende Hypothesen testen, die genau auf diese Unterschiede abzielen.

Zweitens wurde die Balancetheorie um einen neuen Zustand dyadischer Beziehungen erweitert. Konkret wurden die beiden Zustände einer positiven Beziehung und einer negativen Beziehung durch den Zustand einer „*expliziten Neutralität*“ erweitert.

Dennoch stellt sich an dieser Stelle die Frage nach der Übertragbarkeit der Studienergebnisse auf Wahlen im Allgemeinen. RfAs haben mehrere Charakteristika, die eine einfache Übertragbarkeit der Studienergebnisse auf Wahlen im Allgemeinen in Frage stellen. Erstens sind RfAs nicht geheim. Zweitens sind neutrale Stimmen in Wikipedia mit einem Kommentar bzw. einer Begründung für die Stimmabgabe versehen. Drittens wird jede Stimme und deren Begründung mit einem Zeitstempel dokumentiert. Während längst nicht jede Wahl geheim ist, sind die sukzessive Stimmabgabe und deren Dokumentation durchaus als besondere Merkmale der RfAs zu begreifen. Dennoch denken wir, dass wir mit diesem Papier dadurch einen theoretischen Beitrag leisten, dass wir die Anwendbarkeit der Reziprozitätstheorie und der Balancetheorie in einem neuen, wenn auch speziellen Kontext zeigen.

In Paragraph 2.1 haben wir das große Interesse der Forschungsgemeinschaft an diesem speziellen Kontext bereits aufgezeigt. Insbesondere hat die Forschungsgemeinschaft auch hier ein großes Interesse daran gezeigt, die RfAs aus einer Perspektive der Analyse sozialer Netzwerke heraus zu analysieren (vgl. [5-12]). Dennoch geht dieses Forschungspapier mit der formalen Herleitung seiner Hypothesen und deren Test weit über diese Arbeiten hinaus. Als neu dabei ist hier vor allem die Fokussierung auf neutrale Stimmen in den Wahlen zu sehen, die in vorherigen Analysen sogar oftmals ausgeschlossen worden sind.

5.2 Limitationen und zukünftige Forschung

Wie jede empirische Studie unterliegt auch diese Studie Limitationen, die ihre Relevanz und Rigorität (*engl. „rigor“*) einschränken. Wir denken nicht, dass diese Limitationen die Ergebnisse obsolet machen, so lange sich der Leser derer bewusst ist, während er seine Schlussfolgerungen zieht. Vielmehr bieten sie Raum für zukünftige Forschung und zur Weiterentwicklung dieses Papiers in einen Fachzeitschriftenartikel.

Erstens wird keine Maßzahl für die Anpassungsgüte des Modells berichtet. Jedoch existiert für die Klasse der stochastischen, akteurs-orientierten Modelle bisher kein globales Anpassungsgütemaß wie etwa R^2 in der linearen Regression (z. B. [47]). Eine Alternative könnte es sein, die Modellgüte durch Score-Tests [48] oder einen Monte-Carlo-Mahalanobis-Distanz-Test auf Basis einer Hilfsstatistik (wie etwa der „*indegree distribution*“) zu bestimmen.[7] Unglücklicherweise ist das untersuchte Netzwerk jedoch aufgrund der Rechenzeiten zu groß, um diese Tests auf handelsüblichen PCs durchzuführen. Diese Tests wären jedoch ein lohnendes Unterfangen für zukünftige Forschung.

[7] Diese Art von Test wurde von Lospinoso vorgeschlagen. Nach unserem Kenntnisstand wurde bisher kein Artikel mit einer fundamentalen Beschreibung dieser Methode publiziert. Der interessierte Leser findet eine Präsentation über diese Art von Test unter http://www.stats.ox.ac.uk/~snijders/siena/SienaGOF_s.pdf (Aufgerufen: 07.04.2016). Eine Anwendung dieses Tests in der IS Forschung findet sich in [49].

Zweitens wurden keine Robustheits-Checks für das Modell ausgeführt. Zukünftige Forschung sollte das Modell zum Beispiel auch mit einigen Kontrollvariablen schätzen.

Drittens wurde der Datensatz für die Analyse in drei äquidistante Zeitperioden aufgespalten, wodurch Zeit-Informationen verloren gingen. Zukünftige Forschung könnte daher darüber nachdenken, die Daten als Event-Daten zu modellieren.

Viertens wurden in unseren Analysen die Fürstimmen vernachlässigt. Auch wenn diese in der bisherigen Forschung bereits intensiv untersucht worden sind, könnte die zukünftige Forschung das Zusammenspiel von neutralen, positiven und negativen Stimmen im Detail untersuchen. Als ersten Schritt in diese Richtung untersuchten wir, ob positive oder neutrale Stimmen nach negativen Stimmen weniger wahrscheinlich sind und ob positive oder negative Stimmen nach neutralen Stimmen weniger wahrscheinlich sind. In Tabelle 3 finden sich in den ersten drei Zeilen die unbedingten Wahrscheinlichkeiten für eine negative, neutrale und positive Stimme (ohne die Anfangsstimmen der Wahl) als Vergleichswert. In den übrigen Zeilen der Tabelle stehen die bedingten Wahrscheinlichkeiten für eine negative (neutrale, positive) Stimme unter der Bedingung, dass die Vorstimme negativ (neutral, positiv) war. Auch diese Analysen stützen unsere Ergebnisse und zeigen die Bedeutung von neutralen Stimmen für Wahlprozesse in Wikipedia auf.

Fünftens wählten wir mit nicht-anonymen Online-Wahlen von Führern in einer virtuellen Gemeinschaft einen sehr spezifischen Rahmen. Daher besteht nach wie vor die Frage, ob die Ergebnisse dieser Studie (neben den oben genannten besonderen Merkmalen der RfAs) auch auf Wahlen im Allgemeinen übertragbar sind. Zukünftige Forschung sollte diesen Punkt im Detail untersuchen.

Tabelle 3. Wahrscheinlichkeiten für eine negative, neutrale und positive Stimme

	# Stimmen	*Wahrscheinlichkeit in %*
Unbedingte Wahrscheinlichkeiten		
Negative Stimme	22332	20.0744
Neutrale Stimme	6791	6.1045
Positive Stimme	82123	73.8211
Bedingte Wahrscheinlichkeiten		
Negative Stimme **|** *Vorstimme negativ*	11237	50.9153
Neutrale Stimme **|** *Vorstimme negativ*	2632	11.9257
Positive Stimme **|** *Vorstimme negativ*	8201	37.1590
Negative Stimme **|** *Vorstimme neutral*	2493	37.0982
Neutrale Stimme **|** *Vorstimme neutral*	993	14.7768
Positive Stimme **|** *Vorstimme neutral*	3234	48.1250
Negative Stimme **|** *Vorstimme positiv*	8602	10.4322
Neutrale Stimme **|** *Vorstimme positiv*	3166	3.8396
Positive Stimme **|** *Vorstimme positiv*	70688	85.7281

The Role of Information Elaboration for Co-Construction of Meaning during Idea Convergence: A Causal Mediation Analysis

Isabella Seeber

University of Innsbruck, Department of Information Systems, Innsbruck, Austria
isabella.seeber@uibk.ac.at

Abstract. Teams need to co-construct meaning to establish shared understanding about concepts when converging on the best ideas generated from crowdsourcing events. Facilitation interventions can aid the co-construction of meaning. The causal mechanism is believed to be the extent exchanged information is elaborated on. However, this mediating role has not been empirically confirmed in past research. Information elaboration in teams with and without facilitation intervention was tested with causal mediation analysis by drawing on data collected in a laboratory experiment. The findings suggest that facilitated teams had better information elaboration and co-construction than non-facilitated teams. Moreover, information elaboration could be identified as a strong causal mechanism through which facilitation interventions affect the co-construction of meaning. The study contributes to unravelling the black box of team processes through which this causal effect of facilitation intervention arises and helps fostering the design of improved automated feedback mechanisms.

Keywords: causal mediation analysis; co-construction; facilitation intervention; feedback; idea convergence

1 Introduction

In practice this means that teams need to identify 10 – 40 ideas out of hundreds and thousands of ideas [1-3]. It is difficult to deduce the value of an idea [2, 4], which makes idea convergence a demanding decision-making process [3]. Unlike traditional convergence teams, teams working with crowdsourced ideas need to converge on ideas that are not their own. This requires convergence teams to elaborate on raw idea descriptions without knowing how the idea came about [5]. For this purpose, they need to establish shared knowledge [6]. Facilitation techniques for idea convergence allow intervening into information elaboration processes in order to drive shared understanding [7]. Empirical evidence investigating *how* such facilitation interventions can achieve better convergence outcomes is scarce [6] particularly in crowd settings [5]. It is unclear to what extent facilitation interventions affect information elaboration among team members and if the extent of information elaboration is the *causal mechanism* for the co-construction of meaning, an antecedent of shared understanding.

13th International Conference on Wirtschaftsinformatik,

Seeber, I. (2017): The Role of Information Elaboration for Co-Construction of Meaning during Idea Convergence: A Causal Mediation Analysis, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 697-700

This study contributes to closing this gap by investigating the mediating role of information elaboration in teams that converge on crowdsourced ideas with or without facilitation intervention.

2 Background and Hypotheses Development

The team learning processes of individual construction, co-construction, and constructive conflict have been established as antecedents of shared understanding [8]. The team learning process of co-construction is particularly relevant to idea convergence, which strives to establish a shared understanding of the meaning of concepts [9]. Over the last decade, facilitation techniques have been designed that directly aim at helping team members to converge on ideas [9]. By actively intervening into the execution of the process and the discussion, the facilitator affects information processing in teams [10], which, in turn, alters how the team co-constructs the meaning of shared concepts [6]. Thus, *H1: Teams with facilitation intervention will have better co-construction of knowledge than teams without facilitation intervention*.

Team members need to elaborate on exchanged information [11] in order to synthesize individual understandings into shared meaning [12]. While information elaboration is conceptualized in this study as exchanges about the nature of knowledge in different domains, such as viewpoints or beliefs, co-construction of meaning is about the joint construction from previous exchanges [13]. Facilitation stimulates such kinds of deeper information processing of team members with feedback cues. Thus, *H2: Teams with facilitation intervention will have more information elaboration than teams without facilitation intervention.*

It is not clear to what extent the team process of information elaboration is affected by facilitation intervention and in case it is affected, if the extent of information elaboration is the *causal mechanisms* that defines the co-construction of meaning, an antecedent of shared understanding [8]. It is argued that facilitators can intervene into interaction processes to avoid shallow processing of exchanged information [14] and keep the team's interaction on topic [10]. This can be accomplished by asking questions, clarifying statements, and co-creating artefacts representing their common understanding [15]. Thus, *H3: The effect of facilitation intervention on co-construction of meaning will be mediated by the extent of information elaboration in teams.*

3 Methods

A laboratory experiment was conducted to test the hypotheses. The treatment condition was instantiated with a facilitation technique from the design pattern language for collaborative work practices called thinkLets [16]. The external facilitators were trained by a professional facilitator and worked at the department as PhD-students or post-doctoral students. For their interventions, facilitators relied on a pre-tested and predefined script that included step-wise instructions how to run the convergence process and 26 prompts. Subjects were recruited from an undergraduate information systems course and were randomly assigned to the experimental condition. The task described a flooding event in the fictitious city called Norvos, which was based on another emergency response task [17]. All teams were supported by the collaboration software ThinkTank by GroupsSystems. Co-Construction of meaning was adopted from [8]. Information elaboration was measured with two items adopted and adapted from [18]. Two additional items were added. The control variables were collaborative orientation, working history, gender, and team size. Validity tests were satisfactory.

4 Results, Contribution, and Limitations

Hypothesis 1 ($F(1,84)=10.272$, $p < 0.05$) and 2 ($F(1,84)=11.454$, $p < 0.05$) were accepted and suggest that teams with facilitation intervention will differ from teams without facilitation intervention. H3 suggested that the extent of information elaboration is the causal mechanism through which facilitated teams will show higher co-creation of meaning. The result shows that the indirect effect (ACME) [19] due to information elaboration is in fact significantly mediating the relationship between the treatment and the outcome with an estimate of 0.439 ($p < 0.01$). Sensitivity analyses were conducted and also found that the causal mediation results seem to be robust to unmeasured confounders.This study found support for the mediating role of information elaboration. Findings of this study help to unravel the black box of team processes through which the causal effect induced by facilitation or feedback arises [20]. Given the increasing demand to design effective automated feedback mechanisms [10] into collaboration environments, it is important to understand what team processes are affected, how they change and if they change into what direction team processes should change. There are some limitations to consider that provide additional avenues for future work. First, the causal mediation analysis did not consider any moderating influence on the mediation path. Second, the construct information elaboration is a mix of items deduced from past research and self-developed items. Third, this study focused on a single causal mechanism, information elaboration.

Inductive Reference Modelling Based on Simulated Social Collaboration

Andreas Sonntag[1], Peter Fettke[1], Peter Loos[1]

[1] German Research Center for Artificial Intelligence at Saarland University, Institute for Information Systems, Saarbrücken, Germany
{andreas.sonntag,peter.fettke,peter.loos}@iwi.dfki.de

Abstract. Organizations nowadays possess huge repositories of process models. Inductive reference modelling can save costs and time by reusing process parts of process models belonging to a common domain. The inductive development of a reference model for a large corpus of process models is a difficult problem. Quite a few, primarily heuristic approaches have been proposed to the research community that require an approximate matching between the single processes. With our approach, we introduce a new concept that brings in for the first time an abstract efficiency simulation of the social collaboration around knowledge-based process models. A reference model is assembled featuring at least the topological minimum requirements to be significantly more efficient than the input process models. Our evaluation indicates that the approach is able to generate reference process models that are more efficient than the input process models and at least as a reference model designed by an expert.

Keywords: Social Collaboration, Knowledge Work, Social Network Analysis, Reference model mining

1 Introduction

1.1 Research Motivation

Business process models, as event-driven process chains (PMs), are representatives of processes in an enterprise or in an organization. Current processes may be analysed in order to be improved. Organizations maintain huge repositories of these PMs. Therefore, the PMs have to be analysed as it is necessary for optimizing and managing the repositories. Typically, business analysts have specialized knowledge of the processes and provide expertise in modelling reference process models (RMs). These RMs enable reusability, modularity and avoiding redundancy by the design of new models which saves costs and time. They represent a best practice in a domain and can be extended for individual requirements [1]. The inductive development of universally applicable and reusable RMs (reference modelling in the following) is of great importance in the field of business process management as it seeks to infer generic models or patterns of a domain [2]. A strategy of reference modelling is to

Sonntag, A.; Fettke, P.; Loos, P. (2017): Inductive Reference Modelling Based on Simulated Social Collaboration, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 701-715

identify similarities between individual PMs and to derive an abstracted PM [3]. In contrast to deductive approaches, general theories and concepts are not applied for the development of RMs [4]. The utilization of RMs can save time and costs towards single PM variants [17] which makes their execution efficient. The efficiency of a RM hence should be considered when aiming at developing RMs.

1.2 Related Work

Prior respecters of reference modelling are: [25] mine RMs by analyzing desired behavior from event log data. [27] and [26] develop a RM that has a minimal graph-edit distance respectively a minimal cost of change to given process variants. [7] and [30] apply genetic algorithms. [32] apply factor analysis to find statistical commonalities in the process structures. [33] assemble a RM from hierarchical clustered process fragment. [28] seek to identify similar frequent substructures among PMs. [29] derive a RM by gathering similarities of given PMs not only by their structure but by their behavior profile. [31] iteratively create a RM based on the proximity of node pairs.

The named previous automatic reference modelling approaches develop a RM "bottom-up" by comparing the node labels or PM topology. This comparison requires critical assumptions such as a certain model design quality, consistent syntax and language. The understanding of the semantics or similarity of process elements is subject to the process matching problem whose underlying graph matching problem is principally NP-complete [16]. There are heuristic approaches for the problem that achieve an approximate solution which is not generally unique and is afflicted with a loss of information [5].

1.3 Research Problem and Approach

Social collaboration in organizations is a competitive advantage as it is a driver for efficiency, time and money saving potential, product quality and knowledge diffusion [15]. Reference modelling has to be seen under several facets simultaneously in regard to quality and usability [18]. We belief that social collaboration around PMs is an important facet for reference modelling, especially in the context of knowledge-based processes. In the field of inductive reference process model mining, a social perspective for matching the process flow is missing. Prior approaches are primarily based on label matchings and similar graph structure detection in the process models. The influence of the topology of social collaboration between the humans that work around the process (performers) is neglected. Our research question thus is, what is an efficient collaboration topology between performers for a corpus of process models.

Therefore, we want to conceptualize and implement in this work an approach for the inductive development of a RM from a corpus of knowledge-based business process models applying a social perspective for matching the process flow. The resulting RM shall consist of an efficient collaboration topology for the performers working at their associated process functions. Following the concept of [9], the RM is a PM derived from a performer network (PN) that represents at least the minimum requirements of the PM to be efficiently executed. The PN for the RM development is optimized to fit best to the efficiency of the input PMs. The definition of efficiency can be found in section 2.2. The RM development and interpretation does not need a label matching. The resulting RM consists the minimum process elements for being as efficient as the PMs from it was derived. It can be tailored to concrete organizations and processes. Thereby, risks for the execution potential of a PM can be identified and reduced; needed key performers and their influence can be tracked; the structure of successful co-workership and knowledge/information transfer can be disclosed. The organization becomes more transparent and costs as well as managing effort are reducible.

Our approach relies on social network analysis and evolution strategy [10]. Its empirical evaluation follows [8] and the prototypical implementation is based on design research [14]. The validation of our concept faces three scenarios in which our prototypical implementation develops RMs from three PM corpora of different domains and two languages. The developed RMs are compared to the given respective gold RMs of each scenario. Gold RMs are designed by domain experts.

The paper is structured as follows: After fundamental concepts and terms are introduced, our approach is described followed by the validation of our concept with the experimental design, the evaluation and the discussion of our results. Afterwards, a conclusion brings this work to a close.

2 Fundamentals

2.1 Social Network Analysis

A social network represents the relation between agents. Agents are constituted as nodes and the links between them as edges. The agents are atomic units and they can only communicate and collaborate with agents that are directly connected to them. Social network analysis (SNA) seeks to disclose social interactions, political power and co-workership by abstracting from social relationships [6]. A social network has *n* agents/nodes and *m* edges. People tend to form clusters which are groups of directly connected individuals [20]. Those edges are called local edges. Edges between clusters are called global. The extend of this tendency can be measured by the average clustering coefficient of a network, *CC*. *CC* is the number of the actual- in relation to the possible number of edges between an agent's neighbours, averaged over all agents. The number of an agent's neighbours is called degree. The mean degree of a network *md* is the average number of all agents' neighbours. The number of agents on the shortest path between two gents is called path length. The network density *dens* is defined as $\frac{2m}{n*(n-1)}$. It describes the relation between existing and possible edges in the network which makes it a measure for being sparse. Being sparse is an essential property of many social networks as they tend to form relatively small butt dense clusters with few global edges between them [19]. Among others, this makes such social networks a "small world", in which all individuals, e.g. independent from geographic distances, are separated by only a few edges [20]. Another important peculiarity of social networks is the appearance of hubs as [22] suggested in theory- and [21] in an empirical study as they confirmed the appearance of hubs in a real organization over time. Hubs are nodes that have a much higher degree than the most other nodes. Hubs constitute hierarchy which is a necessary empirical implication of social networks. The outcome of actual relationships strongly depends on structural network properties [23]. The identification of critical joints in the network such as the collaboration of working individuals that are geographically separated and that may belong to different functional- and hierarchical positions, is of strategic importance for collaboration [24].

2.2 Efficiency of Process Models

The concept of performer networks (PNs) and their efficiency is introduced by [9]. Almost every business process needs social collaboration to be efficiently executed [12]. The concept of PNs connects the aim of business process management to design, model and execute efficient processes with the potential of SNA. Performers are agents working on process functions with a set of capabilities in a PN. Capabilities for this study are simplified as a mapping between a process function and a number indicating the extent of being capable/efficient to work at this function.

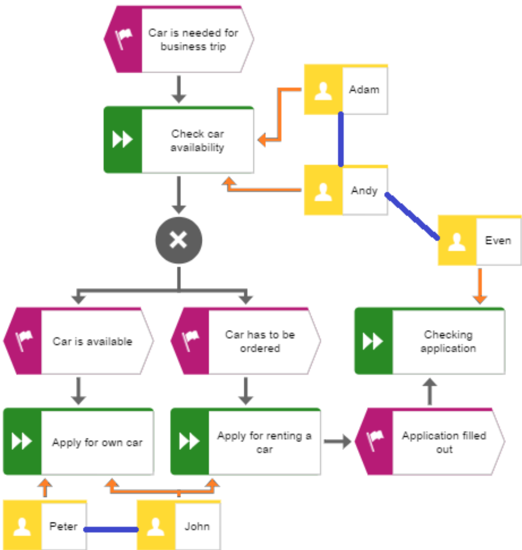

Figure 1. An example PN fragment around a PM

PNs represent a minimal topology of co-workership around business processes in an organization. PNs are formalized as social networks in which exist two kinds of edges: social edges that connect performers and functional edges that connect performers with process functions (*assigned_nodes*). An example PN fragment around a PM is presented in figure 1. The blue edges between the performers (named nodes) are social edges and the black edges/arrows between performers and process functions are functional edges. The other edges are process edges, connecting process nodes. The efficiency of a PM is the efficiency of the most efficient combination of a generated PN and the PM. The efficiency of a PN/PM combination is computed with an algorithm based on social network analysis and evolution strategy. Several repeated simulations of a work package, processed through the control flow of the PM, count how many iterations were needed to complete the whole process. Only performers associated to a process function (*involved_performers*) process the work package. They are much faster if they have the proper capability for this function. At the same time, neighbours of the performer collaborate which increases the PN efficiency PNE. PNE corresponds to the standardized PN efficiency definition of [9]. $PNE = 1 - (\frac{mean(\#neededIterations)}{max\#Iterations})$. PNE is the inverse of the relation between the number of needed iterations, averaged over all simulation runs $mean(\#neededIterations)$ and the maximal possible number of iterations. $max\#Iterations$ refers to a PN with one incompetent performer assigned to each process function. A PN can be generated by every social network generator that assigns at least one performer to a process function. The evaluation of PNs in [9] implies that a performer topology with hierarchy, short paths and significant clustering generates efficient PNs. Their suggested network generator by [11], PN generation algorithm and parameters are the basis for our PN generation in *generatePN* (see algorithm 5).

3 Approach

For our approach, we consider real-world PMs as event-driven process chains which are directed graph structures, consisting of a set of edges that indicates an order between a set of nodes. Each node has a label, as a linguistic expression of natural language, describing the node's function. Other (meta) information that might be provided is ignored. The fundamental assumption of our approach is that a RM must be efficient at least significantly more efficient than the most efficient input PM. We want to develop a reference PN from the input PMs entailing at least the topological minimum requirements to be efficient around all input PMs. It can be interpreted as a reference for positioning and putting people on team tasks for the whole organization in which all input PMs are assumed to be executed. Our approach's advantage is that no label matching or PM topology matching has to be considered as prior approaches require.

In this section we describe our approach on a high level. The procedure for the development of a RM from a set of input PMs is presented in algorithm 1. It is based on an evolutionary strategy which is an optimization driven only by mutating and selecting individuals [10]. The mutation rate can be increased every run, if no convergence was reached, which allows bigger steps through the solution space. The evolutionary strategy itself runs in linear time and can achieve a fitness/solution quality convergence to an acceptable solution after only a few iterations. The apparent advantage of evolutionary strategy, in contrast to other evolutionary algorithms, is to be fast and parallelizable because the population has only to be evaluated once per iteration. If it becomes foreseeable after many iterations that the individual's fitness will not improve, converges or even impairs, the evolutionary strategy can be run again or parallel runs on many processors at the same time can be executed until an acceptable solution occurs. The disadvantage on the other hand is that an evolutionary strategy can converge towards a local optimum in only few iterations but there is no proof that a global optimum will ever be reached [13].

Every PN is considered as an individual/possible solution. Its efficiency can only be seen in connection to a PM / or a set of PMs. The fittest resulting individual is the reference PN for the input PMs. In order to ensure reliability, the evolution strategy is repeated 1000 times as this meets the limitation of our computing time. We circumvent the label matching problem by mutating the individuals. The mutation is a random decision about how to arrange information inside an individual. This random decision made during the evolution compensates that we have no distinct knowledge about the distribution of the decision's quality. The selection forces the mutation quality to become better over many iterations. Therefore, a fitness function is defined in algorithm 4 that evaluates the sum of the efficiency of an individual towards all input PMs weighted by the inverse of its density. The efficiency of a PN/PM combination is evaluated with the procedure by [9]. The additional weight is necessary because otherwise a super PN with thousands of performers and functional edges would receive the highest fitness. A small/sparse PN with similar efficiency is to prefer. The same goes for a RM because the more process nodes a RM comprises, the bigger it becomes since there is no matching which would condense multiple nodes. As an objective evaluation criterion, a smaller RM with similar efficiency is likewise to prefer. "Super-models" with many nodes overloaded a user/modeller and prevented him from brining in own ideas [7].

The development of a RM follows the evolutionary strategy in *developReferenceModel* (algorithm 1): At first, for each PM in the set of input PMs *Models* an efficient PN is generated with *generatePN* in algorithm 5. Those PNs represent the initial population and are only optimized to be efficient for their respective PM. The best individual out of this population is picked by the selection operator who calculates all individuals' fitness values and chooses the individual with the highest fitness value. This individual is now called *best_individual* and its fitness is *best_fitness*. In the same step, *cur_fitness* and *minimum_fitness* are set to the same fitness value. The current individual *cur_individual* on which the mutation and selection operators are applied on is now created and initially set to a copy of *best_individual*. *cur_fitness* is the fitness of the current individual. The minimum fitness *minimum_fitness* is the fitness that must be significantly exceeded by *cur_fitness* during the evolution strategy (step 5) in which the mutation and selection operators drive *cur_individual* to reach a fitness convergence significantly greater than the minimum fitness. The mutation of an individual (algorithm 2) assigns random capabilities out of the possible capabilities in the input PMs to a randomly chosen portion of performers (between 0 and 100%) and flips their edges. When the evolution strategy found a good PN, a RM is derived from it (see *deriveEfficientModel* in algorithm 3): The RM contains all process functions to which the performers of the PN are assigned. A process edge between two functions is added if any pair of performers is connected so that the first performer is assigned to the first function and the other one to the second function. Conversely, that means that a generated PN around the RM is efficient in all combinations with the input PMs.

The developed RM is to understand as a minimum model that exhibits at least the efficiency of the input PMs and simultaneously it has relatively few nodes. By extending the fitness function, the resulting RM can be adapted to concrete requirements. The final step in the RM development would be to specify the performers in the real organization and bringing the reference PN and the developed RM together. The developed RM has to be seen as a combination of a reference PN with its corresponding PM. Only this combination can be interpreted and compared. This is a comparable constraint to a RM developed with the help of a label matching as that RM can only be used if the matching is of suitable quality which is subjective and difficult to measure.

Algorithm 1: Development of a RM:
developReferenceModel(Models)
Input: *Models*, A set of process models   Output: A RM

1. Let *best_individual* be a PN = *pn* that maximizes *fitness(pn, Models)* with *pn* = *generatePN(m)* for each PM *m* ∈ *Models*
2. *best_fitness* = *cur_fitness* = *minimum_fitness* = *fitness(best_individual, Models)*
3. *cur_individual* = *best_individual*
4. **Repeat** until convergence of *cur _fitness* >> *minimum_fitness*:
    a. *mutate(cur_individual, mutation_rate, Models)*
    b. *cur_fitness* = *fitness(cur_individual, Models)*
    c. **If** *cur_fitness* > *best_fitness* **Then**:
        i. *best_individual* = *cur_individual*
        ii. *best_fitness* = *fitness(best_individual, Models)*
5. **return** *deriveEfficientModel(best_individual)*

Algorithm 2: Mutation of a PN: *mutate(PN, mutation_rate, Models)*
Input: A PN, *PN*, *Models* and *mutation_rate* in [0;1]

1. *portion* = a set with (*mutation_rate* * 100%) of *PN.performers*
2. **For Each** *performer* in *portion* **Do**:
    a. *performer.capabilities* = random capabilities from *Models*
3. **For Each** edge *(p1, p2)* with *p1,p2* ∈ *portion* **Do**:
    a. flip edge *(p1, p2)*

Algorithm 3: Deriving an Efficient PM from a PN:
deriveEfficientModel(PN)
Input: A PN, *PN*   Output: A PM

1. *M* = empty PM
2. *M.add_nodes(PN.assigned_process.functions)*
3. **For Each** edge *(p1, p2)* **In** *PN.social_edges* **Do**:
    a. **For Each** (*n1, n2*) ∈ *(p1.assigned_nodes, p2.assigned_nodes)* **Do**:
        i. **If** there is at least one edge (*ip1*, *ip2*) in (*n1.involved_performers*, *n2.involved_performers*) **Then**:
            1. *M.add_edge(n1, n2)*
4. *M.delete_unconnected_nodes()*
5. **return** *M*

Algorithm 4: Fitness of a PN: *fitness(PN, Models)*
Input: A PN, *PN*   Output: A numeric fitness

1. **return** $\sum efficiency(PN, m) * (1 - dens(PN))$ for each *m* in *Models*

Algorithm 5: Efficient PN Generation around a PM Based on [9]: *generatePN(PM)*
Input: A PM, *PM*   Output: A PN

1. let *PN* be a random social network
2. assign *PN.performers* to random capabilities from *PM*
3. assign *PN.performers* to random process functions from *PM*
4. simulate *PN* around *PM*
5. **Repeat** 1-4 until *PN.efficiency* reaches a local optimum after an adequate number of iterations
6. **return** *PN*

4 Validation of Concept

4.1 Experimental Design

The validation of concept elucidates its potential and applicability. Herby, the concept approach is validated to be able to reproduce its results (reliability), to explain the increase of result quality (intern validity) and to produce a result that is generalizable/transferable (extern validity) [8]. For that purpose, we implemented our approach within the "Refmod-miner" framework which is a prototypical software platform (http://refmod-miner.dfki.de/). All algorithms described in the approach section were implemented in Java, the used network generators and SNA algorithms in section 2.1 were taken from the Python library NetworkX 1.11. The hardware configuration on which the implementation of our approach was executed involves an Intel(R) Core(TM) i7-3610QM CPU @ 2.30GHz and 8GB of RAM.

We provide three evaluation scenarios in which we demonstrate the reliability, intern validity and extern validity of our approach. The scenarios rely on three different real-world knowledge-based domains and two different languages, German and English. The three scenarios cover S1: 5 knowledge transfer PMs from knowledge management in outsourcing relationships and knowledge progress control [34], S2: 10 PMs created during the workshop for modelling in higher education (MoHoL 2016) [35]. S3: 7 PM variants/solutions about business trip admission for business informatics assignments in exams at a German university [36]. For each scenario, also a gold RM is provided, made by a domain expert, whose execution comes to an exemplary result comparing to the models in its scenario. For example, in S2, at the end, a customer is informed and in S3, a car for a business trip is ordered. PM properties, such as the sum, minimum value, first, second and third quartile and the maximum value for the number of nodes, start nodes, number of process edges and graph density, are presented in table 1.

Table 1. Overview over PM metrics: sum, minimum, maximum and quartiles

S1|**S2**|S3	sum	min	q25	median	q75	max
nodes	194|**187**|264	18|**15**|19	22|**17**|36	28.5|**18.5**|41	35|**19**|43	62|**26**|43
start nodes	6|**9**|11	1|**1**|1	1|**1**|1	1|**1**|2	1|**1**|2	1|**1**|2
edges	221|**200**|280	23|**17**|20	23|**18**|38	30|**20.5**|44	39|**21**|45	76|**25**|46
density in %	26|**62**|21	2|**4**|3	3|**6**|3	4|**6**|3	5|**7**|3	8|**8**|6

As described in the approach, our prototypical concept implementation runs *developReferenceModel(Models)* 1000 times. The mutation rate was set to 0.2 as this rate indicated significantly better results than 0.1, 0.3 and 0.4 in the first 10 runs. For each scenario corpus, each evaluation of PNs is repeated 100 times, and records these topological properties of the evolving individuals in every iteration: *num_per* (number of performers), *md* (average performer degree), *CC* (average clustering coefficient), *dens* (the PN density), *minimum_fitness* (defined in *developReferenceModel* as the fitness of the best PN for the input PMs, respectively the best initial individual (remains constant during the algorithm run), *cur_fitness* (fitness of the actual evolving individual), *best_fitness* (fitness of the present best individual). The fitness of the respective gold RM *gold_fitness* is measured to ensure that the gold RMs are comparable to our generated models. The fitness of a gold RM is evaluated by the same procedure as the minimum fitness is calculated, namely by the fitness sum of its most efficient PN towards all input PMs.

4.2 Evaluation

The runtime of *developReferenceModel* took on average 15 seconds per run. Runs in scenario S2 took on average 20% longer than the others and runs in S3 took on average 7% longer than S1. One iteration took between 0.25 and 2 seconds. The fitness of evolving individuals increases with the number of iterations in one run for reaching *cur_fitness (#iterations*) during the algorithm ($p < 0.001$) in all scenarios which can be observed in figure 2. Each point stands for a run of the PN development algorithm (the respective scenario that was run is marked with its own colour).

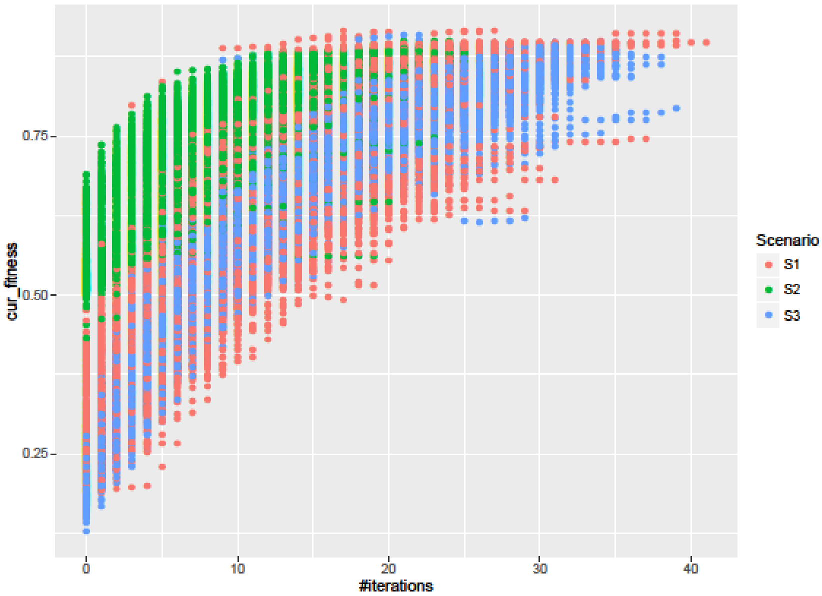

Figure 2. *#iterations* vs *cur_fitness* for all scenarios

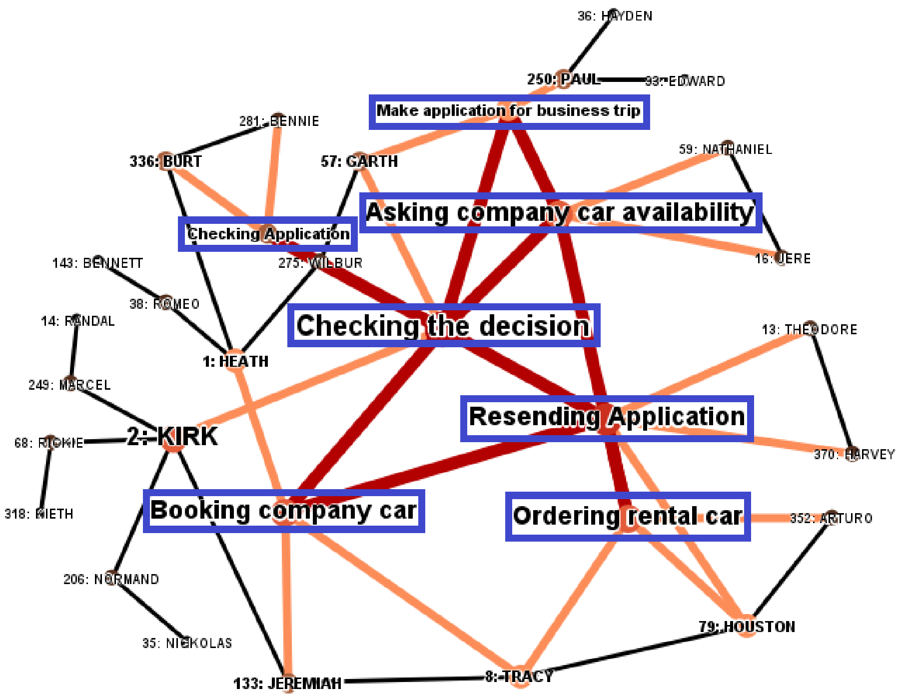

Figure 3. Reference PN with its derived RM for S3

Table 2. Descriptives for *best_fitness* over all runs with smallest value (Min), arithmetic mean (Mean), standard deviation (SD) and highest value (Max)

Scenario	Min	Mean	SD	Max
S1	0.84	0.89	0.01	0.92
S2	0.84	0.88	0.01	0.90
S3	0.84	0.88	0.01	0.91

Table 3. Average efficiency over all algorithm runs with standard deviation in brackets

Scenario	*best_fitness / minimum_fitness*	*best_fitness / gold_fitness*	*gold_fitness / minimum_fitness*
S1	4.67 (0.07)	1.19 (0.04)	3.92 (0.13)
S2	1.76 (0.02)	1.56 (0.04)	1.13 (0.03)
S3	6.01 (0.10)	2.58 (0.12)	2.33 (0.10)

Table 4. Correlations between respective variable and *cur_fitness*, $p < 0.01$

Scenario	*#iterations*	*num_per*	*md*	*CC*	*dens*
S1	0.86	0.86	-0.90	0.86	-0.88
S2	0.80	0.80	-0.82	0.77	-0.79
S3	0.92	0.93	-0.92	0.86	-0.88

In no run, more than 42 iterations were needed to reach convergence. As we can see in table 2, the mean best reached fitness lies nearer to its maximum than to its minimum. The standard deviation of *best_fitness* amounts to 0.01 for all scenarios. All PNs generated from the scenario respective gold RMs have a very low *num_per*, *CC* and *dens* with a simultaneously high efficiency and fitness over all input PMs. Figure 3 presents the fittest PN together with its derived PM, which we see as RM for all input PMs in S3. The figure contains process functions and process edges of the RM, performers of the reference PN and the related functional as well as social edges. All edges are undirected indicating mutual relations. Nodes with numbers are generated performers and the others with blue boxes are process functions. Black curves are social edges, red curves are process edges and orange curves are functional edges. Size and colour intensity of nodes and edges indicate the strength of their degrees. For reasons of clarity and comprehensibility only performers and process functions with a degree greater than 2 are plotted. In table 3, the average efficiency of all algorithm runs is presented. The average efficiency is the ratio between *best_fitness* and *minimum_fitness* of a run, averaged over all runs. The same applies for the relations between *best_fitness* and *gold_fitness* and *gold_fitness* and *minimum_fitness*. As an example, the fitness of the most efficient evolved PN in S3 was 2.58 higher than the respective gold PN and 6.01 times higher than the highest fitness of all individuals from the initial population (*minimum_fitness*). The fitness of the gold PN was 2.33 times greater than the minimum fitness. The relation between the fitness of the gold PN and the best initial individual was 2.33. Each standard deviation is significantly lower than a tenth of the corresponding average relation which speaks for a sufficient number of algorithm runs for this evaluation.

4.3 Discussion

The mutation rate of 0.2 reached a fitness convergence in all scenarios. Maximal 5 runs were needed to find an acceptable individual. The degree distributions of all efficient PNs around the gold RM and the best evolved PN, for all scenarios show the existence of hubs. Also, those PNs exhibit a significant but low clustering and density. The existence of hubs is an evidence for hierarchy which means that teams/clusters have single members that are much more central (between more people) than others [22]. This finding seems to be a condition for efficiency which is also confirmed by [9] for knowledge working processes. The number of performers correlates with the fitness over many iterations which means that more performers make the evolving PN more efficiently but this effect is compensated by the negative influence of the mean degree. All correlations in table 4 are stable over the scenarios in the meaning of their equal sign. The topological PN properties density, clustering and mean degree seem to be fitness drivers. For the approach's reliability pleads this stability after 1000 repetitions of the algorithm and of the repeated generation/evaluation of each PN.

According to our experimental design, we see the intern validity as confirmed by the significant fitness increase towards the minimum fitness for all scenarios over all runs (h0: *cur_fitness* < *minimum_fitness*; $p < 0.001$). Also there is a significant correlation between the number of iterations and the fitness ($p < 0.001$). Our algorithm so has an ascertainable influence on the evolvement of better individuals. For the extern validity, we tested the significant fitness increase towards the fitness of the gold reference PNs for all scenarios over all runs (h0: *cur_fitness* < gold_fitness; $p < 0.001$). The relation between the gold reference PN and the minimum fitness was always significantly greater than 1.0. That is an assertive indicator for our algorithm to be able to generate efficient reference PNs for various scenarios. All gold RMs were evaluated to be highly efficient and fit. This speaks for the validity of our approach because arbitrary models out of the initial population are significantly less efficient (h0: *fitness(generatePN(m), Models) > fitness(generatePN (gold_PM), Models)* for each PM *m* in the input PMs *Models* and the respective gold RM; $p < 0.01$). That means that the generated PN around the gold RM is efficient for all input PMs. Considering the low density and the random assignment of capabilities to performers in an efficient generated PN, its performers have only the most critical capabilities to work on the most critical process functions over all input PMs. This also means that the gold RMs' efficiency can be compared to other RMs for the input PMs which makes our fitness function a valid indicator for the quality of a RM.

The advantage of our approach is that the RMs can be generated valid over different domains. The proposed PN/RM combination describes a minimum topology of performers and their assigned process functions that is efficient towards the set of given input PMs. This proposed PN and RM can be adapted for specific stated requirements such as pre-given teams or pre-assigned performers to certain process functions. For a real environment, their efficiency comparing to other team/hierarchy constellations can then be simulated and evaluated. The RM in figure 3, as an example, indicates that the work flow between "Booking company car", "Ordering rental car" and "Checking the decision" is most critical for the efficiency of all process variants in S3 as they have the highest degrees of all process functions which makes them central in the RM. These process functions lie on critical paths in most process variants in S3, in the meaning of paths that reach from start nodes to end nodes and lie on many other paths at the same time. For that reason, most of all hub performers, such as "Kirk" "Jeremiah" and "Heath", were placed to work with their subordinated teams at this process functions. This can be interpreted as a recommendation or reference for a modeller to focus on needed capabilities for this process region when positioning real personal, e.g. at checking the decision for booking a car.

Limitations: Our approach focusing only on PN/PM topology is quite abstract and based on simplified assumptions about real processes and organizations. Organizations in our approach only consist of a set of performer networks and PMs. Their execution environment, social behaviour, resource allocation, communication- and production/processing capacities are not considered. In order to demonstrate the potential of our approach, the implemented algorithm produces quickly an acceptable result but will hardly reach a global optimum. For achieving a much better result, the number of performers should be reduced nearly to the number of needed performers in the gold RMs. An adapted, organization-specified implementation that considers the environment, the concrete performer capabilities and restrictions for their process assignment will be imperative for our approach to be utilized by practitioners.

5 Conclusion

In this paper we introduce a new concept for the inductive development of reference process models. A social perspective for matching the process flow is applied, rather than a traditional label matching which is an inexact and subjective approach. For a given set of input PMs, a reference process model is developed, in a few seconds of runtime, by including all process functions that are minimum requirements for the resulting model to be efficient. The efficiency is measured by the time that simulated performers need to complete the process. Three evaluation scenarios are provided to evaluate our approach. The evaluation indicates that the generated reference process models are at least as efficient as the input PMs and as a RM designed by an expert. Our results confirm the potential of our approach as they confirm its extern validity.

From a theoretical point of view that means that the efficiency of RMs designed by experts can be compared to our developed RMs which makes our fitness function a valid indicator for the quality of a RM. This in turn implies social collaboration to be an important facet for reference modelling. Our approach can be tailored to concrete organizations and processes. Practitioners take advantage of pre-selecting efficient sub corpora out of many models and identifying maybe invisible lead performers / critical junctures, in contrast to the formal structure, constituting efficient structures of co-worker ship around process models.

In future works, we want to provide a method to evaluate the quality of reference process models based on this approach. Also we will evaluate event logs of the execution of business processes to add a time/cost component to our fitness function for developing reference process models.

Functional Interdependencies between Quality Techniques reverting to Meta Models

Florian Johannsen[1]

[1] University of Regensburg, Management Information Systems, Regensburg, Germany
florian.johannsen@wiwi.uni-regensburg.de

Abstract. Considering the digitalization of the economy, process-oriented quality management (PQM) has increasingly been gaining attention. In the course of a PQM project, quality techniques are applied to elicit employees' process knowledge and transform it into solutions to overcome process weaknesses. However, quality techniques may support each other during application or produce contradictory results, depending on the so-called "functional interdependencies (FIs)" between them. Little understanding exists of how such FIs can be properly identified, which is a prerequisite to exploit valuable synergies between quality techniques. To uncover the corresponding interdependencies, we revert to meta models in this paper, which allow to precisely describe a technique's functionality. Generally valid indicators on a meta model level are derived to unveil the existence of FIs.

Keywords: Process knowledge, meta model, quality technique.

1 Introduction

Many enterprises go through profound transformations these days triggered by the increasing digitalization of the economy [1]. Against this background, the improvement or redesign of business processes, in the context of process-oriented quality management (PQM) projects, is an important task [2], [3]. Only if the business processes are aligned with the expectations of internal and external customers, the purposeful definition of business services and the introduction of IT systems to beneficially support a company's value creation are possible [4].

However, the execution of PQM projects is challenging and many initiatives fall short of expectations [2], [5]. The success of PQM projects largely depends on the participation of employees from all cooperating partners in an inter-organizational business network and the goal-oriented elicitation [6] of their process knowledge to derive opportunities for process improvement (cf. [7]).

In this respect, the PQM discipline has brought forth a variety of methods (e.g., Six Sigma) that can be applied to improve or redesign business processes [3]. However, many employees do not have the time to become acquainted with such holistic methods (cf. [8]). Further, their application is increasingly perceived as too resource-consuming for projects with a limited scope (cf. [9]). Thus, enterprises often prefer a manageable

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Johannsen, F. (2017): Functional Interdependencies between Quality Techniques reverting to Meta Models, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 716-730

and limited set of quality techniques (e.g., Ishikawa Diagram, etc.) instead of extensive quality management methods (cf. [9]), even though the selection of adequate quality techniques is time-consuming (cf. [10]). Further, there are "functional interdependencies (FIs)" between quality techniques, i.e., they may complement each other during application or pursue diverging goals, e.g., cost-orientation vs. customer-orientation [11]. The knowledge of these interdependencies is decisive to understand which quality techniques may be purposefully combined in a project. For example, the CTQ/CTB-Matrix (Critical-to-Quality/Critical-to-Business-Matrix) helps to define quality goals, which are the base for developing Key Performance Indicators (KPIs) to measure process performance, e.g., via the Measurement-Matrix (cf. [12]). However, little understanding exists on such fertile FIs between quality techniques in practice and literature (e.g., [8], [11]). This is a drawback because such knowledge is crucial for method engineers to develop enterprise-adapted PQM methods and the corresponding software support (e.g., [13]). Therefore, our research aims at finding indicators that point to valuable FIs between quality techniques. For that purpose, we revert to meta models (cf. [14]). Meta models are suitable to capture the core concepts of quality techniques and to explicate their functionalities to transform particular types of input information (e.g., customer requirements) to output information (e.g., project goals) (cf. [10]). Accordingly, meta models allow to describe the nature of quality techniques and to derive indicators as to whether quality techniques can be beneficially combined in the course of a project or not. Thus, the following research question (RQ) is posed: *How can indicators of functional interdependencies (FIs) between quality techniques be purposefully identified on a meta model level and what FIs do typically exist between quality techniques of a representative set?*

Based on the findings, quality techniques with beneficial synergies can be precisely identified by reverting to meta models. Individual PQM approaches and corresponding software tools may then be designed.

This paper is structured as follows: first, foundations of quality techniques and meta models are explained. Afterwards, the research procedure is described and the design of meta models is explicated. In the main part of the paper, the indicators of FIs are derived. Afterwards, their benefits are presented. The paper concludes with an outlook.

2 Foundations

2.1 Quality Techniques and Functional Interdependencies (FIs)

A quality technique is a guideline for the creation of results in PQM projects (cf. [12], [15]). In that context, a quality technique supports the elicitation of employees' process knowledge (cf. [6]), derives some type of input information that is transformed to output information and thus (partial) results (cf. [10]). This perception is similar to the definition of a "technique" in IS method engineering (cf. [15]). An example for a quality technique is the Ishikawa Diagram (Fishbone Diagram), which serves the classification of problem causes for insufficient process performance (cf. [16]). According to *Bruhn* [11], functional, temporal as well as hierarchical interdependencies exist between quality techniques. Temporal interdependencies refer to the chronological sequencing of quality techniques in projects [11]. Hierarchical interdependencies differentiate whether a quality technique pursues strategic (e.g., definition of business objectives) or operational goals (e.g., definition of KPIs) [11]. Regarding the identification of valuable synergies between quality techniques, however, FIs are of interest (cf. [11]). FIs analyze the conjoint application of quality techniques considering their individual functioning, i.e., the way each technique converts input to output information, as well as the nature of the input and output itself. By taking this detailed perspective on how information is processed, it becomes obvious whether techniques may complement each other, produce identical outcomes or even require their mutual application (cf. [11]). Considering this, FIs are suitable to describe the interplay between quality techniques in the course of a project, and different types can be distinguished (Table 1).

Table 1. Types of FIs

Interdependency type (derived from [11])	Examples
Conditional: A quality technique requires other techniques to be applied in a project in addition.	Creating a Data Collection Plan requires the definition of KPIs in advance, e.g., by means of the Measurement-Matrix (e.g., [12]).
Complementary: Two or more quality techniques support each other during application.	The Failure-Mode-and-Effects-Analysis (FMEA) is purposefully complemented by the KANO Model, as the severity of potential "defects" during process execution can be precisely quantified that way (e.g., [12], [32]).
Substituting: The application of two or more quality techniques leads to identical types of output information.	The CTQ/CTB-Matrix as well as the Driver Tree can be used for specifying process-related quality goals (CTQ/CTB factors) for instance (e.g., [12], [17]).
Rivalling: The application of particular quality techniques produces results that are contradictory to one another.	Applying the FMEA and the Value-Stream-Map (VSM) may generate contradictory suggestions on the should-be process design (e.g., [12]).
Note: *Bruhn* [11] also mentions "indifferent interdependencies" indicating that the application of certain techniques has no mutual influence on one another. However, this type is not further considered because the corresponding techniques are not interrelated in terms of above described specification.	

Against this background, the beneficial synergies between quality techniques are primarily determined by conditional and complementary interdependencies. In case of a conditional interdependency, the application of a quality technique produces output information (e.g., KPIs) that is taken up and further processed as input information by another technique. In case of a complementary interdependency, the combined usage of certain techniques leads to results that are more precise in nature (e.g., KPIs aligned with project goals), while inherent drawbacks of a quality technique can be mitigated at the same time (see Table 1).

2.2 Meta Models and Process Knowledge in PQM Projects

Meta modeling is a widely-established discipline in the field of model-driven design and development of IS and software, respectively [14], [18]. In this regards, the behavior of software or an IT system is specified via conceptual models [18]. The meta model defines the concepts that can be expressed in such conceptual models designed with the help of a modeling language, i.e., what modeling elements may be applied [14]. Hence, a conceptual model is created as an instance of the corresponding meta model [13]. In the research at hand, we use meta models to describe the constituting elements (core concepts) of a quality technique as well as the type of input information (e.g., project goal) that is transformed to a particular type of output information accordingly (e.g., improvement idea). In so doing, an unambiguous description of a technique's functionality is achieved. Applying quality techniques in the course of projects results in diagrams, tables or sketches (cf. [19]), allowing to capture emerging process knowledge as conceptual models, which are specified by meta models accordingly. Thus, the documented result (e.g., conceptual model) received by applying a particular technique represents an instance of the corresponding meta model. For the design of meta models, we generally revert to UML class diagrams, which have proven suitable for creating meta models in research and practice alike (e.g., [20]).

Process knowledge plays a decisive role in light of organizational learning (cf. [7], [21], [22]). In this regards, "learning" specifies a firm's efforts to "retain and improve competitiveness, productivity, and innovativeness in uncertain technological and market circumstances" [22, p. 378]. Process knowledge is a multi-dimensional construct, comprising knowledge about the process structure, the training and management efforts required for achieving desired outcomes or knowledge directly linked to process execution (e.g., factors impacting efficiency) amongst others [21]. The challenge in PQM projects is to elicit employees' tacit process knowledge and convert it into explicit knowledge (cf. [23]) that can be used to derive opportunities for process improvement. Quality techniques support this conversion because employees' ideas, which are based on their individual process knowledge, are used as input to be transformed into results visualized as diagrams or conceptual models for instance (e.g., [19]). Meta models are suitable to capture the core concepts of quality techniques and to explain how the aforementioned conversion is performed. Further, the combination of discrete pieces of explicit knowledge [23] to come to improvement suggestions is fostered by techniques since the information processed may stem from diverse sources such as reports or IT-systems (e.g., [12]). The research contributes to developing means to uncover FIs between quality techniques and thus to support the purposive externalization and use of process knowledge to improve process performance.

3 Procedure of the Research

The study at hand is part of a larger Design Science (DS) project (cf. [24]), which aims at the development of a modeling tool to document, communicate and analyze knowledge on process weaknesses and process improvement opportunities. A central requirement on the tool is to support users in the selection and combined application of quality techniques based on FIs. For the implementation, the meta modeling platform ADOxx *(www.adoxx.org)* will be reverted to, which has been successfully applied in industry for more than 15 years now [13]. However, prior to the implementation, indicators for FIs on a meta model level are to be identified that allow to unambiguously decide whether quality techniques complement one another or not. Our paper deals with the identification of corresponding indicators and follows a four-step procedure building on the principles of inductive logic (cf. [25]). Thus, based on a sample set of quality techniques, the corresponding meta models are analyzed to derive generally valid indicators explaining the occurrence of FIs (see Fig. 1).

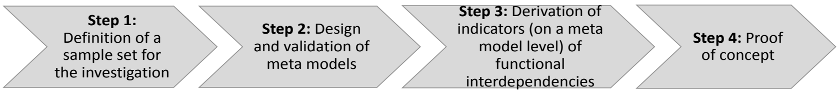

Figure 1. Procedure for identifying indicators

Considering the huge number of existing quality techniques (e.g., [12]), a representative set (sample set) is selected as a subject of investigation in a first step **(step 1)**. The techniques of our set along with the knowledge of the interdependencies between them represented the "instances" of the "phenomenon" [25] investigated. Afterwards, meta models for the quality techniques are generated and validated (**step 2**). Indicators explaining the occurrence of FIs between techniques are derived in **step 3**. Their applicability is demonstrated in **step 4** reverting to a prototypical realization.

4 Sample Set, Design and Validation of the Meta Models

4.1 Sample Set of the Investigation (Step 1)

On the one hand, the toolbox of quality techniques of a German automotive bank was reverted to for this research, comprising 30 techniques in total. This bank has a long tradition regarding the adaption and usage of methods for PQM (e.g., Lean Six Sigma, Total Quality Management, GE Work-Out) making it a suitable candidate for the investigation. Further, the author of this study participated in various PQM projects at the bank, taking the role of a "team member", over a period of three years. That way, profound insights into the beneficial combination of quality techniques were gained.

On the other hand, publications explicating FIs between quality techniques, e.g., in the form of an efficient further processing of results (conditional interdependency), were reverted to that were derived from a previously conducted literature review on the integration of quality methods and techniques (cf. [26]). Considering these findings, techniques not considered by the toolbox of the automotive bank were added to our sample set for the study, comprising 34 techniques in the end (see Appendix).

Next, the FIs between these quality techniques were specified according to the types as introduced in Table 1. That way, a complete overview of the FIs for the sample set emerged. For that purpose, the descriptions in literature were reverted to as well as the insights gained by actively participating in projects at the automotive bank. The Appendix exemplifies the results of this process for the CTQ/CTB-Matrix or the Driver Tree (cf. [17]) amongst others. The derivation of FIs was performed by two researchers, who consolidated the results afterwards. Further, the findings on FIs were validated in discussions with leaders of PQM initiatives at the automotive bank.

4.2 Design and Validation of the Meta Models (Step 2)

The subsequent design of meta models for the quality techniques of the set was done as follows: first, the core concepts of a quality technique were identified by analyzing its functioning. For example, the CTQ/CTB-Matrix supports the user in defining "Critical-to-Quality (CTQ)" and "Critical-to-Business (CTB)" factors based on customer (Voice of the Customer – VOC) and employee requirements (Voice of the Business – VOB), which are classified into core statements correspondingly (cf. [12]). Then, we considered the relations between the core concepts. For instance, each VOC or VOB statement in a CTQ/CTB-Matrix is assigned to one core statement at least. The core concepts and the relations were transformed into corresponding classes and relations of a meta model (MM) afterwards. Finally, the cardinalities of the meta model were to be set. Fig. 2 shows the meta model for the CTQ/CTB-Matrix.

A decisive aspect concerns the validation of meta models. In this context, formalization is an established means of uncovering inconsistencies, syntactical errors and incompleteness of the meta model design [27]. A generally valid formalization approach for domain-independent meta models is FDMM (Formalism for Describing ADOxx Meta Models and Models) (cf. [28]). Due to its general applicability across domains, differentiating FDMM from formalization approaches such as EMOF or KM3, which were developed for specifying software architectures in particular, it was chosen for the study at hand. All meta models established for the quality techniques of our sample set were formalized via FDMM making it possible to check them for inconsistencies (e.g., wrong cardinalities), syntactical errors (e.g., in case the meta model of the CTQ/CTB-Matrix would allow to connect instances of the class "VOC statement" to instances of the class "CTQ factor") and incompleteness (e.g., missing cardinalities). Generally, meta models in FDMM are represented as a tuple of a set of object types (O_i^T), data types (D_i^T) and attributes (A_j) [28], which is exemplified for the CTQ/CTB-Matrix in equation (1) (see [28] for details on FDMM).

$$\mathrm{MT}_{CTQ/CTB-Matrix} = \langle O^T_{CTQ/CTB-Matrix}, D^T_{CTQ/CTB-Matrix}, A_{CTQ/CTB-Matrix} \rangle \quad (1)$$

Further, the meta models were discussed with four researchers renowned for their expertise in the field of meta modeling and two practitioners who had a consultancy industry background and had been heavily involved in PQM projects for several years. The discussion partners were not involved in the development of the meta models and thus unbiased. Their feedback was gathered and modifications were made, if necessary. After these steps, the validity of the meta models was seen as sufficiently confirmed.

5 Indicators of Functional Interdependencies (Step 3)

Based on the meta models created in the prior step *(step 2)* and the FIs between the techniques of our sample set *(step 1)*, indicators of FIs on a meta model level were derived. Therefore, for each type of FI (see Table 1), we specified the synergies between the corresponding quality techniques of our sample set more profoundly and, if different forms of synergies could be distinguished, we defined subtypes of a FI *(step 3.1)*. Afterwards, each subtype (or form of synergy) was analyzed in detail by reverting to the meta models of the quality techniques, which allowed for explaining the FI by means of the meta models' classes *(step 3.2)*. Based on these findings, indicators on a meta model level could be derived characterizing each type of FI *(step 3.3)*. To reduce complexity, the indicators analyze quality techniques following a binary strategy (cf. [29]), i.e., it is determined whether two particular quality techniques considered hold an interdependency or not. The three steps were performed by two researchers – to reduce subjectivity – with the results being discussed and consolidated afterwards.

5.1 Conditional Interdependencies

Conditional interdependencies exist in case two or more quality techniques presuppose their mutual application (cf. [11]).

Step 3.1: In our sample set, conditional interdependencies between techniques were characterized by one particular form of synergy. In this respect, a technique produced a certain type of output information, which represented a specific type of input information for another technique simultaneously. For instance, the CTQ/CTB-Matrix provides the "CTQ" and "CTB factors" as types of output information (cf. [12]). These are referred to by the Measurement-Matrix for the definition of KPIs (cf. [12]). The use of the Measurement-Matrix is thus bound to techniques enabling the derivation of CTQ and CTB factors, e.g., the CTQ/CTB-Matrix (a more comprehensive example can be found at: *http://tinyurl.com/zbctxt8*).

Step 3.2: On the level of meta models (MM), the aforementioned synergy between quality techniques is visually exemplified in Fig. 2 reverting to the CTQ/CTB-Matrix and the Measurement-Matrix. The dotted line highlights the common classes across the meta models. It becomes obvious that the classes "Critical-to-Quality (CTQ) factor" and "Critical-to-Business (CTB) factor" can be found in both meta models, while they represent output information types (colored "black") in MM_1 (meta model of the CTQ/CTB-Matrix) and input information types (colored "grey") in MM_2 (meta model of the Measurement-Matrix). In this regards, the CTQ or CTB factors captured by an instance of MM_1 (CTQ/CTB-Matrix) serve as input information for an instance of MM_2 (Measurement-Matrix). This kind of relation between classes was similarly observed for all other techniques of the sample set regarding conditional interdependencies.

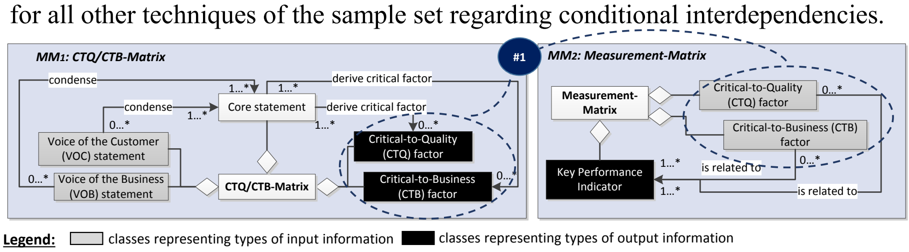

Figure 2. Example for conditional interdependencies (indicator #1)

Step 3.3: Based on these insights, the following indicator pointing to a conditional interdependency between two quality techniques, on a meta model level, was derived:

Indicator #1: A conditional interdependency between two *quality techniques i* and *j* is given, if the corresponding meta models (MM_i and MM_j) share identical classes while these represent types of output information of *quality technique i* in MM_i and types of input information of *quality technique j* in MM_j (or vice versa).[1] The results of the *technique i* thus represent decisive input information for *quality technique j* (or vice versa).

[1] In the following, *i* and *j* are continuous indices with the following assumptions: 1) $i \in \mathbb{N}$, 2) $j \in \mathbb{N}$ and 3) $i \neq j$. *Technique i* or *j* are thus representatives for any kind of quality technique.

5.2 Complementary Interdependencies

Generally, complementary interdependencies are observed for quality techniques that support each other during application (cf. [11]). Detailed examples of each subtype as described in the following can be found at: *http://tinyurl.com/zbctxt8*.

Step 3.1: In total, we identified four different subtypes (forms of synergy) of complementary interdependencies (A to D) between techniques based on our set.

Subtype A: The first subtype of complementary interdependencies builds on the use of common concepts, by different quality techniques, to transform input information to output information. For instance, both the KANO Model and the Driver Tree use the KANO categories "basic requirements", "breakthrough customer needs" and "core competitive requirements" [30], [31] to enable the prioritization of customer and employee requirements on process execution. The KANO Model prioritizes process-related VOC and VOB statements and its application thus clarifies which requirements are of particular interest to process stakeholders. Based on these insights, KPIs can be developed (Driver Tree) considering requirements with a high priority in special [17].

Subtype B: A second subtype of complementary interdependencies is given in case quality techniques contain core concepts that pursue a common purpose of transforming input information to output information (e.g., analysis, classification, comparison of information, etc.) [10], but are not identical per se. For example, the FMEA may be applied to identify potential "defects" during process execution and to judge their severity [12]. A classification of customer or employee requirements according to the KANO categories (cf. [30]) provides hints as to which potential "defects" will most probably affect customer satisfaction in a negative way [32]. Thus, a complementary interdependency between the KANO Model and the FMEA exists.

Subtype C: Further, a complementary interdependency exists, if the results gained by applying a particular quality technique help to specify the input information processed by another technique more precisely. However, the results produced by the first technique are not a mandatory prerequisite for applying the second one, which demarcates *subtype C* from a conditional interdependency. In a project for instance, the results generated via the CTQ/CTB-Matrix (CTQ and CTB factors) may trigger the purposeful search for causes of insufficient process performance reverting to the Ishikawa Diagram (cf. [16]). However, the process weaknesses to be investigated by means of the Ishikawa Diagram do not necessarily have to be derived from the CTQ or CTB factors but can also be defined "ad-hoc" in the course of a project (cf. [16]).

Subtype D: Yet another subtype addresses the usage of a quality technique to further refine the output information generated by another technique. An example would be the combined use of the Affinity Diagram and the Payoff-Matrix (cf. [12], [33]). By using the Affinity Diagram, suggestions for process improvement are purposefully classified (e.g., cost-oriented solutions, IT-related solutions) and this classification can be refined by a prioritization of the ideas via the Payoff-Matrix (e.g., Quick Win).

Step 3.2: Fig. 3 exemplifies the subtypes of complementary interdependencies on a meta model level. Considering the *subtype A*, the meta models of techniques (e.g., KANO Model and Driver Tree) share identical classes. This is indicated by the dotted line "#2", hinting at the common class "KANO category" in MM_1 and MM_2.

Concerning the *subtype B* on a meta model level, a relationship exists between core concepts of different techniques (e.g., KANO Model and FMEA), which are represented by dissimilar classes, e.g., "KANO category" and "severity number" (dotted line "#3"). However, the core concepts follow a common purpose (cf. [10]) of transforming input to output information. Regarding *subtype C*, the meta model of a quality technique has one or more classes representing types of output information that are related to classes representing input information types of another meta model. In so doing, the classes representing types of input and output information are not identical as exemplified for the CTQ/CTB-Matrix and the Ishikawa Diagram (see MM_4 and MM_5 – dotted line "#4"). Finally *(subtype D)*, core concepts of quality techniques supporting the transformation of input information to output information, e.g., by prioritizing or categorizing information, may cause a complementary interdependency. Such concepts, e.g., "payoff category", are explicitly represented by separate classes in the meta models and implicitly become evident in the labels of the classes representing types of output information. Further, identical classes representing types of input information are given (e.g., improvement idea). Fig. 3 and the dotted lines "#5" demonstrate this particular form of synergy (MM_6 and MM_7).

Step 3.3: Based on these findings, four indicators of complementary interdependencies on a meta model level, numbered #2 to #5, were derived:

Table 2. Indicators of complementary interdependencies on a meta model level

Indicator #2 *(subtype A):* Two *quality techniques i and j* have a complementary interdependency in case their corresponding meta models (MM_i and MM_j) share one or more identical classes representing common core concepts serving a particular purpose (e.g., prioritization) during the transformation of input to output information. The affected classes represent neither output nor input information types on a meta model level.
Indicator #3 *(subtype B):* Two *quality techniques i and j* have a complementary interdependency if the corresponding meta models (MM_i and MM_j) contain classes representing concepts serving a common purpose during the transformation of input to output information in a particular project (e.g., classification of information) but are not identical per se. In that context, the output information created by applying *technique i* creates knowledge that facilitates the use of *technique j*.
Indicator #4 *(subtype C):* Two *quality techniques i and j* with the corresponding meta models (MM_i and MM_j) have a complementary interdependency, if the output information represented by classes in MM_i on a type level facilitates the specification of input information for *technique j*, represented by classes indicating types of input information in MM_j. However, the output information produced by *quality technique i* is no mandatory prerequisite for applying *quality technique j* in a project.
Indicator #5 *(subtype D):* Two *quality techniques i and j* have a complementary interdependency, if the corresponding meta models (MM_i and MM_j) contain classes representing particular concepts to transform input to output information, whereas the general purpose of the concepts (e.g., prioritization, classification) varies for the *techniques i and j*. The nature of these concepts becomes evident by the classes representing types of output information in the meta models MM_i and MM_j. The combined use of the techniques allows to reflect results from complementary perspectives (e.g., classified and prioritized improvement ideas). MM_i and MM_j share identical classes for representing types of input information.

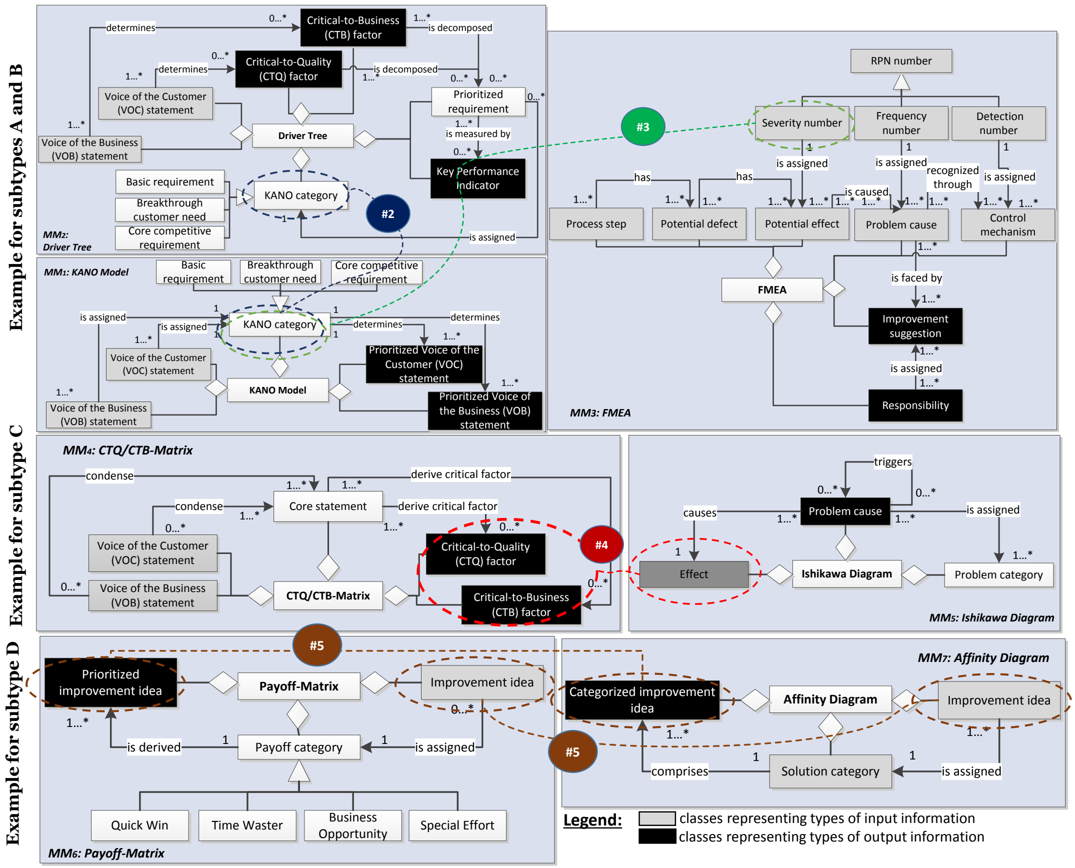

Figure 3. Example for complementary interdependencies (indicators #2 to #5)

5.3 Summary of Substituting and Rivalling Interdependencies

As mentioned, beneficial synergies between quality techniques are primarily determined by conditional and complementary interdependencies. However, further types exist (see Table 1) for which we will briefly summarize the results.

Substituting interdependencies are given in case two or more quality techniques follow the same purpose and produce an identical type of output information (e.g., improvement ideas) (cf. [11]). Substituting interdependencies were given for those quality techniques in our sample that shared a common purpose (e.g., identification of problem causes) and aimed at the production of identical types of output information. An example would be the interdependency between the Measurement-Matrix and the Driver Tree (cf. [12], [17]), with both techniques sharing the purpose of defining KPIs. Accordingly, on a meta model level, substituting interdependencies become obvious by common output information type classes of the techniques. The classes representing types of input information may be different though because the information processed by the techniques may vary. The following indicator was thus derived:

Indicator #6: Two *quality techniques i* and *j* have a substituting interdependency in case the corresponding meta models (MM_i and MM_j) have identical classes representing types of output information, with the *techniques i and j* sharing a common purpose within a project. The classes representing types of input information may be identical or different from one another.

Rivalling interdependencies exist, in case the combined application of quality techniques might lead to results that are contradictory to one another (cf. [11]). On a meta model level, rivalling interdependencies cannot be identified unambiguously. Generally, the types of output information generated are decisive, which is similar to substituting interdependencies. Thus, there is the danger of producing identical types of output information (e.g., improvement ideas), which, however, may contradict each other (cost-oriented vs. customer-oriented improvement ideas) (cf. [11]). Nevertheless, an unambiguous characterization by means of classes of a meta model cannot be done and thus no indicators were derived.

In summary, six indicators were defined pointing to FIs on a meta model level allowing to identify synergies between techniques. No further indicators or subtypes of a FI, allowing to specify the interplay between techniques in a generally valid manner, were found by the researchers performing steps 3.1 to 3.3. More, any interplay between quality techniques in the sample set could be expressed by the indicators as introduced.

6 Proof of Concept (Step 4)

The applicability as well as the usability of the indicators were to be validated. For that purpose, we created a prototype of the aforementioned modeling tool (see section 3) building on FIs in a first step. The prototype served as a proof of concept (cf. [24]) evidencing that the concept of indicators of FIs as well as the corresponding meta models could be realized in the form of an executable software tool. This was important considering the feasibility of the aforementioned DS project (see section 3).

In a second step, a usability study was conducted, reverting to the prototype and two case studies, to prove the beneficial impact of FIs between quality techniques on the development of process improvement suggestions.

Our prototype contains the 14 quality techniques of the sample set that were most frequently applied by the said automotive bank *(tool download as an MS Windows installation package: http://tinyurl.com/zc9rpnp)*. The quality techniques were realized as model types based on the corresponding meta models (see section 4.2). The receipt of an executable prototype demonstrated the validity of these meta models once again in terms of consistency, syntactical correctness and completeness. The model types could be used by project participants straight away for creating results and documenting outcomes in PQM initiatives. The indicators, which specify beneficial interdependencies between the techniques, enabled the development of algorithms that either allow the user to automatically transfer results between particular quality techniques (conditional interdependencies) or to specify and refine the outcomes of a technique by using complementary techniques in addition (complementary interdependencies). In the prototype, conditional interdependencies are automatically exploited whereas complementary interdependencies can be drawn upon optionally. Fig. 4 gives an example for conditional interdependencies. The model on the left shows an excerpt of the CTQ/CTB-Matrix designed as a model type, codifying customer statements (VOC statements) stemming from a project to improve the document management process at the aforementioned automotive bank. From these, the CTQ factor *"reduction of cycle time (…) to two working days"* is derived. Because of a conditional interdependency (indicator #1), the CTQ factor as defined is automatically referenced by the Measurement-Matrix straight away without the data having to be re-entered from the user side. Accordingly, KPIs such as the "overall cycle time" or the "number of errors in archiving" are specified to measure the goal achievement.

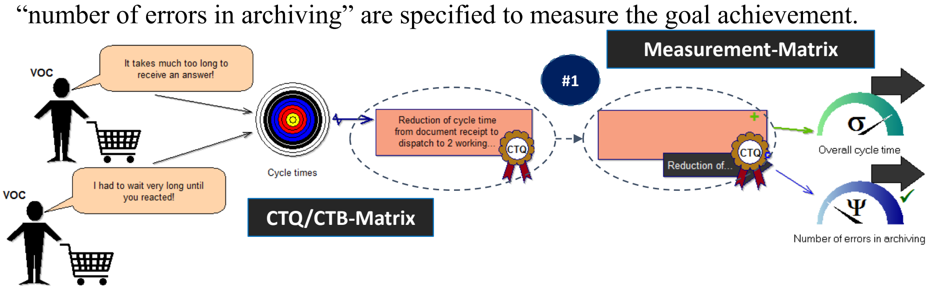

Figure 4. Example from the prototype

An example of a complementary interdependency would be the use of the "payoff categories" in the Affinity Diagram (see the following link for a detailed example: *http://tinyurl.com/zbctxt8*). As an additional proof of the beneficial impact of FIs in terms of project conduction, a usability study of the prototype by means of the SUMI questionnaire (Software Usability Measurement Inventory) *(http://sumi.ucc.ie/)* was performed with 32 Master degree students of a German university. The SUMI questionnaire is a well-established standard for measuring software usability and builds on the five dimensions "efficiency", "affect", "helpfulness", "control", and "learnability" [34]. The intention was to investigate whether users perceived the synergetic use of quality techniques (with complementary and conditional interdependencies) as beneficial for developing process improvement ideas or not. For that purpose, two case studies were drawn upon. The first case study was based on a real life project conducted in cooperation with the mentioned automotive bank to improve the end-of-terms process. The second case study described a fictitious check-in process at an airport. 17 students worked on the first case study and 15 dealt with the second one. Based on given problem statements, the students were supposed to develop suggestions to overcome process weaknesses using the prototype *(material download and detailed results of the study: http://tinyurl.com/zb5r5lk)*. Afterwards, they were asked to fill out the SUMI questionnaire, and an aggregated usability rating was received across both case studies. Taking into account two case studies enabled a more nuanced assessment of usability, because the results were not imprinted by one particular scenario only. In our context, the ratings for the dimension "efficiency" were of particular interest, because it captures the degree as to which the software supports a user in conducting tasks (cf. [34]). Considering the reference score of "50" as proposed by the SUMI reference database (cf. [34]), the users felt well supported by the prototype in deriving improvement suggestions, as indicated by the efficiency ratings *(mean: 51,56; median: 53)*. Making use of the references between the quality techniques, due to beneficial FIs, definitely had a huge share in that, which becomes evident by the SUMI item consensual analysis [34] and the user comments. Users highly appreciated the tool's functionality to easily move from one task to another and, hence, to further refine or process results by using beneficial combinations of techniques (see also: *http://tinyurl.com/zb5r5lk*).

7 Discussion

First, referring to our RQ, it was shown that meta modeling allows researchers to precisely assess the essence of quality techniques and to identify FIs on the base of indicators, respectively. The indicators foster knowledge creation regarding those quality techniques that may be beneficially combined in a project and, thus, help to develop methodological support for quality initiatives. Hence, synergetic quality techniques can be logically arranged and integrated by method or software engineers to come to an enterprise-adapted PQM method (cf. [13], [35]) that meets a firm's specific needs (cf. [9]). In this respect, the combined use of synergetic quality techniques backs the goal-oriented elicitation of process knowledge and its transformation into improvement opportunities, with process knowledge being a key factor to influencing project success (cf. [7]). Considering the toolbox of the automotive bank, which was part of our sample set, we found all FIs as introduced in Table 1 with the corresponding subtypes, which we were able to delineate in this study. However, especially conditional and complementary interdependencies were encountered particularly often.

Second, software support for practitioners for systematically eliciting, documenting and communicating results in the course of a PQM project – even across company borders – can be established as indicated in sections 3 and 6. On that base, project data may be further analyzed by means of reports promoting the querying and capitalization of process-related knowledge generated in PQM projects (cf. [36]). In the paper at hand, the indicators on a meta model level, specifying beneficial FIs, enabled to create algorithms for the automated transfer of project data between quality techniques to be further processed (see section 6).

However, as a restriction, meta modeling requires particular skills and knowledge from the user side. Thus, identifying and exploiting FIs on the base of indicators on a meta model level is an approach, which is most likely interesting for method or software engineers but probably only of little interest to employees who are less of an expert.

8 Conclusion

This research dealt with the question of how to purposefully identify FIs between quality techniques by reverting to their meta models. We learned that meta models, widely established in IS research, are helpful to explicate the functionality of quality techniques and to generally explain the occurrence of FIs. However, there are limitations to this study: the set of techniques analyzed for the derivation of indicators was restricted to the toolbox applied at an automotive bank and to those techniques derived from literature. Thus, further subtypes of FIs may potentially exist, building on fruitful combinations of techniques neither literature nor practice is yet aware of.

Therefore, further research to consider additional techniques is required, although our sample set comprises techniques that are widespread in practice and frequently used in PQM projects across different industries (cf. [10], [12]), which contributes to the general validity of the results. Generally, subjectivity cannot be entirely excluded considering the derivation of FIs as well as the definition of indicators. However, by the discussion between researchers and the consolidation of results, subjective imprints were to be minimized as far as possible. Nonetheless, further indicators for subtypes of FIs not unveiled by this research may occur. Yet, the indicators proved suitable to fully explain the interplay between techniques in the sample set at hand. In future, the indicators will be used for developing guidelines for practitioners explicating which techniques can be beneficially used in combination. More, the prototype will be revised considering practitioners' feedback and designed to run on different platforms.

Appendix

The following list presents the sample set of the quality techniques of our study. Due to page restrictions, the FIs are only exemplified for four techniques. More details on the techniques and interdependencies can be found at: *http://tinyurl.com/zbctxt8*

Abstract. Knowledge protection serves as the means to securing valuable knowledge assets, the basis of firm strategy according to the resource-based view. Current research has not taken into account external strategic drivers. This study focuses on identifying these strategic drivers and identifies related patterns in protection approaches. I employ an explorative qualitative research design, including 9 German SMEs. The results show that firms can be categorized into 3 protection approaches. Firms set up protection like Doves, Magpies or Urban Sparrows. They are peaceful, protecting their most-valuable assets or invest in general knowledge protection, respectively. The results show that the approach depends on the external strategic drivers of an industry. Consequently, the external perspective should be included in future research. Managers can use the insights to set up knowledge protection in a focused and strategy-aligned manner.

Keywords: knowledge management, knowledge protection, knowledge security, industry-oriented view, resource-based view

1 Introduction

Knowledge is an important source of competitive advantage [1]. Its protection strives to ensures its sustainability [2]. However, what are the external drivers that make protection necessary and is protection of competitive advantage the only reason? Research on protection focuses on knowledge as a source of competitive advantage, the internal strategic perspective known as the resource- and knowledge-based view (RBV and KBV, respectively)[2, 3]. Thus, researchers focused on the mechanisms for protecting knowledge [4] and mechanism effectiveness [5, 6]. Effectiveness is influenced by firm-context and characteristics [7]. Therefore, knowledge protection is more than generalized protection [8].

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Nienaber, D. (2017): From Doves, Magpies and Urban Sparrows: The External Strategic Forces Driving Knowledge Protection Approaches in German SMEs, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 731-745

As research focused on the internal perspective, our understanding of external drivers is limited to date. Once a firm has decided to enter competition in an industry, it has to adapt itself to this environment [9]. The goal of this study is to shed light on the external strategic drivers of knowledge protection. Specifically, I aim to understand a) the protection of competitive advantage from the industry perspective and b) the influence of industry characteristics on protection strategy. Porter's five forces, the industry-oriented view (IoV), provide the theoretical lens [9, 10]. I use an explorative qualitative study analyzing the protection approaches of 9 German SMEs [11].

This paper contributes insights how external strategic drivers lead to the protection types, the Doves, Magpies and Urban Sparrows, identified in this paper. First, external strategic drivers relating to competitive advantage, (1) competitive position and (2) knowledge-based entry barriers refine the need for protection derived from the RBV. Furthermore, I discuss that the impact of knowledge loss is more significant relating to competitive positioning as opposed to entry barriers. Regarding knowledge diffusion the impact is significant for competitive positioning and entry barriers. Second, external strategic drivers beyond competitive advantage, (3) protection itself as an entry barrier, (4) entry barriers through regulation and (5) protection-related cost-shifts affect the protection type. Third, the paper shows that a firm's protection type focuses on a firm's owned knowledge but also on knowledge that other firms entrust to it. As these three aspects lead to the variation in protection types, researchers and practitioners should consider all three aspects when defining and evaluating protection approaches.

The remainder of this paper is structured as follows. Section 2 elaborates on the research gap, introduces the industry-oriented view and details knowledge protection as perceived in this paper. Section 3 describes the explorative qualitative research design. Section 4 details our findings on the types of knowledge protection and external strategic drivers. Section 5 discusses the interrelation between external drivers and protection types for owned and entrusted knowledge. Section 6 concludes the paper.

2 Extant Literature and Theoretical Background

This section focuses on the connection between knowledge protection and firm strategy. Section 2.1 shows that the external perspective complements the RBV. As protection should align with strategy and research has focused on the RBV, this paper focuses on the external drivers. Section 2.2 details Porter's framework that focuses on strategy in general. Section 2.3 presents related aspects of knowledge protection.

2.1 External strategic drivers – Complementing the resource-based view on knowledge protection

This section shows how the external strategic perspective helps a firm use its competitive advantage to define competitive position and adapt to its environment. Knowledge plays an important role in this strategic process [1, 3]. Therefore, investigating the external aspects of knowledge protection should complement the current focus on internals.

A protection approach should align with a firm's strategy. The internal and the external strategic perspective both shape that strategy. The external aspects provide the boundaries for a firm. Specifically, external aspects determine how competitive advantage can be used to position a firm relative to its competitors, i.e. a cost-based or a differentiation strategy [9]. As the internals and externals complement each other, both together explain firm performance better than standalone [12]. Internals refer to exploiting strengths and coping with weaknesses whereas externals refer to how a company deals with opportunities and threats [13]. Taking the internal perspective, it is the RBV that focuses on the strengths and weaknesses, specifically on how competitive advantage is derived from a firm's capabilities and strategic resources, especially knowledge [14]. Taking the external perspective, the choice of industry sets not only the threats and opportunities but also the boundaries under which a firm adapts to its environment [9]. Both perspectives are connected. A firm's strategic position in an industry is determined relative to its competitors. The basis is comparing a firm's advantages with competitors [9]. Porter's cost-based and differentiation strategies are such strategic positions. On the one hand, certain advantages lead to lower costs, e.g. due to a superior production technique. On the other hand, advantages lead to differentiating features like superior designs that competitors cannot offer. Many of the advantages are based on exclusive knowledge [1]. The decision which competitive advantages to foster illustrates how a firm can use its knowledge to derive an industry-oriented strategy, a position relative to its competitors. Depending on the chosen strategy, some advantages and related knowledge become important others obsolete.

Extant research on knowledge protection follows the notion of knowledge as a driver of competitive advantage, the internal strategic perspective. The vast majority of studies focuses on ways to protect competitive advantage by protecting the underlying knowledge. Desouza summarized the state of research in the protection of assets as the gap between knowledge management and information security [15]. Addressing the gap in his studies, the link to knowledge as a driver of competitive advantage remains the underlying assumption [16, 17]. In a recent structured literature review, Manhart and Thalmann identify 4 research streams that are all fiercely related to the RBV [4]. Though some studies cope with external aspects of the firm, for example protecting knowledge in partnerships, securing competitive advantage remains in the focus.

In order to complement the internal perspective, this paper explores the externals of protection by asking how external strategic drivers shape protection in SMEs. In detail, the paper focuses on strategic drivers related to knowledge-based competitive advantage and drivers beyond as well as their impact on a firm's protection approach.

2.2 The Industry-oriented View – Providing the Theoretical Lens

This paper uses Porter's five forces framework to analyze the external strategic drivers of a firm [10]. The framework focuses on general strategic aspects of a firm, not on protection itself. As protection should align with strategy, I use the framework to identify the strategic drivers and relate them with knowledge protection in the findings and discussion section. The external drivers are determined by vertical competition, horizontal competition and the threat of substitutes [9, 10]. Along the horizontal dimension, a company may use competitive positioning based on cost or differentiation, set up entry barriers or use signaling to fight industry participants. Along the vertical dimension, suppliers and customers may demand extended services and thereby shift the costs of performing these services. Furthermore, they may integrate forward or backward in the value chain, respectively. Entry barriers can prevent integration. I do not discuss the threat of substitutes as it did not provide any insights from the data.

The horizontal dimension focuses on existing competitors and potential new entrants into the industry. Existing competitors are fought by defining competitive strategies, i.e. cost-based or differentiation-based competition [10]. Both strategies are based on the competitive advantages of a firm. The specific advantages are selected and put together into a single competitive strategy. Furthermore, a firm can fend off new entrants by building entry barriers and by signaling [10]. Entry barriers are advantages of established firms in comparison to new entrants. They can take the form of competitive advantages that the entrants need before entering competition or regulations to comply with. Signaling describes messages that firms send to new entrants about their reactions [10]. A firm may say, if you enter our market we will cut prices dramatically. Thereby, the industry may become unattractive for the entrant.

The vertical dimension focuses on a firm's customers and their suppliers. Vertical firms may shift costs to other players or perform integration [10]. Integration means that firms on another level of the value chain enter competition with the company. Suppliers may integrate forward; customers may integrate backward. Thereby, they extend their value chain by offering similar goods and services. To fend off integration behavior, firms need to set up entry barriers. Furthermore, the shifting of costs means that suppliers or customers demand the company to execute additional activities. Therefore, the costs of performing the activities are shifted to the firm.

2.3 Knowledge Protection, Implementation and SMEs

The paper views protection as strategy and means to protect knowledge from loss [18], unintended diffusion [19] and to reduce its visibility [20]. In contrast to knowledge security, the study excludes knowledge being altered, becoming obsolete or unavailable [8]. Knowledge is an intangible asset. It is embedded in people's minds, tacit knowledge [3]. It can be documented to store and share it, codified knowledge [17]. Codified knowledge shows characteristics similar to information assets. Thus, information security is a part of knowledge protection with a focus on codified knowledge [15]. However, knowledge protection focuses on all knowledge assets.

Protection mechanisms are formal or informal [7, 21, 22]. Formal mechanisms are intellectual property rights, contracts and labor legislation. Informal mechanisms take the form of secrecy, lead-time and tacitness. The mechanisms are often used in combination [23]. In order to implement mechanisms, specific measures are used [4]. They are grouped into legal, organizational, and technical measures [5, 6, 24]. Legal measures refer to contracts like non-disclosure-agreements [6] and intellectual property rights [5], for example. Organizational measures refer to recruiting [17], training [17], organizational culture [3] and alike. Technical measures refer to means by which access to knowledge is protected, e.g. by firewalls, passwords or physical security [4].

The focus on SMEs prays for attention to informal mechanisms. SMEs are resource-constrained. Thus, they favor informal mechanisms as they come at lower costs [21]. Especially secrecy plays an important role compared to formal mechanisms such as patents [22]. Additionally, protection in SMEs focuses on owned and entrusted knowledge. The latter is important as SMEs operate relatively large firm networks. This helps SMEs allocating resources to core activities [21]. Such a network requires vast knowledge exchange. Thus, firm's entrust their knowledge to the SMEs and vice versa.

3 Method

I employ a qualitative, explorative research design. The design is applicable, as external factors are not yet well understood [11]. The study focuses on German SMEs. Located in a knowledge society, they understand the importance to protect knowledge. Extensive variation in external factors is expected as in most other aspects of SMEs. SMEs are defined following the IfM Bonn [25], excluding blue collars from head count.

Firms were identified using theoretical sampling based on firm characteristics [26]. Seek maximum variation [27], I added firms until the results appeared mature and validated. Firms had to show high variance in characteristics that likely impact knowledge protection, size, industry, service orientation, R&D intensity, competition, network complexity and legal risk. Thereby, I ensured retrieval of rich data. Participants were chosen as they a) had personal interest, b) perceived threats to their firm or c) expect their firm to be confronted with this topic. In summary, I expect deep insights and high variation in external strategic drivers and protection types.

The study investigates the firm level using interviews and additional data as the main sources. 34 interviews were conducted with 14 managers of 9 firms. Three steps were taken to gather firm-level data via the interviews. First, all questions specifically address the firm, not the individual's opinion. Second, multiple interviewees were conducted in 5 firms. Triangulation between interviewees ensures further traceability to the firm level. Third, participants had insights in the firm's strategic dealings and protection approach due to their positions, managing director, CIO, Head of Business Development, Heads of Sales and Head of Marketing. On average 3.8 interviews per firm were conducted. The duration of interviews ranges from 0.5 up to 3 hours.

Knowledge protection approaches are highly sensitive to the firms. Recording was not allowed in 79% of the interviews. Thus, I defined a strategy to ensure data validity using semi-structured guides, active listening and triangulation. The semi-structured guides allowed for extensive note taking. Active listening served as the immediate validation step to retain the original voice by mirroring the information to the interviewee. All notes were reviewed with the participant after each section. For final validation, follow-up calls and meetings were used in situations where doubt remained.

Triangulation of interview data with firm-level data sources ensured data validity. The sources comprise 67 public and private documents. Public documents are brochures, websites, studies, financial reports, product brochures, corporate videos, general terms and conditions as well as newspaper articles. Private documents are auditor reports, non-disclosure-agreements, code-of-conducts, internal policies and brochures on compliant behavior.

Coding and analysis focused on the external factors, identified along the vertical and horizontal dimensions [10]. I extracted the codes to a new document for focused analysis (see [28] for a details). Along each dimension, distinct themes emerged (c.f. section 4). The relative number of code segments per theme is stored in a firm-vector (x_i,y_i,z_i) with dimension i. A theme was assigned, if it scored 30% or more. Beyond pure types, mixed types with two or more themes along a dimension and themes that vary across dimensions emerged. Expert interviews served as final validation.

4 Findings

This chapter presents the external drivers and protection types. The results reveal systematic variation along the horizontal and vertical dimension. The variation leads to three distinct themes for each dimension, based on the external drivers (c.f. Table 1). Drivers and themes result in the Dove, Magpie and Urban Sparrow protection type (c.f. Table 1). I begin with a summary of the themes, followed by a detailed illustration of the protection types. The external strategic drivers are discussed in section 5.

Along the horizontal dimension, firms take different approaches to fend off competitors and new entrants. Specifically, firms a) underestimate threats and perceive protection as an insignificant matter while relying on informal mechanisms on an as it happens basis; others are aware and react by b) focusing protection on their most valuable assets, their crown-jewels, or by c) implementing a broad protection that covers all knowledge, whether valuable or not. The important difference is that broad protection tries to prevent a breakdown of operations, which is a knowledge security topic, whereas the crown-jewel approach tries to stop knowledge loss and theft.

Along the vertical dimension, firms cope with threats from suppliers and customers, pursuing different approaches as well. Either, they a) misinterpret the threats, or b) protect entrusted knowledge, which is knowledge that a third party provides to the firm, and owned knowledge based on project protection requirements, or c) follow a broad protection approach. In essence, firms extend protection approaches aimed at their own assets to the assets of third parties, especially customers, and vice versa.

4.1 Doves

Doves resemble the first type of protection approaches. Doves perceive the business world as peaceful. They believe in fair business practices and protection is a matter of little significance to them. Doves as the symbol of peace do not get intentionally into struggles with competitors or other third parties. When forced into a struggle, Doves solely care about their own assets. Here they rely on informal protection mechanisms or formal protection mechanisms that come at little cost, such as contracts. Small firms often behave like Doves. They do not perceive competition as intense. Their network is small. Usually, they do not do international business and do not face legal risks (c.f. Table 2). The themes along the dimensions illustrate the Dove-view on protection.

Table 1. The variance along strategic dimensions that drive knowledge protection

Strategic Dimensions	*Variance in Meanings* *Doves*	*Magpies*	*Urban Sparrows*
Horizontal	*Underestimation & insignificance:* - Underestimation of threats. - Focus on informal mechanisms. - Insignificance as protection seems unnecessary or ineffective.	*Focused protection:* - Protection of crown jewels only. - Knowledge that is at the basis of firm success belongs to the crown jewels.	*Derivation from information security:* - Heterogeneity of knowledge leads to a general broad approach. - General protection of decision systems and production processes. - Regulatory requirements.
Vertical	*Misinterpretation of threats:.* - Informal approach: Personal and reputation-based customer relations. - Perceived threat: Stealing of customers instead of knowledge theft by third parties.	*Project protection requirements:* - Project-based protection of customer knowledge. - Entry barriers by customer-specific protection and trust. - Protection against forward integration of suppliers by tailored approach.	*General protection requirements:* - Broad protection approach for customer knowledge. - Broad protection of supplier and partner portals. - Protection as a part of the firm's product or services.
External Strategic Drivers	***Competitive advantage:*** - Threats from competitors. - Focus on own knowledge. - Ignoring vertical and entry threats.	***Competitive advantage:*** - Vertical and horizontal threats. - Protection of crown jewels. ***Entry barriers:*** - Customer trust. ***Cost-shift – 3rd party requirements:*** - Customer-specific protection.	***Competitive advantage:*** - Vertical and horizontal threats. - Heterogeneity of knowledge. - Focus on securing operations. ***Entry barriers:*** - Customer trust. - Compliance with regulation. ***Cost-shift – 3rd party requirements:*** - General third-party requirements.

Along the horizontal dimension, Doves underestimate the threat from competitors and new entrants. They use informal protection mechanisms. They perceive protection as insignificant as they feel that protection mechanisms are ineffective. Regarding competitor and entrant threats, the case of the event equipment rental company exemplifies how Doves perceive their threat situation. In the firm's business knowledge like product rental margins and optimal product stocking is key knowledge. Discussing its protection with his managing director, the company's IT manager received the following reaction.

What I just wanted to say, when you are discussing this with our managing director… he only says… hm, who should ever attack us?

Doves perceive formal protection measures as unnecessary, relying on informal measures. The electrical engineering company is based on a patent for inductive transmission. After expiration, the technology proved inimitably due to its tacitness, rather by accident. Only the managing director knows it well enough so he can sell it. The engineer's job is to set up the products to a solution based on the technology and given specifications. The business development manager of the company elaborates first on the tacit protection before addressing the critical role of the managing director.

The whole customer-specific area…[…] you just cannot copy it. […] The transfer method, the technology that forms the origin of the company, was a patent. So, it is public now as it is older than 20 years. But … even this is too complicated for people so that they wouldn't even want to imitate it. It is not a technology, which you simply cut open. You can't just look inside and see how it works. […]

So our managing director is responsible for sales and that is just right. So, we had one that wanted to do sales and he left. You have to say, that was unproblematic. He went to another industry…because, how shall I say, the composition, the customer-specific thing is tough. So … he (the customer) asks something and in that moment you have to run through your 100.000 options, because it is not a product, you have to give a solution. […] And of that, no one else is capable of.

Doves even perceive formal and informal protection mechanisms as ineffective. Therefore, the protection is of little significance. The building company provides an example. It uses secrecy in combination with motivational HR measures. It aims to prevent employees leaving. Labor legislation complements the informal mechanisms. Yet, the managing director feels that he is helpless in case key employees leave and take the most important asset, knowledge about customers with them. After elaborating on the HR perspective, he jumps quite agitated to the problem of managers leaving the firm. He even shows some degree of personal insult taken from such events.

*We try to keep our employees happy. We provide them with a car, flexibility on maternal leaves and other things to make them stay. But, this is no assurance that they stay and won't take things with them. […] In that context, you can see a dictum that I much like to use: "The worst scam happens within your innermost circle!" So secrecy is highly important in management, but how can I ever enforce this?**[1]

[1] An asterisk indicates a quote, originating from an interview where recording was not allowed.

Along the vertical dimension, managers do not realize the threat from forward integrating suppliers and backward integrating customers. Their only concern is competitors trying to woo their customers. To prevent customers from leaving, Doves use open communication and build personal as well as reputation-based customer relations. To that end, Doves use informal measures such as employee retention. Thereby, they try to keep employees that have important customer relations. The business development manager illustrates the informal nature of relationship building.

But, let me say it this way. Let's go back one step. Type MAN company xy, ok? The company was served quite well from our side. And now, firm xyz (a competitor) calls, ok? The chance that the MAN manager says ... yes the other one (the competitor) fits well, everything is fine…is really small. Yes, I mean in that regard our customer list is not uncritical when stolen, but…you see.

4.2 Magpies

Magpies are the second type of firms. Magpies like all that glitters, according to folk tale. For a firm, these glittering things are their most valuable assets, crown jewels. They comprise of knowledge owned by Magpies themselves as well as knowledge, which customers entrust to the Magpies. Magpies are rather independent of size. They likely serve a specialized market by a project-driven business model. For example, Magpies implement protection specific to a project in a high legal-risk country (c.f. Table 2). The themes along the dimensions illustrate the Magpie-view on protection.

Along the horizontal dimension, magpies perceive the threat of competitors and new entrants. Magpies derive their competitive strategy from crown jewels. Thus, Magpies focus on protecting these assets. An exemplification of the importance of crown jewels is the following statement by the managing director of an equipment manufacturer. She clearly states what the firm's crown jewels are and how they use tacitness to protect its process technology.

So, let's put it that way. You always have to be ahead. The big know-how is our process technology. Because you cannot see it. But, when you are having a look at the machines, you quickly see how it works. Another topic is automation, all control technology, the controlling, and how a plant is planned and conceptualized. This is another topic, where you can be well ahead of your competitors.

The statement by the CIO of a manufacturer of embedded systems illustrates how the firm derives its competitive strategy from its crown jewel, service delivery. Though he refrains from stating how the related product strategy is protected, this part shows the firm's focus on this important aspect of firm strategy.

*…our focus on Added Services and the planning, which services shall be delivered in the future. This is where we are a big step ahead of our competitors. If they would know about our product strategy, they would enter the market earlier and would start competition much earlier.**

Table 2. Sample characteristics

Characteristics	*Dove*	*Magpie*	*Urban Sparrow*	*Mixed Type*
Number of firms	3	2	2	2
No/partial/Management ownership	0/1/2	0/1/1	0/0/2	1/0/1
Listed stock	0	0	0	1
Low/medium/high size	1/2/0	1/0/1	0/1/1	0/0/2
Service/product/mixed orientation	2/1/0	1/1/0	0/2/0	0/1/1
No/occasional/continuous R&D	2/0/1	1/0/1	0/0/2	0/0/2
Low/medium/high competition	1/1/1	1/0/1	0/1/1	0/0/2
Low/medium/high network complexity	1/2/0	0/2/0	1/0/1	0/0/2
Global legal risks	0	1	2	1

Along the vertical dimension, magpies implement a project-based approach. They implement protection based on customer requirements, building trust. Furthermore, they implement protection measures on a case-by-case basis, preventing forward and backward integration. The managing director of a consulting firm illustrates customer-specific requirements and building trust as follows. He states how his customer's demand protection of specific knowledge that they will share with the firm throughout the engagement.

> *The project documentation contains our methods to a certain extent. And it reflects the customer situation. Moreover, it often contains more sensitive information of the customer, well … also information how a customer approaches specific situations. As this is highly important to his competitors, it has to be protected. Customers use NDAs to protect the project documentation and to put protection requirements on all our activities. […] Customers give their sensitive information to us, so that we can do our work. So we need to build an environment of trust. One main aspect to build trust is an adequate protection of knowledge. […] Customers, especially in the defense & military sector, have levels of security. Here, customers make prescriptions how to handle information of a certain security level.**

Regarding the protection of its own knowledge, Magpies protect their crown jewels in the vertical dimension. Magpies make case-specific decisions about who is provided with which crown jewels. The managing director of the equipment manufacturer describes how the firm gives its crown jewels (see first quote in this section) to its suppliers, according to situation. The decision is project-specific.

> *And, well, … yes, you know it yourself. It is not easy to protect know-how. As said. Reengineering machines, that's what we do every day. You just can't do anything about it. You can only make sure that you are working with suppliers. With which you get along well and… yes, you give them only the information that is absolutely necessary (for project delivery).*

4.3 Urban Sparrows

Urban sparrows invest vast resources for protecting assets, just like the bird. Resources are readily available as the bird lives in a city. Therefore, he can focus on his territorial fights. The territorial fights stand for a broad protection approach against any threat. The firm has resources available and invests in this fight. Large firms with continuous R&D and a complex firm network are likely to employ this approach. Furthermore, global activities lead to high legal risks. Thus, Urban Sparrows cannot rely on legislation for protecting their assts. The themes along the strategic dimensions illustrate the Urban Sparrow-view on knowledge protection.

Along the horizontal dimension, Urban Sparrows implement a broad protection approach that is derived from and a benefit of information security. The reason is heterogeneity of knowledge. The approach focuses on the management decision systems and continuity of production processes, preventing firm breakdown. So, Urban Sparrows tend to derive knowledge protection largely from information security. In addition, Urban Sparrows focus on complying with regulatory standards. The managing director of a wholesaler provides an illustration of heterogeneity. He shows how he uses information security in order to maintain secrecy of codified knowledge. His quote illustrates how heterogeneity of knowledge, as the firm varies in distribution of knowledge assets, leads to the focus on security, rather than focused protection.

> *Relevance of secrecy is quite limited and present in certain parts of the firm, only. It varies from division to division. […] We have a single IT company located in our Group, it is ISO 27001 certified and copes with all IT aspects.*

Protecting decision systems and production processes results in heterogeneity as well. All IT systems, all employees and all customer or supplier knowledge that belong to both or either one system, need protection. The broad protection of knowledge can be described as a benefit of information security measures as well. The following extract of an internal policy shows that secrecy is but a part of the overall approach. Secrecy, as the part relevant to knowledge protection, is only driven by regulation. Again, Sparrows derive protection of codified knowledge from information security.

> *Our data and our IT systems in all technical and business divisions are protected in such a way that expected shutdown periods could be tolerated. […] The requirements of secrecy have a normal level that is oriented towards regulatory compliance. For data of the human resource department, maximum secrecy requirements apply. […]*
>
> *Delayed or erroneous management decision can have widespread consequences. Therefore, the access to current controlling data is highly important when management faces important decisions. For this type of information, a high level of security in terms of availability and integrity has to be guaranteed.*

Along the vertical dimension, Urban Sparrows follow a broad approach as well. Heterogeneity of customer, supplier and partner knowledge, e.g. in IT portals, drive the approach. Even so, knowledge protection can form part of the firm's offerings. A third party manufacturer exemplifies the heterogeneity of customer knowledge. He builds seals based on customer specifications and knowledge.

*As a third party manufacturer, the firm does not just have customer contact data but receives sensitive information like product specifications as well. The specifications are guiding our work. Therefore, it is self-evident that the specifications contain customer secrets.**

The official internal policy illustrates the importance of customer requirements.

As the customer is located in the center of all our activities, the protection of (customer) information from unauthorized access and manipulation is of existential importance for the firm.

Knowledge protection as part of a firm's offerings is driven by customer demand as well. Here, customer demand leads again to a focus on information security. Naturally, these are used to protect codified knowledge. A managing director of a cloud provider, that is active in logistics and production as well, illustrates the logic of applying protection capabilities into other parts of one's firm.

The second topic is our data center, hmm, where in the end only authorized personnel can get in through iris-scanning-systems. These are all topics (knowledge protection), well that have been done back then, as they were customer relevant. Well, you have a point there, so that you can say to the customer, listen up, your data is safe here. Well, in the end it is part of a product. So, it is driven from outside then.

5 Discussion

The protection types show, that protection strategy depends on how a firm wants to and has to protect knowledge. It is important that firms focus on knowledge owned by and entrusted to it. The external strategic drivers affect its protection and set the boundaries. Within the boundaries, firms can decide whether the benefits of protection exceed costs and whether to focus on crown jewels or on all knowledge. Based on the external factors and these two questions, firms adopt a Dove, Magpie or Urban Sparrow protection. In addition, the protection approaches for owned and entrusted knowledge complement or extend each other. The logistics software company, for example uses an Urban Sparrow approach for their customer's knowledge. Yet, they implement additional protection specific for their crown jewels. Figure 1 illustrates and the following paragraphs discuss the external drivers related to and beyond competitive advantage as well as the protection of owned and entrusted knowledge in more detail.

The results reveal external drivers relating to competitive advantage and the RBV. Such drivers determine the protection type along the horizontal and vertical dimension. Here, knowledge needs protection as it either defines a firm's competitive position or builds entry barriers. This differentiation reveals two important insights. First, some firms do not acknowledge the threat posed from all industry participants. Doves only perceive a threat to competitive position and to entry barriers against entrants. However, they neglect the threats posed by integrating suppliers and customers. Thus, the IoV helps firms to fully assess all threats. Second, knowledge loss has a significant impact concerning competitive positioning but has a marginal impact considering entry barriers. From a diffusion perspective both have significant impact. The impact of knowledge loss related to competitive position equals a negative shift relative to competitors. With the competitive advantage gone, competitors are likely to do more business. However, loss at one firm does not alter the barriers of the whole industry. Others will hold up the barrier. Thus, entry gets more likely but the impact on industry attractiveness is marginal. Shifting perspective to diffusion, the impact is significant on position and barriers. Competitors acquiring knowledge that builds a competitive advantage shifts competitive position. The competitor improves his own position, resulting in a negative shift of one's own position. This leads to intensified competition. Similarly, potential entrants use acquired knowledge to overcome entry barriers. For example, a production technique is important to produce at a certain price. Without the technique, products would be too costly and entry into the industry unattractive.

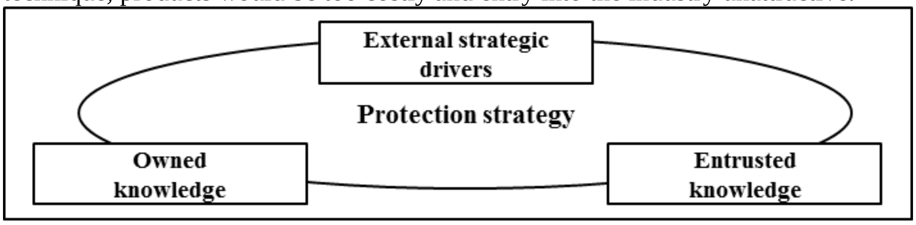

Figure 1: Industry factors and knowledge types as determinants of knowledge protection

The findings present external drivers beyond competitive advantage and the RBV, namely entry barriers relating to protection itself and regulation as well as shifts of protection costs. Such drivers determine the protection type along the vertical dimension. First, protection can build trust of customers and business partners, which serves as an entry barrier. Entrants, forward-integrating suppliers and backward integrating customers, have to implement protection. Otherwise, they cannot enter the market. As such, protection serves as a prerequisite for a business relation. Second, firms have to comply with regulations. While it is natural that firms have to comply with regulations, firms can indeed shape regulations and determine industry standards on the degree of compliance. Depending on this decision, firms can use knowledge protection to set up barriers grounded in regulation. Third, suppliers, customers and business partners may shift costs for knowledge protection on a firm due to their bargaining power. They make another firm protect the knowledge entrust to it. The downside are higher costs, when third parties force a certain degree of protection. The need to protect third party knowledge is a shift of costs on this firm. The upside is a new entry barrier and the option to use the protection level for one's own knowledge.

Protection does not just focus on a firm's owned knowledge but on knowledge entrusted to the firm as well. The Mixed Types show that a firm can protect owned and entrusted knowledge differently. Again, protection depends on the external drivers. Owned knowledge builds strategic position and entry barriers. Entrusted knowledge needs protection to build entry barriers and derive benefits from cost shifts. Thus, protection aims at both, owned and entrusted knowledge. Both aspects interact with each other. The protection mechanisms that are set up for protecting entrusted knowledge can also protect one's own knowledge. It is management's decision in what way to comply with the requirements of industry participants and whether and how to apply these measures to a company's own knowledge.

6 Conclusion

This study has investigated the external strategic drivers of knowledge protection. The drivers were analyzed along the dimensions of Porter's industry-oriented view [9, 10]. The results were structured into themes of protection in the vertical and horizontal industry dimensions. Thereby, the paper identifies external strategic drivers. Thereby, I identified three types of protection, the Doves, Magpies and Urban Sparrows.

In addition, the paper contributes insights into the external strategic drivers of protection. They relate to competitive advantage on the one hand. These drivers are competitive position and knowledge-based entry barriers. On the other hand, they go beyond competitive advantage. Such drivers are protection itself as an entry barrier, entry barriers through regulation and protection-related cost-shifts. Furthermore, the paper calls for considering not only the protection of a firm's own knowledge but also of knowledge that other firms entrust to it. In summary, research and practice should consider these externals when setting up and evaluating protection.

The study has four main limitations, the focus on Germany, the focus on SMEs, the limited amount of interview transcripts and the use of interview data for analyzing organizations. The focus on Germany and SMEs limits generalizability. Firms in other countries act in different environments. Thus, they may encounter further strategic drivers that affect knowledge protection. The focus on SMEs may restrict insights as large firms have more resources available. Thus, protection approaches may not vary as intensively as for SMEs. The third topic limits the validity of our results. In 79% of the interviews, recording was forbidden. The last topic addresses the issue that interview data was used though the object of interest is the firm. The interviewee may be biased towards the firm. Thereby, he may try to shed a firm in a more positive light. Furthermore, interviewees may not report on the situation in a firm but on their general experience. However, I believe that the results are robust due to the measures taken. Future studies should overcome our limitations. Researchers should include firms of all sizes and outside of Germany. In addition, research should try to develop an objective checklist for protection types and conduct interviews with multiple persons per firm.

Mobiles Lernen für Industrie 4.0: Probleme, Ziele, Lernarrangements

Andreas Engelmann[1], Peter Heinrich[1], Gerhard Schwabe[1]

{engelmann,peterhe,schwabe}@ifi.uzh.ch

Abstract. Bestrebungen im Bereich Industrie 4.0 verändern die Rolle des Menschen in der Produktion nachhaltig. Dadurch verändern sich auch die Anforderungen an die Kompetenzen bei den Mitarbeitern. Anhand des konkreten Fallbeispiels eines Unternehmens im Wandel (Segment Automobilzulieferer), zeigen wir Probleme der Personalentwicklung auf und erstellen konkrete Zielvorgaben an das Kompetenzmanagement. Eine besondere Herausforderung stellt die Transformation von fachspezifischen hin zu fachübergreifenden Aufgabenfeldern dar, ohne dabei langfristig Expertenwissen zu verlieren. Als möglichen Lösungsweg schlagen wir mobile Lernarrangements vor, welche dieses Wissen kapseln und individuell, dezentral und bedarfsgerecht zur Weiterbildung anbieten. Neu erarbeitetes, situatives Wissen erweitert diese Lernumgebung dabei sukzessiv. Der Artikel konkretisiert die Anforderungen an den Kompetenzaufbau im „Industrie 4.0"-Umfeld und leistet auch einen Beitrag zur praktischen Umsetzung.

Keywords: mobiles Lernen, Lernarrangements, Personalentwicklung, Industrie 4.0

1 Einleitung

In den letzten Jahrzehnten sind die Anforderungen an die Qualifikation der Mitarbeiter in nahezu jedem kleinen und mittelständischen Unternehmen, sowie auch in Großunternehmen der Fertigungsindustrie kontinuierlich gestiegen. Man geht davon aus, dass sich dieser Trend durch Entwicklungen in Richtung „Industrie 4.0" noch verstärken wird. Die Produktionsstätten werden dabei grundlegend reorganisiert wobei den Menschen neue Rollen zukommen sollen [1]. Arbeitsabläufe werden flexibilisiert [2] wobei der zukünftige Produktionsmitarbeiter sich insbesondere durch seine Problemlösungsfähigkeiten auszeichnet und im Zusammenspiel mit der Automatisierung eine möglichst hohe Effizienz anstrebt. Ähnliche Konzepte zu Industrie 4.0 werden auch unter den Begriffen „Smart Manufacturing" [3] oder „Advanced Manufacturing" diskutiert [4]. Mitarbeiter werden sich in diesen Umgebungen situationsabhängig neues Spezialwissen in sich fortlaufend verändernden Arbeitsumfeldern aneignen müssen. Das einmalige Lernen von Faktenwissen muss daher einem individuellen „just-in-time" Lernen von Spezialwissen weichen. Dieses Wissen ist aber meist „tacit" oder „internalisiert" (z.B. eigene Erkenntnisse oder

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Engelmann, A.; Heinrich, P.; Schwabe, G. (2017): Mobiles Lernen für Industrie 4.0: Probleme, Ziele, Lernarrangements, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 746-760

Intuitionen) wodurch es schwierig zu formalisieren und auf andere übertragbar ist [5]. Polanyi [6] führte den Begriff des taziten Wissen gar als umfassende Form der Erkenntnis ein, von dem sich nur ein kleiner Teil formalisieren und einfach übertragen lässt. Diese Übertragung kann mit den heute etablierten, oftmals stark standardisierten Lern- und Lehrsettings in Unternehmen nicht befriedigend erreicht werden. Nonaka und Takeuchi [5] bieten das SECI-Modell (Socialization, Externalization, Combination, Internalization) an, welches die kontinuierliche Transformation zwischen implizitem und explizitem Wissen beschreibt [5]. Daraus folgernd müssen Wege gefunden werden, neben dem expliziten Wissen auch das internalisierte (Erfahrungs-) Wissen verfügbar zu machen (Externalization) und individuell oder durch soziale Interaktion weiterzugeben (Socialization).

Mobiles Lernen ist in der Literatur als geeignetes Konzept beschrieben um Wissen individuell und kontextbezogen zu vermitteln [7, 8]. Dabei beschränken sich die Kontexte aber meist auf Situationen der reinen Wissensvermittlung, wie beispielsweise Universitäten [9] oder Museen [10]. Der von der Industrie geforderte arbeitsbegleitende Kompetenzaufbau wurde bisher nur unzureichend beleuchtet. Gerade die technische Fortentwicklung durch Sensorik und Vernetzung erweitern die Umsetzungs-möglichkeiten und bilden die Basis für völlig neue Lernarrangements im „Industrie 4.0“-Umfeld. Die Forschungsfrage lautet daher: „Wo liegen konkrete Potentiale für mobiles Lernen im „Industrie 4.0“-Kontext?“

Anhand des Fallbeispiels eines großen deutschen Automobilzulieferers, der sich gerade in einer Reorganisationsphase der Produktion befindet, konkretisieren wir diese Fragestellung und demonstrieren deren praktische Relevanz. Im Rahmen eines Design-Research-Projektes wollen wir in Zusammenarbeit mit diesem Unternehmen mobile Lernumgebungen „Industrie 4.0“-gerecht gestalten und real einführen. Dieser Artikel fokussiert dabei auf die ersten Phasen des Entwicklungszyklus; der Problemerhebung und Zieldefinition.

2 Grundlagen

Der richtige Umgang mit Wissen und Information ist grundlegend für den Unternehmenserfolg – in jeder Sparte und in jeder Unternehmensgröße. Grant [11] hat Wissen und den Umgang als das grundlegende Konzept für sein Modell „Towards a knowledge based theory of the firm“ benutzt und argumentiert, dass der primäre Zweck einer jeden Firma die Anwendung und Nutzung von Wissen ist. Dabei ist insbesondere zu beachten, dass es um das verkörperte Wissen geht – in den Köpfen der Mitarbeiter gleichermaßen wie auch verkörpert durch Produktionsmaschinen [11]. Grant argumentiert darüber hinaus, dass aufgrund der hohen Komplexität und der begrenzten Aufnahmefähigkeit der Menschen eine Spezialisierung der Arbeitskräfte unumgänglich ist, um das benötigte Wissen an den richtigen Stellen vorzuhalten [11].

Eine breit akzeptierte Definition für „Industrie 4.0“ lässt sich zum gegenwärtigen Zeitpunkt noch nicht finden. Die bestehenden Definitionsversuche sind bislang sehr komplex und beziehen sich meistens auf das Thema der Produktionsautomatisation, obwohl der Themenkomplex auch organisatorische und soziale Bereiche einschließt [12]. Für die Zwecke dieses Artikels legen wir Folgendes fest:

Als Industrie 4.0 verstehen wir technologieunterstützte Reorganisationen industrieller Arbeitsumgebungen mit dem Ziel einer menschzentrierten Selbstorganisation der Abläufe. Diese Sichtweise ist kompatibel mit den bestehenden Definitionsversuchen [1, 12, 13], berücksichtigt aber insbesondere den Menschen in der Rolle des Entscheidungsträgers [14]. „Industrie 4.0"-Umgebungen synchronisieren dabei die digitale und physische Welt durch den Einsatz von Sensoren und Aktuatoren [14] und vernetzten zuvor isolierte Wissensinseln. Der Mensch soll dabei in der Rolle des Erfahrungsträgers, Entscheiders und Koordinators flexibel in die Arbeitswelt eingebunden bleiben [13]. Auch eine vollständig automatisierte und menschenleere Fabrik wäre zwar ein denkbares Zukunftsszenario, scheint aber unrealistisch [15]. Viel wahrscheinlicher hingegen wäre ein „Werkzeug-" oder „Hybrid-Szenario", in welchem der Mensch die Kontrolle über die Prozesse behält [15]. Dies erfordert aber auch, dass sich die Mitarbeiter das notwendige Wissen über die Produktionsabläufe aneignen können, trotz eines höheren Grades an Automatisierung. Kagermann [13] stellt in Aussicht, dass Mitarbeiter in diesen Szenarien eben nicht nur als „Maschinenbediener" fungieren sondern ein interdisziplinäres Wissen haben um adäquat auf die jeweilige Situation reagieren und entscheiden zu können. Somit ändern sich die Kompetenzanforderungen an den einzelnen Mitarbeiter grundlegend: Während in klassischen Produktionsumgebungen fokussiert Expertise in einem Spezialgebiet gefordert ist, zeichnen sich „Industrie 4.0"-Umgebungen durch einen breiten Kompetenzbedarf aus, der mehrere Fachdisziplinen vereint oder sogar ganz neue Berufsbilder hervorbringen soll [16].

2.1 Wissensmanagement während der Transition zu Industrie 4.0

Es stellt sich hierbei jedoch die Frage, wie eine Transformation in der Praxis erfolgen kann und was eine solche Umstellung hin zu flexibel einsetzbaren Mitarbeitern mit Breitenwissen für ein Unternehmen langfristig bedeutet.

Kompetenzaufbau erfolgt in konventionellen Unternehmen meist im Rahmen der Personalentwicklung (PE). Maßnahmen der PE unterstützen Mitarbeiter ihre Beschäftigungsfähigkeit in einem sich dynamisch veränderten Berufsumfeld zu erhalten [17]. Im Gegensatz zur Organisationsentwicklung zielt sie auf den einzelnen Menschen ab und fasst alle geeigneten und geplanten Anstrengungen zusammen, welche die individuelle berufliche Handlungskompetenz der Belegschaft entwickeln und erhalten [18]. Die PE folgt den Phasen (1) Bedarfsanalyse, (2) Konzeption, (3) Durchführung und (4) Transfer [19]. Während die Bedarfsanalyse und die Konzeption im Vorfeld einmal durchlaufen werden müssen, können die Durchführung und der Transfer wiederholt für jeden Mitarbeiter repetitiv stattfinden. Damit können im konventionellen Rahmen viele Mitarbeiter auf den gleichen Wissensstand gebracht werden. Durch die Flexibilisierung der Arbeit ist dies aber nicht mehr notwendig und muss stattdessen einem Prozess weichen, der das Lernen mit den tatsächlichen, individuellen Arbeitsprozessen synchronisiert [20]. Damit wird die Lernaktivität aber auch nicht mehr von außen initiiert, d.h. der Bedarf wird nicht zentral erkannt (Bedarfsanalyse), sondern entsteht ad-hoc anhand der aktuellen Situation.

Dies erfordert den Einsatz *didaktischer Datenbanken*, welche die Lerninhalte modularisiert abspeichern und verteilt zur Verfügung stellen [20]. Mobile Endgeräte bringen den Zugang zu diesen didaktischen Datenbanken nahe an den Arbeitsplatz [21] oder in beliebige andere Kontexte. Je nach Lernziel ist der Kontext für die Wissensvermittlung aber entscheidend. So ist beispielsweise das Wissen über die Wartung einer Maschine in einem Seminarraum anders, als die Situation des Lernenden, wenn er in einer Werkhalle direkt vor der Maschine steht. Es gibt vier Kontexte, in denen Lernen stattfinden kann [7]: (1) *Irrelevanter Kontext*: der Lerner hat keine wesentliche Beziehung zur aktuellen Umgebung. (2) *Formalisierter Kontext*: Ein Ort mit einer organisatorischen Funktion, welcher eine Gruppe von Lernern innerhalb desselben Kontextes (z.B. Klassenraum) synchronisiert. (3) *Physischer Kontext*: Der Ort, an dem sich der Lerner aufhält, ist für das Lernen relevant. (4) *Sozialisierender Kontext*: Lerner teilen dauerhafte, zwischenmenschliche Beziehungen. Im physischen und sozialisierenden Kontext kann Lernen arbeitsprozess-begleitend erfolgen. Der physische Kontext ist dabei besonders relevant, da er eine direkte Kontextualisierung des Wissens anbietet: Informationen sind direkt am Ort des Geschehens verfügbar; der Lerner kann reale Erfahrungen sammeln und sein gelerntes Wissen anwenden und erweitern. Lernen durch Erfahrungsepisoden (vgl. Experiential-Leanring [22]) gilt dabei als leistungsfähige Methode um kausale Zusammenhänge durch eigenes Erleben zu begreifen. Zwar rücken die Lerninhalte heute schon mit der Unterstützung durch mobile Technologien nahe an den Einsatzort heran, lassen sich aber trotzdem nicht vollständig darin integrieren. So bleiben z.B. die Transaktionskosten des einzelnen Mitarbeiters (suchen, konsumieren und anwenden) weiterhin bestehen. Die Frage wie diese Integration zu leisten ist bleibt unbeantwortet.

Einen Anhaltspunkt könnten die neuen Möglichkeiten geben, die im Rahmen einer „Industrie 4.0"-Vision technische Grundlagen schaffen könnten, um eine Umgebung zu erstellen die Lernkomponenten durch einen cyber-physischen Ansatz direkt in die Produktionsumgebung integriert. Dadurch werden die Produktionsmittel selbst Teil des Lernarrangements.

Die Erwartungen an diese technologische Entwicklung sind jedoch zum heutigen Zeitpunkt noch sehr spekulativ und reichen weit in die Zukunft. Visionen umfassen mehrere Stufen der Entwicklung von dem heutigen Bild der Fabrik als *Netzwerk mechatronischer Systeme* hin zu einer sich selbstoptimierenden, intelligent handelnden Produktionsumgebung [23]. Folgendes längeres Zitat zeigt wie weit diese Spekulationen gehen: *„Cyber-physische Systeme können ihre Umwelt unmittelbar mit ihrer entsprechenden Sensorik erfassen, sie mit Hilfe weltweit verfügbarer Daten und Dienste auswerten, speichern und sie können mit Hilfe von Aktoren auf die physikalische Welt einwirken. […] Diese CPS können sich dann vernetzen und autonom und dezentral – also ganz im Zeichen dieser selbstähnlichen Produktionsfraktale – Netzwerke aufbauen und sich eigenständig selbst optimieren. Sie können im Zusammenspiel mit dem Menschen eigenständig Probleme lösen."* [1, Seite 16] Was jedoch fehlt ist eine realistische Betrachtung der kurzfristigen Potentiale, die mit dem heutigen Stand der Technik erreicht werden können, um die Grundlage für ein integriertes, mobiles Lernen auf dem Weg zur intelligenten Fabrik zu bilden.

In anderen Feldern werden aber schon heute kontextsensitive Lernumgebungen [24] erprobt. Zum Beispiel in der Medizin-Ausbildung. Hier existieren Ansätze, um das Lernsystem mit in Dummies verbauten Sensoren zu verbinden, wodurch das Lernsystem direkt Feedback über die ausgeführten Handlungen am Körper bekommt [25]. Auch im Industrieumfeld sind erste Praxisberichte verfügbar, die von einem erfolgreichen Einsatz von mobile Learning in der Produktion berichten [26]. Auch wurden beispielsweise in einem kollaborativen Action-Design-Research (ADR) Projekt zwischen 15 Industrieunternehmen der Raumfahrt- und Autoindustrie und dem Production Technology Center (PTC) der Universität West in Schweden über 2 Jahre hinweg eLearning Kurse entwickelt. Das Kurs-Design bestand aus formalen Vorlesungen und verfügbaren eLearning Technologien am Arbeitsplatz, zu Hause oder mobil [27].

Ein konkretes Vorgehen zur Umgestaltung der Personalentwicklung aufgrund der neuen Anforderungen ist noch wenig unterstützt. Mobiles kontextsensitives Lernen scheint hier Potential zu haben diese Lücke zu schließen. Bisherige Lösungen bringen die Lernumgebungen zwar nah an den Arbeitskontext, eine vollständige Einbettung ist mit den bisherigen mobilen Technologien aber noch problematisch. Durch die Entwicklungen und Visionen von Industrie 4.0 eröffnen sich grundlegend neue Möglichkeiten für die Erfassung und Interpretation des Arbeitskontextes, den Handlungen von Menschen und den Zuständen von Maschinen. Vor diesem Hintergrund fragen wir nach dem Potential von mobilem Lernen unter den geänderten Voraussetzungen durch Industrie 4.0.

3 Methode

Die Forschungsfrage soll mittels Design-Science [28] beantwortet werden. Dabei versucht Design Science im Allgemeinen menschliche und organisatorische Fähigkeiten durch die Gestaltung neuer Artefakte zu verbessern [28]. Insbesondere dort, wo ein Routine-Design aufgrund von fehlendem Wissen oder aufgrund der hohen Komplexität der Situation und der darin notwendigen menschlichen Interaktionen nicht zielführend ist, liegt die Stärke dieses Ansatzes [28]. Die Projektstruktur orientiert sich dabei an der Design-Science-Research-Methodology [29], die sich in sechs Phasen gliedert: (1) Problemidentifikation, (2) Definition des Ziels, (3) Design und Entwicklung, (4) Demonstration, (5) Evaluation und (6) Kommunikation.

In dieser Publikation stehen die beiden ersten Phasen im Vordergrund, wodurch wir generische Probleme von konventionellen Lernarrangements in „Industrie 4.0"-Umgebungen aufzeigen und anhand einer Fallstudie an einem konkreten Beispiel veranschaulichen und detaillieren. Dennoch entwerfen wir erste, mögliche und zukunftstaugliche Lernarrangements für den diskutierten Fall.

Das Vorgehen ist kompatibel mit dem Evaluations-Framework von Sonnenberg und vom Brocke [30], die gezielte Evaluationsschritte nach jeder DSR-Aktivität des DSRM-Frameworks [29] vorsehen. In diesem Fall ist dies die Ex-Ante-Evaluation der Probleme. Konkrete und abstrakte Probleme sowie Lösungen halten wir mit Hilfe des Design-Theorizing Frameworks [31] auseinander. Wir beginnen also mit dem abstrakten Problem, welches durch die Fallstudie zum spezifischen Problem erweitert wird und geben anschließend einen ersten Ausblick auf die abstrakte Lösung. Das abstrakte Problem beschreiben wir (analog zum Vorgehen der Explanatory Design-Theory [32]) mit Hilfe von Requirements, die als Gegebenheiten der Problemsituation (Conditions) und notwendige Fähigkeiten (Capabilities) der Akteure beschrieben werden.

4 Abstrakte Problemsituation

Ausgehend von den im Literaturteil aufgezeigten Grundlagen beschreiben wir in diesem Abschnitt die generischen Anforderungen an zukünftige Lernarrangements im Industrieumfeld. Wie im Literaturteil bereits ausgeführt ist die menschliche Kapazität für Wissensaufnahme begrenzt **(CON1)**. Daraus folgt auch, dass nicht gleichzeitig Tiefenwissen in allen Bereichen erlangt werden kann [11] und daher bei Bedarf Wissen aufgebaut werden muss, sofern es noch nicht vorhanden ist. Eine weitere Gegebenheit entsteht durch die Vergänglichkeit von gelerntem Wissen **(CON2)**: Wissen, dass nicht aktiv benötigt wird, gerät in Vergessenheit [33]. Es sollte daher nur das Wissen vermittelt werden, dass auch zeitnah in der Arbeitssituation benötigt wird. „Just-in-Case"-Lernen muss daher eher einem „Just-in-Time"-Ansatz weichen [34]. In einem formellen Lernkontext ist dies schwierig zu realisieren, weil der momentane Wissensbedarf instabil ist und sich auch der Anwendungszeitpunkt des vermittelten Wissens nur unscharf voraussagen lässt.

Daher formulieren wir folgende **generische Anforderung (CAP1)**: *Der zukünftige Lerner erhält Grundlagenwissen individualisiert, modularisiert und zeitlich flexibel.*

Wie allgemein gefordert, muss Erfahrungswissen auch erhalten werden. Zu einem gewissen Grad lässt sich dies durch sozialisierende Ansätze lösen. Dieser Ansatz stößt jedoch schnell an seine Grenzen, da das vermittelte Wissen nur innerhalb einer (kleinen) Gruppe von involvierten Akteuren verbleibt.

Daher formulieren wir folgende **generische Anforderung (CAP2)**: *Der zukünftige Lerner kann sein persönliches Erfahrungswissen an andere Lernende weitergeben und sein eigenes Wissen um das Erfahrungswissen anderer erweitern.*

Insbesondere dadurch, dass Lernen und Arbeiten zu einer untrennbaren Einheit werden soll, müssen sich die Lernaktivitäten zu einem Großteil nahtlos in die Arbeitsprozesse einfügen. Dabei soll der Wissenstransfer direkt am Arbeitsplatz ermöglicht werden.

Daher formulieren wir folgende **generische Anforderung (CAP3)**: *Der zukünftige Lerner verknüpft (z.B. durch Erfahrungsepisoden) selbstständig reale Problemlösungssituationen mit kontextspezifischen Lerninhalten und bindet Experten bei Bedarf ein.*

5 Fallstudie eines Unternehmens im Wandel zu Industrie 4.0

> *„[...] ich brauche einen Mitarbeiter, der Know-How hat von der spanenden Bearbeitung bis zur […] prüftechnischen Ablaufprogrammierung. Und das ist natürlich ein enormes Spektrum an Fachkenntnis."* (Zitat Führungskraft QS)

5.1 Betrachtetes Unternehmen

Die Automobilzulieferer AG (AZ AG) arbeitet schon im Wertstrom-Design und hat dieses jetzt bis auf Teamleiterebene heruntergebrochen. Zum Zeitpunkt der Erhebung ist diese Transformation bereits erfolgt und die Belegschaft arbeitet in diesem neuen Muster fachübergreifend. Besonders gut können sich die Auswirkungen dieser Transformation an den Kompetenzanforderungen der Mitarbeiter der Qualitätssicherung (QS) aufzeigen lassen, da diese Tätigkeit schon bisher informationslastig war und viel Erfahrungswissen von hoch spezialisierten Mitarbeitern gebildet wurde. Im neuen wertstromorientierten Design werden diese Spezialisierungs-Silos aufgebrochen und in fachübergreifenden Tätigkeiten entlang des Wertstroms transformiert. Der Wissensaustausch des erlernten spezifischen Wissens zwischen den Mitarbeitern der Qualitätssicherung bekommt damit einen höheren Stellenwert. Zusätzlich haben auch die Produktionsmitarbeiter eine erhöhte Eigenverantwortung für die Qualitätssicherung übernommen und müssen daher von der QS geschult werden.

Das Problem, welches wir hier betrachten können, erstreckt sich über zwei Phasen: (1) die Reorganisationsphase, in der die bestehende Belegschaft neu qualifiziert werden muss und (2) die kontinuierliche Phase in der das Wissen langfristig erhalten bleiben muss.

Zu beiden Phasen sammeln wir mit Hilfe einer Vor-Ort-Erhebung Probleme und setzen diese mit der Literatur in Verbindung.

5.2 Datenerhebung

Die Datenerhebung für die Fallanalyse fand zwischen 05.2015 und 11.2015 statt. An insgesamt 5 Tagen konnten im Unternehmen Beobachtungen gemacht und Interviews geführt werden. Insgesamt wurden 3 Interviews mit Produktionsmitarbeitern, 5 Interviews mit Mitarbeitern der Qualitätssicherung und 3 weitere Interviews mit Kontaktpersonen der QS im Unternehmen geführt. Die Interviewten der Produktion haben eine Berufserfahrung zwischen 5 und 27 Jahren, die der QS zwischen 6 und 33 Jahren und die Kontaktpersonen der QS haben bis zu 20 Jahre Erfahrung. Die Interviews mit der QS wurden über alle Hierarchieebenen geführt, vom Leiter der QS, über die Fachleiter bis hin zu den Prüfern. Die Interviews dauerten 33 bis 85, im Mittel etwa 50 Minuten. Sie wurden aufgezeichnet (Ton) und anschließend transkribiert. Die konkreten Probleme wurden aus den Interviews extrahiert, in Form von Problemszenarien dargestellt [vgl. 35] und dem Unternehmen anschließend zur Validierung in Schriftform zur Verfügung gestellt. Die Teilnehmer wurden vom Unternehmen vorgeschlagen. Die Teilnahme erfolgte auf freiwilliger Basis. Alle Befragten haben einen „Informed Consent“ unterzeichnet in dem sie über die ethischen Grundsätze und ihre Rechte aufgeklärt wurden – dazu gehörte insbesondere, dass die Weiterverarbeitung der Daten ausschließlich anonymisiert oder aggregiert erfolgt.

5.3 Konkrete Probleme der aktuellen Lernsituation im Unternehmen

Der Kompetenzaufbau bei der AZ AG findet zum heutigen Zeitpunkt in drei Stufen statt. Für neue Mitarbeiter wird dies formell in individuellen Einarbeitungsplänen festgehalten, für bestehende Mitarbeiter erfolgt dies bedarfsorientiert. Für die verschiedenen Stufen kommen unterschiedliche Lernarrangements zum Einsatz. Für Faktenwissen werden nach wie vor Grundlagenschulungen angeboten. Zum Transfer von Expertenwissen wird den auszubildenden Mitarbeitern ein Mentor zur Seite gestellt. In der letzten Stufe lernen die Beteiligten situativ vor Ort mit Unterstützung von erfahrenen Mitarbeitern bei Bedarf.

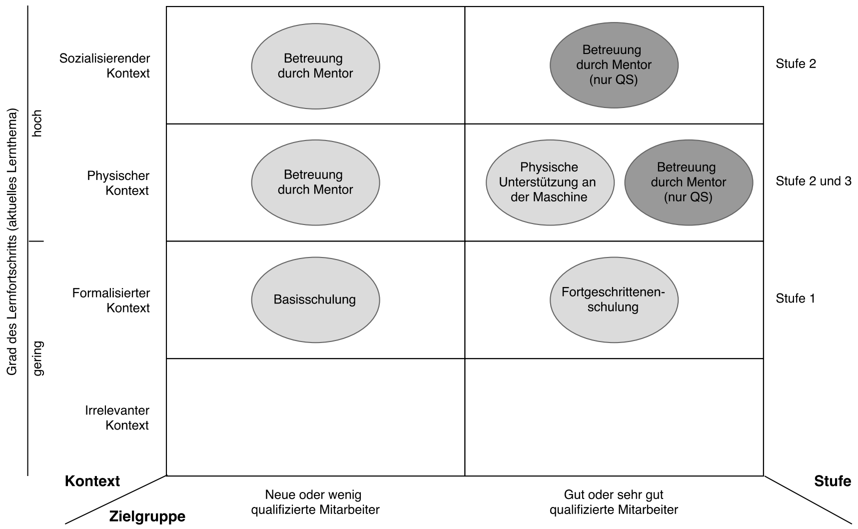

Abbildung 1. Aktuelle Lernarrangements bei der AZ AG

Viele Lernsituationen finden in der AZ AG mobil statt. Deshalb bietet es sich an, die Lernsituationen nach dem Mobile Learning Framework von Frohberg et al. [7] zu strukturieren, das Lernumgebungen in die vier Kontexte einteilt, welche bereits im Literaturteil beschrieben wurden. Da verschiedene Zielgruppen für die Arbeits- und Lernprozesse zentral sind, wird das Mobile Learning Framework um diese Dimension erweitert. Relevante Zielgruppen sind: wenig und gut bis sehr gut qualifizierte Mitarbeiter (diese können in Produktionsarbeiter auf dem Shopfloor und Mitarbeiter der Qualitätssicherung kategorisiert werden). Die Darstellung der Lernarrangements in Abbildung 1 zeigt den Zusammenhang zwischen Kontext und Zielgruppe, und der Zuordnung der Kontexte zu den drei Stufen.

Hierbei ist auch ersichtlich, für welchen Grad des Lernfortschritts des aktuellen Lernthemas der jeweilige Kontext eher geeignet ist (im physischen und sozialisierenden Kontext ist der Grund für das Lernen beispielsweise bereits vorhandenes Wissen anzuwenden und zu erweitern) [36]. Zur Erreichung der Qualifikation sind auf jeder Stufe Lernarrangements etabliert, welche im Folgenden auf ihre Probleme hin beschrieben werden.

5.3.1 Stufe 1: Mitarbeiterschulungen im formalisierten Kontext

Die aktuelle Praxis der Aus- und Weiterbildung bei der AZ AG basiert primär auf unterschiedlichen Arten von Schulungen und Workshops. Es gibt ein- bis zweitägige Basiskurse, die alle Mitarbeiter durchlaufen, um allgemeines Grundlagenwissen über Messmittel und deren Verwendung zu erhalten. Arbeitsplatzspezifische Wissensanforderungen werden über Einarbeitungspläne festgelegt:

„Im Einarbeitungsplan sind auch zum Beispiel Grundschulungen von allen Messmitteln, also Rundheitsmessgerät, Rauheitsmessgerät, Konturograph, Projektor, Optic Line […] enthalten […]“ (Zitat Führungskraft QS)

Weiterhin werden Schulungen für Fortgeschrittene angeboten, welche Prozesswissen (z.B. 5S, Kanban, Shopfloor-Management) vermitteln. Die Schulungen und Workshops werden sowohl für Produktionsmitarbeiter, als auch für Mitarbeiter der QS angeboten. Sie finden in einem formalisierten Kontext statt. Erfahrene Mitarbeiter der Qualitätssicherung bereiten diese Schulungen vor und planen die Termine zur Durchführung. Mitarbeiter der verschiedenen Abteilungen können dann an diesen Maßnahmen teilnehmen. Die Veranstaltungen finden in speziell dafür vorbereiteten Schulungsräumen und im Frontalunterricht statt. Dadurch entsteht das Problem (P1), dass die Mitarbeiter an einem bestimmten Zeitpunkt zu einem Thema geschult werden, ohne dass kontext- oder situationsspezifische Anforderungen an die Lehrinhalte existieren, was der generischen Anforderung (CAP1) des zeitlich flexiblen Wissensaufbaus entgegensteht:

„Sie (die Mitarbeiter, Anmerkung des Verfassers) haben es gelernt, [...] mit einem bestimmten Messmittel […] umzugehen, die Programme entsprechend einzustellen. Dann sind sie vielleicht [...] ein halbes Jahr in einem anderen Bereich eingesetzt […]. Dann kommt er nach einem halben Jahr wieder zurück und dann hat er natürlich diese [...] gelernten Fertigkeiten [...] durchaus vergessen [...].“ (Zitat Führungskraft QS)

Erschwerend kommt als Problem (P2) hinzu, dass es durch den flexiblen Einsatz der Mitarbeiter schwierig ist, abteilungsübergreifende Termine für gemeinsame Schulungen zu finden, was die generische Anforderung (CAP1) weiter substantiviert. Im Extremfall fallen die bereits organisierten Schulungen aufgrund von spontanen Änderungen im Arbeitsplan sogar aus:

„[…] wir bieten bestimmte Schulungen an, halten uns ein Zeitfenster frei [...]: Dann stehen wir bereit, Messmittel, alles haben wir entsprechend hergerichtet und dann kommt [...] kein Mitarbeiter, weil plötzlich krank, nicht da, muss anderweitig eingesetzt werden, weil wir einen Engpass an einer anderen Maschine haben.“ (Zitat Führungskraft QS)

5.3.2 Stufe 2: Mentoring im sozialisierenden Kontext

In der Qualitätssicherung der Fertigung teilen sich zwei erfahrene Mitarbeiter unterschiedlicher Spezialisierungen ein Büro, lösen auftretende Probleme gemeinsam direkt auf dem Shopfloor und übertragen so gegenseitig Wissen auf einander. D.h. beide Mitarbeiter laufen für mehrere Wochen zusammen an die Maschinen und Anlagen, um die Produktionsmitarbeiter zu unterstützen und Probleme zu lösen. Im

Falle von neuen oder weiter auszubildenden Mitarbeitern erfolgt das Mentoring nur in eine Richtung. Für diese Mitarbeiter wird der Mentor im Einarbeitungsplan festgelegt.

Das Problem (P3) dieses Ansatzes ist, dass sich der Lehrinhalt ausschließlich an den tatsächlich auftretenden Gegebenheiten und Problemen definiert. Das heißt, dass einerseits nur Wissen über Probleme transferiert wird, die in diesem Zeitraum auftreten. Andererseits verbleibt das Gelernte ausschließlich in dieser Dyade und ist für andere Mitarbeiter und Mentoring-Gruppen somit nicht zugänglich, was der Anforderung (CAP2) eines teilbaren Erfahrungswissens im Weg steht:

> *„Die Störung an sich wird zwar dokumentiert, aber der Weg dahin und die Störungsbeseitigung, das ist also wenig beschrieben, […]. Das ist [...] die Erfahrung des Mitarbeiters, […]" (Zitat Führungskraft QS)*

5.3.3 Stufe 3: Situative, persönliche Unterstützung im physischen Kontext

Hierbei tritt die QS als Helfer bei schwierigen Problemen und Störungen gegenüber den Produktionsmitarbeitern auf. Diese Experten sind eine begrenzte Ressource, da sie über Langzeiterfahrung im Unternehmen verfügen müssen:

> *„Die Mitarbeiter, die lange in dem Bereich tätig sind, die beheben die Störung, sagen dem Mitarbeiter: Hei, so oder so musst du es das nächste Mal machen, [...]" (Zitat Führungskraft QS)*

Die Situation wird noch verschärft, da die hilfesuchenden Mitarbeiter in der Regel keine Vorleistungen erbringen. D.h. bekommt der Experte vorher keine Information von seinen Kollegen vor Ort (z.B. vom Einsteller), muss er sich beim Eintreffen erst selbst ein Bild der Situation machen:

> *„[…] wenn er bloß sagt: Ja, der (Kolben, Anmerkung des Verfassers) geht nicht rein [...]: Ja, dann habe ich verschiedene Kriterien wie Durchmesser, Rundheit oder Konizität oder wie auch immer. Wenn ich da schon gewisse Sachen von vornherein als nicht so dringlich erachten kann, dann kann ich mich auf die [...] möglicherweise eigentliche Ursache besser konzentrieren." (Zitat QS-Mitarbeiter)*

Das Problem (P4) dieses Settings ist die Verfügbarkeit und Auslastung dieser Experten und bekräftigt die Anforderung (CAP3) nach selbstständigen Problemlösungskompetenzen. Fehlt diese Kompetenz, müssen die anfallenden Probleme warten, bis ein Experte verfügbar ist.

Zusammenfassend lässt sich also festhalten, dass in der kürzlich reorganisierten flexiblen Arbeitsumgebung Probleme entstehen, wenn Mitarbeiter (1) unabhängig vom Arbeitskontext geschult werden, (2) weiterhin in formellen Kontexten geschult werden, (3) sich Erfahrungswissen in Kleingruppen aneignen, dadurch Lernziele verpassen oder das eigene Wissen nicht weitergeben können und (4) durch Experten unterstützt werden, die ihnen die komplette Problemlösungsarbeit abnehmen.

6 Diskussion

Die identifizierten abstrakten Probleme lassen sich einerseits aus der Literatur argumentativ ableiten, mit dem Fallbeispiel konnten wir aber zeigen, wie sich diese in einem realen Unternehmen in einer Transitionsphase hin zu Industrie 4.0 manifestieren.

In den folgenden Sektionen bieten wir eine Diskussion an, wie sich die neuen Ansätze von Industrie 4.0 eignen würden, um eine angemessene Lernunterstützung zu ermöglichen.

6.1 „Industrie 4.0“-Technologien als Enabler zukünftiger Lernarrangements

Wir kombinieren die Ansätze des kontextsensitiven mobilen Lernens mit der Vision von cyber-physischen-Systemen, um die angeführten Anforderungen zu erfüllen. In einem Industrieumfeld lässt sich der Lernkontext durch den Zustand der Produktion und der aktuellen Tätigkeit der Mitarbeiter beschreiben. Soll ein Lernsystem kontextsensitiv sein, muss es Zugang zu diesen Informationen erhalten. In einem „Industrie 4.0“-Umfeld existieren diese Daten bereits in Form von vernetzten IoT-Systemen[1], die fortlaufend den Zustand der Maschinen überwachen. Dadurch werden Informationen zu (sich anbahnenden) Problemsituationen zugänglich, wodurch das Lernsystem die relevanten Inhalte offerieren kann, um damit die notwendige Unterstützung zur Problemlösung zu bieten und direkt ein problemorientiertes Lernen [vgl. 36] zu unterstützen.

Diese Sensoren erfassen (als Teil der Mensch-Maschine-Schnittstelle) auch die Handlungen der Bediener. Dies liefert dem Lernsystem Rückschlüsse auf die korrekte Ausführung der zur Problemlösung erforderlichen Operationen und der darin inhärent enthaltenen Lernziele. Dies transportiert somit den sensorbasierten Ansatz aus der Medizinausbildung [25] in die Produktionsumgebung.

Bei bislang unbekannten Problemen können Bedienungsabläufe aufgezeichnet werden. Damit wird Feedback über die Problemlösung geliefert (neues Wissen extrahiert), das anderen zur Verfügung gestellt werden kann.

Erkennt das System Lernmöglichkeiten und lässt die Umgebung eine Lernepisode zu, bietet das Lernsystem dies automatisch an. Dies unterstützt das individualisierte Lernen und kann den aktuellen Kontext berücksichtigen oder frei davon (irrelevanter Kontext) Weiterbildung ermöglichen. Tritt ein unbekanntes Problem auf, entscheidet das System, ob ein bekannter Lösungsweg vorhanden ist oder ein Experte herangezogen werden muss. Via Audio/Video-Telekooperation können die Experten bei Bedarf vorerst auch nur remote eingebunden werden. Wenn Bild und Ton aufgezeichnet wird, kann das so entstandene Material auch anderen Gruppen und Mitarbeitern zur Verfügung gestellt werden. Augmented Reality lässt die Grenzen zwischen Arbeits- und Lernkontext vollständig verschwinden. Dadurch, dass kein zusätzliches Gerät mehr in der Hand gehalten oder damit bedient werden muss, wird ein echt paralleles Arbeiten und Lernen möglich was die bisherigen Ansätze mobiler Lern-Technologien im Industrieumfeld erweitert [26].

[1] Internet of Things: „intelligente Objekte“, welche an den Cyberspace angebunden und miteinander vernetzt sind, unterstützen den Menschen, ohne abzulenken oder aufzufallen. [37]

6.2 Konzept zukünftiger Lernarrangements

Auf dieser Basis zielen die Gestaltungsüberlegungen daher auf das Konzept des mobilen, kontextsensitiven Lernens ab, um den zukünftigen Bedarf an Aus- und Weiterbildung umfänglich zu adressieren. Die schon in der Praxis erfolgreich angewendeten didaktischen Datenbanken [20] können durch den gezeigten integrierten Ansatz nochmals deutlich aufgewertet werden. Die damit für den Nutzer einhergehenden Transaktionskosten (Suchen und Konsumieren) könnten durch Automatisation unter Einbezug der Kontextinformation verringert werden.

Um die Auswirkungen dieser Entwicklungen zu zeigen, wollen wir nun kurz darstellen, wie sich die in der Fallstudie identifizierten Lernarrangements verändern ließen. Abbildung 2 zeigt eine Übersicht der Lernangebote nach einer solchen Transformation. Man sieht, dass der irrelevante Kontext jetzt nutzbar wird und große Teile der formellen Lehrsituationen aufnimmt. Entsprechend der Anforderung CAP1 werden Lerninhalte für Novizen und Fortgeschrittene dynamisch, orts- und zeitunabhängig abrufbar. Weiterhin können Qualifikationsmaßnahmen mit zugehörigen Lernkontrollen in diesen Kontext transportiert werden, die notwendig sind, um Arbeitsplatzanforderungen zu erfüllen und welche vorher ausschließlich dem formalisierten Kontext vorbehalten waren.

Die im „Industrie 4.0“-Umfeld mögliche Auswertung von Telemetriedaten für eine präventive oder Problem-Analyse ist nun ebenfalls orts- und zeitunabhängig möglich. Hierbei wird auch ein situatives Lernen [vgl. 38] unterstützt, indem anhand von Maschinendaten zeitnah die Auswirkungen von geänderten Einstellungen analysiert werden können.

Gänzlich auflösen lässt sich der formalisierte Kontext aber nicht [39] und würde auch weiterhin für Pflichtveranstaltungen, wie Grundlagenschulungen und praktische Übungen/Prüfungen im Rahmen von Qualifikationsmaßnahmen, genutzt werden können.

Im Zentrum der Innovation steht die Unterstützung des arbeitsprozessbegleitenden Lernens im physischen Kontext – d.h. direkt an der laufenden Maschine und parallel zur Produktion, was direkt die Anforderung CAP3 adressiert. Sowohl hierbei, als auch bei der, in komplexeren Problemsituationen notwendigen, Expertenunterstützung würde das System den Lernenden mit bekanntem Problemlösungswissen unterstützen und ermöglichen, neu erarbeitetes Wissen zu externalisieren und im Unternehmen zu verteilen um somit die Anforderung CAP2 zu unterstützen. Dabei soll der soziale Kontakt zwischen Ratsuchendem und Experten ungestört verlaufen können – das System dient hier lediglich zur (Nach-) Dokumentation und zum Wissenstransport.

Eine weitere Innovation stellt die Unterstützung der Belegschaft im sozialisierten Kontext durch eine entsprechend gestaltete Community für die Diskussion und Lösung von nicht-akuten Problemen (akute Probleme müssen sofort gelöst werden) dar. Hier findet ein Lernen direkt zwischen den Mitarbeitern auf Shopfloor-Ebene statt.

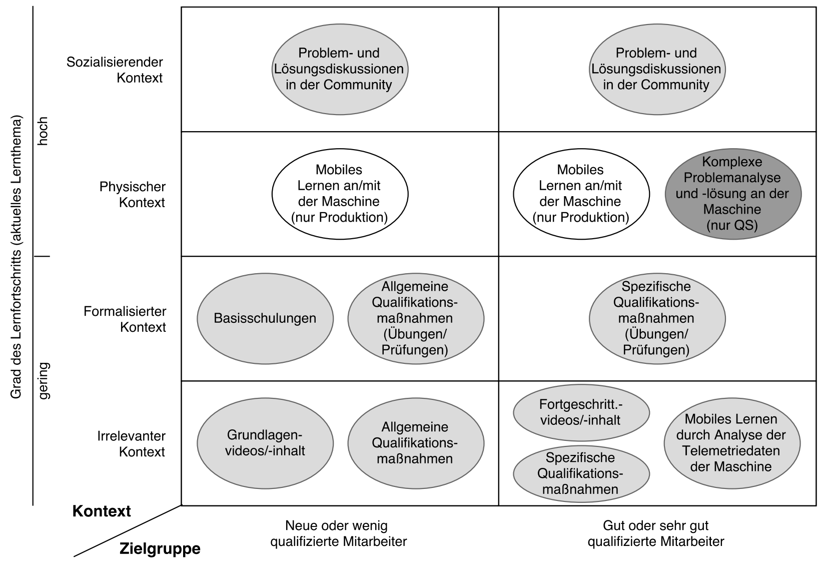

Abbildung 2. Lernarrangements bei der AZ AG mit optimierter Lösung

Die ohnehin schon existierenden sozialisierten Kleingruppen an den Anlagen, welche aus den Mitarbeitern der entsprechenden Arbeitsschichten bestehen, werden somit ausgedehnt und schichtübergreifend, anlagenübergreifend, zeit- und ortsunabhängig in ihrer Kommunikation unterstützt. Durch die individuelle Förderung der Mitarbeiter werden Kompetenzen anhand des tatsächlichen Bedarfs aufgebaut. Bedarfsanalysen im klassischen Sinne entfallen, da sich das System selbst reguliert – nicht mehr gebrauchtes Wissen wird vergessen und benötigtes Wissen punktgenau akquiriert. Die Personalkompetenz passt sich damit auch global den wechselnden Bedürfnissen des Unternehmens an. So behält der Mensch seine wichtige Rolle als Entscheidungsträger auch bei weiterer Zunahme der Komplexität in der Produktion.

Dieses Paper beschreibt dabei erst den Anfang des Design Research Prozesses. Momentan ist die Erkenntnis über mögliche Lösungen noch limitiert. Einerseits, weil sich die Untersuchung bisher nur auf einen konkreten Fall stützt und, weil die vorgeschlagenen Lösungen noch nicht im Unternehmen eingeführt sind. Andererseits zeigt sich durch diese Konstellation die praktische Relevanz am Fallbeispiel und im Laufe des Projektes können die vorgeschlagenen Interventionen in einem echten Kontext erprobt werden.

Abstract. Fostering higher-level learning in the disciplines of problem-solving and critical thinking becomes important when educating knowledge workers. By taking part in collaborative learning (CL) activities, e.g., interactive discussions, learners have the chance to develop, defend, and critique positions. However, implementing CL activities is often complex because this requires knowledge in designing effective collaboration. We build on insights from learning and collaboration engineering literature to develop an IT-based Collaborative-Learning-Pattern Approach (CLPA) that consists of two patterns, each describing a process design – one for training problem-solving, and the other for attaining critical thinking abilities. To evaluate the CLPA, we use simulations, walk-throughs among lecturers, and pilot-tests among students. Results show that the CLPA empowers lecturers to implement respective activities in the classroom, takes into account pedagogical demands, and satisfies lecturers as well as learners. We contribute several findings toward a design theory for empowering lecturers to implement CL activities in their classes.

Keywords: collaborative learning, collaborative-learning-pattern approach, higher-level learning, collaboration engineering, design science research.

(Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 761-775

1 Introduction

Approaches for training *higher-level learning (HLL)* on the upper levels of Bloom's taxonomy (apply, analyze, evaluate, create) [1] in the disciplines of problem-solving and critical thinking are becoming increasingly important in the digital age, which is characterized by an increasing availability of information. Furthermore, to remain competitive, innovative companies are in demand for highly educated knowledge workers. Competences such as teamwork and communication abilities are highly relevant as well [2]. The performance of knowledge workers depends on the degree to which they master those skills. Thus, universities have to provide learning experiences that help learners to develop those skills. However, traditional lectures – characterized by a low level of interaction among learners and a focus on factual knowledge [3] – are still popular. The reasons are for example declining state funding and increasing student numbers [4]. This means that learners often lack the chance to develop, defend, and critique positions, which would be vital for achieving HLL. Collaborative learning (CL) approaches ground on insights from *constructive learning theory* that posits that learning occurs by experiencing an environment through interactions with other individuals [5]. These approaches seem to be promising when it comes to overcoming existing shortcomings. However, CL approaches that focus on HLL are typically less predictive and hardly replicable, demand an understanding of how to design effective collaboration, and do not restrict learners in their experiences [6]. Lecturers lack validated out-off-the-box techniques to conduct and stimulate CL activities among learners. While lecturers struggle with less predictive and hardly replicable learner interactions and outcomes, learners struggle with CL techniques in terms of HLL tasks. These tasks provide learners with a problem situation. Such situations require that learners develop a solution that represents a sophisticated understanding of knowledge concepts and their relationships and thus, train problem-solving abilities. Furthermore, these situations require that learners analyze and evaluate the situation and, thus, train critical-thinking abilities. Inexperienced learners not familiar with these HLL learning techniques are often overstrained since e.g. tasks seem to be unclear and open-ended; instructions focus on learning content, but often do not provide training or guidance on how to proceed through the CL experience for HLL. In contrast to constructivist learning literature that argues learning processes should be ad hoc [6, 7], collaboration literature shows that process structures can under certain conditions increase the number, quality, and creativity of ideas a group creates. They may also increase the number of communication cues exchanged within a group, and improve the quality of its work products while reducing cognitive load [8]. Most individuals – lecturers as well as learners – do not have an intuitive grasp of effective collaboration. In cases of inventing ad hoc collaboration, most groups tend to be ineffective [8]. This leads to the assumption that CL experiences may benefit from systematically designed collaboration that guides lecturers and learners. Therefore, applying insights from collaboration literature to the domain of learning might be a solution. A design methodology is needed that a) provides procedural guidance on how to split structure and that describes CL activities for HLL in a way that helps lecturers and learners proceed through CL activities in a predictive and effective way; and b) helps lecturers implement CL activities for HLL as building blocks in their classes. In that context, *collaboration engineering* is an approach that designs and deploys high-value recurring tasks and transfers them to practitioners (lecturers, learners) without the ongoing support from expert facilitators [8].

The goal of this paper is to help lecturers and learners overcome this challenge by answering the following research question: *How can CL knowledge be packaged in a reusable way so that it comprises sufficient collaboration techniques to empower lecturers (and learners) to conduct (and follow) CL activities for HLL in the classroom?* The objective of this paper is to develop the *Collaborative-Learning-Pattern Approach (CLPA)* comprising two process designs inherent in patterns for enhancing HLL – the *Problem-Solving Pattern (PSP);* and the *Critical-Thinking Pattern (CTP).* The *design goals* of CLPA are: (1) to help lecturers enhance CL activities for HLL in the areas of problem-solving and critical thinking in classes in a predictive way; (2) to help learners proceed through CL activities with assisting guidance on collaboration. We focus on these two patterns for two reasons. First, they enhance cognitive processes that refer to applying, analyzing, evaluating, and creating knowledge, and thus focus on the upper levels of Bloom's taxonomy [1]; and second, they help enhance skills relevant for knowledge workers such as teamwork and communication. Each pattern represents a design for a reusable and structured collaboration process that packages sufficient collaboration expertise so that non-experts (lecturers, learners) can execute and follow a well-designed work practice without training in tools and techniques. We follow the idea of patterns, because *patterns* "[…] exist as means of deriving useful solutions to recurring problems within specific contexts" [9]. Consequently, a pattern describes a recurring problem as well as the core of the solution for that problem in such a way that the solution can be used unlimitedly [9]. To guide our design choices, we rely on insights from collaboration engineering literature and use the *six-layer-model* to design and present the CLPA with its patterns [10]. The layers comprise the definition and configuration of a group *goal*, *products*, *activities*, *procedures*, *tools*, and *behavior* [10].

2 Design Science Research Framework

In this paper, we report a Design Science Research (DSR) study and structure our paper along Hevner's 2007 [11] three-cycle view (Figure 1). First, we start the *relevance cycle* by identifying a set of unsolved problems inherent in packaging sufficient collaboration expertise to enhance CL activities for HLL in the classroom (activity #1 | section 1). Second, we initiate the *rigor cycle* by drawing on justificatory knowledge from CL literature with respect to training problem-solving and critical thinking abilities (activity #2 | section 3). Thirdly, we start the *design cycle* and provide principles of form and function inherent in generalizable requirements for CL activities for HLL, and the CLPA design with its two patterns as a generalizable solution (activity #3 | section 4). In section 5, we complete several iterative design and relevance cycles by describing the procedures of testing three iterative exemplar instances of the CLPA in terms of a multi-method evaluation (activity #4 – simulation with designers │ activity #5 – walk-through with lecturers │ activity #6 – pilot-test with students in the classroom). The results show that the designed artifact of CLPA meets the design goals. In section 6, we complete the rigor cycle by adding *prescriptive knowledge*[1] [12] to the literature before we close with an outlook on future research in section 7. According to Gregor's 2006 descriptions [13], our CLPA resembles a theory of '*design and action*'. More precisely, it is of the type '*improvement*'. Lecturers can use CLPA to create their own instances [12].

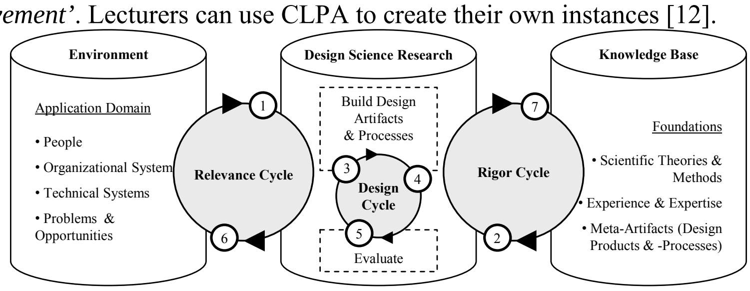

Figure 1. DSR Three-Cycle View in the Context of the Study

3 Theoretical Background of Collaborative Learning

Collaborative learning (CL) is based on constructivist learning theory [14]. According to this theory, learners learn from experiences that they gain through interactions with their environment and each other [15]. If well designed, CL may relieve the lecturer from some labor-intensive tasks, particularly in large classes, such as giving individual feedback on assignments. Learners benefit from such interactions in several ways: e.g. discussions can enable a direct exchange between learners that fosters reflection of knowledge, and thus, critical thinking; and can increase motivation, participation [16], and learning success [17]. This helps learners improve job-relevant competences like teamwork and communication [14]. The range of CL activities comprises discussions, co-construction of solutions, or giving mutual feedback. Literature on peer discussion of multiple-choice tasks, for example, describes positive learning effects when learners first reflect knowledge on their own, then discuss their choice with others, and finally re-evaluate their choice [18]. The co-construction of a solution, for example, helps learners explain and challenge ideas to each other, and stimulates knowledge creation [19]. Moreover, mutual assessment among learners has the potential to correct mistakes and to clarify unclear issues [20].

To enhance such CL experiences, lecturers need to respect several aspects. They have to ensure reciprocity in social interactions among learners, e.g. when it comes to direct feedback [21]. They also have to ensure that learners are responsible for their outcome [19] and that assignments and instructions are clear [22]. In a class, however, there are high- and less-experienced learners. Hence, it is hard for a lecturer to create a learning experience that challenges the top learners without losing the bottom

[1] *Prescriptive knowledge* describes artifacts designed by humans to improve the natural world. It is inherent in the form of models, methods, instantiations, and design theories.

learners. A shared understanding of knowledge concepts therefore is necessary to foster social interactions toward a development, modification, and reinforcement of shared mental models [23]. Van den Bossche et al. [24] identify *team learning behaviors* as follows: learners should express and share their individual understanding, and listen to each other (construction), discuss and clarify their understanding to reach mutual understanding (co-construction), and negotiate an agreement on a mutually shared perspective (constructive conflict). *Problem-based learning* is known to generate HLL. This is focused experiential learning that is organized around the investigation, explanation, and resolution of meaningful problems [25]. This way it refers to metacognitive knowledge on the upper levels of Bloom's taxonomy [1]. Learners collaborate in small groups and solve a problem. Depending on the assignment, the learners train *problem-solving abilities* by creating a common solution for a complex situation. They can also train *critical thinking abilities* by evaluating, analyzing, interpreting or explaining a problem situation with the aim of making a reflective judgement [26]. The lecturer facilitates and guides learners through the learning experience [27]. Although a wide range of variations of problem-based learning have evolved in literature and educational practice, there are some core characteristics: (1) learning needs to be learner-centered; (2) learning has to occur in small groups under the guidance of a tutor; (3) the tutor needs to act as a facilitator; (4) authentic problems are primarily encountered in the learning sequence, before a preparation has occurred; (5) the problems encountered are used as a tool to achieve knowledge and skills that are necessary for problem-solving [25]. Fifty years after problem-based learning had evolved; it was applied to various educational contexts. Much evidence suggests that it is more effective than traditional methods with regard to enhancing learners' problem-solving and critical thinking abilities. However, skeptics argue that it is ineffective because it provides only minimum guidance and therefore is too complex and not compatible with human cognitive architecture [28]. From a meta-study, Hmelo-Silver 2004 [27] derives a research agenda that calls for more work in the areas of collaboration, scaffolding structures for inexperienced learners, and approaches to overcome the lack of skilled facilitators. "Classrooms have more students than one person can easily facilitate, and learning to facilitate well is a challenge" [27]. She suggests techniques such as procedural facilitation or scripted cooperation to address this challenge.

4 The Collaborative-Learning-Pattern Approach (CLPA)

4.1 Generalizable Requirements to Enhance Collaborative Learning for HLL

In the following, we describe the design cycle of our study. We present generalizable requirements for enhancing CL activities for HLL (section 4.1) and then describe the CLPA with its two patterns as a generalizable solution (section 4.2). Following the DSR paradigm, we derive generalizable requirements (see Table 1) to design CL activities for HLL by completing a relevance cycle (section 1) and a rigor cycle (section 3). Based on this we derive the CLPA as our generalizable solution.

Table 1. Generalizable Requirements to Enhance CL Activities for HLL

Relevance cylce – lecturers' requirements (see the specific challenges/sources in brackets):
(GR 1) Set-up Guidance*:* The CLPA shall provide instructions for the task choice, as well as definition, set-up, and configuration of CL activities (lack of CL design experience of lecturers).
(GR 2) Facilitation Guidance: The CLPA shall provide detailed instructions on the facilitation actions, e.g. statements and questions the lecturer needs to work with during the CL experience (unpredictable moderation of CL).
Relevance cylce – learners' requirements (see the specific challenges/sources in brackets):
(GR 3) Simplified Process Structure*:* The CLPA shall divide CL into activities with defined subtasks (learners' resistance to open-ended and highly complex task structures).
(GR 4) Collaborative Interaction Support*:* The CLPA shall provide instructions on how interactions among learners should be organized in each phase (high cognitive load because of inventing ad-hoc collaboration parallel to task solving)
(GR 5) Clear Goal/Outcome Specifications*:* The CLPA shall define clear final and intermediate goals and outcomes for the learners for a specific task (risk to self-efficacy and satisfaction in case of transparency)
Rigor cycle – collaborative learning literature:
(GR 6) Individual Reflection*:* The CLPA shall support individual construction and reflection of knowledge [24].
(GR 7) Mutual Feedback*:* The CLPA shall provide structured support for constructive feedback, sense making [20, 24].
(GR 8) Consolidation of Solutions*:* The CLPA shall provide structured support for negotiating and consolidating different perspectives towards a shared solution [22, 24].
(GR 9) Access to Solution: Exemplary solutions shall be provided to all learners or discussed after the task completion (given the partly unpredictable outcome of CL, all learners shall have the chance to receive a correct solution) [19].
(GR 10) Task Responsibility in Small Breakout Groups*:* The CLPA shall assign distinct, complementary subtasks to breakout groups small enough for each learner to feel responsible for the result [19, 21].

4.2 The Pattern-Based Process Designs as a Generalizable Solution

The aim of the CLPA is to initiate predictive small-group CL activities for HLL in the disciplines of problem-solving and critical thinking. Thus, the CLPA comprises two patterns – the PSP (see section 4.2.1 [Table 3]), and the CTP (see section 4.2.2 [Table 4]). To develop and describe the CLPA we use the six-layer model [10] as a design methodology in order to apply insights from collaboration engineering literature, such as process restrictions and structuration of collaboration, to the domain of CL [10]. By following the layers we systematically derive a reusable process design for each pattern that structures CL in a sequence of activities with several outcomes. Our generalizable requirements guide our design choices. To conduct the two patterns of CLPA in a scalable manner, the lecturer has to prepare some conditions (see Table 2):

Table 2. General Conditions to Conduct the Patterns of CLPA

Parameter	Description
Problem situation	Define an overall complex problem situation with action items in which the subtasks become embedded. A problem situation is a situation that covers the intended content to be learned as well as the specific and unique contextual factors to be considered, and that considers the conceptual connections of the problem within the curriculum [29].
Choose and create task structure	Define 2 up to 15 independent subtasks that refer to learning objectives (task specifics described in each pattern); pay attention that its execution takes place in parallel sub-/ breakout groups.
Specify deliverables	Realize learning objectives within the demands of the group deliverable (e.g. visualization and explanation) and pay attention to the fact that it is easy to present in the plenary group.
Breakdown group structure	The whole class is the plenary group. A plenary group can be divided into at least 2 up to 15 subgroups (4 to 30 participants each), working simultaneously. A subgroup can be divided into several breakout groups (2 to 6 participants each) [30].
Dependencies groups and tasks	Each participant is part of a breakout group and works on a specific subtask (number of subtasks = number of breakout groups). A subgroup receives all subtasks.
Scalability	The problem situation and its subtasks can be assigned to more than one subgroup and their breakout groups. Use tools that provide a shared working space for all breakout groups.

4.2.1 Problem-Solving Pattern (PSP)

The *group goal* of PSP is that learners simultaneously and collaboratively clarify, discuss, and develop a solution for a subtask within two hours. To keep learners motivated, the task should be appealing to them, e.g. by being relevant for learners' future career or addressing their personal interests [29]. The collaboration helps learners to satisfy individual goals such as becoming qualified knowledge workers by experiencing HLL in the discipline of problem-solving as well as training teamwork and communication abilities. To operationalize the goal we use an instrumental *group product*: each subtask solution has to be reported as a group deliverable in the form of text and visualizations to illustrate all relevant knowledge concepts and their relationships in a correct and abstract manner and thus, new knowledge is created. To operationalize the group product we define group activities to structure the collaboration. The PSP comprises three distinct steps, each using a *thinkLet*[2] to structure *group activities*. While the learners work in a subgroup in step 1, they collaborate within breakout groups in steps 2 and 3. In step 1, each learner receives access to all subtasks. On their own, learners brainstorm solution ideas while having the chance to read the contributions from their teammates. This activates chunking and thus, cognitive mechanisms to build relationships among knowledge frames. Reading ideas from other learners triggers cognitive effects among the less-experienced learners. In step 2, learners are assigned to breakout groups, each of which receives a subtask with the deliverables from step 1. In the breakout groups, learners discuss, organize, and summarize contributions and add missing knowledge aspects. This helps them consider and juxtapose the knowledge to create a solution for a problem situation. In step 3, learners report the solution by using text descriptions and visualizations. The *tool* support provides shared writing pages (e.g., GSS with separated groups, text editing, visualizations [e.g., ThinkTank, GoogleDocs, Google Slides]; flip charts; cards) so that the learners are able to make contributions while reading the contributions from other learners (step 1), and to discuss with other learners and visualize their solution (steps 2, 3). After each step the tools generate a report of the group deliverables (e.g. list of ideas). The *group behavior* restricts learner interactions toward solving the task. After each step, learners are stopped from editing documents and become automatically assigned to their group (plenary group, subgroup, or breakout group). Learners receive guidance via clear instructions, enabling them to cope with subtasks, showing them how to complete the activities, giving them orientation, e.g. with a list of teammates. Table 3 illustrates the PSP and serves as a moderation plan.

Table 3. Problem-Solving Pattern (PSP): Overview and Moderation Plan

Learning objective	Apply, analyze, evaluate, create	**Task specification**	Content, context, connection
Individual goal	Training HLL in the discipline of problem-solving and, teamwork and, communication abilities.		
Group product	For each subtask a solution in the form of meaningful text and visualizations (e.g., storyline/scenes, slide show).		
Group changes	2: subgroup to breakout group; breakout group to plenary group		
Tool support	GSS – functionalities for separate groups, text editing, visualizations: e.g., ThinkTank, GoogleDocs, flip charts, cards		

[2] *thinkLets* are packaged collaborative activities that serve as validated building blocks [33].

	Group activity & general description	Group product & quality indicator	Group procedures (thinkLet, pattern of collaboration) [8]
Step 1: 20 min	Subgroups: Each subgroup receives all subtasks. Each learner brainstorms ideas to create a solution for a problem situation among all subtasks.	Product: Per subgroup, a document with a set of solution ideas for each subtask. Quality: Contributions are solution ideas that represent knowledge concepts in the form of meaningful keywords.	LeafHopper (brainstorm): For each subgroup a bundle of shared writing pages, each with a subtask. a) Explain learners the subtasks and how to contribute. b) Explain expectations regarding quality aspects of contributions. c) Prompt learners to work on subtasks in which they have the most expertise; to look at each subtask, read it, and add contributions. d) Indicate that learners will not be able to work on every subtask during the available time.
Step 2: 40 min	Breakout groups: Subgroups are divided into breakout groups, each assigned to a subtask. Learners discuss, organize, and summarize solution aspects for a subtask.	Product: Per breakout group, a document with a clarified and summarized set of solution aspects for each subtask. Quality: Organized, corrected, and completed solution aspects.	PopcornSort (organize): For each breakout group a shared writing page with a subtask. a) Explain and verify instructions and converge categories (not relevant, correct, missing aspects). b) Explain that contributions are to be assigned to categories? c) Summarize the correct aspects in a meaningful explanation.
Step 3: 60 min	Breakout groups: Learners report their solution in the form of text and visualizations. Plenary group: Lecturer and learners discuss exemplary solutions.	Product: Per breakout group a report for a subtask in the form of text and visualizations. Quality: Report comprises all relevant knowledge concepts in the form of text and meaningful visualizations.	BucketBriefing (clarify): For each breakout group a shared writing page for text and visualization. a) Explain that learners are to work on the shared writing page. b) Explain to learners quality criteria to report the solution. c) Explain that discussion of exemplary solutions after the remaining time within the plenary group takes place.

4.2.2 Critical-Thinking Pattern (CTP)

The *group goal* of the CTP is that learners simultaneously and collaboratively correct and improve an existing solution from a subtask within two hours. The collaboration helps them to achieve HLL effects in the discipline of critical thinking as well as teamwork and communication abilities. Typically, abstract solutions of HLL knowledge look professional, complex and thus, seem to be correct. Hence, the *group product* is an improved solution comprising text and visualizations for each subtask. This leads to subtasks that constitute sample solutions that challenge the learners in a way that HLL on the upper levels of Bloom's taxonomy (analyze, evaluate, create) will be addressed. The CTP comprises three distinct steps, each using a thinkLet to structure *group activities* to improve an existing solution. While the learners work within a subgroup in step 1, they collaborate in step 2 and rate their results individually in step 3. In step 1, each learner receives access to the existing solutions of all subtasks. On their own, each learner analyzes all provided solutions, marks mistakes, and makes notes for improvements. In step 2, learners are assigned to breakout groups. Each receives a subtask solution with a list of marked mistakes and improvements. Within breakout groups learners evaluate, interpret, and explain the solutions. They clarify improvement suggestions and write down a revised solution in the form of text and visualizations. A member of each breakout group presents the revised solution to the subgroup. In step 3, learners evaluate on their own whether the solutions of the subtasks are correct and whether they are satisfied with it. The *tool* support in steps 1 to 3 provides similar collaborative working spaces as the PSP with shared writing pages. Here, learners can mark mistakes (step 1), create a revised solution (step 2), and rate the revised solutions (step 3). After each step the tools generate a report of the current deliverables of the step (e.g. list of mistakes). The *group behavior* is restricted toward a focused collaboration like in the PSP. Table 4 illustrates the CTP and serves as moderation plan.

Table 4. Critical-Thinking Pattern (CTP): Overview and Moderation Plan

Learning objective	Analyze, evaluate, and create.	**Task specification** Content, context, connection, appeal to learners. Subtasks are exemplary solutions with mistakes.
Individual goal	Training HLL in the discipline of critical thinking, and teamwork and, communication abilities.	
Group product	Correct and abstract solution in the form of text and/or visualization.	
Group changes	1: subgroup to breakout group	
Tool support	GSS – separate groups, text editing, visualizations, voting: e.g., ThinkTank, GoogleDocs; flip charts, post-its, cards	

	Group activity & general description	Group product & quality indicator	Group procedures (thinkLet, PoC) [8]
Step 1: 30 min	Subgroup: Presentation of the solution of all subtasks and identification of mistakes and inconsistencies.	Product: Per subgroup, a list with identified mistakes and suggestions for improvements for each subtask. Quality: Each mistake comprises a constructive suggestion for improvement.	BucketWalk (evaluate): For each subgroup a bundle of shared writing pages, each with a subtask solution. a) Learners read and walk through the subtask solutions. b) Learners mark aspects that are: false/not relevant, redundant/inconsistent, poorly formulated. c) Learners write down suggestions for improvements (e.g., better formulation, correct knowledge concepts).
Step 2: 80 min	Breakout group & subgroup: Correction of mistakes and inconsistencies. Finalization of correct solution and its presentation.	Product: Per breakout group, revised mistakes and inconsistencies of the solution. Quality: Revised solution comprises all relevant knowledge concepts in form of text and meaningful visualizations.	BucketBriefing (clarify) : For each breakout group a shared writing page for a subtask. a) Learners discuss and clarify marked mistakes and improvement suggestions. b) Learners write down a revised solution for their subtask. c) A member of each breakout group presents revised solution in front of the subgroup (max. 5 min).
Step 3: 10 min	Breakout group: Assessment of the final solution by learners.	Product: Per breakout group, a rated solution of every subtask. Quality: Positive values for correctness and satisfaction with the revised solutions.	MultiCriteria (evaluate): For each breakout group a shared voting page, each for a subtask. a) Post a list of evaluation criteria (level of correctness, level of sophistication, satisfaction with revised solution) for each subtask solution. b) Learners rate each subtask solution on a scale from 1[very bad] to 7 [very good].

5 Evaluation of Collaborative-Learning-Pattern Approach

5.1 Research Method

Data Collection and Measures: We started in 2014 and iteratively designed and evaluated the CLPA using a mixed method approach in line with collaboration engineering to evaluate our design goals [31] (Table 5). We raised explorative findings with real stakeholders and based the evaluation on qualitative and quantitative data [32] that comprised simulations [requirement-based evaluation and identification of stumbling blocks], walk-throughs [interview for stumbling blocks in the process design] by lecturers, and pilot-tests [survey, pre/post knowledge test] by learners (see Table 5). Based on established scales, measures were adapted from Petter et al. 2010 (*plausible; effective; feasible; predictive; reliable*) [9] to build the category system for a content analysis to analyze the qualitative data; and from Briggs et al. 2013 (5-item scales – *satisfaction with process [SP]; satisfaction with outcome [SO]; tool difficulty [TOOLDIF]; process difficulty [PROCDIF]*) [8]. Moreover, we used a pre/post knowledge test, each comprising five single-choice questions to investigate findings for knowledge increases among the learners for each treatment.

Table 5. Mixed-Method Approach to Evaluate the CLPA

	Iterative evaluations	1st	2nd	3rd
Qual. data	Simulation [requirement-based evaluation] (by designer)	N = 1	N = 1	N = 1
	Walk-through [interview] (by lecturers)	-	N = 4	N = 2
Quant. data	Pilot-test [survey, pre/post knowledge test (by learners)	-	-	N = 36

Context and background of the study / participants: All independent lecturers participating in the study teach information systems courses at master levels. The pilot tests were conducted in the same master's course on the topic of "Collaboration Procedures" and thus, with the same tasks. The participants were students from German and Swiss universities. In each semester the course was usually attended by 10 to 20 students. Among all pilot-tests a total of N = 36 students [17 males, 19 females], aged 22 to 34 years [mw = 26 years], participated in the CLPA. The CLPA with IT-supported tools (ThinkTank) and paper-based tools (flip chart, cards) was conducted by us as designers and by two lecturers, leading to four subgroups, each representing a treatment (Figure 2). *Procedures:* Before the evaluation in the field, the quality of the CLPA was assessed using a requirement-based evaluation by us as designers to investigate whether the design of CLPA meets the generalizable requirements. During the walk-through, the design of the CLPA was presented to lecturers and they were asked to identify inconsistencies. Participating in the pilot-test was voluntary and served as preparation for the final exam of the course. The two patterns were bundled, which created a 5-hour learning experience. Learners of a subgroup received a problem situation with four subtasks that required them to describe a blueprint of effective collaboration in the form of a storyline with scenes; each scene had to be described in an abstract and sophisticated way using text and visualizations to demonstrate knowledge concepts. The four subtasks constituted several sequences of scenes. First, learners completed a pre knowledge test, then passed the PSP and CLT, and finally completed a post knowledge test and a survey.

		CLPA experience	
		paper-based tools	IT-supported tools

	Lecturer	Treatment 3: [group C]	Treatment 4: [group D]

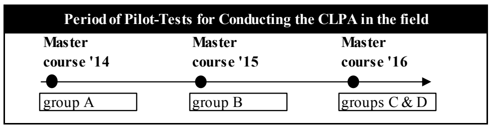

Figure 2. Treatments in the Pilot-Tests

5.2 Results

Simulation by designers and walk-throughs with lecturers. We used a content analysis based on Kohlbacher 2006 [32] and grounded a category system on measures for pattern evaluation based on Petter et al. 2010 [9] (Table 5). *1st evaluation:* Plausibility, effectivity, and feasibility were examined by a simulation. There were no inconsistencies. To judge whether the CLPA is predictive or reliable was not possible. *2nd evaluation:* Walk-throughs with lecturers resulted in statements such as *"when do the learners work in groups and when do they work alone"*. We refined the comprehensiveness of instructions for the lecturer and the subtask wording for learners to improve effectivity. We also refined the grouping structure to improve instructions and rewrote its wording. With regard to the question whether the CLPA is predictive and reliable, the lecturers felt comfortable and were sure that *"the activities will work and the learners will be motivated"*. *3rd evaluation*: A lecturer stated his *"[…] feeling of being a coach"*. The discussion with each lecturer was, inter alia, about whether the process design of CLPA was effective and whether it was reliable. With the help of statements like *"[…] whether the time of that activity is realistic,* *depends upon the number of subtasks […]"* or *"how does that subsolution serve as relevant input for the next subtask; what are input-output relations between the subtasks?"* we improved the time and the sequence of activities, and thus the granularity of activities. We bundled activities to blocks and adapted validated thinkLets from CE. Moreover, the requirement-based evaluation was in line with Hevner 2004 and 2007 [11, 33], and indicated that the process designs of CLPA met the generalizable requirements and thus, coped with the demands of the environment and the body of CL literature. *Pilot-Tests with learners* helped examine whether CLPA met the design goals. We derived three hypotheses, each with exploratory research questions that guided our data analysis:

$H_{1:}$ The CLPA conducted by the designer results in high learner satisfaction.

- $Q_{1a:}$ Did CLPA with paper-based tools result in high learner satisfaction (T1)?
- $Q_{1b:}$ Did CLPA with IT-supported tools result in high learner satisfaction (T2)?

$H_{2:}$ Lecturers are able to conduct the CLPA as good as the designer of the CLPA, so that learners are equally satisfied regardless of the moderator.

- $Q_{2a:}$ Did conduction of CLPA by different moderators and with the same paper-based tools result in similar learner satisfaction comparing treatment 1 and 3?
- $Q_{2b:}$ Did conduction of CLPA by different moderators and with the same IT-supported tools result in similar learner satisfaction comparing treatment 2 and 4?

$H_{3:}$ The conduction of the CLPA with different tool support leads to comparable scores of perceived satisfaction by the learners.

- $Q_{3a:}$ Did conduction of the CLPA by the designer and with different tool support lead to a difference in learner satisfaction in treatment 1 and 2?
- $Q_{3b:}$ Did conduction of the CLPA by lecturers and with different tool support lead to a difference in learner satisfaction in treatment 3 and 4?

To make sure that groups started with no bias with regard to group size, gender, and age, we ran a Kruskal-Wallis test. The results showed no significant difference. To investigate findings for design goal 1 with regard to knowledge increases we compared the means of pre/post-knowledge tests in all treatments. There was a significant difference in the knowledge test performance in each treatment. Learners performed better in the post knowledge test (mean = 3.6) than in the pre knowledge test (mean = 3.0) (Table 6). To verify whether the construct scores have a better mean than a test score (neutral average score on 7-point Likert scale) we run a 1-sided t-test [34] to examine H1. The analysis of Q1a and Q1b showed that all constructs differed significantly, except in terms of TOOLDF for Q1b. Means were better than the average test score and thus on average and upper levels of the 7-point Likert scale (Table 7). To analyse H_2 and H_3, we run a Mann-Whitney test. The results indicate that learners rated the satisfaction in all treatments on upper levels. To investigate H_2, we analysed whether the CLPA can be conducted by different moderators (designer vs. lecturer). Q_{2a} focused on the paper-based tool conduction of the CLPA by different moderators. We compared the means from treatment 1 and 3. There is no significant difference in the means of SP, SO, and PROCDIF. However, for TOOLDIF ($p<0.000$)

learners in treatment 1 (mean = 6.138) scored significantly higher than learners in treatment 3 (mean = 4.100). Q_{2b} focused on the IT-supported CLPA conduction by different moderators. Thus, we compared the means from treatment 2 and 4. There is no significant difference in the means of SP, SO, TOOLDIF, and PROCDIF. To investigate H_3, we analysed whether the CLPA can be conducted with different tool support (paper-based tools vs. IT-supported). Q_{3a} focused on the CLPA conduction by a designer with different tool support. A comparison of the means from treatment 1 and 2 showed no significant difference for SP, SO, and PROCDIF. However, for TOOLDIF there was a significant difference by treatment ($p<0.000$). Learners in the paper-based treatment 1 (mean = 6.138) scored significantly higher than learners in IT-supported treatment 2 (mean = 4.089). Q_{3b} focused on the conduction with different tool support by lecturers. There is no significant difference for SP, TOOLDIF, and PROCDIF when comparing the means from treatment 3 and 4. But learners in the paper-based treatment 3 (mean = 5.640) scored significantly higher than learners in the IT-supported treatment (mean = 6.514).

Table 6. Subgroup Structure: Manipulation Check and Knowledge Increases

Note: Mann-Whitney test; 7-point Likert scale (1= very less; 7 = very high); mean difference significant **p< 0.01, *p < 0.05, ns = not significant

6 Discussion

In the following, we discuss the results with respect to the two design goals defined at the outset of this paper. *DG 1 – help lecturers to conduct CL activities for HLL in the classroom:* Results from the qualitative content analysis provided insights on how to improve the design of the CLPA. Two lecturers conducted CLPA during several pilot schemes and achieved comparable results (increases in knowledge test performance; satisfaction measures) with the learners compared to the conduction by the designer. The results regarding H_2 with Q_{2a} and Q_{2b} showed no significant difference in the scores; except for TOOLDIF in Q_{2a}. The difference in the TOOLDIF may indicate that use of paper-based tool support should be described in more detail. The results show that lecturers become empowered to conduct CLPA and that the CLPA has the potential to enable knowledge increase among learners. *DG 2 – help learners to proceed through CL activities for HLL:* Among all treatments the satisfaction scores were above an average score of 4 and thus, on average and upper levels of the 7-point Likert scale (H_1). This indicates that learners are able to follow the CL activities in a positive manner. H_3 focused on whether there is a difference in the conduction of CLPA with paper-based tools and IT-supported tools and thus, which way of tool support is easier for learners to follow. To avoid bias by moderator we compared treatments 1 and 2 (both moderated by the designer) to gain insights for Q_{3a}; and treatments 3 and 4 (both moderated by a lecturer) to gain insights for Q_{3b}. Q_{3a} showed a significant difference in the measures of TOOLDIF ($p<0.000$). Learners felt more comfortable with paper-based tool support, since they may have perceived the collaboration as being closer. Another explanation could be that they perceived visualizing or editing contributions as a more flexible way, and thus felt more comfortable with it. However, comparing lecturer moderated treatment 3 and 4 results showed no significant difference in TOOLDIF. Thus, the difference in treatment 1 and 2 may be attributed to the facilitation skills of the designer who moderated the CLPA experience. A similar conclusion can be drawn with regard to Q_{3b} for SO ($p<0.025$). Learners in IT-supported treatment 4 are more satisfied with the outcome than learners in paper-based treatment 3. Thus, the SO with IT-supported tools seems to be more satisfying. However, when comparing treatment 1 and 2, there is no significant difference in means of SO. An explanation for the significant difference of SO in treatment 3 and 4 may be attributed to the facilitation skills of the lecturer.

7 Limitations, Future Research, Contribution, and Conclusion

This study is not without limitations, which provide future research opportunities. First, the evaluation of CLPA was communicated as a HLL experience. For that reason we built exemplary instances that bundled the PSP and the CTP. Consequently, learners followed a HLL experience in which they passed the PSP and then the CTP. It would be valuable for future research to evaluate each pattern on its own. Second, in total we have N = 36 learners that participated in the CLPA (four subgroups). To strengthen our results, it would be valuable for future research to evaluate the CLPA with more groups in a large-scale lecture. Thirdly, the design goals of this study referred to enhancing lecturers to conduct CL activities for HLL and to providing learners guidance to proceed through these activities. The focus was not on evaluating learning success. Hence, future research should investigate knowledge increases among learners in more detail – e.g. group deliverable evaluations by independent lecturers. In particular, follow-up evaluation will need to assess critical thinking and problem-solving skills in more detail. The contributions of the study are positioned along the components of DSR: The purpose and scope of the CLPA is to package sufficient collaboration expertise to conduct CL activities for HLL. To address this set of unsolved problems we provide principles of form and function inherent in generalizable requirements and the CLPA design with its two patterns. This provides guidelines to enable CL activities for HLL in the classroom.

We outlined the CLPA as an approach that helps lecturers to leverage the power of HLL in the disciplines of problem-solving and critical thinking. We based our research on justificatory knowledge from CL and collaboration engineering, and thus, postulate CLPA's potential for enhancing HLL. With three design and evaluation cycles we build expository instantiations of CLPA and evaluated it with real stakeholders by using a mixed methods approach. The results provide insights for CL literature since they show that principles from CE literature can be applied to the field of learning in a way that process restrictions have the potential to support learners in their HLL experience. With the CLPA design we provide insights on how to design CL activities that package sufficient collaboration expertise to empower lecturers to conduct those activities in a predictive way and provide learners guidance to cope with open-ended HLL tasks. Scalability of CLPA is given when several subgroups (with breakout groups) work simultaneously, since CL activities take place there. The CLPA provides prescriptive knowledge and resembles a *'theory of design and action'* [13] of the contribution type *'improvement'* [12].

Abstract. Information systems (IS) lectures often address audiences that consist of over one hundred students. In this setting, it is arguably difficult to consider the individual interests of each participant. This may result in students not being motivated, decreased learning outcomes as well as an overall low effectiveness of IS lectures. Self-determination theory suggests that perceived autonomy increases intrinsic motivation, which may in turn lead to improved learning outcomes. We therefore propose to foster perceived autonomy among students by introducing elected elements (e.g., practical examples and topics) that students can vote for with an audience response system. To investigate this instructional approach and to provide an instrument for its evaluation, we conducted a preliminary study that shows positive associations between perceived autonomy, intrinsic motivation, as well as acceptance among students. Based on these findings, we derive several avenues for future research regarding the use of elected elements in large-scale IS lectures.

1 Introduction

Undergraduate enrollment in degree-granting postsecondary institutions has continuously grown over the past decades. For instance, in the year 2013, this enrollment has increased by 46 percent in the United States compared to the year 1990 [1]. This growth results in information systems (IS) lectures that often address audiences consisting of over one hundred students that passively listen to instructors [2]. In this setting, it is arguably difficult to meet the individual interests of each participant for instance in terms of how the knowledge is embedded in practical examples. This may result in students not being motivated, decreased learning outcomes as well as an overall low effectiveness of IS lectures [3, 4]. Self-determination theory suggests that a possible way to foster students' intrinsic motivation is increasing their perceived autonomy [5], i.e. their perception of being able to choose topics and to influence the course of the lectures. However, asking each and every student about how the lectures should unfold is practically impossible in large-scale lectures.

We therefore propose to use pre-fabricated elements (e.g., practical examples, topics, etc.) that students can choose from in every lecture by voting in an audience response system (ARS). The main idea is that every lecture contains both mandatory elements to ensure certain learning outcomes are met as well as elected elements that meet students' interests and provide a feeling of influence on the course. We therefore pose the following overarching question of our research project:

RQ: What are the impacts of providing elected elements in large-scale information systems lectures on students' intrinsic motivation and learning outcomes?

In this paper, we report the results of a preliminary, cross-sectional study conducted in an introductory IS course at a German university, where students were given the choice over several elected elements in each lecture. After the course was finished, different aspects of intrinsic motivation and perceived autonomy were assessed with a brief questionnaire based on the intrinsic motivation inventory [6]. In the present study we were primarily interested in (a) analyzing the psychometric properties of the items and respective scales to provide a reasonable and valid measurement for a subsequent quasi-experimental field study, (b) exploring the acceptance and practicability of the instructional approach by gathering students' qualitative feedback as well as their ratings on an additional "Desirability" scale, and (c) providing first indications regarding its motivational benefits by examining qualitative feedback and performing correlational analyses of students' self-reported perceived autonomy, intrinsic motivation (in terms of interest/enjoyment), and subjective value (in terms of perceived usefulness) of elected elements. Based on the theoretical assumptions of self-determination theory, we expected positive associations between perceived autonomy and intrinsic motivation on the one hand, and intrinsic motivation and perceived value of elected elements. Due to privacy concerns, we were not able to collect performance data (i.e., learning outcomes) in the present study, which will be included in the subsequent study by using anonymous ID-codes.

The remainder of this paper is organized as follows: First, we provide the theoretical background for this study as well as related work. We then report the setup, method, and results of the preliminary study. Afterwards, these results are discussed and avenues for future research are shown in the concluding section.

2 Theoretical Background and Related Work

Self-determination theory stems from motivational psychology and provides several explanations for human motivation [5]. One of its central assumptions is that intrinsic motivation (i.e., the highest level of self-determination; when individuals engage in behavior for the pleasure and satisfaction that they inherently experience with participation [5]) requires the satisfaction of three basic psychological needs: Perceived competence, relatedness, and autonomy [7]. While perceived competence in lectures is already addressed by approaches that test knowledge and understanding of students [8] and relatedness might be covered with peer-reviewing activities [9], perceived autonomy (i.e., being able to influence the course of the lectures) is still rarely addressed by existing studies. While achieving intrinsic motivation among students is one goal of higher education, increased motivation should also lead to better learning outcomes. Indeed, several studies have provided evidence for a link between intrinsic motivation and learning outcomes, such as improved grades [10] or high academic performance through increased study effort and deep learning [11].

By using ARS, which are sometimes also called Audience Response Technology, Personal Response Systems, Electronic Voting Systems or simply “clickers” [12], students may participate in votes with electronic devices. Depending on the infrastructure of the institution (e.g., wireless LAN), this approach may involve many participants [2], which makes it applicable in large-scale lectures (100+ students) as well as in smaller lectures. In addition, studies show that technology-savvy students appreciate ARS, which indicates its usefulness in IS lectures [8]. Several different electronic voting mechanisms have been proposed and used thus far. One popular approach is to distribute designated voting devices to students which they sometimes also have to purchase [8]. However, since the advent of smart phones and tablets, ARS that allow students to use their own devices promise to lower expenses on infrastructure [13]. For this reason, we used such an ARS in the present study. Previous studies that investigated the use of ARS to alleviate the consequences of passive listening in large-scale lectures reported increased engagement [14–17], increased overall satisfaction of students [18–20] as well as increased learning outcomes [14, 21, 22]. However, most of these studies only use ARS to test knowledge of students [16, 17, 22] or to ask for their opinions regarding the content [8]. Only one approach we found in literature might facilitate perceived autonomy by utilizing so-called “clicker cases”, where ARS were used by students to choose several actions in a case study [14]. Although this approach shows how ARS can lead to improved participation, the authors did not examine whether these choices actually had an impact on perceived autonomy of students. Since this theoretical lens may increase our understanding of ways to foster students’ perceived autonomy and ultimately intrinsic motivation in large-scale IS lectures, we focused on perceived autonomy and its associations with other motivational constructs that are described in the following. It is important to note, however, that in this preliminary study we solely address these motivational aspects and the practicability of this specific instructional approach. On the basis of the present findings (improved measurements and instructional approach), the effects of elected elements will be examined in a subsequent quasi-experimental field study with "using elected elements" as independent variable and students' motivation and performance as dependent variables.

3 Preliminary Study

3.1 Implementing Elected Elements in IS Lectures

To investigate the associations between providing elected elements in large-scale IS lectures and students' perceived autonomy as well as intrinsic motivation, we implemented such elements in an introductory IS course at a German university. The course consisted of 12 lectures that were given weekly over a period of 6 months. At the end of each lecture, students were able to vote which element they wanted to be addressed in the following lecture out of 2-4 options. To foster student participation, we used an ARS that allowed students to use their mobile devices (e.g., smart phones, tablets) for voting anonymously [13]. Figure 1 provides a visualization of lectures incorporating elected elements.

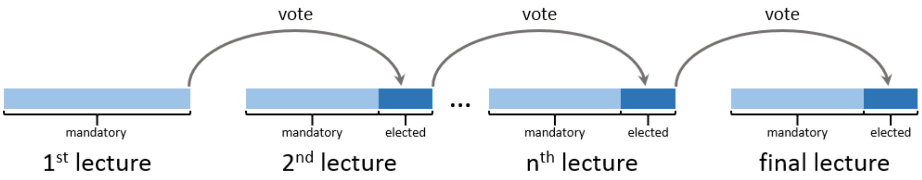

Figure 1. Lectures incorporating elected elements

The elected elements ranged from choosing between different practical examples to choosing between different software demonstrations. For instance, one week before the lecture about business process modeling took place, students were able to choose between activity diagrams and business process model and notation (BPMN) as additional modeling notations. Although these notations are quite similar regarding how they depict business processes, students may get a feeling to be able to choose between a more universal notation (activity diagram) and a notation specifically designed for business processes (BPMN). This way, certain learning outcomes may be enforced while still providing a sense of influence. After voting, students were able to see the distribution of votes between the elected elements. They hence received immediate feedback whether their vote belonged to the majority or not. Due to the fact that every student could participate in many polls, it was very unlikely that they always ended up in the minority, which would arguably reduce their perceived autonomy.

3.2 Method

At the end of the course, after all lectures were finished, we conducted a paper-based questionnaire (see Appendix) in class. Hence, we followed a cross-sectional design in this preliminary study. Data collection was conducted by the first author. Out of the 64 questionnaires we received, 58 have been valid (i.e., 6 were discarded because of obvious dishonesty like wrong fields of study or because they could not participate in the polls due to technical errors with their mobile devices). Since the average number of participants in the votes is 57, the dropout rate appears to be low. Participants consisted of 44 males and 14 females, enrolled in two different fields of study (45 participants studied business and information systems engineering and 13 studied computer science). The age was 20.2 years on average (*SD*=2.7).

The questionnaire adapted items from the intrinsic motivation inventory (IMI) that has been used in many studies to measure perceived autonomy as well as intrinsic motivation of participants [6, 23, 24]. For our preliminary study, we chose three items from each of the following subscales: "Interest/Enjoyment" (e.g., "I would describe the elected elements as very interesting") was used to assess intrinsic motivation, "Perceived Choice" (e.g., "I voted for elected elements because I wanted to") was selected to measure perceived autonomy, and "Value/Usefulness" (e.g., "I think the possibility to vote for elected elements is important") was used to gather an overall rating of subjective value of providing elected elements. Judging an activity to have personal value and importance can be seen as (antecedent) part of intrinsic motivation [5], and therefore it should be positively related to interest and enjoyment. All items were modified to relate to the context and translated into German. However, since these adapted items did not fully cover our research question, we added two self-developed subscales, each comprising three items. "Perceived Influence" (e.g., "By voting for elected elements I felt that I could influence the lectures") addressed an additional aspect of perceived autonomy, since the "Perceived Choice" subscale exclusively asked whether students believed that they participated voluntarily in the polls. However, we also wanted to know whether they believed that their votes had an impact on the lectures. Finally, "Desirability" (e.g., "I wish I had the possibility to vote for elected elements in other courses, too") was added as another way of asking for an overall rating of providing elected elements, since the "Value/Usefulness" subscale only asked whether elected elements are important to students. While this is a possible approach to determine an overall rating, we also wanted to know whether students thought that providing elected elements makes sense and whether they wish having these elements in other courses, too. Every subscale except for "Value/Usefulness" contained one reversely coded item that was used to identify fraudulent questionnaires (i.e., there should be no contradictions). Each item in the questionnaire was assessed using a 5-point scale, ranging from 1 = *not at all true* to 5 = *very true*, and they were randomized across all subscales. In addition to the quantitative items, students were provided with space for leaving any comments or suggestions on the possibility of voting for elected elements. All subscales as well as their respective internal consistencies (Cronbach's α) are presented in Table 1. Reliabilities were satisfactory for all subscales, except

“Perceived Choice”. Thus, the subscale “Perceived Influence” provided a more consistent measurement of perceived autonomy, and “Perceived Choice” was omitted.

Table 1. Subscales and Cronbach’s α

Subscale	Number of Items	Cronbach’s α
Interest/Enjoyment	3	0.79
Perceived Choice	3	0.43
Perceived Influence	3	0.82
Value/Usefulness	3	0.83
Desirability	3	0.83

3.3 Results

Confirmatory factor analysis, used to verify the latent factor structure (i.e., subscales) of the measurement instrument, revealed an acceptable fit for the remaining four subscales (χ^2=68.19, *df*=48, *p*=0.03, CFI=0.95, TLI=0.92, RMSEA=0.08). Standardized item loadings were in the range of λ = 0.67 - 0.85, thus satisfactory. The usual and recommended cut-off scores for RMSEA are ≤ 0.05 for a good fit and ≤ 0.08 for an acceptable fit. CFI and TLI should be ≤ 0.95 for a good fit, and ≤ 0.90 for an acceptable fit [25]. Hence, all further analyses were based on the four subscales “Interest/Enjoyment”, “Perceived Influence”, “Value/Usefulness”, and “Desirability”. The descriptive statistics are shown in Table 2. The item numbers indicate the sequence of questions. Bivariate intercorrelations (manifest) also indicate discriminant validity of the different aspects of motivation (see Table 3).

Table 2. Descriptive statistics of the results (N=58)

Subscale	Item No.	Mean	SD	Power	Loading
Interest/Enjoyment	3	3.76	0.84	0.70	0.78
	12	4.03	0.83	0.63	0.79
	15	3.59	0.74	0.57	0.67
	Total	**3.79**	**0.67**		
Perceived Influence	4	3.60	0.95	0.64	0.70
	7	3.45	0.95	0.69	0.84
	8	3.86	0.95	0.68	0.76
	Total	**3.64**	**0.81**		
Value/Usefulness	9	3.53	0.99	0.60	0.69
	14	3.36	0.96	0.73	0.83
	10	3.40	1.08	0.73	0.85
	Total	**3.43**	**0.87**		
Desirability	5	4.12	0.97	0.72	0.79
	16	3.98	0.88	0.60	0.77
	11	4.40	0.83	0.75	0.81
	Total	**4.17**	**0.77**		

A closer look at the distributions of these subscales is provided in Figure 2.

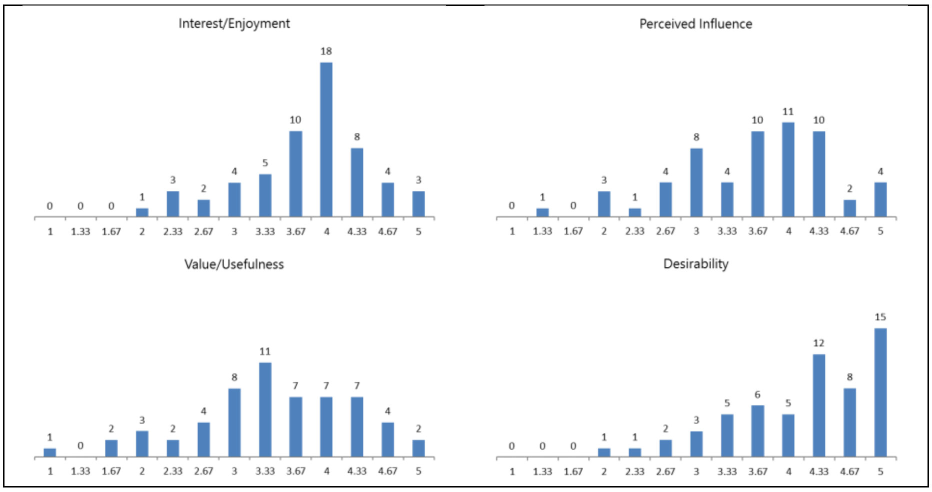

Figure 2. Distribution of each subscale

As Figure 2 shows, particularly the distribution of “Desirability” was more concentrated towards the higher end of the scale (negative skew) whereas the distribution of “Perceived Influence” was rather scattered. Students generally reported rather high levels of interest and enjoyment after using elected elements and they reported a strong desire to have such elements in other courses. Students’ ratings regarding the value and importance of these elements as well as the amount of perceived autonomy in terms of perceived influence they had on the course differed.

Students’ qualitative feedback supports these assumptions by comprising both positive as well as negative comments on the implemented instructional approach. Many students appreciated being able to vote for elected elements in each lecture. Some of the comments also directly state that the interest in the lecture increased by choosing elected elements (45% of all comments):

“By being able to vote for elected elements, one is able to influence the content of the lectures -> increased interest.”

“The interest in the course increases when elected topics are covered.”

“I really liked deciding for the topics that I was most interested in.”

However, there was also criticism regarding how the elected elements were covered in the lectures. The main concern was that they have been too short compared to the mandatory parts of the lectures (36% of all comments):

"The idea of providing elected elements is very good. However, they often have been addressed shortly at the end of the lectures. For example, we were shown how a system from SAP looks, however, I seldom understood how it worked."

"I like being able to vote for elected elements as well as the use of them – However, they have been covered too short in the lectures. When using elected elements, you should take enough time for them."

"Despite the elected elements often being very interesting, they have been covered way too short in the lectures, which made the choices feel pretty pointless."

Additional criticism addressed both the amount of information that was provided before voting for elected elements as well as the unclear relevance of these elements in the examination (18% of all comments):

"More info about the elected elements would have sometimes been useful for better forming an opinion."

"The relevance of the elected elements for the examination has sometimes been unclear (they don't appear in the script and there is no handout)."

In summary, the qualitative feedback emphasized that providing elected elements in IS lectures may lead to increased interest and motivation. It also shows, however, that these elected elements should have more room inside the lecture. Otherwise, they could be perceived as pointless which may reduce perceived autonomy. Finally, students have to be supplied with enough information about each alternative to be able to make a well-informed decision.

Regarding the associations between perceived autonomy and intrinsic motivation due to elected elements in IS lectures, we found a significant positive correlation between students' interest/enjoyment and perceived influence (see Table 3). In addition, we found a positive correlation between interest/enjoyment and perceived value in terms of the rated usefulness of elected elements and the desire to use ARS in other lectures as well. Finally, the latter was positively correlated with perceived influence.

Table 3. Bivariate correlations (**p < 0.01)

	Interest/ Enjoyment	Perceived Influence	Value/ Usefulness	Desirability
Interest/Enjoyment	1			
Perceived Influence	0.55**	1		
Value/Usefulness	0.58**	0.49**	1	
Desirability	0.78**	0.60**	0.62**	1

These positive correlations support our initial expectations concerning the associations between perceived autonomy and intrinsic motivation due to elected elements. We hence propose that fostering perceived autonomy by using elected elements in large-scale IS lectures may have the potential to increase students' motivation in terms of subjective value, interest and enjoyment. These correlational findings provide a basis for future research, more specifically for the intended quasi-experimental study with a comparable student population, to examine causal effects of this instructional approach on students' motivation and achievement.

4 Discussion

The results of this preliminary study indicate that providing elected elements in IS lectures might lead to perceived autonomy and increased intrinsic motivation among students. Our findings, based on qualitative and quantitative data, provide a first step towards understanding the effects of using elected elements in large-scale IS lectures. In addition, these elements are perceived well by the participants. The short-scale measures used in this study proved to be reliable to assess "Interest/Enjoyment", "Value/Usefulness", "Perceived Influence", and "Desirability". Since most students enrolled in IS programs are equipped with mobile devices, they provide a good opportunity to let students vote for their favorite content. Once these elected elements are created by the instructor, they may be used several times and even in several different courses. Because many ARS have been improved over the years, conducting these polls is uncomplicated and arguably fewer effort than for example setting up blended learning scenarios with extensive online content. The present study extends prior research by adding a self-determination theory perspective to explain increased motivation when using ARS by increased perceived autonomy during the lectures.

There are, however, some limitations to this study. First, due to the selected ARS, individual choices of students have not been tracked. We were hence unable to investigate motivational differences between students who often voted like the majority compared to those who did not. This might have been one reason for students' differences in perceived influence. Some students also reported technical problems either with their devices or with the network inside the lecture room. To ensure scalability, an ARS that is able to handle many connections at the same time should be used. According to the comments of students, elected elements should have more room inside each lecture. Indeed, these elements sometimes just comprised 10 minutes inside a 90-minute lecture. We will hence prolong them in future investigations. Another limitation of the study is the lack of a control group. We therefore cannot compare the achieved level of intrinsic motivation from using elected elements with a group that did not use these elements. In addition, performance data of students could not be mapped to the questionnaires due to privacy concerns. Hence, we could not investigate whether those students who reported higher levels of perceived autonomy and intrinsic motivation actually performed better than their peers with lower levels, respectively. In a next step, we will include these aspects in the subsequent study design following a quasi-experimental design.

5 Conclusion

In regard to the findings above, instructors from the IS domain may consider incorporating elected elements into their lectures. When doing so, these elements should noticeably influence the contents of the lectures and students must be supplied with sufficient information about every alternative before voting. Due to the limitations mentioned earlier, this study is only a first step towards understanding the use of elected elements in IS lectures. In the subsequent study, we will track individual choices of each participant to see whether students who have often voted like the majority are more motivated than others. Additionally, performance data of each student will be tracked to investigate effects on student learning. This may include results from examinations as well as other performance indicators, such as regularly performed quizzes. Since offering lectures is often a necessity due to increasing enrollment, our preliminary results highlight one feasible opportunity to improve this experience for both students as well as instructors.

Appendix

Questionnaire. Reversely coded items are marked with (R)

Subscale	No.	Item
Interest/Enjoyment	3	The elected elements have been fun.
Interest/Enjoyment	12	I thought the elected elements have been boring. (R)
Interest/Enjoyment	15	I would describe the elected elements as very interesting.
Perceived Choice	13	I voted for elected elements because I wanted to.
Perceived Choice	6	I felt like I had to vote for elected elements. (R)
Perceived Choice	2	I believe I could choose whether to vote for elected elements or not.
Value/Usefulness	9	I think the possibility to vote for elected elements is important.
Value/Usefulness	14	I believe the possibility to vote for elected elements could be beneficial to me.
Value/Usefulness	10	I believe the possibility to vote for elected elements could be of some value to me.
Perceived Influence	4	By voting for elected elements I felt that I could influence the lectures.
Perceived Influence	7	By voting for elected elements I had the impression of being able to codetermine the contents that have been taught.
Perceived Influence	8	I believe that by voting for elected elements I was unable to influence the lectures. (R)
Desirability	5	I think that the possibility to vote for elected elements makes sense.
Desirability	16	I wish I had the possibility to vote for elected elements in other courses, too.
Desirability	11	The possibility to vote for elected elements should be dropped from the course. (R)
Comment (open ended question)	-	I want to note the following regarding the possibility to vote for elected elements at the end of each lecture.

The Twofold Value of IT-Based Peer Assessment in Management Information Systems Education

Abstract. Feedback is one of the most influential factor when it comes to learning success of students. Especially large-scale classes at universities often lack feedback caused by the scarcity of resources. Even though a lack of feedback is problematic across all domains, especially when educating future IS executives, who are supposed to lead team members by providing effective feedback. In this study, we use IT-based peer assessment (ITPA) in a large-scale class to support students with feedback during their learning-process. Specifically, our results show that participating in ITPA lead to an increase in knowledge on the content of the class of about 28% on average. Furthermore, students train their ability to provide feedback, measured twice, self-reported and as quality of the feedback received – increased significantly during the class.

Keywords: IT-based peer assessment, feedback, higher-education, large-scale class, technology-mediated learning

1 Introduction

In the last years, the number of students has been constantly rising while the amount of lecturers stayed steady [1]. Thus, the current condition at universities is that many classes consist of hundreds of students and are taught by one lecturer [2]. One consequence of these large-scale classes is the lack of feedback for students [3]. According to Hatti et al. [4], feedback is the third most influential factor for student learning success. Despite the known importance of feedback in the learning process, the final exam is often the only time students receive feedback in those classes, and this feedback is often aggregated into a single performance score providing hardly any insights into strengths and areas that need to be improved.

We argue that especially future managers need to develop their own ability to provide feedback to become an effective leader in business [5]. Thus, the lack of feedback is even more crucial in this domain, since it a) hinders learners in assessing their current state of knowledge and identifying areas for improvement, and b) restrains them from improving their own ability to provide feedback to other people. A possible solution to overcome both barriers and to ensure that students of large-scale classes have the possibility to train their ability to provide feedback, as well as to receive

Rietsche, R.; Lehmann, K.; Haas, P.; Söllner, M. (2017): The Twofold Value of IT-Based Peer Assessment in Management Information Systems Education, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 788-791

feedback to assess their current state of knowledge and to adapt their learning process, is IT-based peer assessment (ITPA). To assess the value of using ITPA in large-scale classes, we seek to answer research question of:

RQ1: To what extent does participating in an ITPA help to train the learners' ability to provide feedback?

RQ2: To what extent does participating in an ITPA contribute to the learners' knowledge of the learning contents?

According to Hattie and Timperley [4] feedback is conceptualized as information provided by an agent, for example a lecturer who provides corrective information [4]. Hence, feedback is provided a consequence of students' performance. Whereas the outcome of feedback is an information, specifically relating to the task or process of learning that fills a gap between what is understood and what is aimed to be understood [6].

2 Methodology and ITPA process

ITPA was used in a quasi-experiment with a one-group pretest-posttest design in a large-scale university classes on information systems at Master's level. The quasi-experiment consisted of seven ITPAs, which took place on a regular manner over a time period of one semester and in each participating between 73 and 101 students.

Figure 1 shows the process of an ITPA. All steps shown in the process were conducted within a web-based learn management system (LMS). In the first step each student carries out the self-assessment (SA), using a survey including questions of their perception of their ability to provide feedback. In the second step the student creates the assignment and the LMS sends the completed assignments to the three anonymous peer reviewers – other students of the same class– (the reviewers were randomly selected in each ITPA by the LMS).

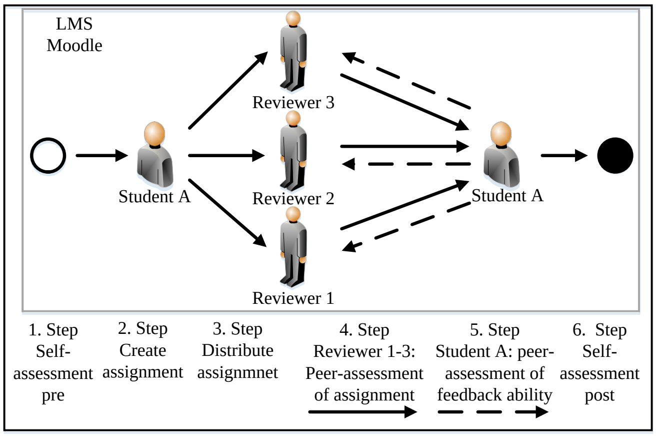

Figure 1. Overview of the ITPA Process

In the fourth step, each reviewer carries out a peer-assessment (PA) of the assignment using a standardized review template. Including questions concerning the strengths and weaknesses of the assignment and how it could be improved. Bevor the students provided their first PA a hands-on instruction of how to provide constructive feedback was carried out. After the PA the reviews are automatically sent back to the respective student by the LMS. In the fifths step, each student revises the initial solution, creates a change history, and rates the quality of the feedback provided by each reviewer based on the same questions as the SA. In the last step, each student carries out another SA. For the post SA the same survey was used as in the pre SA. In case a student did not participate in an ITPA, which leads to a missing value, this was statistically considered (marked as NA in R).

3 Results

The graph in Figure 2 shows the survey results for the question "How do you assess your personal ability to provide feedback to your peers?". The first measurement t0 is the baseline measurement in which the students were asked to self-assess their ability in providing feedback. The data of t0 represents that no ITPA is used at all and t1 that the ITPA is used one time. The students benefited using ITPA one time significantly ($p < .001$). Moreover, using ITPA multiple times, even further enhances the students' ability which shows the increase for SA and PA from t1 to t7 ($p < .05$). Figure 3 shows the survey results of "What is your current state of knowledge concerning the current learning unit?". The results show that students benefit from using ITPA in terms of perceived knowledge growth. The study showed a statistically highly significant increase of in average 28.3 percent from the pre-measurement to the post-measurement of the students' current state of knowledge concerning the current learning unit.

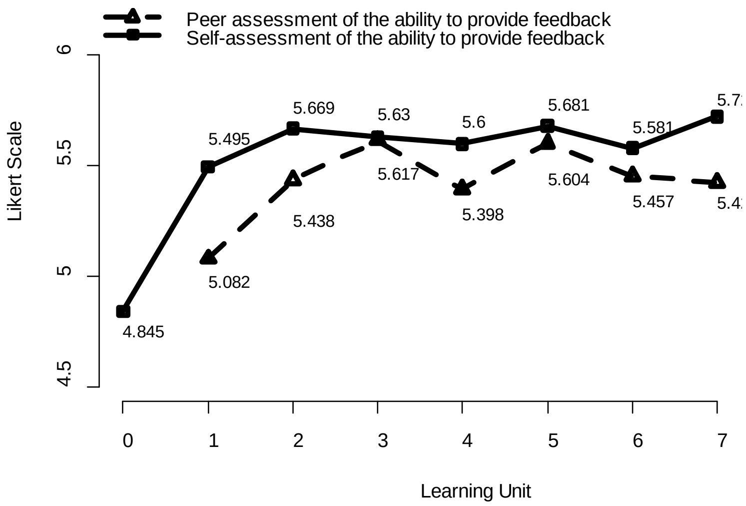

Figure 2. How do you assess your personal ability to provide feedback to your peers?

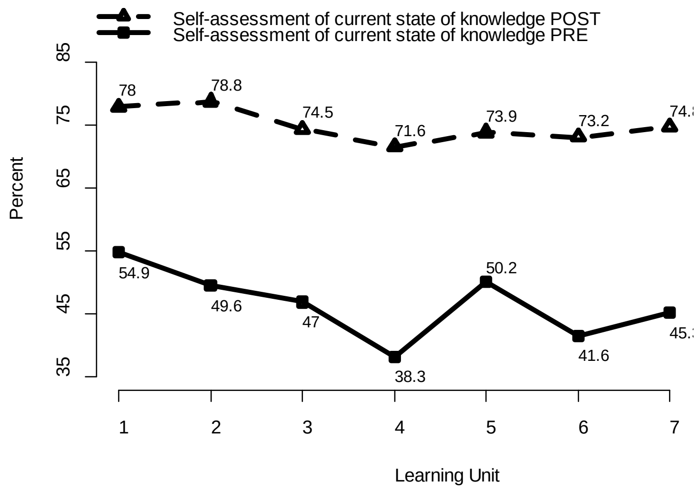

Figure 3. What is your current state of knowledge concerning the current learning unit?

4 Conclusion

This paper describes the usage of ITPA in large-scale classes to train the student's ability to provide feedback. The results show that using ITPA could enable the lecturer to support students in their learning process in a resource-saving way and to provide an environment in which students can anonymously train their ability to provide feedback. Furthermore, the results show that students using ITPA have a perceived increase of knowledge concerning the particular learning unit. With our paper we contribute to the body of literature of feedback in higher-education by providing empirical results from our quasi-experiment.

Abstract. Information privacy and personal data in information systems are referred to as the 'new oil' of the 21st century. The mass adoption of smart mobile devices, sensor-enabled smart IoT-devices, and mobile applications provide virtually endless possibilities of gathering users' personal information. Previous research suggests that users attribute very little monetary value to their information privacy. The current paper assumes that users are not able to monetize their value of privacy due to its abstract nature and non-transparent context. By defining privacy as a crucial product attribute of mobile applications the authors provide an approach to measure the importance of privacy as part of users' preference structure. The results of the conducted choice-based conjoint Analysis emphasize the high relevance of privacy in users' preference structure when downloading an app and provide an interesting contribution for theory and practice.

Keywords: Information Privacy, Personal Data, Product Attribute, Preference Structure, Mobile Applications.

1 Introduction

With the disruptive innovations of e.g. the iPhone and the iPad software in the form of mobile applications (apps) diffused in the everyday life of users. Apps are integral to the functioning of Smart Mobile Devices (SMD) like smartphones or tablets and are key elements for the interface design and functionality. Apps can be interpreted as the embodiment of ubiquitous computing, i.e. the creation of environments saturated with computing and communication capability, integrated with human users [1]. While ubiquitous computing focuses on hardware components, today's apps are the logical consequence of experiential computing; the "digitally mediated embodied experiences in everyday activities through everyday artifacts with embedded computing capabilities" [2].

At the same time, this development has considerably contributed to the emergence of a new user type of information systems. These new users integrate apps into their

everyday lives, which leads to fundamental changes concerning how users interact with computing devices and systems [3].

However, this excessive level of integration does not come without consequences. Many business models are based on the user data collected by SMD, which grants the marketing industry the access to exceptionally valuable information about current and potential customers [4]. Thanks to the mechanics and the real life integration of modern information systems, the value of user data is unique. Thus, users' privacy, increasingly gets at risk.

Given the fact that users' information privacy is a major part of the economic exchange when downloading apps, privacy, and the corresponding settings, have to be determined as an attribute of the value proposition of apps. In order to understand users' concerns and clearly define the necessity of user data protection, it is crucial to determine the value of privacy for users. Caused by the (perceived) abstract nature of personal data and privacy, the current paper states that users are not able to value personal data and privacy in a monetary amount. Consequently, this paper targets users' preference structures when downloading apps. With this in mind, we formulate the following research question:

- Does the protection of privacy, when downloading an app, represent a crucial product attribute for the user?

To answer this research questions, two examinations were conducted both reflecting the importance of privacy as an important attribute when purchasing an app. The HB-based utility value and the estimations of the CBC, show significantly high levels of importance for privacy. In fact, privacy is on first-place in both rankings. The remainder of this article is structured as follows: in the subsequent section, we lay out the groundwork for the definition of privacy as a value and its measurement. Following this, we will describe the methodology conjoint analysis, present our choice based conjoint analysis and its key findings. Finally, we will discuss our findings, address some limitations and conclude with suggestions for further research.

2 The Value of App Privacy

2.1 Information Privacy in the Context of Mobile Applications

Since privacy is addressed in many fields of social sciences and different definitions are used in various areas of everyday life it lacks a holistic definition [4, 5]. First of all, physical and information privacy have to be distinguished. Physical privacy relates to the "access of an individual and/or the individual's surroundings and private space" [4]. Contrary, information privacy only refers to information that is individually identifiable or describes the private informational spheres of an individual. Although information privacy is rooted in the fundamental concept of physical privacy, both are subsumed under the term of "general privacy" [4].

Even though privacy has developed and changed drastically over the last decades, Westin's definition from 1967 still holds true: information privacy is defined as "the claim of an individual to determine what information about himself or herself should be known to others" [6]. Following Westin, 'control' is construed as an instrument of the protection of privacy, that privacy itself is often defined as the control over personal information [5]. Consequently, in this paper information privacy is defined as the ability to control the acquisition and use of one's personal information [7].

As the "pocket knife of communication" [8], SMD possess a vast amount of connected sensors, devices, and functions. SMD in combination with apps are the most common user interface to merge the broad opportunities given by the connected sensors and devices. Throughout these functions, the possibilities of gathering personal data are virtually endless. Future prospects in relation to these applications promise even more opportunities to expand data collection and immediate analysis of data. Regarding data quality, recent developments in mobile technology and an ever-increasing digitization of everyday tasks, lead to an unprecedented precision of continuously updated and integrated personal data, which is generated within mobile ecosystems like iOS and Android [9]. Consequently, apps, as the most common user interface for digitized solutions (e.g., smart services, smart homes, wearables, etc.), layer everyday activities and lives in a digital way; or how Clarke rephrased it: "Cyberspace is invading private space" [10].

In app markets, users are able to control their privacy disclosure during the purchasing process. Thus, users can actively control their disclosure of personal data and the grasping of privacy from third parties [11].

2.2 The Value of App Privacy

Dinev and Hart [12] stated that privacy "is a highly cherished value, few would argue that absolute privacy is unattainable." Privacy as digital personal information and highly personalized data collected via apps has a huge economic value [13]. With the description of personal data as a new asset class, the World Economic Forum [14] is in line with the argumentation of many researchers [4, 15]. Derived from the perspective of personal data and privacy as a commodity [16], many researchers conceive privacy as a tradeable good or asset [15]. According to this view, privacy is no longer an absolute societal value, but has an economic value, which leads to the possibility of a cost-benefit trade-off calculation made by individuals or a society [4].

Nevertheless, the authors of this article argue that privacy cannot be seen as an economic value with (for users) available market prices. First, users' distortion regarding the valuation of their own information privacy is caused by the nature of data collection, aggregation and secondary use of app markets [17]. Following Flender and Müller [18], apps are data-centric services and value is generated on different levels: e.g. between the user and the app provider, the aggregated value of the app as data centric service, and the aggregated data from various apps and underlying ecosystems by third parties [19]. As a result, in app markets it is not possible for users' to reliably evaluate their value of privacy in the moment of releasing personal information. However, major parts of the resulting costs of releasing personal informatio arise by the access, use and transfer of the data on multiple levels. Third parties (e.g., retailers, advertisers, and insurance companies) could, for instance, use that information for issues like price discrimination, advertising or risk surcharges [15]. Accordingly, the value of users' privacy is originated in the release of the information but realized in a sphere, which cannot be controlled by the initial owner (user). In addition, users are often not aware of the possibilities of collection, aggregation and analyzation of digital information [15].

Taking the paradigm of experiential computing into account, the value of privacy increases with the (perceived) invisibility of the connected devices. With the increasing everyday life integration, devices and sensors become more and more invisible but are an increasingly self-evident part of users' daily routine. Because of the establishment in users most intimate privacy sphere, users' awareness regarding their information privacy is affected in a paradox way. In the end, privacy is perceived subjective and individually and the value of different information types and spheres is abstract and intangible. Following these arguments, the presented paper defines privacy as an abstract value. Consequently, users are not able to evaluate the monetary value of their information privacy.

2.3 Related work

When the measurement of the (perceived) value of consumers' information privacy is observed the theory of the privacy calculus has to be considered [20]. Therefore, users are supposed to undertake an anticipatory, rational weighing of risks and benefits when confronted with the decision to disclose personal information [21, 22] or conduct transactions [23]. The privacy calculus model assumes a correct and objectified understanding of the monetary value of privacy and therewith a tangible willingness to pay for privacy of the users [24, 25]. IS privacy research focused on the marketing-based concept of willingness-to-accept (WTA) and willingness-to-pay (WTP) [15]. Although asymmetries and disparities between WTA and WTP have been observed, both concepts are well established in academic research and have been applied to the topic of personal user data multiple times [15, 26]. Besides those disparities and the fact that the ownership of privacy control rights remains difficult to define in the context of apps, WTA and WTP are based on the user's perceived value for privacy and the purchased good or service. As stated above, users are indeed not able to evaluate the monetary value of their privacy, which leads to the impossibility to define the perceived value and thereby the needed maximization or reservation price for WTA or WTP. In the light of the definition of privacy as an abstract value studies which directly elicit users' valuation of privacy in survey settings gain distorted results [27–30] (see for an overview [31]). This is also described by the well-observed phenomena of the privacy paradox [24], which claims that individuals value privacy less than stating in studies and polls. It has been subject of various research in the field of information privacy, but there is no comprehensive explanation why individuals show this paradoxical behavior [24]. Consequently, WTA or WTP do not offer an adequate set of instruments to measure users' privacy concerns or the value they assign to their privacy.

Stemming from that, we recommend the approach of a choice-based conjoint analysis (CBC) to examine users' preference structure when purchasing an app. Some studies measured the preference structure as a proxy for the willingness-to-pay for privacy. Most of these studies are desktop driven and focus on the disclosure on websites and online social networks [31–33] or social app adoption [34]. Despite the increasing studies applying decomposition methods there is no investigation of privacy as a stand-alone product attribute correlated with the provided functionality of the app. Therefore, a CBC is provided which outlines privacy on equal terms to other attributes like price. Hereby we are able to determine if the user only states that he values privacy or if he actually does value it in real life purchase decisions.

Accordingly, a high evaluation of privacy can be assumed when privacy is seen as a crucial product attribute of apps. Therefore, privacy has to be an important product attribute in users' preference structure when buying apps. A well-known and established methodological approach for measuring users' preferences is the Conjoint Analysis (CA). CA is an individual analysis based on the observed evaluation behavior of one specific individual [35]. The observed behavior is used to define a preference, which is a one-dimensional indicator of individual's preference structure [36]. The structure describes what object is favored by the individual. While compositional methods ask individuals about their preference for certain attributes and compose an overall judgment from it, decomposition methods, such as the CA, calculate the partial utility values for each attribute from the overall judgement of the participants [36].

3 Empirical Study

3.1 Methodological Approach

In the current study the choice-based conjoint analysis (CBC) was chosen because of its methodological and practical strengths [37]. CBC is based on the work of Louviere and Woodworth from 1983 [38] and combines the discrete choice analysis (DCA) with the Traditional Conjoint Analysis (TCA) [37]. Therefore, it is measuring population's utility functions. Those functions are estimated by representative utility functions. First, the most important assumptions are that participants always choose the product profile with the highest individual utility. Thus, it is possible to draw conclusions from the purchase decisions and the utility functions of the users [37]. Second, it is assumed that the utility function consists of a deterministic and a stochastic component, which are summed up. The main difference between CBC and TCA is that instead of ranking stimuli, the CBC wants its participants to rank different choice tasks. Those options consist of a product with a bundle of chosen attributes and their levels [37]. Instead of ranking different profiles against each other like TCA, participants have to perform fictitious purchase decisions [39]. Those choice tasks consist of the predetermined product profiles (choices) that display the attributes and their levels [37]. In the current paper a CBC following the steps of Backhaus et al. [40] was designed: definition of stimuli, design choice situation, utility model, choice model, and estimation of utility values. The CBC proves to avoid the distortions in surveys caused by group dynamics and social desirability. The advantages of the indirect measurement of preferences for certain product attributes utilizing the CBC approach shine especially against the background of the privacy paradox.

3.2 Survey Design

Apps where chosen as research objects, due to their broad diffusion in mass user markets and their everyday life integration. To ensure participants common understanding regarding e.g. functionality, provider, and the privacy level of access privileges an appealing CampusApp was defined and conducted at a German university. The functionality of the app was designed similar to campus apps of comparable universities (navigation on campus, information about public transportation, library services, organization of studies incl. online platform of the university, food on campus, university sports programs).

To keep a low stress level for the study participants, the number of attributes was set to four. To determine the attributes, different steps were conducted. First, the recent literature about apps' product attributes, as well as their assigned categories and their influence to the users' decision-making process when purchasing an app were analyzed [41]. Second, a word-frequency text analysis of 73 apps from the categories 'most popular' and 'top 10' apps with and without a purchase price was performed. In the third step the available types of information in the two most common app stores (Android Play Store and Apple App Store) were examined. Their separate information was compared to one another, as well as categorized into five different groups. With the broad variety of app product attributes, an online survey (N=151) to estimate the perceived importance of the different information types was conducted and narrowed down to a suitable amount of four attributes for the CBC. Attributes and levels are shown in table 1.

Table 1. App Attributes and Levels by Groups

Groups	Level 1	Level 2	Level 3
I - Price	0,00 €	0,99 €	2,77 €
II - Privacy	Only functionally required permissions requested with privacy policy	More than functionally required permissions requested with privacy policy	More than functionally required permissions requested without privacy policy
III - Rating	4 stars	3 stars	2 stars
IV - App	0-500 MB	500 MB - 1 GB	> 1 GB

The attribute's levels of the price group (I) were defined by taking a closer look at the common prices in the app stores. With over 60% of all apps since 2009, the price of 0,00 € is by far the most common [42]. Although the average app price is reported between $1.13 [43] and $1.91 [44] by different sources, researchers agree that this price is decreasing. Following, and to design an attractive price in the middle for the second level, 0,99€ was determined. In order to create a realistic high-end price, the price of 2,77€ was chosen. This price is based on a bidding game for a messenger app by Buck [45].

In the privacy-related group (II), the handling of personal user data and the technical access to personal user data were combined into one attribute. Taking a closer look at the current handling of personal user data, Sunyaev, Dehling, Taylor, and Mandl's [46] work shows that only 30.5% of the examined mobile health apps had a privacy policy. Additionally, and since advertising is one of the most used mobile app monetization models of developers [47], apps frequently request more technical access and permissions than they actually need to function properly. Based on those findings, only the first level of privacy was designed to request the required amount of permissions and a privacy policy. The other two levels both requested more technical permissions than necessary. The difference between those last two levels is that the second level possesses a privacy policy, but the third level does not. In the survey itself, required permissions were displayed with an exemplary set of functionally required permissions and an exemplary set of permissions which exceed the functionally required amount and permission types significantly. Both sets were modeled on the basis of permission groups given in the Android OS, which are very similar to the ones in the iOS.

Within the app ratings group (III), the average rating in stars was the only attribute reaching a Likert-scale average above five. Although rankings and ratings in the app stores have proven to suffer from fraud [48], based on the pre-study, app users are familiar and relying on the star ratings. Following, the levels for average app rating in stars were determined to two, three, and four stars. Zero stars and five stars were not considered because those ratings mostly consist of as little as one review or none at all.

In the last considered group of directly app-related information attributes (IV), the 'compatibility with own devices' was the most important attribute. Due to the fact that this is certainly a deal-breaker attribute for users [35], the second most important attribute was chosen for that group: needed size on device in MB/GB. Since there are all kinds of different apps, the levels were set to <500 MB, 500 MB -1 GB and >1 GB.

To avoid the phenomenon of forced choice and to design the choice situation as realistic as possible, an additional 'none' option is included [40]. Additionally, an unrealistic set containing level one of price and privacy were not included to ensure a realistic choice situation for the participants. With the four chosen attributes their three levels, a total of 81 different stimuli sets are possible. The stimuli were presented in the form of virtual cards with descriptions.

In order to match the recommended range, a fractional design with 10 randomized stimuli and two fixed stimuli was chosen. Based on the recommended number of choices per set of $K \leq 7$ [40], four randomized choices and a 'none' option were chosen for the CBC. The fixed choice tasks were designed to confront the participants with a trade-off situation between price and privacy, as shown in figure 1.

In choice 1 and 3, the attributes of rating and app-related are both marked as level 1. The difference between those two options is to be found in the attributes of price and privacy. Choice 1 has a level 1 privacy scheme, but a level 3 price (2,77€). Choice 3 has a level 1 price (0,00€), but a level 3 privacy scheme. Choice 2 and 4 are designed to be middle-class options with level 2 compositions for price and privacy. Nevertheless, choice 2 is dominated by choice 4, since it is shaped significantly worse in the rating and size attributes. With four attributes and three levels each in a choice situation with a choice set of four plus a 'none' option, so-called overlaps occur in every single choice set. These overlaps allow improvement in the measurement of precise interactions between the attributes [49]. Still, and in order to prevent impacts that are too drastic on the main effects, the balanced overlap was chosen as task generation method [49]. Since the recommended range of choice tasks is 8 to 20 and the participants' concentration decreases significantly with every choice task [50], only 10 randomized choice tasks were displayed.

Figure 1. Exemplary Random Choice Set with Four Stimuli

3.3 Data Collection

The CBC was conducted via an online survey using Sawtooth Software. Since the study was conducted at a German university, all questions were presented in German only. At the beginning of the study, a skip logic question was given with the aim to select only participants with ties to this specific university. This was established to ensure a minimum involvement regarding the usage and functionalities were given and the incentive for downloading the CampusApp was comparable. Following, the participants were asked technical context information (e.g. SMD usage, on-device installed apps, app downloading habits, and buying likelihood of apps in the near future). Afterwards, the participants were asked to rank six different attributes according to their importance when considering to download an app. In order to introduce the CBC, the CampusApp was explained with an image and a list of functions. A second explanation including how the following choice sets will look and introductions for the CBC were displayed on next screen.

As outlined before, the CBC itself consists of 10 randomized, as well as two fixed, choice tasks. The fixed choice tasks were designed to examine a direct trade-off between price and privacy, as well as to conduct a hold-out analysis to predict the prognosis validity. After the CBC, participants were asked for their gender, age, and the brand of their SMD.

In total, 221 respondents participated in the online survey. However, 71 responses were incomplete and therefore excluded from the analysis. The participants who reported having no existing relationship to the university in the skip logic question were part of this exclusion as well. Additionally, all participants who answered more than 50% 'none' in the choice tasks were also eliminated. This step was conducted in order to reduce the weakening impact of the attribute utility values and their levels. In total, the results of 111 responses were analyzed.

3.4 Results

Out of the 111 participants who partook in the survey, 43% were female and 57% were male. The average age (mean value) of all participants was 24.99 years. The participants were asked to rank six different attributes by importance when purchasing an app (Table 2). In order to prevent the participants from focusing on any one specific attribute and eventually influencing their answering behavior later, two additional attributes were included in the conscious priority ranking: Vendor's Reputation and Number of Ratings.

Table 2. Priority Ranking

Attribute	Rank 1	Rank 2	Rank 3	Rank 4	Rank 5	Rank 6
Reputation	8,11%	29,73%	0,90%	48,65%	9,01%	3,60%
Av. Rating	10,81%	36,04%	15,32%	16,22%	16,22%	5,41%
No. of Ratings	12,61%	15,32%	24,32%	16,22%	19,82%	11,71%
Price	17,12%	14,41%	20,72%	10,81%	23,42%	13,51%
Privacy	30,63%	2,70%	18,92%	7,21%	23,42%	17,12%
Space	20,72%	1,80%	19,82%	0,90%	8,11%	48,65%

Ranked with just over 30%, most participants named privacy as rank 1. Privacy is followed on rank 1 by required space (MB/GB) with 20.72% and price with 17.12%. In rank 2, average rating with 36.04%, vendor's reputation with 29.73%, and number of ratings with 15.32% was valued most. Based on those consciously rated importance rankings, the first indication for privacy's crucial status among app product attributes occurs.

Based on the choices made by the participants in the CBC section of the online survey, average utilities for each level of each attribute were calculated by using Sawtooth Software. As for analysis type, Hierarchical Bayes (HB), the go-to standard for utility estimations in CBC, was chosen. In total, a number of 20,000 iterations were used. Hereby, only the second 10,000 iterations were used to avoid assuming convergence too early.

As a result, utility values and standard deviations for all attributes' levels, as well as the 'none' option, are calculated (Table 3). At first sight, the negative impacts of the third levels of each attribute are noticed. In contrast to that, the first and second levels of all attributes have a positive impact on the individuals' utility values. Nevertheless, it is not possible to tell how much more or less importance an attribute or its levels have while solely regarding absolute utility values. Therefore, the average importance of each attribute is calculated in percentages based on the relative utility ranges (Table 4).

Table 3. Average Utilities (Zero-Centered Diffs)

Attributes' Levels	Average Utilities	SD
4 stars	52.25	32.13
3 stars	8.75	8.63
2 stars	-61.00	29.65
Permissions (functional) & privacy policy	52.11	46.28
Permissions (more) & privacy policy	16.25	18.83
Permissions (more) & no privacy policy	-68.36	41.65
0 - 500 MB	6.23	14.63
500 MB - 1 GB	6.57	11.90
> 1 GB	-12.80	12.04
0,00 €	53.36	34.80
0,99 €	10.40	14.44
2,77 €	-63.76	33.27
NONE	24.67	47.74

Taking a closer look at the 'Average Importance', privacy turns out to be the most important attribute with over 32%. Closely after privacy follows price with just over 30%. On the third position sits average rating with nearly 29%. With around 8%, required space (in MB/GB) is least important.

Table 4. Average Importance

Attributes	Average Importance	SD
Average Rating	28.92	14.27
Permissions & Privacy Policy	32.80	18.38
Required Space (MB/GB)	8.06	4.40
Price	30.21	15.41

Comparing the results of the consciously ranked attributes and the CBC-based results of the HB estimation for attribute importance, privacy is named as the most important attribute when buying an app in both cases. Privacy is reported as rank 1 priority with over 30% in the direct ranking question, as well as calculated as most important through the CBC's utility estimations.

Although required space is named second-important in the priority ranking, the importance percentage of only 8% shows that users do not actually value this attribute as much as they state. Price, with 17.12% is third-ranked in the priority ranking. The importance of this specific attribute is validated by the results of the CBC's HB estimation. With over 30%, price's importance is second-placed. Additionally, average rating is ranked most important on rank 2 in the priority rating. The importance, slightly below privacy and price, is to be found in the percentages of the HB estimation as well.

Tests show high values for face validity, intern validity, and prognosis validity [51]. The hit rate of 68.47% indicates decent results for the study. The study's average root likelihood is 0.6 which proves an accurate internal validity. The hit rate of 76.58% is significantly bigger than 20% which shows a promising prognosis of validity for the study.

4 Privacy as a Crucial Product Attribute

Concluding, the results of both examinations of the attributes' importance through the priority ranking, as well as the HB-based utility value and importance estimation of the CBC, show significantly high levels of importance for privacy. In fact, privacy is on first-place in both rankings. Following the research question of whether or not privacy in the area of SMD and SMA represents a crucial product attribute for the user, must be affirmed. The fact that privacy ranks even more important than price in the consciously answered priority ranking, as well as in the CBC, shows an exceptional observation. Especially the result that privacy is ranked as no. 1 in the preference structure provides novel insights in users' intention when downloading apps. In contrast to many WTP-studies, where users were only willing to pay a very small amount of money for their privacy, the results of the conducted CBC suggest that there is a high preference for controlling privacy. This could indicate that users are willing to pay a higher purchase price than they currently do, when their privacy protection is ensured and promoted as an outlined product attribute.

In consequence, the results show valuable implication for theory and practice. The significantly high level of privacy in importance, which is even higher than price, indicates that SMD users demand more options to handle their user data and to protect their privacy. In contrary, customers of the two biggest app stores do not usually have the option of choosing between paying a monetary price or revealing their private user data. This imbalance provides a huge potential for innovating apps business models and its monetization. As for now, the user mostly has to decide if the apps provided utility is worth a privacy intrusion or not – meaning the user cannot use the app although a certain willingness-to-pay might exist. The study shows that at least offering apps in an alternative version with a monetary price and no usage of private user data could bear a great potential for success. Other options, such as permission management or administration of user data, could be another potential, but would represent a more restrictive way to deal with the privacy issue within SMD and apps. Since most of the apps requesting permissions regarding private user data do not function correctly without certain permissions, this approach might prove difficult to provide the full amount of utility of an app while containing only restricted permissions. Nevertheless, first developments to single permission management for each app in the Android OS are observable when taking a closer look at the newest OS 'Android 6.0 Marshmallow' [52].

5 Limitations and Future Research

Our paper deals with the question whether privacy is a crucial product attribute for users when buying apps. The results of the conducted CBC outline privacy as the product attribute ranking at the highest importance level and generating the highest utility value.

Due to the nature of our research, our study has some limitations. For example, in this paper we refer to the ‘download’ or purchase of apps. However, we are aware, that disclosing personal data is also related by app usage and deletion, which should be considered in future studies related to the topic. Furthermore, a particular app as a study object was required. Since the variety of apps could not be displayed with one app and the functionality has to be defined for the study object, the fictional CampusApp was selected. Our sample is not representative of all app users, as it includes a large group of university related participants. Based on the choice of the study object mostly students and employees of the addressed university were asked to answer the CBC. Although the focus on the four product attribute groups of price, privacy, ranking, and app-related was necessary due to the CBC complexity and justified by the low importance of vendor-related attributes in the pre-study, the results indicate that at least in the conscious priority ranking, vendor’s reputation was considered quite important. Moreover, the preference structures’ stability is questionable over time.

Starting with the high importance level of privacy within the purchase situation of apps, other privacy-sensitive areas, like private banking, insurance services, online social networks, or all kind of digital services linked with personal data could be investigated in more detail by using the CBC. This leads to the need of contemporarily and repeatedly conducted CBC in the future to maintain the topicality of the results and to validate privacy’s standing as a crucial product attribute. Future CBC in the area of SMD and apps might include vendor-related attributes. Moreover, the elimination of choice sets could distort the results. Especially in the light of low effort situations and behavioral effects [25], taking a closer look at apps from various categories might offer interesting insights. Based on the social, political, legal, and additionally personal salience of privacy, further research in the area of privacy is essential. For example, the understanding and determination of the value term regarding privacy, the valuation of users’ preference structures, or the explanation of the privacy paradox, offer a great deal of opportunities for future theoretical research and for a deeper understanding for more adequate attempts to assign a monetary value to privacy. Practically, research might focus on the options of permission management without losing functionality or the economical options of offering the same app in different versions regarding price and privacy. Additionally, those implications for apps, as well as SMD, and their relation towards privacy are also applicable to a very wide range of different research topics, e.g. investigation of the influence of privacy on different app types, as well as different demographical, social, or national groups.

Following the understanding of privacy as a crucial product attribute of apps, the legal regulation is called upon to preserve users of disclose their personal data in purchase situation they cannot control.

Beyond Mere Compliance – Delighting Customers by Implementing Data Privacy Measures?

Dominikus Kleindienst[1], Niclas Nüske[1], Daniel Rau[1], and Fabian Schmied[1]

[1] FIM Research Center, University of Augsburg, Augsburg, Germany

Abstract. The importance of customer data for business models is increasing, as is the relevance of customers' concerns regarding privacy aspects. To prevent data privacy incidents and to mitigate the associated risks, companies need to implement appropriate measures. Furthermore, it is unclear whether their implementation – beyond mere compliance – has the potential to actually delight customers and yields competitive advantages. In this paper, we derive specific measures to deal with customers' data privacy concerns based on the literature, legislative texts, and expert interviews. Next, we leverage the Kano model via an Internet-based survey to analyze the measures' evaluation by customers. As a result, most measures are considered basic needs of must-be quality. Their implementation is obligatory and is not rewarded by customers. However, delighters of attractive quality do exist and have the potential to create a competitive advantage.

Keywords: Data Privacy, Customer Satisfaction, Kano Model

1 Introduction

With the growing amount of data generated worldwide, digital business models emerge that are based on insights gained from customer data [1-2]. At the same time, trust in data privacy is becoming more relevant for customers [3-4], which is amplified by several data privacy scandals in the recent past. Examples range from Ashley Madison, an online dating portal that lost user data of 37 million registered married men and women to the public, to Apple, which was accused of collecting location data on iPhones and iPads without authorization from and without notifying their customers, to Facebook, which was discovered to be collecting data from user profiles and transmitting these data to advertising companies and others. For companies, such publicly exploited scandals cause economic damage [5-6] and competitive disadvantages in brand image and customer satisfaction. Thus, companies that perform well in improving data privacy could increase customer satisfaction and gain a competitive advantage. For instance, companies such as DuckDuckGo or Silent Circle already try to differentiate themselves by providing privacy friendly services [7]. However, for many companies, it is often unclear how to manage data privacy, which is viewed as a necessary evil. As such, data privacy limits the opportunities to gain

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Kleindienst, D.; Nüske, N.; Rau, D.; Schmied, F. (2017): Beyond Mere Compliance — Delighting Customers by Implementing Data Privacy Measures?, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 807-821

valuable customer insights, and its implementation binds valuable resources. In addition to that downside perspective, for integrated management of data privacy, an upside perspective is also necessary. Moreover, practitioners should be aware of specific available data privacy measures that enable their companies to differentiate themselves from their competitors.

In the literature, data privacy management is mostly seen from a downside perspective that focuses on risk management. For instance, Buhl [8] state that data privacy measures should be implemented only if the risk-reducing effects outweigh the related costs. Acquisti et al. [5] link a company's privacy incidents to the negative impacts on its market value. Only to a small extent does the literature consider an upside perspective on data privacy, such as Preibusch et al. [4], who found that customers of privacy-friendly but more expensive firms are more satisfied than customers of cheaper but privacy-unfriendly firms. Even so, specific data privacy measures that might be implemented to increase customer satisfaction are yet to be considered in the literature. Thus, we investigate the following research question: Can companies delight customers by implementing specific data privacy measures?

To answer this research question, we firstly develop an overview of data privacy measures by investigating and consolidating the literature, legislative texts, and findings from expert interviews. Secondly, using the Kano model, we evaluate customers' perception of these different measures, that is, whether different measures are considered "must-be," "one-dimensional," or "attractive," or whether customers are "indifferent." Thereby, this paper is organized as follows. We discuss the context of the problem and related work. Using this discussion, we outline our methodical approach, derive measures that can be taken by companies to address data privacy concerns, and analyze customers' perceptions of these measures on the basis of the results of a survey. The conclusion summarizes the results, addresses limitations, and discusses areas of possible future research.

2 Problem Context

As previously motivated, public attention to data privacy issues is growing. This attention is reflected in different scientific disciplines, such as philosophy, psychology, economics, marketing, law, and information systems [9-10]. Moreover, privacy incidents, such as the scandals previously mentioned, are the subject of research projects (e.g., [5], [11-14]). Privacy incidents appear regularly and have consequences for both companies and customers. They are defined by Acquisti et al. [5] as events "involving misuses of individuals' personal information." Consequently, customers might become victims of fraud or identity theft [5]. Typical customers' data privacy concerns are composed by Smith et al. [15], namely, Data Collection or Combination, Internal and External Secondary Usage, Errors, Improper Access, and Reduced Judgement. The literature provides recommendations for customers and public authorities responsible for protecting customers' privacy rights through laws and regulations [16-17]. From a company perspective, privacy incidents may be caused by technical, managerial, organizational, or human failures [5]. Companies might suffer direct economic damage, such as punishment by penalties or loss of market value, as well as indirect effects, such as increasing insurance fees or decreasing customer satisfaction [5], [11].

Consequently, companies must decide on how to deal with data privacy issues and the related risks. In line with that issue, articles that address companies' handling of data privacy focus on potential threats and how to avoid their occurrence. Conversely, only a limited set of articles considers data privacy measures as an opportunity to create a competitive advantage. For instance, Preibusch et al. [4] show that appropriate management of data privacy issues may have positive implications on customer satisfaction, whereas Sarathy and Robertson [18] provide a framework that assists companies in implementing a data privacy strategy that considers ethical aspects. However, neither article provides recommendations for specific data privacy measures that can be implemented to address customers' data privacy concerns and increase customer satisfaction.

Hence, to the best of our knowledge, using data privacy to delight customers to gain a competitive advantage has yet to be comprehensively examined. More precisely, the literature has yet to provide insights into addressing customers' different privacy concerns using concrete measures and the extent to which such measures affect customer satisfaction. Thus, we raise the research question of whether companies can delight customers by implementing specific data privacy measures.

3 Research Method

To answer the research question, we firstly need to structure the field of possible data privacy measures. Accordingly, this section starts with outlining the identification process of possible data privacy measures. After a short discussion of models that intend to measure customer satisfaction, we describe how we used the Kano model to evaluate customers' perceptions regarding different data privacy measures. The third part of this section describes the design and participants of an online survey used to collect customers' evaluations.

3.1 Identification of Data Privacy Measures

As a basis for identifying data privacy measures, we conducted a comprehensive search for relevant statements, that is, any piece of information on any type of action that addresses customers' data privacy concerns. Therefore, our sources are legislative texts in particular (European General Data Protection Regulation, Bundesdatenschutzgesetz, Telemediengesetz), but also scientific and practitioner-oriented literature found in the databases Springerlink, AISeL, ProQuest, ScienceDirect, EBSCO host, and JSTOR without timeframe limitation and including back-forward search. However, we find that literature does only address data privacy measures to a very small extent. Thus, despite having found 31 relevant papers dealing with managing data privacy in terms of data privacy measures, only two papers contain statements relevant for deriving feasible data privacy measures. Additionally, we conducted three expert interviews, each lasting approximately 30 to 60 minutes and being divided in two parts. The first part was a free talk with the goal of gaining new insights. In particular, this part was used to identify additional statements regarding data privacy measures. In the second part, already identified statements from other sources were evaluated by the interviewee. All statements were then grouped by semantic similarity. In doing so, all authors jointly decided on the grouping of the statements. Without having pre-defined groups, each statement was either used to create a new group with a particular data privacy measure or mapped to an existing group. As a result, all groups consisted of one or several statements regarding a particular data privacy measure. From each of the groups of statements, we derived a single measure that addresses all statements within the group. After the formulation of the measures, we assigned each of the measures to one or more specific customer data privacy concerns.

3.2 Kano Model

After the derivation of data privacy measures and their assignment to specific data privacy concerns, we now focus on determining their effect on customer satisfaction. Approaches to measuring customer satisfaction can be differentiated into subjective and objective methods. The latter can be further distinguished between event-oriented, problem-oriented, and attribute-oriented techniques [19]. As our research focusses on service attributes (measures), we focus on attribute-oriented techniques. In this context, the most commonly used method to measure service quality is SERVQUAL [20-21], but also structural equation modelling and neural networks [22] are viable options. Bartikowski and Llosa [23] analyze further methods, namely Penalty Reward Contrast Analysis, Correspondence Analysis, Dual Importance Mapping, and the Simulation Method. The context at hand requires the possibility of individual investigation of each measure and applicability to hypothetical cases. These criteria are only fulfilled by the Simulation Method, which is most prominently represented by Kano [23]. Accordingly, we use the Kano model to determine customers' evaluation of the identified data privacy measures. The Kano model has been discussed and applied in many theoretical and empirical research projects [24-25], as it provides a comprehensible presentation of attributes of products or services which influence the degree of customer satisfaction. For instance, the model has been used by Lai and Wu [26] in order to gain insights in the customers' needs of a Taiwanese public transport company and by Arbore and Busacca [27], who studied determinants of customer satisfaction for an Italian retail bank.

The Kano model describes customer satisfaction on the basis of the degree of implementation or availability, respectively, of certain attributes of products or services [28-29]. The model differentiates between four major types of factors. In Table 1, we list the factors and apply the remarks of Matzler et al. [28] to data privacy measures. In Figure 1, we illustrate the dimensions and possible factors of the Kano model in the context of data privacy measures that refer to Matzler et al. [28].

Table 1. Details on the factors of the Kano model [29] as described by Matzler et al. [28]

Factor	*Customers' expectations and resulting effect on satisfaction*
Delighter (attractive quality)	Customers do not expect implementation of measure: • Implementation has a positive effect on satisfaction • Non-implementation has no effect on satisfaction
Performance need (one-dimensional quality)	Customers explicitly demand implementation of measure: • Implementation has a positive effect on satisfaction • Non-implementation has a negative effect on satisfaction
Basic need (must-be quality)	Customers implicitly demand implementation of measure: • Implementation has no effect on satisfaction • Non-implementation has a negative effect on satisfaction
Indifferent quality	Customers are indifferent to implementation of measure: • Implementation has no effect on satisfaction • Non-implementation has no effect on satisfaction

To determine the categorization of customer requirements as one of the Kano model factors, it is most common to use a two-question approach [25]. This original approach by Kano has been found to be the most reliable one in a comparison with four other methods and to be one of only two approaches that are suitable to be used in the design stage of products or services [30].

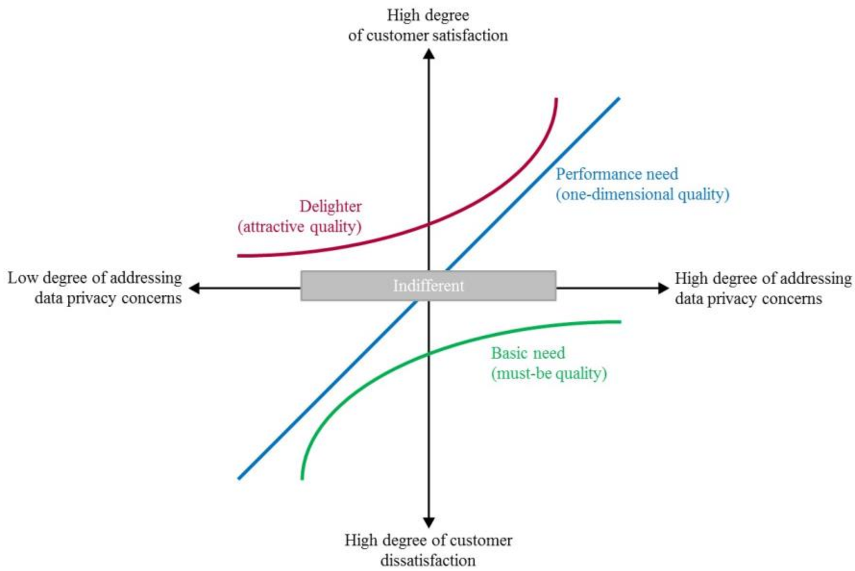

Figure 1. Factors of the Kano model [29] as described by Matzler et al. [28] and applied to the context of data privacy

The classification of a measure as a certain factor depends on customers' answers to both a functional and a dysfunctional question. That is, customers are asked about their evaluation of the hypothetical case in which a measure is implemented and a case in which it is not. Each time, they can choose one of five possible answers: “I like it that way,” “It must be that way,” “I am neutral,” “I can live with it that way,” and “I dislike it that way.” The different answers do not stand for a level of acceptance and there is no ordinal scale. According to Kano et al. [29], each possible combination of answers can be interpreted in an individual manner and leads to a certain pre-defined classification [28], as shown in Figure 2. As proposed by Matzler et al. [28], we derive the final classification of a measure from the respective most frequent individual result.

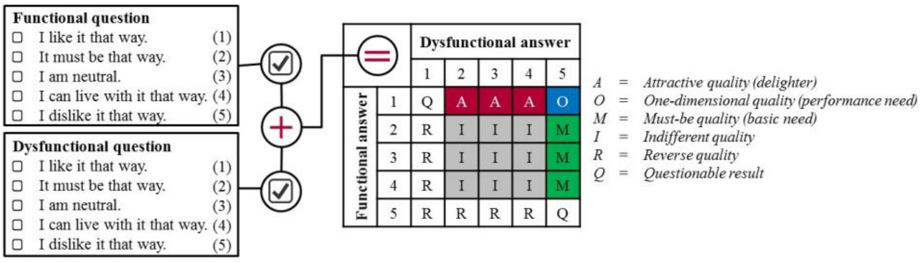

Figure 2. Derivation of Kano model factors based on Matzler et al. [28]

3.3 Survey

Scenario. In order to determine the customers’ evaluation of the identified data privacy measures, we conduct an Internet-based survey. To enable the participants to assume a perspective as natural as possible and to illustrate the situation, we need to use a specific, well-known, and simple scenario that relates to an exemplary industry sector, for which data privacy is a considerable issue. That is, the sector should feature a business-to-consumer market with a significant occurrence of processed customer data. To be able to consider the possible exchange of customer data between companies, cooperation agreements should exist between major industry actors. Furthermore, companies should provide loyalty programs because they are typically based on gathering data on a customer’s behavior over a long period.

The aviation sector as a commonly known industry with a considerable amount of customer data collected at different interaction points [31], transmission of data to public authorities, airport operators, or other airlines that are partners in global alliances [32], and loyalty programs, fulfills all of these requirements.

Design. To ensure high quality results, we first ran a pretest followed by the main survey. In the pretest, we asked 85 German-speaking participants to imagine booking a flight through an airline’s website. Each participant was asked a functional and a dysfunctional question for each of the measures. Using the insights of the pretest, we made several modifications to the main survey: for improving the response rate, we mixed the questions with invitations to guess the correct answers to fun-fact questions about the aviation sector. For improving understandability, we grouped the questions with regard to data privacy concerns preceded by short explanations of the respective concerns. The following example of an explanation, a functional, and a dysfunctional question demonstrates the survey's design. *Explanation:* "Your customer data may be used by a third party outside of the company for a purpose not previously agreed upon. The company implements the following measures." *Functional question:* "You are informed if your customer data are passed on to external third parties." *Dysfunctional question:* "You are not informed if your customer data are passed on to external third parties." To answer the functional and the dysfunctional question, the participants can choose one of the five previously mentioned possible answers. In this way, we ask the participants about each of the 32 identified measures, resulting in a total of 32 question pairs, each of them addressing one of the data privacy concerns.

Participants. The main survey has 227 German-speaking participants, 219 of whom correctly answered a control question. Invitations were distributed via social media and email, and participation was incentivized through a lottery of vouchers for an online retailer. The sample mostly consists of students (78%) and employees (16%). The age of the participants is between 18 and 57 years (average age 25.4 years). The survey was completed by both women (55%) and men (45%). The majority of the participants is well-educated. The share of participants holding a university degree is 51%. Another 42% of the participants achieved degrees with the matriculation standard.

4 Results

In the following section, we present the overview of possible data privacy measures for companies in section 4.1 that resulted from the research process previously described. This overview forms the basis of the presentation of the survey results in section 4.2, that is, the perceptions that customers have of the identified privacy measures.

4.1 Data Privacy Concerns and Measures

The overview of possible data privacy measures is compiled from the literature, legislative texts, and expert interviews. Two publications contain various starting points for measures that can be taken to ease customers' concerns: Morey et al. [33], who describe the role of transparency regarding data collection and usage, and Payne et al. [34], who focus on a list of different laws, regulations, and frameworks, and attempt to reconcile the conflicting agendas of companies and customers. Practical recommendations from Audatis Consulting [35] were used to complement the statements from a practitioner-oriented perspective. Furthermore, we use legislative texts: the European General Data Protection Regulation, which will become applicable law for countries in the European Union in May 2018, the German Bundesdatenschutzgesetz, and the German Telemediengesetz, both finding predominant application with respect to data privacy. To check the completeness of and to verify the previously found statements, we performed three expert interviews in the way described in section 3.1. In the first interview, we talked to an in-house data privacy officer of a German automotive company in order to gain an overview of potential and existing data privacy measures as well as the challenges and difficulties entailed. To verify existing statements and to check whether we had covered all relevant aspects, we conducted a second interview with a researcher who was working on a project with the goal of developing a long-term data privacy strategy for a German bank. To complement our research with input from a legal perspective, we interviewed a lawyer.

From all sources, we collected 141 statements merged to 32 groups. From these groups we derived a particular data privacy measure. All 32 measures can be mapped to one of seven privacy concerns following Smith et al. [15], and as listed in Table **2**.

Table 2. Data privacy concerns presented by Smith et al. [15]

Concern	*Description*
Data Collection	Concern that companies store large amounts of personal customer data.
Data Combination	Concern that customer data from different databases may be combined to gain additional information about a customer.
Internal Secondary Usage	Concern that companies use customer data for a secondary unauthorized purpose.
External Secondary Usage	Concern that customer data are disclosed to a third party and used for a secondary unauthorized purpose.
Errors	Concern that customer data may contain deliberate or accidental errors.
Improper Access	Concern that unauthorized persons are able to view and edit customer data.
Reduced Judgment	Concern that decisions are made in an automated manner and that human intervention in decision-making processes is not possible.

The measures are presented in Tables 3 to 9, grouped by the seven concerns. First, Table 3 represents measures that address customers' privacy concern of Data Collection, meaning that companies might store large amounts of personal customer data.

Table 3. Measures addressing customers' privacy concern of Data Collection

#	*Measure description*
A1	The purpose, scope, and storage time of the data collection and the involved advantages, risks, resulting rights, and obligations are clearly explained to the customer.
A2	Customer data are, as best as is possible, stored anonymously to prevent backtracking of individual customers.
A3	Only the customer data absolutely necessary to provide the agreed service are collected.
A4	Altering or exiting the contractual agreement with regard to personal data is as easy as entering into it. Among others, processing requests occurs quickly and is free of charge.
A5	At the request of the customer and without a long delay, the company provides a set of his personal data free of charge in an easily readable form. Furthermore, the customer has the right to pass these data to other companies.

Table 4 comprises measures that address customers' privacy concern of Data Combination. That is, customer data out of different databases might be combined to gain additional information about a customer.

Table 4. Measures addressing customers' privacy concern of Data Combination

#	*Measure description*
B1	The customer is informed if the company combines his data from various internal and external sources.
B2	If the company combines customer data from various internal and external sources, combination and storage are carried out using anonymous data to prevent backtracking of individual customers.
B3	If customer data are collected for different purposes, the data sets are stored in different databases and are not combined.
B4	The customer decides on whether the company is allowed to combine data from various internal and external sources and can change his decision at any time.

Customers might be concerned that companies use customer data for a secondary unauthorized purpose within the company. Measures addressing the concern of Internal Secondary Usage are listed in Table 5.

Table 5. Measures addressing customers' privacy concern of Internal Secondary Usage

#	*Measure description*
C1	The customer is informed whether and what data are passed on within the company or group of companies and for what purpose.
C2	Customer data are deleted as soon as the original reason for the collection no longer applies or the customer withdraws his permission.
C3	Entering, viewing, altering, and deleting customer data are recorded to make it possible to retrace who changed the data when, and in what manner at any time. The customer can either directly view the log file or is informed about any alterations of his personal data.
C4	If customer data are collected for different purposes, the data sets are stored in different databases and are not combined.
C5	Customers have the opportunity to easily decide which of their personal data are shared with other departments of the company and/or used for other purposes.

Measures addressing customers' privacy concern of External Secondary Usage are presented in Table 6. Customer data might be disclosed to a third party and used for a secondary unauthorized purpose.

Table 6. Measures addressing customers' privacy concern of External Secondary Usage

#	*Measure description*
D1	If customer data are passed on to external third parties, the customer is informed. If customer data are passed on to external third parties, the company ensures that the data are only used in the manner agreed on with the customer through contracts or binding commitments to data protection regulations.

Table 7 cont'd. Measures addressing customers' privacy concern of External Secondary Usage

#	*Measure description*
D3	If customer data are passed on to external third parties, the company or an independent certification organization regularly checks the external third party's compliance with data privacy regulations.
D4	If customer data are passed on to external third parties, data are only forwarded in aggregated or codified form (e.g., income class instead of exact yearly income).
D5	If customer data are passed on to external third parties, the data are – as best as possible – forwarded anonymously.
D6	The company does not pass on customer data to external third parties.
D7	The customer has the choice to easily deny sharing his data with external parties even if doing so results in compromising or the complete abortion of the value delivery.

Customer data might contain deliberate or accidental errors. Measures addressing the concern of Errors are listed in Table 8.

Table 8. Measures addressing customers' privacy concern of Errors

#	*Measure description*
E1	Customer data are checked regularly by the company for completeness, accuracy, and being up-to-date.
E2	The company ensures that no customer data are destroyed or lost by technical and organizational means.
E3	Employees with access to customer data are selected carefully, their behavior is checked regularly, and they are held responsible for malpractice.
E4	Entering, viewing, altering, and deleting customer data are recorded to enable retracing at any time who changed the data when, and in what manner. The customer can either view the log file directly or is informed about any alterations to his personal data.
E5	The customer has access to his data to correct errors, make alterations, or delete data. If he is not provided with direct access to edit his data, they are changed by the company on request.

Table 8 contains measures addressing the concern of Improper Access, which means that unauthorized people might be able to view and edit customer data.

Table 9. Measures addressing customers' privacy concern of Improper Access

#	*Measure description*
F1	If the protection of customer data was violated and their security is at risk, the company immediately informs the customer and the authorities.
F2	Storage and transmission of customer data are protected by technical (e.g., password protection, encryption) and organizational means (e.g., access control, companywide standards regarding handling customer data).
F3	The company ensures that customer data are stored and processed only on its own servers within the European Union or countries trusted by the European Commission.

Customers might be concerned that decisions are taken in an automated manner and that people cannot intervene in decision-making processes, if necessary. This concern, Reduced Judgment, can be addressed by the measures listed in Table 10.

Table 10. Measures addressing customers' privacy concern of Reduced Judgment

#	*Measure description*
G1	The customer is informed whether a decision was made through an automated systems or through an employee of the company. At the customer's request, the reasons for the decision are communicated and explained.
G2	Automated decision processes are continuously tested and checked for deviations.
G3	Decisions that entail legal consequences (e.g., granting a credit) are never made only on the basis of automated systems.

In summary, Tables 3 to 9 represent a comprehensive list of actions that can be taken by companies to mitigate the risk of displeasing customers and to create the potential for delighting customers regarding data privacy.

4.2 Customers' Evaluation of Data Privacy Measures

Companies need to be aware of customers' evaluation of these data privacy measures, which forms the basis for deriving implications for companies' data privacy policies. To determine whether customers consider the implementation of the different identified data privacy measures as "must-be" (basic need), "one-dimensional" (performance need), "attractive" (delighters), or "indifferent," we analyzed the survey's results using the Kano model as described in the previous section. These results are illustrated in Figure 3. Thereby, the measures are numbered as defined in Tables 3 to 9. The abscissa denotes the majority-share of survey participants that determined the measure's classification as one of the four Kano model factors. The ordinate states the spread between the majority-share and the second highest share to evaluate the result's clarity. In the illustration, a green square represents a measure considered to be a basic need by the majority of the participants. Analogously, red dots symbolize measures that are considered to be delighters and gray triangles mark the respective measures as being of indifferent quality. There are no measures considered to be performance needs. To illustrate this approach, we use measure D5 as an example. According to their choice of answers, the majority of the participants (57%, abscissa) see it as a basic need, whereas the second largest group (23%) consider it as a performance need. Thus, the ordinate is 34% (57%–23%), representing a relatively clear result. Overall, the unity among survey participants regarding the classification of a data privacy measure is the smallest bottom left and increases along the bisector. Thus, the distinctiveness of a categorization is highest toward the top right. Valid implications can be derived from the results starting from a spread of at least 10% on the ordinate in Figure **3**.

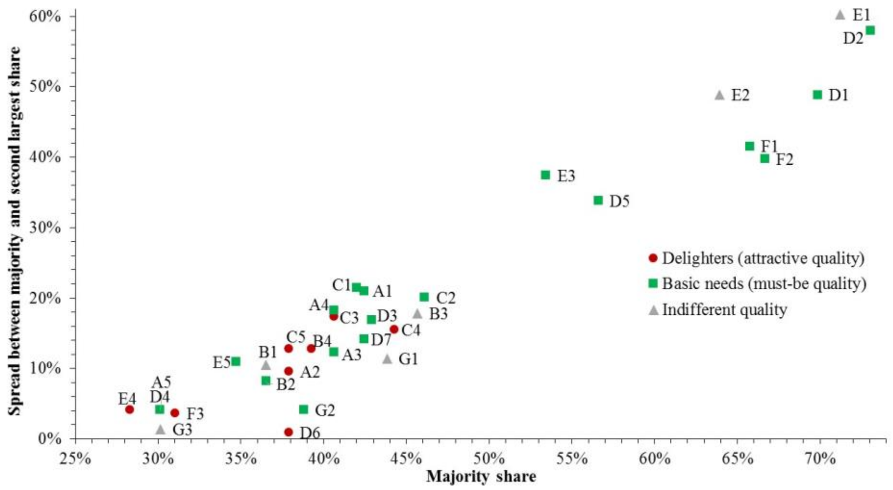

Figure 3. Visualization of the empirical results

Survey participants see 18 out of 32 measures as basic needs. That is, the realization of these measures is neither rewarded nor explicitly demanded by customers. Instead, it is a basic prerequisite when engaging in business with the company. In particular, basic needs can be found among measures addressing the concerns Collection (4 measures out of 5 categorized as a basic need), External Secondary Usage (6/7), and Improper Access (2/3). Hence, these basic needs can be considered a necessary evil because they have downside risk if not implemented but offer no upside opportunities if implemented. The most distinctive example is measure D2, stating that external secondary usage is to be regulated by contracts or other provisions to ensure that data are only used in the manner agreed on with the customer.

Furthermore, no measures are considered to be performance needs. Their constituting properties are, in addition to having a negative impact if not implemented, that they also have the ability to increase customer satisfaction when implemented properly. The total lack of such factors with upside potential is another emphasis of the necessary-evil quality of most data privacy measures.

Entirely, six measures are considered by the survey's participants to be of indifferent quality and, in particular, can be found when addressing the concerns Combining Data (2 measures out of 4 categorized as indifferent) and Reduced Judgment (2/3). These measures do not allow distinctive interpretations toward any direction.

However, there are eight measures categorized as delighters, which are measures that are not required by the customer but may please them, and have no negative impact if not implemented. These measures go beyond the data privacy measures that customers expect. Their implementation positions a company at a level of data privacy commitment higher than anticipated, which has the potential to be rewarded with higher customer satisfaction. Thus, delighters enable companies to differentiate themselves from competitors and to gain a competitive advantage. For instance, Internal Secondary Usage is the concern with the highest share of measures classified as delighters (3/5). In particular, customers can be delighted by providing them with the ability to retrace who changed the data, how, and when (measure C3), or by storing customer data in different and not combined databases, if the data are collected for different purposes (measure C4).

In summary, most of the identified data privacy measures are classified as basic needs. However, survey participants' answers lead to the classification of some data privacy measures as delighters. Thus, our results show that the implementation of data privacy measures has the potential to delight customers.

5 Summary, Limitations, and Future Research

This paper provides an overview of data privacy measures collected from scientific and practitioner-oriented literature, legislative texts, and expert interviews, and can be useful for researchers and practitioners. On top of this overview, this paper provides first insights into customers' perceptions of the identified data privacy measures. By using the Kano model to design a survey with more than 200 participants, we could show that the majority of data privacy measures must be considered as necessary evils for companies. Nevertheless, some data privacy measures can even delight customers. Thus, this paper's result is that certain data privacy measures have the potential to increase customer satisfaction and enable a competitive advantage for companies. Accordingly, researchers and practitioners may use our approach as inspiration when deriving a data privacy strategy because evaluating customers' perception may assist in prioritizing the implementation of data privacy measures. Measures classified as basic needs should be implemented by every company to avoid data privacy incidents and negative effects on customer satisfaction. Companies that strive for delighting customers through data privacy may also implement measures classified as delighters.

However, researchers and practitioners need to be aware of our research having some limitations. First, the research approach is limited to the consideration of a specific aviation sector scenario. To verify the general validity of the conclusions, the survey has to be rerun for further settings that refer to other industries. Second, in the field of data privacy, statements of customers in empirical surveys do not necessarily match their actions in the real world. According to Norberg et al. [36] and Acquisti and Grossklags [37], the so-called privacy paradox describes the discrepancy between customers' intentions to protect their own privacy and their real-world behavior. To take into account this phenomenon, the results of the survey should be verified in real-world situations. Third, in general, the classification of delighters is less clear than the classification of basic needs. That is, when interpreting this paper's results, implications must be challenged according to the principle of prudence. When in doubt, a measure should rather be considered a basic need than being of indifferent quality or a delighter. Future research could follow Matzler et al. [18], who state that unclear results spread out over several categories can be a starting point for market segmentation. Thus, further research could examine the categorization of data privacy measures as Kano model factors depending on demographic characteristics.

When providing an overview of data privacy measures and outlining the potential to increase customer satisfaction by applying certain data privacy measures, we could also point out main areas of further research relevant to both researchers and practitioners. Specifically, we plan to extend our research to other industries to evaluate general validity in the near future. Further research can also focus on a break-down of single data privacy measures into its individual components and the influence of these granular aspects on customers' satisfaction with a particular data privacy measure.

Social Network Services: Competition and Privacy

Claus-Georg Nolte, Jonas Schwarz, Christian Zimmermann

University of Freiburg, Institute of Computer Science and Social Studies,
Department of Telematics, Freiburg, Germany
{nolte,schwarz,zimmermann}@iig.uni-freiburg.de

Abstract. Social Network Services (SNS) business models highly depend on the gathering and analyzation of user data to obtain an advantage in competition for advertising clients. Nevertheless, an extensive collection and analysis of this data poses a threat to users' privacy. Based on an economic perspective it seems rational for Social Network Operators (SNO) to ignore the users' desire for privacy. However, privacy-friendly services might have the potential to earn users' trust, leading to an increased revelation of personal data. Addressing these issues, we examine the existing privacy problem in SNS in the context of competition between SNO to investigate whether competition tend to enhance user privacy or whether it is the root of its violation. Therefore, this paper investigates the interconnectedness of the market structure and privacy problems in SNS. After analyzing the users' and the advertisers' side of SNS, their competitiveness and its influence on user privacy are examined.

Keywords: Privacy, Social Network Services, Competition, Multi-Sided Platforms, Two-Sided Markets

1 Introduction

At least since Facebook was published in 2004, social network services (SNS) have constantly been on the rise and consume evermore of our daily online time and, thereby, of our personal data. Moreover, since the beginning of the smartphone age SNS have even been following us from our desktops to every place we go. They demand us to share every bit of our lives with our friends within the network and, thus, with the network itself. Consequently, Harvard Law professor Jonathan Zittrain deduced in 2008 that this technology threatens "to push everyone towards treating each public encounter as if it were a press conference" [1]. This thirst for user data can be explained with the business model of SNS which heavily depends on gathering and analyzing user data to deliver targeted advertisements [2]. This extensive collection and analysis of user data poses a severe threat to users' privacy. Hence, Margo Seltzer, professor in computer systems at Harvard University, sets it straight at the Davos Forum in 2015 stating that "privacy as we knew it in the past is no longer feasible" [3].

Disclosed data itself is necessary for SNS businesses to improve their targeting of advertisements and thereby obtain an advantage in competition for business customers,

13th International Conference on Wirtschaftsinformatik,

Wirtschaftsinformatik (WI 2017), St. Gallen, S. 822-836

which demand for precisely targeted advertising. Hence, users' demand for privacy-friendliness only becomes important insofar as it is helps providers to gain trust and to get users to reveal even more personal data [4]. Thus, it seems not an irrational ignorance of users' desire for privacy by the providers but a rational choice in an economic competition not to prioritize this desire.

The paper takes an economic perspective on the present privacy problem in SNS to investigate whether competition between providers tends to enhance user privacy or whether it is the root of its violation. For this purpose we investigate privacy in those business focusing on the market structure, thereby taking into account that SNS constitute multi-sided platforms (MSP) [5]. Analyzing the users' and the advertisers' side of SNS, we compare their competitiveness and its influence on user privacy. Therefore, we build upon insights from theoretical literature concerning MSP, behavioral research papers about SNS and privacy, as well as market evidence.

In the following we will first state the essential definitions for our investigation in section 1.1 and further give a brief overview of the related literature in section 2. Thereafter, we start with the analysis of the influence of SNS competition on user privacy, firstly by examining the characteristics of the goods which are up for rivalry on the different market sides in the SNS environment, and secondly, by investigating those goods and competitions in detail considering appropriate findings from scientific literature (see section 3.1). Thirdly, we will analyze their impact on user privacy in section 3.2 and following. Finally, we will discuss our results, match them with empirical evidence (see section 4) and give a summary of our paper in the conclusion.

1.1 Essential Definitions

As mentioned above, we aim at investigating the interrelation of the market structure in social networks services (SNS) and user privacy. Hence, there is a need to clarify the term and interpretation of SNS. According to the updated definition of Kane et al. [6], which builds upon the earlier characterization of Ellison [7], SNS contain the following features: "users (1) have a unique user profile that is constructed by the users, by members of their network, and by the platform; (2) access digital content through, and protect it from, various search mechanisms provided by the platform; (3) can articulate a list of other users with whom they share a relational connection; and (4) view and traverse their connections and those made by others on the platform" [6]. In the following we use this definition as a basis to describe and understand SNS. However, we add the restraint that the main revenue source of the SNS should be advertising to ensure the multi-sided platform character of our investigation object. Hence, the scope of our analysis contains SNS such as Facebook, Google+ and Twitter.

Moreover, we define the term of Social Network Operators (SNO) as companies, which "provide the underlying basic services and infrastructures, needed by users to interact with each other" [8]. In the case of Facebook, the website facebook.com constitutes the SNS while the company Facebook Inc. is the SNO.

Further, the term multi-sided platform, also known as two-sided platform or market, requires a clear definition, too. Therefore, we draw on the work of Staykova and Damsgaard [5]. According to their research, MSP (1) enable direct interaction between two or more participants affiliated to them; (2) are containing homing and switching costs for those participants; and (3) include direct and indirect network effects [5] (see Fig. 1). In our setting, homing costs are the costs in money, effort, time and other aspects of entering and using an MSP. Moreover, switching costs are similar onetime costs that occur if participants switch from one platform to another. Additionally, network effects occur when the value of the platform or its product for one participant is influenced by the total number of participants (of the same or another side). Those effects can be both positive or negative and are seen as a key aspect of MSP [9].

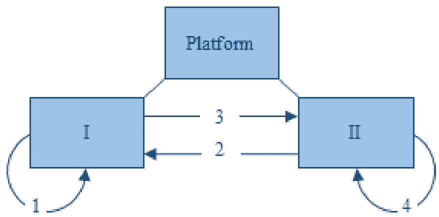

Figure 1. MSP model, including platform participants (I&II), same-side network effects (1&4), and cross-side network effects (2&3) [5].

The privacy definition used in this paper builds upon Westin's definition of privacy. Hereby, he defines it as "the claim of individuals, groups or institutions to determine for themselves when, how, and to what extent information about them is communicated to others” [10]. For him, “this, also, involves when such information will be obtained and what uses will be made of it by others” [11]. In the context of SNS, we consider privacy as the capability of SNS users to control their personal data and its collection, aggregation, analysis and possible transfer by the SNO and third parties, as well as users' ability to optimize the amount of data disclosure and its security against misuse with respect to their preferences.

The legal definition for personal data is provided by the EU data protection directive as “any information relating to an identified or identifiable natural person”.[1] However, for our case a broader classification is useful. Drawing from Nolte, we define personal data as “any data revealed by user action, starting from simple likes, to direct personal information, and even analysis of users click and browse behavior” [12]. This diversification is necessary to capture that by the aggregation and combination of meta- and behavioral data, inferences can be drawn. Those can constitute sensitive information for users and sometimes even personal data in the definition of European data protection law [13]. Given this definition, it is obvious that the data-centric business model described above constitutes a severe threat to users' privacy.

[1] EU Data Protection Directive (95/46/EC), 1995.

2 Related Literature

User privacy in SNS is a widely examined and discussed issue. Basically, the topic can be divided into two main research streams: Behavioral and user-focused research as well as provider-focused research. The former offers the seemingly contradictive result that users on the one hand care for privacy and try to preserve it with privacy-seeking behavior [14], but on the other hand do not act privacy-aware and seemingly carelessly disclose personal data when using Internet services [15]. Those findings led to the definition of the so-called "privacy paradox" [16]. Furthermore, provider-focused research has shown that privacy is not a major market factor in the competition for user attraction although users estimate it of high importance for them [17, 18].

However, the question wherefrom this dynamism arises which drives SNS providers to claim more and more user data and thereby restrict user privacy is still open to research. Different forces interact which each other and the participants in an SNS. Most of those forces have direct or indirect influences on privacy [19]. One popular assumption is that users' demand for privacy is of minor priority for SNS providers because users are not willing to pay for it [20] and the monetary income is generated by advertisement customers [2]. However, recent successful mail services show that a minority of users is willing to spend small monetary amounts for increased communication privacy.[2] Other companies in the Internet search business even display the possibility to succeed without demanding any money for a privacy respecting service [21]. Nevertheless, this willingness to pay for privacy either in a monetary way or in terms of switching costs seems of no significance for SNS [15, 22, 23].

Further, the more general question of competition in MSP has been addressed from different angles. The economics of two-sided markets have most notably been explored by Rochet and Tirole [24]. Further research into MSP market structures has been conducted by Armstrong [25], Evans and Schmalensee [26] and others [5, 27]. While these highly recognized works provide deep insights into the economics of MSP, they do not cover privacy issues. A variety of publications address the questions of competition and monopolistic tendencies in online MSP, while focusing on the search engine market and Google's market position in particular [28, 29] or on SNS and Internet services in general [30]. However, the potential interrelation of the privacy problems in SNS and the market structure are not in the focus of current research.

3 Economic Analysis

In the following section we introduce and clarify the MSP business of SNS. Further, the traded goods in an SNS environment are examined from different angles to determine their competitive character. Afterwards, we consider their influences on user privacy for both sides of the SNS/MSP entity, namely the users' and the advertisers' side. For simplicity other SNS participants, like application developers, are bypassed.

[2] Mailbox.org, Posteo.de and others.

As argued above, SNS in general constitute an MSP, generating revenue by brokerage of targeted advertising to its users for business partners [2, 31, 32]. A closer view on the market structure reveals strong direct same-side network effects between its users, because each additional user makes the SNS more attractive to others [33, 34]. Moreover, there are indirect cross-side network effects between users and advertisers. Each additional user makes the network more valuable for advertising clients. This is due, firstly, to a broader audience for targeted advertisement and, secondly, to a higher amount of user data, which elicits the possibility of drawing inferences and thereby creates more precise profiles [5]. On the other side, users are at least accepting personalized advertisements as a price to use SNS free of monetary charge [32]. However, there are no positive network effects between the advertisers, rather the opposite can be assumed. While advertisers profit from additional SNS users and often perform side-advertisement by promoting their SNS company profiles (e.g. advertising the company's Facebook-page or Twitter-account), they are rivals to other advertisers within the same network for the limited space of targeted advertisements (see Fig. 2).

3.1 Features of Social Network Service Goods

As already stated, advertising companies are in rivalry for the limited space for targeted advertisements. More precisely, currently leading SNS auction targeted advertisement for specific audiences or keywords in a real-time bidding system between interested advertisers. The space for advertisement in the network is limited and advertising clients can exclude each other through a higher bid for the same keyword or target group, thus, the good of advertisement is exclusive and a rival good. Furthermore, a SNO can decide to exclude some advertisers from its service. Hence, advertisement in SNS is a classic private good (see Table 1). Thus, one has to assume that there exists a strong rivalry between similar advertisers. Classifying this insights into a feature of goods table shows that the service of providing targeted advertisement within SNS is to be considered a private good [35].

Categorizing the SNS users-side is more complicated. First of all, we have to distinguish between two different goods: the plain SNS membership and the actual usage of the network. The first requires usually only a valid email address and roughly two minutes for filling out the application form and confirming one's mail address. The second comprises the aforementioned homing costs, time and effort to understand the SNS' practice as well as adding user created content. Both add up to the aforementioned switching costs (c.f. section 1.1). We already argued that users experience same-side network effects from other users. Hence, profile creating and SNS usage is non-rival. Creating a profile and actively participating in an SNS prevents no one else from joining or using it.[3] In addition, the question to be answered is whether those user-sided goods are excludable or not which makes the difference between a public good and a club good. At first glance, it seems intuitively to argue that those goods are public because no one seems to be able to exclude someone else from the usage. However, people from Turkey trying to access Facebook during the military coup in July 2016 or generally

[3] Except for server overload which is not discussed here for simplicity.

trying to use it in China or North Korea will disagree. Countries as well as SNO have technical instruments to restrict SNS access or directly ban specific users.[4] Hence, the SNS registration and usage is non-rival but excludable for users' side whereby it complies with the characteristics of a club good (see Table 1).

Table 1. Feature of Goods Classification for SNS

	excludable	**non-excludable**
rival	*"private good"* targeted advertisement	*"common good"*
non-rival	*"club good"* SNS registration & usage	*"public good"*

3.2 The Social Network Operator Viewpoint

The last angle missing is the SNO perspective. First, the providers compete among themselves for advertising clients. All SNS are offering roughly the same product on this market side: targeted advertisement. It applies here that neither can money spent by an advertiser in one network be spent twice, nor can advertisement space be assigned multiple times. Accordingly, one can assume that the SNS advertisement market side is in strong competition because several providers supply a comparable private good to a high quantity of advertisement-willing companies (see Fig. 2).

Second, user registration and membership seems non-rival from an SNO perspective because users can easily set up multiple accounts in different SNS. Moreover, a provider is not able to prohibit its members from registering at other networks nor to hinder other services to open their registration for them. Yet, users can decide to refuse a certain SNS. However, competition undoubtedly exists for attracting users between SNO, since the quantity of accounts is a signal to attract advertisers.

Third and most interesting from an SNO perspective is the time users spend in the network. It seems to be a highly valuable good for providers, because it increases the possible quantity of advertisements shown to users and probably the amount of data disclosed by them [14]. Further, users' time and attention is limited and can only be spent once to an SNS. A strong competition for users' time between SNS and also other services can thus be presumed [36]. As a result, users are not only paying for an SNS with revealed personal data but also with their time and attention (see Fig. 2).

[4] Technical workarounds for users are neglectable for our analysis.

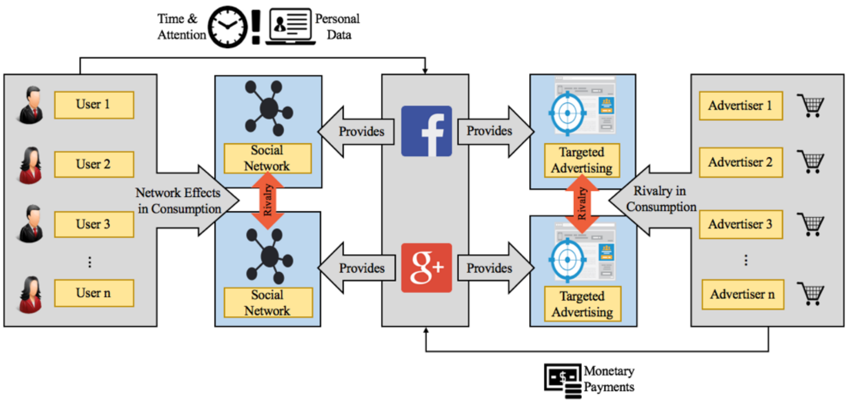

Figure 2. The market structure of SNS

3.3 Competition on Users' Side

Analyzing the SNS' competition on the users' side of the market structure, we firstly identified two relevant factors: trust and enjoyment [33, 34]. On the one side, as described before, the SNO wants to receive users' time and therewith their attention for advertisements and their disclosed personal data for improved targeting of those advertisements [37]. On the other side, users want to enjoy an SNS and demand it trustworthy [4, 33, 34], while enjoyment also includes strong same-side network effects, i.e. finding the own friends within the same SNS [34].

Targeting the trust factor first, literature shows that increasing trust in their SNS can be achieved for SNO by implementing privacy controls [33, 38]. This is not only relevant because improved trust increases the SNS usage but also the quantity of disclosed data and the acceptance of advertising [39, 40]. Hence, trustworthiness is beneficial for SNS to bind users to the service as well as to receive more user-generated content and reliable user data. Undoubtedly the implementation of privacy controls has a positive influence on user privacy in SNS [19]. However, findings suggest a design conflict between privacy and usability and, thus, enjoyment [18].

Talking about the enjoyment of an SNS, it seems to be the most crucial factor in SNO competition. Firstly, because it attracts users to join a network and, thus, self-evidently increases positive same-side network effects between the users as well as positive cross-side network effects from the users' side to the advertisers'. Secondly, enjoyment tempts users to spend more time with the network, leading again to positive influence on advertisers. Additionally, more time spent in an SNS also increases the quantity of user-generated content because content creators value a platform more if they have a larger audience [41]. Further, a higher amount of content again attracts more advertisers because it enhances the providers' targeting ability for advertisement. To conclude, we find plenty of motives for providers to compete with enjoyment for user registrations and user time. SNO are facing this competition by increasing their own platform stickiness. Literature results show that there exist mainly two ways of doing so which add to another: increasing the content of the platform and implementing more features and functionalities to it [5, 36]. While the latter seems at first glance privacy neutral for users, changing the platform appearance to entice users to enter more data clearly is a threat to their privacy [14]. However, additional platform features also contain the potential to harm user privacy when they educe additional personal data from users or even leak those data from the platform to third parties if the SNO decides to open her network to external application developers.

3.4 Competition on Advertisers' Side

As already stated, SNO compete for selling targeted advertising to corresponding customers (c.f. section 3.2). To attract those advertisers, we identified four factors as most relevant: the quantity of users, the accuracy in user targeting to serve the advertisements, the time users spend in the network and the price to advertise to the targeted user group. In their evolution, the majority of SNS followed the same path: first starting one-sided and attracting users, and after hitting a critical mass, implementing advertisement and thereby evolving into a two-sided platform [5]. Later, most SNS also included external application developers and other services (e.g. identity management) and, thus, transformed into an MSP. However, we already covered the privacy impacts of competition for user registration in the previous section.

Besides the pure quantity of users, the average time a user spends in the network appears to be the crucial factor in the competition for advertisers [36]. Its theoretical competition and privacy impacts on users' side were already shown above. However, another option for tying users closer and longer to a network seems to enhance the SNS content [6, 42]. This can either happen by tempting users to post more data or by including external content creators and their content directly into the network (e.g. news sites or celebrities). A further method is simply to acquire competitors and include their services into the own SNS. We already showed the possible privacy threats of tempting users to reveal more data above. The method of including further content form external content creators is basically privacy neutral, except for users' active reaction on this content (e.g. likes and comments). However, implementing bought-up competitors and especially merging their existing user data and accounts with already existing in-network user data can be extremely privacy invasive. Merging that data and drawing inferences from the new database can reveal information which the user initially wanted to hide by audience-segmentation via using two separated services.

The third identified factor is the accuracy of user targeting. The most obvious way of improving this factor is to gather more user data, either directly from the users or from external sources, to analyze it with algorithms. The impacts of user data have already been discussed. However, one has to expect that the possibilities of enhancing targeting by user data somewhere hits a limit value where gathering more data does not result in any more improvements. Hence, another method to improve the targeting constitutes a direct inquiry of users either for their interest or indirectly by giving them the controls to correct their information and drawn inferences connected to their account [37]. The latter can be privacy enhancing for users if it is allowed for them to delete data or at least exclude certain information from the targeting mechanisms.

Finally, the cost-benefit-factor of advertising in an SNS depicts a crucial aspect, since the advertisement side is the monetary paying side. As every agent acting in an economic environment, advertisers seek for the most efficient way to spend their money and, thus, to target their audience. Besides the developers' achievement of a leading targeting algorithm and the already treated topic of feeding it with user data, SNO have another factor to influence the efficiency of their advertisement offer: economics of scale. Additionally to non-rivalry and excludability, user membership and activity in SNS have the characteristic of low marginal costs. The costs to provide the service to an additional user are, after establishing a working system, marginal for the SNO. The same holds true for the advertisers' side and the service of automated advertising space auctions. Hence, this leads to rising returns of scale which makes an SNS the more efficient the larger both sides are. Thus, the direct way to increase SNS attractiveness for advertisers is to gain more users joining and spending time in the SNS. This becomes even more efficient if those users originate from different target groups, because the SNS then represents all sections of society. This insight leads us directly back to section 3.3 and the discussed influences on privacy and competition.

3.5 The Trump Side of Competition

In the previous sections, we analyzed the two major sides of SNS regarding competition and their impacts on user privacy. Table 2 summarizes the different activities of SNO and their influences. However, it seems uncertain which side in competition outweighs the other and, thus, whose needs are favored by the SNO for economic reasons. If the users' side and therewith users' needs are preferred it is to be expected that the trust factor could lead to an improvement of users' data control options and, thus, to an enhanced user privacy. We expect the opposite if advertisers are the SNO-favored SNS side, due to the demand of evermore user data for better profiling.

Table 2. SNO activities and their influence on user privacy

SNO Activity	Influence on User Privacy
Implementing Privacy Controls	+
Give Users Control to Correct and Enhance the Information and Drawn Inferences Connected to their Account	+
Implement more Features and Functionalities	❍
Changing Platform Design to Entice User to Enter More Data	-
Merging their Existing User Data and Accounts with Already Existing In-Network User Data	-

Following the influential papers on MSP, the standard link from classical economics between the inverse relation of price over marginal cost and elasticity of demand does not hold true for MSP. In other words, the service on one side will be served by the provider even if this service and the price paid for it by the its participant alone is not profitable [26]. Hence, the loss from one side has to be outweighed by the profits from the other. To identify the provider's cash cow we have to find out on which side multihoming is most prevalent [24, 25]. In other words, the side where the MSP participants use more than one platform simultaneously is expected to be overpriced, while the singlehoming side is expected to be subsidized [43].

4 Discussion

In this section we will match the theoretical analysis of competition and its influence on privacy in SNS with available market observations and empirical evidence. Subsequently, we discuss whether this evidence confirms our theoretical findings.

First, targeting the mentioned trust factor of section 3.3 we find that current developments indicate that SNS and other Internet services recognized the coherency between users' trust and user-generated content. Respectively, Facebook introduced new privacy controls in 2008 [44] and constantly improves them [45] while Google implemented its own user privacy controls lauded by specialized press [46]. However, another reason for this privacy trend in Internet services might be the upcoming reform of the EU Data Protection Directive which comes with rigid laws and harmful financial penalties in case of violations [47]. Hence, the future of this trend is sustainably influenced not only by user behavior but also by the corresponding law. Utterances of the European Commissioner let us assume that the end of the road of regulating Internet services concerning competition and user privacy hast not been yet reached [48].

As showed in sections 3.3 and 3.4, SNO compete against each other for users' time spent on their platform as well as for content. Therefore, they implement new features into their platforms or integrate taken-over services and external apps. Recent developments in Internet services and SNS make this competition visible. The acquisition of WhatsApp by Facebook, as well as the takeover of Instagram led to a domination of Facebook in the branches of mobile messaging and mobile photo sharing. Moreover, Facebook started partly merging Facebook and Instagram accounts and announced in the latest terms and conditions change of WhatsApp that phone numbers and contacts will be transferred to Facebook [49]. Both clearly contain the aforementioned privacy threats of merging different services accounts.

As a result, Facebook's recent introduction of instant articles can not only be interpreted as an attempt to enlarge the own content but also as an attack on Google and Twitter [50]. Furthermore, Facebook included the feature of selling tickets for events and recently announced the possibility to run crowd-funding campaigns and collect money directly inside the SNS [51]. This seems to be an attempt to use its already large user base and the resulting network-effects to include the markets for online ticket-sale and crowd-funding and, thereby, keep the users as long as possible in the Facebook environment. The same applies to implementation of an own browser within the Facebook app, a strategy also used by Twitter.

Moreover, companies like Google, Facebook and Twitter provide identity management features which enable users to log-in with their already existing SNS accounts to external services. What seems like a comfortable feature to make users' life of managing different online accounts easier, can also be interpreted as a way to gather more data from external services, track users beyond the own platform and enhance both targeting and time for displaying advertisement. We already pointed out the privacy threat aspects of those strategies.

However, the most interesting question is which side, the users' or the advertisers', is subsidized and who is the "cash cow" (see section 3.5). Evidence from the magazine industry suggest that users are subsidized and advertisers are the main income source [52, 53]. The fact that users are not paying any monetary price for SNS and advertising is the main income source for SNO strongly supports this view [54]. Nevertheless, considering multihoming as the crucial factor, recent statistics suggest that it is on the rise on users' side with 52% of US users using two or more social media sites in 2014 [55]. However, the relevant factor of SNS competition on users' side is also the time spent in the network (see section 3.2). Facebook leads by far with 70% of its users using the platform daily before Instagram with 49% and Twitter with 36%, while the second also belongs to the Facebook environment. Moreover, "the engagement of Facebook users continues to grow, while daily use on other platforms shows little change" [55].

Because, we lack numbers for multihoming behavior on the advertisers' side we use the market distribution as an indicator. In 2014 Alphabets' share of the net digital advertising revenue was 31%. This revenue includes the income from targeted advertising on the Google search sites and also the advertisement revenue from services like YouTube, Google+ and AdWords. The leader is followed by Facebook with a market share of nearly 8% and the Chinese online search engine Baidu with close to 5% [56]. Despite these distinct numbers the development of the online advertisement market indicates that the competition between the targeted advertisement-offering SNO is rising. While Alphabet was able to keep its market share over the last three years, competitors are catching up. Facebook nearly doubled its market share from 2012 to 2014 from 4% to close to 8%. Besides, except for two, all other market participants beyond the 0,5% market share were able to claim slightly more percentages each year [56]. This development indicates not only that online targeted advertisement is becoming more popular but also let us presume that adverting clients tend to use more than one Internet services and, thus, show multihoming behavior.

The point that both sides of SNS seem to show multihoming behavior and that the users' side does not pay for their usage in terms of money makes it difficult to apply the insights of MSP markets and multihoming here. As mentioned afore, on the one hand one could claim that users are the subsidized side because they are enjoying SNS for free. However, on the other hand one could also argue that advertisers are being favored and thus subsidized because they are the crucial revenue source of SNO. Moreover, advertisement prices in SNS seem comparably low to those paid in print media and we expect the targeting to be more exact due to the revealed user data [54]. Hence, advertisers could be subsidized with better targeting for comparably lower prices while users could be overpriced in terms of private data elicit by the SNS and, thus, lower privacy. However, according to the lack of literature and data available we are not able to finally assess this case.

In summary, our investigation shows that competition between SNO does neither necessarily improve user privacy nor does it generally harm it. Competition in MSP like SNS is complex and our analysis shows that there are indeed various privacy harmful aspects. However, the competition for users could have privacy friendly consequences, if the trust factor outweighs the privacy contrary implementation of additional features and overtaken services.

4.1 Limitations & Future Research

Our work is limited due to the available data about certain market aspects of SNS competitions. We found no data about multihoming behavior of advertisers regarding the purchase of targeted advertising in SNS. Additionally, there is no evidence whether newly integrated privacy controls by Facebook and Google are actively used and, thus, increase user privacy or if they are just having a trust-building and thereby possible privacy harming effect. Moreover, the comparably low costs of targeted advertisement in SNS can partly be explained by the strong economics of scale and the near-zero variable cost of running an SNS and displaying advertisement compared to print media. Hence, future research in this area should tackle and close this data gap.

Furthermore, considering our classification of SNS goods, club goods as the SNS membership and usage from user side also have the characteristic of low marginal costs. This leads to rising returns of scale, which makes club goods ideal for natural monopolies [35]. Considering the costs to set up an SNS by programming the service and establishing the computing power to serve a broad user base as well as the high costs of running such a server infrastructure as fixed costs, there exist monopoly tendencies for this market [57]. Future research could build upon our work to investigate those tendencies and their influence on privacy for the SNS market.

5 Conclusion

In this paper we investigated the challenge of user privacy in SNS from an economic perspective. The aim was to analyze if competition between networks tends to decrease or enhance user privacy. Therefore, we first clarified that SNS are multi-sided platforms with at least two sides: users on the one and advertising clients on the other side. Furthermore, we characterized the traded goods within SNS markets from the three viewpoints of users, advertisers and social network operators showing that SNS membership and usage are club goods from user perspective, while targeted advertisement is a private good from an advertiser and SNO viewpoint.

Moreover, SNO compete for advertisers on the one side. On the other side they compete for users' membership and more intensely for users' time. In order to attract the advertisers, providers have to maximize their targeting for advertisements and the time users spend within their platform. Hence, they have the incentive to gather as much personal data from users as possible and enhance their platform with additional content, features and services to bind users' attention and spend time in the SNS. All analyzed factors of competition in the SNS environment contain unilateral privacy threatening aspects. Except for the factor of user trust for an SNS, gained by implementing privacy controls as one aspect to get users to reveal more data. Furthermore, the fact that users do not pay in monetary terms for SNS usage but that advertising clients are the crucial revenue source for SNO suggests that users might be discriminated against and overpriced in terms of personal data disclosure. However, the validation by the MSP theory where the multihoming side is overpriced and the singlehoming side is subsidized provides no sufficient results to verify or reject this assumption. In summary, this analysis shows that competition in the SNS environment does neither generally harm user privacy nor does it necessarily improve it. However, the latter seems less likely, unless the competition for users' trust outweighs all the other privacy divergent aspects. The case of competition in the Internet MSP is complex and current statistics provide not enough data to give a solid answer to the question whether advertisers or users are subsidized by the SNO. Nevertheless, the analysis of our research question shows that competition can be assumed to have a negative influence on user privacy at the present stage.

Abstract. In the last couple of years, organizations have demonstrated an increased willingness to exchange information and knowledge regarding vulnerabilities, threats, incidents and mitigation strategies in order to collectively protect against today's sophisticated cyberattacks. As a reaction to this trend, software vendors started to create offerings that facilitate this exchange and appear under the umbrella term "Threat Intelligence Sharing Platforms". To which extent these platforms provide the needed means for exchange and information sharing remains unclear as they lack a common definition, innovation in this area is mostly driven by vendors and empirical research is rare. To close this gap, we examine the state-of-the-art software vendor landscape of these platforms, identify gaps and present arising research perspectives. Therefore, we conducted a systematic study of 22 threat intelligence sharing platforms and compared them. We derived eight key findings and discuss how existing gaps should be addressed by future research.

Keywords: Information Security, Threat Intelligence Sharing Platform, Information and Knowledge Sharing

1 Introduction

As information systems used in organizations today are characterized by continuously increased complexity, heterogeneity and interconnectedness, the number and complexity of security related incidents increases accordingly [1, 2]. Recent prominent security incidents have shown the growing spectrum of possible attacks and the immense business harm that result from these attacks, including a devastating loss of intellectual property, productivity, money and reputation [1, 3].

Therefore, the protection of an organization's infrastructure, vulnerability management, internal dissemination of cyber security information and security training have become key activities [4]. Beside these traditional countermeasures, there is an observable trend to increasingly exchange information and knowledge between trusted organizations to aid the management of vulnerabilities and threats and to mitigate incidents [5, 6]. To support these efforts, several standards (e.g. CybOX, STIX, or TAXII) have been developed to enable the automated exchange of threat intelligence [7, 8, 9, 10].

February 12-15, 2017, St. Gallen, Switzerland

Sauerwein, C.; Sillaber, C.; Mussmann, A.; Breu, R. (2017): Threat Intelligence Sharing Platforms: An Exploratory Study of Software Vendors and Research Perspectives, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 837-851

In 2013 Dandurand and Serrano introduced the concept of a threat intelligence sharing platform, whose requirements are to: (a) Facilitate information sharing,

(b) enable automation, and (c) facilitate the generation, refinement and vetting of data [11]. Today's threat intelligence sharing solutions more or less build on these requirements and several software vendors are offering products [12]. While there are already a variety of solutions on the market, the majority of publications investigate fundamental requirements and challenges for the development of threat intelligence sharing platforms [11, 13, 12, 14].

To which extent these platforms provide the needed means for threat intelligence sharing remains unclear since no scientific analysis of the state-of-the-art of threat intelligence sharing platforms exists and no empirical research has been conducted yet. To address this gap, we seek to answer the following research questions: (a) *What is the state-of-the-art of threat intelligence sharing platforms?* (b) *What are existing gaps in currently available threat intelligence sharing platforms?* and (c) *What are the implications for scientific research in this area?*

The goal of our research is therefore to provide a comprehensive analysis and comparison of the threat intelligence sharing platform market. Based on our findings we discuss the implications for scientific research and their significance.

To achieve this goal, we conducted a systematic study of 22 threat intelligence platforms, consisting of open and closed source products. We compared these solutions according to different dimensions, such as covered use cases, intelligence sharing functionalities and collaboration capabilities. Based on these results, we derived eight key findings and discuss their implications for scientific research.

Our research has shown that, although the interest in this domain has considerably increased over the past years, a common definition of threat intelligence sharing platforms is still missing. While STIX is the extensive de-facto standard for describing threat intelligence data, most platforms do not fully utilize its descriptive capabilities. This is illustrated by the fact that the majority of platforms primarily focus on the sharing of indicators of compromise.

The remainder of this paper is structured as follows. Section 2 provides related work regarding threat intelligence sharing platforms and related studies. Section 3 outlines the underlying research methodology and procedure carried out. Section 4 discusses the key findings. Section 5 discusses the results and implications for scientific research. Finally, Section 6 concludes the paper and provides outlook on future research.

2 Related Work

In the past, organizations used ad-hoc solutions such as email messages, phone calls, ticket systems, or face-to-face meetings to communicate security related information. Recently, a trend to form interconnected communities of exchange via associated platforms for the (semi-) automated exchange of security related threat intelligence can be observed [12]. Moreover, the exchange of security knowledge between experts across organizations presents a potential countermeasure to protect against today's sophisticated threat actors, as not every organization has the resources to develop an adequate information security program independently, and organizations can benefit from other organizations' experiences and knowledge [5, 15].

Several researchers identified challenges and requirements for threat intelligence sharing platforms [11, 13, 12, 14]. In addition, several standardization efforts have been made to facilitate cyber security data sharing in a standardized manner, e.g. Open Incident of Compromise(OpenIOC), Cyber Observable eXpression (CybOX), Structured Threat Information eXpression (STIX), Incident Object Description Exchange Format (IODEF) or Trusted Automated eXchange of Indicator Information (TAXII) [8, 9, 10]. Moreover these standards form more or less the basis for today's threat intelligence sharing platforms. In order to select the right standard for a particular use case Burger et al. provide an agnostic framework in which standards can be evaluated and assessed [16].

Only a few studies and descriptions of existing threat intelligence sharing platforms can be identified. In [17] the SANS Institute gives an overview of a small selection of open source threat intelligence platforms, including the Collective Intelligence Framework (CIF), Collaborative Research into Threats (CRITs), MANTIS Cyber-Intelligence Management Framework, Malware Information Sharing Platform (MISP), and Soltra Edge, and conclude that the market for threat intelligence sharing is still developing. Brown et al. discuss the community requirements and expectations of an all-encompassing threat intelligence management platform based on studies on a few threat intelligence sharing platforms [12]. These contributions take into consideration only a subset of available threat intelligence sharing platforms without providing a comprehensive analysis of the state-of-the-art. Several tool and vendor studies loosely related to threat intelligence sharing in organizations can be found, e.g. on software vendors in the area of Governance, Risk & Compliance (GRC) management software [18], cloud providers [19] and the security software market [20].

Moreover, as part of our research methodology we use a multivocal literature review [21]. Only few systematic literature reviews using this methodology can be found in information systems research [22, 23, 24]. As outlined by Garousi et al., multivocal literature reviews can be valuable in closing the gap between academic research and practice [25].

To the best of our knowledge, no prior research has been conducted on threat intelligence sharing platforms in order to provide a comprehensive analysis of existing software solutions and research perspectives that could guide research and industry.

3 Research Methodology

Our research is based on an exploratory study carried out in close collaboration with a security expert group developing a nation-wide threat intelligence sharing community in a German-speaking country. It consisted of two parts and was conducted between May 2016 and July 2016. At first two workshops with the community were held to form the basis of our subsequent multivocal literature review on threat intelligence sharing platforms in industrial and academic context. In order to guarantee reproducibility of the applied research methodology, a research protocol was developed, including workshops transcripts, search term definitions, search results, platform selections, data extractions and platform classifications.

3.1 Workshops

Two focus group discussions [26] with respectively ten security experts from industry being members of the aforementioned security expert group were conducted. Table 1 gives an overview of the participants, their organizational roles, qualifications, type and size of their organizations. The findings from the first round were evaluated and refined in the second round. The primary goal of these two workshops was to get an understanding what the participants recognize as threat intelligence sharing platform and to compile a list of platforms they either use or consider for usage at their organization.

Table 1. Overview Workshop Participants

ID	Organizational Role	Qualifications		Type of Org.	# of Employees
		Security Specific Certifications	*University Degree in CS or IS*		
1	Did not disclose	CISSP	x	Finance	>1000
2	Security Operations Team Leader		x		<150

18	Did not disclose	CISSP	x	Finance	>1000
19	Did not disclose				
20	Did not disclose				

The workshops were held in parallel after the participants were instructed by two researchers. The aim of these parallel workshops was to limit bias from other participants and to get more comprehensive results. The researchers asked questions during the discussions to clarify participant’s statements. Each workshop was recorded and then transcribed. Finally, qualitative summaries were produced [27] from the discussions in order to derive keywords and a common understanding for the subsequent multivocal literature review. In addition, a comprehensive list of threat intelligence sharing platforms used by participants was compiled to evaluate the results of the systematic search.

3.2 Multivocal Literature Review

Secondly, we conducted a multivocal literature review (MLR) to identify relevant threat intelligence sharing platforms used in research and practice through a systematic analysis of academic literature and grey literature (e.g. blogs, white papers, webpages) [21, 25]. Moreover, a MLR closes the gap between research and practice [28] and provide a more comprehensive picture on the state-of-the-art of a particular research field [25]. According to that there are no systematic guidelines for conducting MLRs in computer science [25], we oriented us on [23] which conducted a MLR in information system research. In doing so, we derived the following three research steps:

Search Strategy: At first we conducted a systematic search where we used the following academic search engines as well as ordinary web search engines: ACM Digital Library, Cite Seer, ScienceDirect, Google Scholar, IEEE Digital Library, Springer, Scopus, Taylor&Francis and Wiley, Google and Bing. According due that there isn't a common definition and consistent description for the approach of exchanging threat intelligence we derived the following keywords from the discussions during the two workshops: *(Cyber Security OR Threat) AND (Intelligence OR Information OR Data) AND Sharing (Platform OR Tool)* We used these keywords for our search where we tried to identify threat intelligence sharing platforms through analysis of the titles and reading the abstracts of the obtained academic and grey literature. In doing so, we obtained a list of 31 threat intelligence sharing platforms with corresponding references including academic literature as well as grey literature (e.g. white papers, vendor specific web pages). We compared the resulting list of threat intelligence sharing platforms with the list of platforms compiled by the participants of the workshops and with commercial market studies carried out by Gartner [29] and Forrester [30]. The comparison resulted in an unchanged list of 31 threat intelligence sharing platforms for further investigations.

Inclusion and Exclusion: Based on the list of 31 threat intelligence sharing platforms we collected for each platform as many artifacts as possible. These artifacts included websites, white papers, discussions on blogs/forums, technical reports, scientific papers and tool demos. According to that there are apparent issues of reliability and validity associated with grey literature [23] we ranked the quality of the artifacts with respect to the trustworthiness and reliability of the sources. Based on the compiled list of platforms with corresponding references, we applied the following selection procedure: Based on reading of the identified artifacts, we excluded tools that either do not enable the sharing of threat intelligence or do not address organizational cyber security (such as general purpose wikis). We included tools, when the evaluated quality of artifacts was adequate (e.g. websites provided more than a couple of buzzwords), they were published since 2010, and dealing with (cyber security-) threat intelligence sharing. This procedure resulted in a final set of 22 threat intelligence sharing platforms for further analysis.

Classification of platforms: Finally, we analyzed these 22 platforms. At first, we assessed the platforms' web pages and studied the provided documentations. Secondly, if there was a free or trial-version available, the software was tested locally. Since this was not possible for every threat intelligence sharing platform, we also analyzed all product videos that were available. During our gradual approach we analyzed every platform according to the following perspectives: Licensing model, use cases, supported standards, supported threat intelligence constructs, shared information/threat intelligence, sharing functionalities, collaboration capabilities, integration capabilities, analysis, deployment, and provided user interfaces.

4 Study Results and Key Findings

The applied methodology, described in the previous Section identified the following 22 threat intelligence sharing platforms: Accenture Cyber Intelligence Platform, Anomali ThreatStream, Anubis Networks Cyberfeed, BrightPoint Security Sentinel, Collaborative Research into Threats (CRITs), Comilion, Facebook Threat Exchange, Falcon Intelligence Crowdstrike, MANTIS Cyber Threat Intelligence Management Framework, Malware Information Sharing Platform (MISP), McAfee Threat Intelligence Exchange, Microsoft Interflow, Open Threat Exchange (OTX), Soltra Edge, HP ThreatCentral, ThreatCloud IntelliStore, ThreatConnect, ThreatQ, ThreatTrack ThreatIQ, Eclectic IQ, IBM X-Force Exchange, Collective Intelligence Framework (CIF).

The classification and analysis of the identified platforms resulted in eight key findings. They are described in this chapter and examples are given. A summary of the tool classification is also provided in Table 2.

Table 2. Overview analysed tools

Type of platform	**#**	**Supported standards**	**#**
Sharing of threat intelligence	8	STIX	10
Sharing of aggregated data	7	OpenIOC	2
Security information repository	4	STIX & OpenIOC	2
Other	3	IODEF	1
		Other (proprietary)	7
Shared information focuses on		**Licensing model**	
Indicators of Compromise	10	Closed Source (comm.)	16
All types of STIX's constructs	4	Open Source	4
Other	8	Free-to-use	2

4.1 Key Finding 1: There is no common definition of threat intelligence sharing platforms

Beside the standards for describing (e.g. STIX) and sharing (e.g. TAXII) of threat intelligence, research and practice have not yet developed a comprehensive definition and common understanding of what constitutes a threat intelligence sharing platform. Therefore, different types of platforms were identified:

Eight of the identified platforms focus on the sharing of threat intelligence between organizations. While they aggregate information from the users participating in the platform, seven platforms only share only data (and not intelligence in its strictest sense) that is automatically aggregated from various available paid and open information security data sources (cf. Open Source Intelligence). One of the identified platforms provides a hybrid form of a threat intelligence sharing platform, where data from multiple data sources is combined with the threat intelligence provided by participating users. Moreover, there are four tools which only consist of a central repository which provides context specific security information (e.g. information about malware). The two remaining platforms focus on the sharing of technical data (e.g. SNORT rules) between security applications.

Due to this heterogeneity and diversity of threat intelligence platforms, prospective end users are challenged with the selection of a platform for their particular use case.

4.2 Key Finding 2: STIX is the de-facto standard for describing threat intelligence

The landscape of standards available to describe threat intelligence is rather small compared to the number of sharing platforms available. Our analysis showed that most threat intelligence sharing platforms rely on standards such as OpenIOC, STIX, and IODEF. More than two-thirds of the analyzed platforms provide direct import and export capabilities supporting the standards mentioned above. In detail, ten platforms rely on STIX, two on OpenIOC, two on both of them, and one platform on IODEF. For example, the Open Threat Exchange (OTX) platform provides STIX as well as OpenIOC import and export functionalities.

We found that STIX is the most commonly used standard and can be considered as the de-facto standard for describing threat intelligence. It builds upon the CybOX, CAPEC, MAEC and CVRF standards, and provides a unifying architecture tying together a diverse set of cyber threat information [31]. The STIX architecture consists of eight core cyber threat concepts as independent and reusable constructs and takes their interrelationship into account. The eight constructs describing Cyber Observables (e.g. IP addresses, file names, hashes), Indicators, Incidents, Adversary Tactics Techniques and Procedures (including attack patterns, kill chains, etc.), Exploit Targets (e.g. vulnerabilities, weaknesses), Courses of Action (e.g., incident response, mitigation strategies), Cyber Attack Campaigns, and Cyber Threat Actors. These constructs can be - at least partially - found in all analyzed platforms.

Moreover, these constructs can be used to provide meaningful inputs to information security processes like prevention, detection, or response. For example, valuable inputs for response processes are shared Course of Actions with corresponding Incident descriptions.

4.3 Key Finding 3: Platforms primarily focus on sharing of indicators of compromise

The observed platforms primarily focus on the sharing of indicators of com- promise, e.g. the Open Threat Exchange (OTX) platform. Indicator of compromise include information that enable the identification of potentially malicious activities. For example, indicators of compromise are malicious IP addresses, anomalous user activities, descriptions of malicious files, etc. While the OpenIOC standard is primarily designed to share them, the analyzed platforms use the STIX's Observable and

Indicator constructs to describe them. Although the STIX standard is rather expressive (cf. Key Finding 2), the majority of platforms use the two aforementioned STIX constructs.

4.4 Key Finding 4: The Majority of platforms is closed source

There are six free- to-use threat intelligence sharing platforms available on the market, whereof four are open source tools released under the GNU General Public License, including the Malware Information Sharing Platform (MISP), Collective Intelligence Frame- work (CIF), Collaborative Research Into Threats (CRITs) and MANTIS Cyber- Intelligence Management Framework. The Open Threat Exchange (OTX) and Soltra Edge platform are free-to-use but were not released under an open source license. The remaining 16 are closed source.

4.5 Key Finding 5: Most platforms focus on data collection instead of analysis

The "intelligence" provided by the majority of threat intelligence sharing platforms does not constitute "intelligence" in the traditional sense. In the context of information security "intelligence" is the product of the intelligence lifecycle model, which includes several activities like planning, data collection, analysis and, dissemination [32, 33].

However, we found that the majority of tools primarily focuses on data collection and more or less neglects the other activities of the intelligence lifecycle. Therefore, most currently available threat intelligence platforms resemble data warehouses more than "real" intelligence sharing platforms.

Moreover, they provide limited analysis and visualization capabilities and lag behind comparable knowledge sharing platforms and data mining solutions from other domains. This is insofar surprising as the value of these platforms is constrained by the user's ability to interpret, absorb, enhance and react to the provided information [34]. Moreover, only a few platforms provide interfaces for third party tools that would enable further analysis of the received threat information.

Threat intelligence sharing platforms currently provide basic analysis capabilities, such as browsing, attribute based filtering and searching of information. Additionally, only a small fraction of platforms implement pivot functionalities which enable the visualization of relationships between the threat intelligence constructs.

4.6 Key Finding 6: Trust issues between users and platform providers are mostly neglected

Our research showed that there are two possible perspectives on trust: the organization, which uses such a platform, towards the provider and vice-versa. Since organizations may share private or sensitive information it is necessary to establish a trust-bond between organizations and the provider of said threat intelligence sharing platform. Moreover, the provider or other organizations must be able to trust the information provided by a particular organization. This means that users of a threat intelligence sharing platform must be careful when dealing with intelligence provided by the platform. In addition, the access to these platforms must be restricted in order to avoid any unauthorized access. For example, the shared intelligence might be of potential interest to attackers.

In order to overcome these trust and access control issues, threat intelligence sharing platforms must provide control mechanisms to specify what information is shared, how much of it and with whom. In addition, access control plays an important role to these platform, since these platforms might be of potential interest to attackers.

Accordingly, six platforms provide trust modelling functionalities, like forming trusted and closed communities, peer-to-peer connections, anonymization of shared threat intelligence, or policies for maximum control of privacy and security. However, they are mostly limited to group-based access control and ranking mechanisms.

Moreover, this topic gained traction in research as well. For example, Steinberger et al. present a trust model that determines trust ratings for security events [35]. Murdoch and Leaver discuss the barriers to participate in a threat intelligence sharing platform caused by the conflict between the need for anonymity versus the need to trust the shared information [36]. In [37] the authors introduce privacy principles for sharing cyber security data that can reduce the risk of data exposure and help to manage trust.

4.7 Key Finding 7: Academic and commercial interest in threat intelligence sharing increases

In November 2011, the OpenIOC standard was released and laid the foundation for threat intelligence sharing. Between 2010 and 2012 only little attention was drawn to threat intelligence sharing in research and practice. In 2013 Dandurand and Serrano introduced the first concept of a threat intelligence management platform with associated requirements [11]. Between 2013 and 2014 the comprehensive STIX and TAXII standards were released. Since then, the number of publications and vendors providing threat intelligence sharing platforms has grown remarkably. For example, the total amount of publications in 2015 was more than threefold compared to 2014. As the market for threat intelligence sharing platforms is relatively new and still developing [17], it can be expected that the number of platforms and scientific publications will continue to grow in the near future.

4.8 Key Finding 8: Many manual tasks make the user the bottleneck

Threat intelligence sharing platforms provide limited automated data integration capabilities. Therefore, a lot of manual user interaction for sharing and acquiring valuable intelligence is necessary. Moreover, the success of a threat intelligence platform depends on the willingness of users to share intelligence which is limited by the organizations' availability of free resources and the employee's motivation to actively participate. As most platforms lack automated means of intelligence gathering, and more importantly, automatic sanitation of sensitive intelligence, these activities still require manual effort. Beside classical file importing functionalities, most threat intelligence sharing platforms lack convenient user interfaces for quickly adding new data records and require many user interactions to achieve the desired goal.

5 Discussion and Research Implications

In this section we provide a discussion on the limitations of this exploratory study and a discussion on the results and their implications for research.

5.1 Limitations

Our exploratory study might be limited by certain threats to validity. Limitations that have to be acknowledged and accounted for are an (i) incomplete list of threat intelligence sharing platforms, (ii) wrong definition of key words and inclusion/exclusion criteria, (iii) wrong classification and analysis of platforms, and (iv) incomplete or biased descriptions of platforms.

In order to counteract (i), we evaluated the list of identified platforms with the results of our stakeholder workshops and commercial market studies on threat intelligence sharing platforms. However, there might be the possibility of non-identifiable tools if they were released after our cutoff day (after July 2016) or there is not any public information available about them.

There might be the possibility of type (ii) limitations. In order to avoid them the keywords and inclusion/exclusion criteria were developed based on expert opinions collected during our workshops with the stakeholders.

To inhibit (iii), we have chosen a type of cross-validation approach in which each contributor to this research was given a subset of platforms to analyze and classify that intersected with another contributor's set. Hence, classification discrepancies were discovered and limited through re-classification and analysis. Finally, to overcome (iv), we tried to use more than one information source to classify and analyze a platform.

5.2 Discussion of results and implications for research

Our comprehensive exploratory study pointed out that there is an increasing interest in threat intelligence sharing in research and practice, i.e. the number of publications that apply to his research and number of platforms increased over the last three years. Moreover, it seems that there is a different focus in research and practice since several publications discuss the principles of threat intelligence sharing although there are already a variety of solutions on the market. This might be traced back to a missing common understanding of what threat intelligence sharing is about, due to the diversity of threat intelligence sharing platforms. Hence, one of the biggest gaps is the lack of a common definition and characterization of threat intelligence sharing platforms.

Aware of the possible limitations of the research at hand, the following implications for research, based on the eight key findings, can be derived:

Since key finding 1 and 5 showed that software vendors have a different understanding on threat intelligence sharing, it is necessary to develop a standardized definition and characterization of threat intelligence sharing platforms. In this context it might be beneficial to adopt the wide spread intelligence life cycle model, including planning, collection, analysis, and dissemination activities, to the threat intelligence sharing domain in order to generate intelligence. Thereby, it might be necessary to investigate and define how the different activities within the model can be addressed by a threat intelligence sharing platform. Moreover, these standardization efforts might pave the way for a prospective threat intelligence sharing platform which provides "real" intelligence instead of data warehousing and limited data analysis capabilities. Additionally, organizations might benefit from a common understanding as well, since it might simplify the selection of an appropriate threat intelligence platform.

Key finding 2 showed that three standards are used to facilitate the description of threat intelligence of which STIX is the most used. We believe that it is becoming the de-facto standard in the field. STIX is a detailed and extensive standard consisting of eight constructs which enable the description of a broad range of security related information and their relationships. While the number of standards and available exchange formats is limited at the moment, a trend towards use case specific description formats can be observed (e.g. internal sharing vs sharing across the organizational boundaries).

According to key finding 3 the majority of tools only share indicators of compromise which can be described by two constructs of the STIX standard. Based on this observation the following two implications can be derived: (a) Standards for describing threat intelligence are too generic and powerful, or (b) only the low hanging fruits, namely indicators of compromise, are shared at the moment. In order to get deeper insights on this issue, empirical research on the expected, needed and shared information within a threat intelligence sharing platform is needed.

One argument for using a threat intelligence sharing platform is resource reduction through sharing security knowledge and information. However, as outlined in key finding 5, the majority of tools are rather data-warehouses than intelligence sharing platforms. Consequently, organizations must often evaluate the received information which might result in a lot of additional work. In order to address this issue, research in this area should focus on moving away from mere security data sharing towards knowledge and ultimately intelligence sharing.

As key finding 5 showed that threat intelligence sharing platforms suffer from deficient analysis and visualization functionalities and key finding 8 showed that the submission of new threat intelligence is hindered by limited input options, existing platforms and their user interfaces should be scientifically evaluated to identify potential weaknesses and requirements. In doing so, empirical studies on the required functionalities and visualization options of threat intelligence sharing platforms should be conducted.

Key finding 6 showed that trust plays a paramount role in the context of threat intelligence sharing platforms. To some extent threat intelligence platforms already provide preliminary functionalities to establish trust between the collaborators. In order to support the ongoing research and provide a generally accepted model to guarantee trust, empirical research on the sharing behavior of users and their expectations on data privacy and security is needed.

Key finding 7 showed that there is an increasing interest of threat intelligence sharing in research and practice. Additionally, key finding 4 states that the majority of platforms are closed source. Accordingly, there might be a lack of open threat intelligence platforms and open data sets for scientific research, e.g. to conduct empirical studies.

In order to address this gap it might be necessary that research collaborates with industry. Furthermore, such collaborations imply new research questions resulting from arising problems in practice, and provide potential for future research.

In order to address key finding 8 it is necessary to conduct empirical research on how to motivate users and organization to share information on a threat intelligence sharing platform. For example, it might be necessary to develop and evaluate incentive mechanisms to foster the collaboration within threat intelligence sharing platforms.

Our objective is to explore potential research opportunities by pointing to research questions that (1) investigate threat intelligence as an artifact; (2) see threat intelligence data within an ecosystem of competing and complementary frameworks and standards; or (3) evaluate the usage of threat intelligence in organizations.

Threat intelligence as an artifact: There is a clear need to investigate the foundations, design, applicability, and internal consistency (or lack thereof) in threat intelligence sharing formats and standards. For example, the dominating STIX standard includes many significant artifacts that can be used to describe different aspects of cyber threats (e.g. Indicators of Compromise, Techniques-Tactics & Procedures). However, the success of this expressiveness is not yet clear. Furthermore, little is known about the quality requirements for threat intelligence data artifacts [38]. Questions include: (1) *How can the expressiveness of threat intelligence exchange formats be compared?* (2) *Which concepts of threat intelligence formats are superficial?*

Threat intelligence ecosystem: The core principle of the design of most standards for threat intelligence exchange is to align systematically with cognate standards and formats. These include specialized formats (e.g. IOC, CybOX) as well as formats of higher abstraction (e.g. STIX, TAXII). Understanding how threat intelligence analysis operates in an ecosystem of competing and collaborating standards and frameworks is important. Questions include: *(3) How can organizations manage the integration of different threat intelligence data sources?* (4) *How can organizations decide on which data sources to include?* (5) *How can organizations identify missing data sources?* (6) *Are fewer but complex formats better than many, diversified formats?*

Threat intelligence in use: Little is known on the actual value provided to organizations that participate in threat intelligence sharing platform. There is no academic research about the value proposition of threat intelligence sharing platforms. Questions include: (7) *How can an organization evaluate the impact of threat intelligence sharing platforms?* (8) *How is threat intelligence disseminated within organizations?* (9) *What is the impact of threat intelligence sharing on organizational decision making processes?* (10) *How can organizations be motivated to participate in threat intelligence sharing platforms?* (11) *How can trust be established in threat intelligence sharing platforms?* (12) *How can stakeholders be incentivized to participate in threat intelligence sharing platforms?* (13) *Which visualization and query options are required by organizational stakeholders?* (14) *Which impact do different levels of participation have in threat intelligence sharing platforms?*

6 Conclusion

In this paper we presented an exploratory study on software vendors of threat intelligence sharing platforms and derived future research perspectives. Therefore, we conducted two workshops and a Multivocal Literature Review, including academic and grey literature. It identified a list of 22 threat intelligence sharing platforms used in research and practice. With respect to our research questions we briefly analyzed them and elicited eight key findings. For example, our key findings identified that there is an increasing interest towards threat intelligence sharing, research and practice lacks a consistent definition of threat intelligence sharing, and current threat intelligence sharing is comparable to data warehousing and doesn't provide "real" intelligence. Based on the key findings, we discussed several implications for future research focusing on the creation of a common understanding of threat intelligence sharing and the improvement of current practice. Our future work will focus on empirical research in order to provide a common definition and characterization of threat intelligence sharing platforms for research and practice.

Conceptualization of Relational Assurance Mechanisms – A Literature Review on Relational Assurance Mechanisms, Their Antecedents and Effects

Michael Lang[1], Manuel Wiesche[1], Helmut Krcmar[1]

[1] Technical University of Munich, Department of Informatics, Munich, Germany
{michael.lang,wiesche,krcmar}@in.tum.de

Abstract. Assurance mechanisms are an important element of relational governance and frequently used in information systems (IS) research; still missing in this field, however, is a coherent and interrelated structure to organize available knowledge. In this study, we provide a first step towards development of a conceptualization framework of relational assurance mechanisms to enable their further investigation. From our analysis of existing literature, we discover two gaps in assurance research: (1) a fragmentation of assurance research and (2) a lack of conceptual consensus on relational assurance mechanisms. We provide a theoretical framework consisting of a conceptualization of identified relational assurance mechanisms, their antecedents and effects as a means of advancing theory in this area. Several possibilities for future research are discussed.

Keywords: relational governance, relational assurance mechanism, conceptualization, psychological control perspective, literature review

1 Introduction

In recent years, relational governance of inter-organizational relationships has emerged as a dominant perspective in exchange relationships [1]. Within information systems (IS) research, attention has been focused on how relational governance complements formal contracts in order to increase predictability in interactions or expectations within exchange relationships [2].

Within the higher-order construct of relational governance, relational assurance mechanisms (RAMs), such as monitoring or reputation, are particularly known to increase predictability in interactions or expectations within (potential) exchange relationships [3-5]. According to Yamagishi and Yamagishi [6], assurance is defined as an expectation of benign behavior for reasons other than goodwill of the partner [7]. Hence, RAMs may be conceptualized as an important element of relational governance [3-5] although evidence evolving from research is lacking.

We discovered two key gaps in assurance research. Firstly, investigations related to assurance are fragmented and largely independent of RAMs and assurance as a concept. These investigations do, however, offer insights on the relationship between the antecedents and effects of RAMs. Secondly, our data shows that RAMs lack a

Lang, M.; Wiesche, M.; Krcmar, H. (2017): Conceptualization of Relational Assurance Mechanisms - A Literature Review on Relational Assurance Mechanisms, Their Antecedents and Effects, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 852-866

conceptual consensus. Research is at odds when it comes to a consistent interpretation of the effects of RAMs. It is difficult to advance the theoretical and empirical investigation of RAMs, as existing literature does not provide a coherent and cumulative body of work. The gaps we discovered need to be considered when investigating RAMs as an important element of relational governance. In order to address these gaps, this article attempts to answer the following research questions (RQ). *RQ1: What mechanisms of assurance are exemplary discussed in information systems literature? RQ2: Which concepts are relevant when investigating assurance mechanisms and how are these concepts related?* To reach answers to these two questions, we conducted a systematic literature review and analyzed the results of this review in a structured manner.

Using our analysis results, we provide an overview of and conceptualize RAMs as published in IS literature. Furthermore, we point out identified concerns as the antecedents of RAMs, and the effects of RAMs on individuals within a theoretical framework.

The remainder of this article is structured as follows: In the next section, we describe the design of our literature review, including our methods for selecting journals and articles, and the subsequent analysis of the selected articles. Next, we discuss the theoretical background of our work including a psychological perspective of control as a source of assurance, and subsequently present the findings of our literature review. In the final section of the paper, we discuss our findings, address their theoretical implications and identify the limitations of this study.

2 Methodology

To identify relevant literature regarding our RQ1 and RQ2, we conducted a systematic literature review following the guidelines of Vom Brocke, Simons, Niehaves, Riemer, Plattfaut and Cleven [8] for the literature search, Webster and Watson [9] for literature analysis and synthesis, and Müller-Bloch and Kranz [10] to identify the research gap. According to our RQ1, the primary focus of this review is IS literature, identifying the key-concepts regarding our RQs within this research domain. Hence, the initial set of possible journals was limited to IS journals. As a result, all journals of the AIS senior scholars' "basket of 8 journals" were selected. To consider upcoming research topics as well, we also included high-quality, relevant articles from IS conferences.

We scanned journals using the online literature database EBSCOhost, searching for the term *"assurance"* used in the title, abstract, or keywords. For IS conference proceedings, we used the databases AISELNET and IEEE Xplore and searched abstracts for the word *"assurance"*. Articles published before June 2016 were considered. In order to get a broad overview of the concept "assurance" within exchange relationships, the search string was not limited further. As described below, further restrictions were carried out manually as part of the check for topic relevance. Overall, we initially identified 185 articles.

The articles were screened for relevance by reading title, abstract and, if necessary, the full text. In terms of our research, article relevance was defined as: the article uses the construct “assurance” in an exchange relationship context. Therefore, our selection comprises full research articles focusing on inter-organizational relationships, relationships between organizations and people, and inter-personal relationships. We excluded articles focusing on software development or product quality assurance as those do not cover assurance within an exchange relationship context. As a result, a set of 36 articles were included in our analysis. Next, we applied backward and forward search techniques to identify additional articles relevant for our research [8]. In the backward search, we reviewed the reference lists in our set of articles for appropriate articles. Similarly, we reviewed the citations of the articles in our set in Google Scholar. This final search technique yielded a final set of 52 articles.

After having identified the set of relevant articles, two researchers independently reviewed each article and developed an appropriate coding scheme. The researchers then compared their results and discussed any differences in their findings [9]. After three iterations, the researchers agreed on a final coding scheme, which was used for our analysis. This scheme included the used RAM, concerns as RAM antecedents (privacy concerns, security concerns, business integrity concerns), and the effects of the RAM on individuals (beliefs, intentions, behaviors) [10]. According RQ1 and RQ2, this research addresses a “knowledge void” research gap [10]. The final coding is summarized in a table (see Table 3 in the Appendix).

3 Theoretical Background

3.1 Assurance about Partners’ Intentions

Assurance is defined “as an expectation of benign behavior for reasons other than goodwill of the partner” [6]. Therefore, assurance is based on the knowledge of the incentive structure surrounding the relationship of two parties [6]. Such knowledge is particularly important in situations with high environmental uncertainty in which an actor does not have the capability of correctly detecting the partner’s intentions [11].

To gain knowledge of the incentive structure surrounding a (potential) relationship, individuals seek sources which provide additional information about (potential) partners [12]. These sources either accumulate information sufficient for allowing to be certain about (potential) partner’s intentions, provide deterrence against unilateral defection, or induce the partner to take a certain course of action with the use of strategies such as “tit-for-tat” [6, 13, 14]. Each source increase predictability in interactions or expectations within (potential) exchange relationships for reasons other than only the goodwill of the partner.

3.2 A Psychological Perspective of Control as a Source of Assurance

Research on assurance which considers the knowledge about the incentive structure surrounding (potential) relationships is based on a control agency perspective. In particular, this perspective allows not only an examination of the effects of personal control in which the individual acts as an assurance agent to protect information, but also includes proxy control and collective control [15, 16]. In proxy control, powerful others (such as the government and industry regulators) act as the assurance agents [15, 16]. In collective control, a collective acts as the assurance agent [16].

The personal control approach aims to directly assure outcomes from a client's perspective. People experience greater autonomy when they exercise direct personal control as the assurance agent [15-17]. Such control empowers individuals with mutual control over how their data and information, for example, may be used by service providers via technological and non-technological self-protection approaches [6, 15]. By using personal control, actors induce the partner to take a certain course of action with the use of strategies such as "tit-for-tat" [13, 18, 19]. Using these strategies, actors match their own behaviors to those displayed by personal control mechanisms (e.g. cooperating or trustful versus competing or opportunistic) [13].

The proxy control approach aims to indirectly assure outcomes via powerful others [20-22]. Institutional mechanisms are used from partners with few resources or low power to gain assurance through skillful and powerful third parties (e.g. industry self-control or legislation) [16, 23]. These mechanisms enable partners to access resources from third parties, such as knowledge and power, to assure outcomes. In case of opportunistic behavior, these assurance structure provide mechanisms of voice and recourse for the betrayed, which could create strong incentives for firms to refrain from opportunistic behavior and behave appropriately [14, 19, 24].

In the collective control approach, an individual, as a member of a group or collective that serve as an assurance agent, attempts to control the environment or outsiders. In collective control, responsibility, as well as agency, will be diffused among actors [25]. In the collective control approach, individuals attempt to share responsibilities among actors, internalize reference groups, and use their collective knowledge for decision making [16, 26]. Therefore, the collective is responsible for possible positive and negative outcomes to the same extent [16].

4 Findings

We adopted a psychological perspective of control and developed a theoretical framework for RAMs, its antecedents, and effects to provide a comprehensive overview and conceptual consensus for RAMs.

Therefore, the theoretical framework (Figure 1) posits that three sets of RAMs – personal control, proxy control, and collective control – influence individuals' beliefs, intentions, and behaviors when concerns are in place.

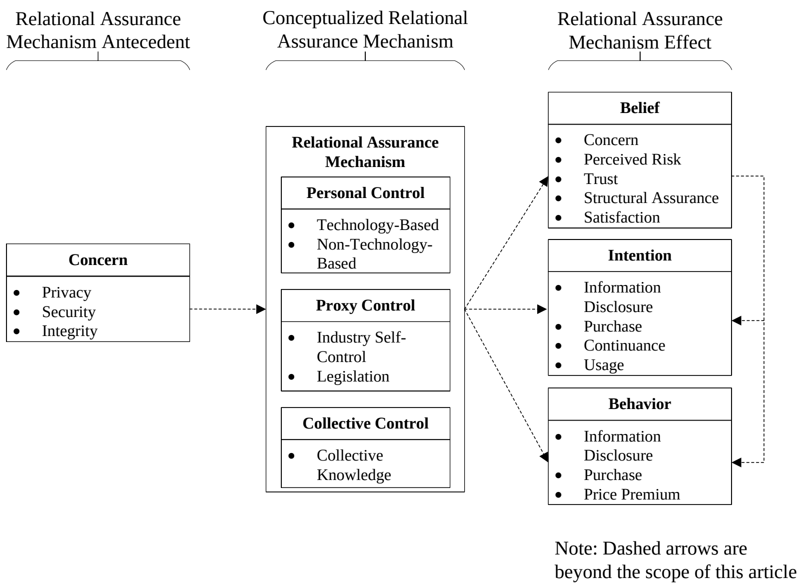

Figure 1. Theoretical Framework for Relational Assurance Mechanisms

Within the following sections, we outline the conceptualization of RAM, its antecedents, and effects in detail.

4.1 Conceptualization of Relational Assurance Mechanism

RAMs provide information about the incentive structure of (potential) partners and therefore, increase predictability in interactions or expectations within (potential) exchange relationships. According this notion, Table 1 summarizes the identified examples of RAMs using the key term "assurance" from our literature review. To distinguish the different examples of RAMs we provide a clear definition for each.

Table 1. Identified Relational Assurance Mechanism Examples and their Definitions

Example	**Definition**	**Source**
Certification	Defines an endorsement from a third-party organization attesting that a (potential) partner adheres to the organization's policy and a set of standards.	[27]
Corporative norm	Cooperative norms are defined as the values, standards, and principles to which a population of organizations adheres.	[28]
Feedback mechanism	Feedback mechanisms accumulate and disseminate information about the past trading behavior of organizations.	[28]
Law	Mandatory legal rules to ensure adequate protection of information.	[15]
Monitoring	A set of activities undertaken to assure that all transactions are performed as specified by a predetermined set of widely accepted agreements and rules.	[28]

Table 1. Identified Relational Assurance Mechanism Examples and their Definitions (Continued)

Example	Definition	Source
Persona-lization	Former mechanism which comprises tools and approaches that enable individuals to directly control outcomes.	[15]
Product description	The extent to which a consumer believes that a website is helpful in terms of fully evaluating a product.	[29]
Redundancy	The inclusion of extra components, which are not strictly necessary to functioning, in case of failure of other components.	[30]
Recommen-dation	A suggestion or proposal as to the best course of action.	[31]
Reputation	Reputation is imperfect and indirect information about a potential partner's traits.	[6]
Site quality	Reflects consumers' overall perceptions of how well they think a site works and looks, particularly in comparison to other sites.	[32]
Social Influence	Individual perceives support in decision making from his or her colleagues and others whose opinions matter.	[26]
Standardi-zation	The extent to which rules, procedures, and standards exist to guide the conduct of an activity and to evaluate performance.	[33]
Statement	A statement supplied by a (potential) partner that provides argumentation and claims to address certain concerns (e.g. privacy concerns).	[34]
Warranty	A warranty signals service quality and provides consumers some assurance in case of service failure.	[35]

Drawing on the work of Yamaguchi [16] on the differentiation of assurance agent perspectives, we conceptualize RAMs using the assurance agent perspectives personal control, proxy control, and collective control and highlight prominent paper examples.

Within personal control, individuals strive for primary control over their environment. For this assurance agent, literature suggest two major types of RAMs: technology-based and non-technology-based approaches [20]. Technology-based approaches include features such as monitoring, personalization, or technology redundancy (e.g. [17, 36]). Non-technological-based approaches are reading corporative norms, product descriptions or statements, providing direct feedback, considering existing warranties, site-quality, or standardization practices (e.g. [36]).

Proxy control describes institutional-based assurance of control whereby powerful forces act as the assurance agents. According to literature, individuals particularly rely on industry self-regulation and legislation to exercise proxy control [15]. Our research identified the use of specific certifications and laws as examples of industry self-regulation and legislation RAMs (e.g. [15]).

In collective control, one attempts to control the environment or outsiders as a member of a group or collective, which serves as an assurance agent. According to Yamaguchi [16], individuals "believe they are more efficacious as a collective than as an individual person". Therefore, individuals use their collective knowledge as a RAM to indirectly control the environment or outsiders. While reputation provides assurance for committed individuals to deal with uncertainty when involved with outsiders, social influence refers to an "individual's internalization of the reference group's subjective culture, and specific interpersonal agreements that the individual has made with others, in specific social situations" [6, 26] (e.g. [27]). Furthermore, by using the collective knowledge provided from internal or external sources, such as recommendations or reviews via feedback mechanisms, individuals overcome their concerns and adopt or continue a relationship [36, 37] (e.g. [38]).

Based on the assurance agent perspective, Table 2 summarizes our conceptualization of RAMs and identifies examples of these mechanisms from our literature review.

Table 2. Conceptualization of Relational Assurance Mechanisms

Assurance Agent	**Relational Assurance Mechanism**	**Identified Examples**
Personal Control	Technology-Based	Monitoring, Personalization, Redundancy
	Non-Technology Based	Corporative Norm, Product Description, Site-Quality, Feedback Mechanism, Standardization, Statement, Warranty
Proxy Control	Industry Self-Regulation	Certification
	Legislation	Law
Collective Control	Collective Knowledge	Reputation, Social Influence, Recommendation, Feedback Mechanism

In order to gain insights about how RAM concepts are interrelated, we next discuss the antecedents of RAMs as identified in literature.

4.2 Concerns as Antecedents of Relational Assurance Mechanisms

Based on the selected literature, we were able to identify three types of concerns that rise an individual's need for RAMs: privacy concerns, security concerns, and business integrity concerns. In the following section, we briefly explain each concern.

Privacy concerns are a primary concern dimension within IS literature, particularly in online transactions [15, 21, 36, 38, 39]. Privacy concerns within an online context are defined as individuals' concerns about the threat to their information privacy when submitting their personal information on the internet [36, 38]. Studies have identified that as privacy concerns increase, individuals seek RAMs [38, 40]; contrastingly, RAMs will lead to lower privacy concerns [15, 39]. Hence, privacy concerns and the presence of RAMs are highly negatively correlated.

Another antecedent of assurance identified in our review are *security concerns* [17, 36, 39, 41]. Based on the dimensions provided by Kim, Sivasailam and Rao [42], we distinguish between three types of security concerns: general security issues, transaction integrity, and authenticity of parties to transact. General security issues consist of insider abuse, unauthorized access, distributed denial of service attacks, and malware [17, 28, 36]. Transaction integrity is based on deletion, duplication, or alteration of documents [39, 43]. Alteration of documents refers to identity theft or authentication issues [44]. Security concerns depend not only on the security level of a firm, but also on the knowledge of individuals: e.g., how effective does the individual perceive the security protection mechanisms to be [39, 45].

Business integrity concerns are almost neglected within IS research even if such concerns have been identified as highly significant inhibitors for adoption decisions [39]. Such concerns are related to how (potential) partners (re-)use collected information from their customers and the possibility that a person or company may not fulfil a promise or complete a task. Especially within high environmental uncertainty, such concerns occur as a result of information asymmetry between (potential) exchange partners [36]. Such concerns may be amplified by the exponential proliferation of online scams and fake websites [42].

In the following section we outline the effects of RAMs on individuals as presented in our literature set.

4.3 Effects of Relational Assurance Mechanisms

This section outlines the effects of RAMs on an individual's beliefs (concern, perceived risk, trust, structural assurance, and satisfaction), intentions (information disclosure, purchase, continuance, and usage), and behaviors (information disclosure, purchase, price premiums).

First, RAMs affect an individual's *beliefs*. As discussed above, RAMs are in place to address certain concerns and therefore, researchers have also examined the effects of RAMs on concerns itself. RAMs, such as laws, certifications, and statements, have negative effects on an individual's concerns [15, 19, 21]. According to Xu, Dinev, Smith and Hart [19], concerns are partly mediated by the individual's perceived sense of control or perceived risk. Furthermore, related to concerns, studies identified the negative effect of product description, site quality, and certification on an indivudal's perceived uncertainty and perceived privacy risk [19, 29, 46]. Contrary to these negative effects, positive effects from RAMs, like certification or statements on trust, have been investigated [34, 36, 47]. Studies point out the positive effects of RAMs on structural assurance beliefs. Structural assurance is defined as the belief that success is likely because contextual conditions, such as statements, certifications and warranties, are in place [48]. Hence, structural assurance represents the perceived effectiveness of RAMs which are in place [49]. Lastly, researchers identified positive effects of perceived monitoring, perceived feedback, and cooperative norms on individual satisfaction with services or products [28].

Second, RAMs affect an individual's *intentions*. All of our identified studies on individuals' intentions considered trusting beliefs as mediators. Such studies point out the positive effects of RAMs, such as statements and site quality, on an individual's intention to disclose information [38, 50]. Furthermore, researchers identified positive effects of RAMs on purchase intentions [36, 39], intention to continue the relationship [28] or intention to use a web site [50]. Since, individuals tend to avoid losses, future research may consider control or risk perceptions as mediators to better explain an individual's intentions [51, 52].

Third, RAMs affect an individual's *behavior*. Studies identified the positive effects of privacy statements, certification, and customization on actual information disclosure [21, 36] and Oezpolat, Gao, Jank and Viswanathan [40] identified the positive effects of certifications on purchasing behavior. Dimoka, Hong and Pavlou [29] identified that product description and certification positivly influence the behavior to pay price premiums. Since the actual behavior can differ from an indiviudal's beliefs and intentions, further research is needed on how RAMs affect an indivudal's behavior [53].

5 Conclusion

This research was motivated by a fragmented body of knowledge, in which recent investigations largely examined assurance independently from the mechanisms and the concept itself. Based on this fragmented research, a conceptual consensus for RAMs is missing, even if RAMs are an important element of relational governance. To address these gaps, we conducted a systematic literature review, and identified examples of RAMs, as reported in IS literature. Based on this comprehensive overview, our subsequent analysis provides a conceptualization of RAMs. Last, our theoretical framework of RAMs further provides insights about antecedents and effects resulting from RAMs.

Before we conclude our major contributions, certain limitations should be considered when interpreting the results. Our literature review focused on RAMs as an important element of relational governance [3-5]. We recognize there are other forms of relational governance mechanisms such as joint actions or trust. While our theoretical arguments should extend to the instantiations of these other mechanisms of relational governance, more empirical work is needed to increase predictability in interactions or expectations within (potential) exchange relationships. Further investigations should particular build on the work of Yamagishi and Yamagishi [6], who distinguish between trust and assurance by taking social uncertainty into account. They claim, assurance is particular important in situations with low social uncertainty, while trust is needed when social uncertainty is high [6]. Another possible area of interest is to consider the influence of RAMs over time. Prior studies already found changes in the relevance of uncertainty for formal governance mechanisms [54, 55].

Our main contribution to the conceptualization framework of RAMs is threefold. First, we provide insights of the interrelation of existing assurance research and offer insights into how RAMs can be conceptualized. Second, we provide a theoretical framework to consider the concepts of RAMs and how these concepts are related to the antecedents and effects of RAMs. Third, we contribute to practice by providing an overview of existing RAMs and their effects [56]. Such findings might be used by practitioners, like security managers or auditing authorities, in order to adopt effective RAMs to increase predictability in interactions within exchange relationships.

Abstract. „Operation Digitales Chamäleon" ist eine IT-Security Schulung in Form eines Serious Games. Zielgruppe des Spiels sind IT-Sicherheitsprofessionals. Teams entwerfen Angriffs- und Verteidigungsstrategien – eingebettet in einen Prozess von Schulung und Debriefing. Die vorliegende Arbeit adressiert die Frage, wie „Operation Digitales Chamäleon" die IT-Security Awareness bei IT-Sicherheitsprofessionals beeinflusst. Hierzu wird im ersten Teil das Design vorgestellt, welches im zweiten Teil um ausgewählte Ergebnisse der Evaluation von sieben Spielen zu Spielerlebnis, Wahrnehmung, Wissensgewinn und geplanten Verhaltensveränderungen ergänzt wird. „Operation Digitales Chamäleon" ist ein Format der IT-Security Matchplays, die im Rahmen des Forschungsprojekts VeSiKi entwickelt und validiert werden.

Keywords: IT-Sicherheit, Sensibilisierung, IT-Security Awareness, IT-Security Matchplay, Serious Game

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Rieb, A.; Hofmann, M.; Laux, A.; Rudel, S.; Lechner, U. (2017): Wie IT-Security Matchplays als Awarenessmaßnahme die IT-Sicherheit verbessern können, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 867-881

1 Einführung

Smartphone-Sticker, Kaffeetassen, Poster, Schulungen und Trainings – die Liste der Maßnahmen, die Anwender oder Mitarbeiter für das Thema IT-Sicherheit sensibilisieren sollen, ist lang. Spaß macht das Thema IT-Sicherheit meistens nicht. IT-Sicherheit Kritischer Infrastrukturen (KRITIS) ist ein neues Thema in der IT-Sicherheit, das die Absicherung von Produktionsanlagen, Logistikketten o.a. thematisiert. Stuxnet hat das Thema IT-Sicherheit für Kritische Infrastrukturen bekannt gemacht. So ist es notwendig, dass sich Mitarbeiter mit dem Thema IT-Sicherheit auseinandersetzen, die bisher die IT lediglich als Enabler im Rahmen der Unternehmensprozesse genutzt haben. Ebenso müssen sich IT-Professionals über IT-Sicherheit von Anlagen Gedanken machen, die bisher nicht als IT-Sicherheitsrisiko betrachtet wurden. Im Spannungsfeld von unpopulärer IT-Sicherheit und drängender Notwendigkeit Kritische Infrastrukturen abzusichern, soll „Operation Digitales Chamäleon“ Mitarbeiter sensibilisieren und befähigen, adäquat auf Bedrohungen der IT-Sicherheit zu reagieren.

„Operation Digitales Chamäleon“ ist eine IT-Sicherheitsschulung, die als ein Serious Game konzipiert und im Rahmen des Forschungsprojektes „Vernetzte IT-Sicherheit Kritischer Infrastrukturen” (VeSiKi) als Teil der IT-Security Matchplay Serie entwickelt und validiert wird. Das Serious Game basiert auf dem Format Wargaming und integriert Elemente der IT-Risiko- und IT-Bedrohungsanalyse. Ziel ist es, IT-Sicherheitsverantwortliche und IT-Sicherheitsprofessionals im Umgang mit Advanced Persistent Threats (APTs) zu schulen, wie sie typisch sind für KRITIS. APTs sind ausgeklügelte, dauerhafte und verschleierte Cyber-Bedrohungen [1]. Symantec beschreibt dies als “An advanced persistent threat (APT) uses multiple phases to break into a network, avoid detection, and harvest valuable information over the long term.“ und vermutet dass „Betrug – oder Schlimmeres“ Teil von APTs sind [2][3]. Zudem modifizieren die Angreifer während ihrer APT-Attacken regelmäßig ihre Angriffsvektoren und ihren Schadcode, um eine Entdeckung zu erschweren [4].

Dieser Artikel erweitert erste Publikationen zum Serious Game „Operation Digitales Chamäleon“. In [5] wurde „Operation Digitales Chamäleon“ als Instrument der Open Innovation mit einer Analyse des Innovationsgrads der APTs aus Spielergebnissen präsentiert. Das Spiel mit ausgewählten Spielergebnissen sind in einem Short Paper dargestellt [6].

2 State of the Art – IT-Security Awarenessmaßnahmen

„Operation Digitales Chamäleon“ wurde als IT-Security Awarenessmaßnahme konzipert. Im ersten Abschnitt wird der State of the Art in IT-Sicherheitsmaßnahmen vor allem in der Praxis zusammengefasst, während im zweiten Abschnitt vor allem der Stand der wissenschaftlichen Literatur zu Awareness dargestellt ist. In beiden Abschnitten sind die Verbindung von (passivem) „Wissen” zu (aktivem) „richtigen Handeln” sowie die Evaluation des Erfolgs besonders berücksichtigt. Der dritte Abschnitt ist „Serious Games” als Methode im Themenfeld IT-Sicherheit gewidmet.

2.1 IT-Security Awareness und Sensibilisierung in der Praxis

Maßnahmen zur Sensibilisierung für das Thema IT-Sicherheit (auch bezeichnet als IT-Security Awareness) sind in der Praxis weit verbreitet. So werden international bspw. in [7] und [8] verschiedene Maßnahmen inkl. Vor- und Nachteilen beschrieben. In einer Studie aus dem Jahr 2007 wurde u.a. untersucht, welche Maßnahmen in der Praxis eingesetzt und wie der Erfolg dieser Maßnahmen gemessen wird [9]. Das Bundesamt für Sicherheit in der Informationstechnik (BSI) bzw. die Allianz für Cyber-Sicherheit zu IT-Security Awareness stellt in ihrer Studie von 2015 [10] fest, dass 63% der Befragten angeben, dass IT-Security Awarenessmaßnahmen in der Organisation durchgeführt werden und dass Awarenessmaßnahmen überwiegend eine Präventivmaßnahme aufgrund wachsender Risiken sind. Als Maßnahmen werden angeführt (in absteigender Reihenfolge der Nennung): Dienstanweisungen/Vorschriften/Policies, Schulungen/Seminare in Gruppen, Informationskampagnen (z.B. Flyer, Poster), Mitarbeiterveranstaltungen (z.B. Roadshow), Einzelunterricht/E-Learning, Testszenarien zur Prüfung des Mitarbeiterverhaltens und andere; wobei als wesentliche Medien Intranet, E-Mail, Folienpräsentationen und Broschüren/Flyer, Poster und Mitarbeiterzeitschriften sowie Videos genannt werden. (Gewinn-)Spiele spielen nur eine untergeordnete Rolle. Diese Maßnahmen werden überwiegend nur sporadisch durchgeführt und eine Erfolgsmessung bleibt meistens aus. Nur ein kleiner Prozentsatz der befragten Unternehmen wertet die Sicherheitsvorfälle zur Erfolgsmessung der Awarenessmaßnahmen aus. Diese Zahlen und Daten decken sich mit der Erfahrung der Autoren dieses Artikels – interaktive Formate für IT-Security Awarenessmaßnahmen werden nur selten verwendet und der Nutzen für die IT-Sicherheit kaum evaluiert.

Für die IT-Sicherheit Kritischer Infrastrukturen stellt das BSI als maßgebliche staatliche Organisation in Deutschland Referenzwerke der Informationssicherheit bereit. Je nach Quelle ist auch von „IT-Sicherheit" die Rede, jedoch wird derzeit dieser Begriff durch den Begriff „Informationssicherheit" ersetzt. Grund dafür ist, dass sich IT-Sicherheit primär mit dem Schutz elektronisch gespeicherter Informationen und deren Verarbeitung beschäftigt, während Informationssicherheit als umfassender zu betrachten ist [11]. Innerhalb der o.a. Referenzwerke beschreibt das BSI auch Maßnahmen zur Sensibilisierung für das Thema Informationssicherheit und motiviert wie folgt: „Aufgrund der Entwicklung, dass inzwischen weder technische noch organisatorische Schutzmaßnahmen allein wirkungsvoll gegen Cyber-Bedrohungen schützen, rückt der Nutzer zunehmend in den Fokus. Er ist bei vielen Arten von Cyber-Angriffen noch häufig als das schwächste Glied in der Angriffskette zu sehen. […] Die kontinuierliche Sensibilisierung von Mitarbeitern für die bestehenden Risiken ist daher unerlässlich." [12]. Als Ziel wird genannt, die „Informationssicherheit in unser tägliches Handeln zu überführen". Als Aufgaben werden bspw. angeführt: „Vermittlung der Ziele der Informationssicherheit", „Empowerment, d.h. Vermittlung (praktischer) Kompetenzen hinsichtlich der Umsetzung von Regelungen" oder „Positionierung von Informationssicherheit durch Kommunikation von Security-Themen,-Aufgaben, -Tools und -Protagonisten mit dem

Ziel, Bekanntheit und Akzeptanz zu steigern bzw. in der Unternehmenskultur als Teil der Sicherheitskultur zu etablieren." [12].

Im Baustein der IT-Grundschutzkataloge zu „Sensibilisierung und Schulung zur Informationssicherheit" (B 1.13) [13] wird motiviert „alle Mitarbeiter erkennen und akzeptieren, dass [die Informationssicherheit] ein bedeutender und notwendiger Faktor für den Erfolg der Institution ist und [die Mitarbeiter] bereit sind, Sicherheitsmaßnahmen wirkungsvoll zu unterstützen". Die Akzeptanz von Sicherheitsmaßnahmen zielt auf „langfristige Verhaltensänderungen" ab, besonders wenn Informationssicherheit mit Komfort- oder Funktionseinbußen verbunden ist [13]. Planspiele werden als eine Maßnahme (M 3.47; [14]) empfohlen, um die Sensibilisierung und Schulung zur Informationssicherheit erfolgreich zu gestalten. Es ist wichtig, „eine positive und konstruktive Grundstimmung" in Planspielen zu haben – denn „Ständige Angst vor Sicherheitsvorfällen kann einerseits zur Verdrängung von Sicherheitsproblemen und andererseits zu Panikreaktionen verleiten." [14]. Das BSI sieht in seinen Referenzwerken der IT-Sicherheit Sensibilisierung der Mitarbeiter als wichtiges Element einer IT-Sicherheitsstrategie an und zeigt auf, dass Planspiele oder Rollenspiele ein geeignetes Instrument wären, Mitarbeiter in einer positiven Atmosphäre zu schulen – im Baustein Planspiele jedoch gibt es außer drei Themen wenig Konkretes zu Planspielen für IT-Sicherheit.

An dieser Stelle soll erwähnt werden, dass sowohl Planspiele als auch Rollenspiele Formen von Serious Games sind [15]. In der Praxis, wie auch in der Literatur werden diese Begrifflichkeiten jedoch häufig synonym verwendet [16].

2.2 IT-Security Awareness aus Sicht der Wissenschaft

Die ausgezeichnete Literaturübersicht von Hänsch und Benenson systematisiert die Definitionen der IT-Security Awareness in Wahrnehmung (Perception), Schutz (Protection) und Verhalten (Behavior) mit den Fähigkeiten Bedrohungen zu erkennen (recognize threat), Wissen über Lösungen zu haben (know solutions) und richtig zu handeln (act right) [17]. Betrachtet werden in dieser Übersicht auch Messkriterien für IT-Security Awareness. Während Wahrnehmung und Schutz – entsprechend dieser Literaturübersicht – in verschiedenen Ansätzen gemessen werden kann, finden sich zu IT-Security Awareness für „richtiges Handeln" nur wenige Methoden.

Die Forschung von Bulgurcu et al. illustriert die zentrale Rolle von IT-Security Awareness: Awareness beeinflusst mittelbar Nutzen von Compliance genau wie wahrgenommene Kosten von Compliance und von Non-Compliance [18]. Nach Johnston und Warketing genügen Wissen über Bedrohungen und Verwundbarkeiten nicht, sondern reduzieren Wirksamkeit und Selbstvertrauen (Response, Self Efficacy) und damit die Bereitschaft (richtig) zu handeln [19].

Das Konzept von IT-Security Literacy schlägt ähnlich wie IT-Security Awareness den Bogen zwischen „Wissen" und „Wahrnehmung" zu „richtigem Handeln" in der IT-Sicherheit speziell in Schulungen und Trainings (vgl. bspw. [20]).

2.3 Serious Games in der IT-Sicherheit

„Operation Digitales Chamäleon“ wurde unter anderem entwickelt, um IT-Sicherheitsverantwortliche und IT-Sicherheitsprofessionals in spielerischer Art und Weise zu sensibilisieren. Die Methode Wargaming, die wir für „Operation Digitales Chamäleon“ adaptieren, hat eine lange Tradition: In der Literatur hat Wargaming seinen Ursprung im 19. Jahrhundert, als Baron von Reisswitz diese Methode nutzte, um Kommandostäbe in ihrer Entscheidungsfindung ,,besonders in dynamischen und unvorhersehbaren Situationen zu schulen“ [21]. Charakteristisches Element des Wargamings ist die durch Regeln gesteuerte und von Schiedsrichtern bewertete Auseinandersetzung der Ideen und Pläne zumindest zweier Teams (Rot und Blau). Die Methode wird vor allem für effektives Training von Kommandostäben verwendet, seltener auch zum Erforschen komplett neuer Bedrohungen. Jedoch ist Wargaming in der Domäne IT-Sicherheit eher neu.

2012 gab ENISA einen Überblick über 85 IT-Security Übungen [22]. Die meisten davon waren theoretische Übungen “to validate plans and integration of procedures prior to moving on to more complex, team-based activities” [22]. Ziele dieser IT-Security Übungen waren u.a. die Steigerung von IT-Security Awareness bzgl. Cyber-Bedrohungen, Rollenidentifikation, Klärung von Verantwortlichkeiten und zuständigen Behörden, Entscheidungsfindung, Überprüfung des Incident Managements oder Vertrauensbildung zwischen Staaten [22]. 2015 wurde der ENISA-Bericht um mehr als 200 Übungen erweitert [23]. Hier hebt ENISA Methoden wie Red Teaming, Diskussionsbasierte Spiele, Capture the Flag, Seminare und weitere hervor. Gemäß ENISA [23] wird nur ein Bruchteil (11%) der Übungen mit gegenüberstehenden Teams durchgeführt.

Weitere Serious Games für IT-Sicherheit sind beispielsweise „Friend Inspector“ – ein softwarebasiertes Serious Game zur Steigerung der IT-Security Awareness unter Facebook-Nutzern [24][25]. Das Kartenspiel „Elevation of Privilege“ dient ebenfalls der Steigerung von IT-Security Awareness, jedoch stehen hier Softwareentwickler im Vordergrund [26]. Die Zielgruppe „Mitarbeiter eines Unternehmens“ adressiert das Kartenspiel von Beckers und Pape zu Gefahren und Methoden des Social Engineerings [27]. „Game of Threats“ adressiert das Management [28].

3 Methode

In der Forschung orientiert sich dieser Beitrag am Paradigma der gestaltungs-orientierten Forschung (Design Science) von Hevner et al. [29]. Wir verwenden einen iterativen Ansatz in Design und Evaluation mit einem kreativen Designprozess – so wie es bspw. Baskerville und Pries-Heje beschreiben [30]. Dieser kreative Designprozess bezieht insbesondere die mehr als 10 jährige Erfahrung des ersten Autors als IT-Security und IT-Security Awareness Spezialist mit ein.

In der Datengenerierung hat der erste Autor des vorliegenden Artikels als Spielleiter die Daten gesammelt, Umfragen durchgeführt und Beobachtungen protokolliert. In einem Fall wurde er von einem Beobachter in der Datensammlung unterstützt.

4 Das Spieldesign von „Operation Digitales Chamäleon”

„Operation Digitales Chamäleon“ ist als IT-Security Awarenessmaßnahme konzipiert und speziell entwickelt für die Schulung zum Thema IT-Sicherheit Kritischer Infrastrukturen. Diese Schulung umfasst neben der eigentlichen Spielphase eine Phase der Wissensvermittlung zu aktuellen IT-Sicherheitstechnologien und -bedrohungen mit ggf. Live-Hackings sowie eine Phase des Debriefings, die u.a. auch eine Umfrage beinhaltet. „Operation Digitales Chamäleon“ ist ein Planspiel und verwendet „traditionelle“, also nicht IT-gestützten Spielmaterialien.

4.1 Teams und Zielgruppe

„Operation Digitales Chamäleon“ ist als IT-Security Awarenessmaßnahme für IT-Sicherheitsverantwortliche und IT-Sicherheitsprofessionals als Zielgruppe konzipiert. Spielteilnehmer füllen in ihren Organisationen IT-Sicherheitsfunktionen aus oder haben berufliche Erfahrung im Themenfeld IT-Sicherheit (bspw. IT-Sicherheitsadministratoren auf operativer Ebene, IT-Security Manager). „Operation Digitales Chamäleon“ wird mit einer Gruppe von 8 bis 20 Personen durchgeführt.

Im Serious Game tritt diese Zielgruppe in Teams gegeneinander an: Team Rot als Angreifer gegen Team Blau als Verteidiger – ein weißes Team übernimmt Spielleitung und Schiedsrichterfunktion. Typischerweise haben Team Rot und Team Blau jeweils drei bis sieben Mitglieder.

Zu Beginn wählt Team Rot eine von fünf vorgegebenen Angreiferrollen (Threat Actors). Die Angreiferrolle beschreibt die Motivation und die Fähigkeiten des Threat Actors, die Grundlage für die zu planenden Angriffsstrategien bilden. In „Operation Digitales Chamäleon“ stehen insgesamt fünf verschiedene Angreiferrollen bzw. Threat Actors zur Verfügung: Script Kiddies, Cyber Criminals, Employees, Nation States und Hacktivists. Die Rolle „Hacktivists“ ist bspw. auf der Basis von Hald und Petersen [31] in den Spielunterlagen beschrieben: Ruhm, Ehre oder ein „moralischer Grund” sind die Motivationen, die finanziellen Ressourcen sind limitiert, jedoch sind die technischen Fähigkeiten „gut“.

Team Blau verteidigt die Kritische Infrastruktur und dem Team ist bekannt, welcher Threat Actor sie angreifen wird. So hat Team Blau die Aufgabe, sich in die Rolle des Angreifers hineinzuversetzen, die kritischen Assets (z.B. Personen, Netzwerkkomponenten, IT-Systeme u.a. Vermögenswerte) zu identifizieren und die IT-Sicherheitsmaßnahmen spezifisch auf zu erwartenden Angriffe auszurichten. Team Blau etabliert Schutzmaßnahmen zu den Faktoren Organisation, Technik und Mensch und erstellt ein IT-Sicherheitskonzept.

Team Weiß trifft als Spielleitung die Entscheidungen über den Spielablauf und überwacht die Einhaltung der Regeln. Beobachter oder Experten dokumentieren Spielverlauf und Ergebnisse und wirken bei der Ermittlung des Siegerteams mit.

Team Rot und Team Blau haben je einen Teamleiter, der durch Losverfahren bestimmt wird. Die Teamleitung organisiert die Teamarbeit, präsentiert die Ergebnisse und wählt (im Fall Rot) die Angreiferrolle.

4.2 Spielbrett und Spielmaterialien

„Operation Digitales Chamäleon“ verwendet konventionelle, nicht-digitale Spielmaterialien. Dazu gehören u.a. ein Spielbrett, auf dem ein Netzplan mit IT-Infrastrukturkomponenten abgebildet ist, wie sie für Kritische Infrastrukturen typisch sind (siehe Abbildung 1). Assets dieses Netzplans sind u.a. eine Industrieanlage sowie Windows PCs mit verschiedenen älteren, teilweise nicht mehr unterstützten Betriebssystemen. Zudem beinhaltet der Netzplan einen Fernwartungszugang, mobile Clients und ein Office-Teilnetz mit aktuelleren Betriebssystemen, Servern und Druckern. Die Teilnetze werden zu Beginn des Serious Games nur durch Router geschützt.

Abbildung 1: Das Spielbrett zu „Operation Digitales Chamäleon“

Mit Karten wird markiert, welches Asset der IT-Infrastruktur angegriffen bzw. verteidigt wird. Auf Post-Its werden Ideen zu Angriffsvektoren oder Schutzmaßnahmen notiert. Das Spielmaterial beinhaltet (pro Team) Karten, die die Rollen beschreiben, einen Satz Spielregeln, sowie Stifte für Notizen auf dem Spielbrett. Spielleibchen in den Farben Rot, Blau oder Weiß markieren die Teamzugehörigkeit. Dem Spielleiter bzw. dem weißen Team stehen für die Unterstützung der Entscheidung über die Machbarkeit diverser Angriffe oder Schutzmaßnahmen Zufallskarten mit unterschiedlichen Wahrscheinlichkeiten zur Verfügung.

4.3 Spielregeln, Spielablauf und Spielmissionen

Zu Beginn der Spielphase wird die Rahmenlage durch die Spielleitung präsentiert. Team Rot wird vorgegeben, dass der Angriff entsprechend der gewählten Spielerrolle eine Wirkung entfalten muss, die es notwendig macht, das BSI entsprechend den Meldepflichten – so wie sie im IT-Sicherheitsgesetz festgelegt sind – zu informieren [32].

Die Teams werden im Briefing ermuntert kreativ zu sein. Somit sind der Phantasie im Spiel nur wenig Grenzen gesetzt – es limitieren Spielzeit und Plausibilität.

Team Rot nimmt die Sicht des gewählten Threat Actors ein und soll einen Angriffspfad entwickeln, der für diese Angreiferrolle hinsichtlich Absichten, Ressourcen und Methoden typisch ist. Dieser Angriffspfad besteht aus voneinander abhängigen und ggf. alternativen Angriffsvektoren. In den weiteren Spielmissionen bekommt Team Rot die Aufgabe, Alternativen zu den einzelnen Angriffsvektoren zu definieren und den Angriffsbaum auch zu präsentieren.

Das blaue Team verfolgt das Ziel, die bevorstehenden Cyberangriffe erfolgreich abzuwehren. Team Blau entwickelt ein IT-Sicherheitskonzept sowie Schutzmaßnahmen zu den Faktoren Organisation, Technik und Mensch. Die Regeln des Spiels legen fest, dass die IT-Sicherheitsstrategie von Team Blau jedoch nicht zu Lasten der Verfügbarkeit und Nutzerfreundlichkeit der IT der KRITIS gehen darf. Die Regeln geben ebenfalls vor, dass die Mitarbeiter (der KRITIS) die Internetanbindung auch für Internetdienste wie Facebook nutzen. Ferner dürfen Netzverbindungen und Fernwartungszugänge nicht aus Gründen der IT-Sicherheit gekappt werden. Solche und andere der Realität entsprechenden Prämissen verhindern, dass Team Blau die „sicherste“ Lösung – das dauerhafte Trennen sämtlicher Internetverbindungen – wählt. Team Blau ist so gefordert, kreative Lösungen zu entwickeln, um die Angriffe von Team Rot zu antizipieren und abzuwehren.

In der Ermittlung des siegreichen Teams sind Nachvollziehbarkeit in der Argumentation und Transparenz der Entscheidungsfindung wichtig. Die Teams präsentieren die erarbeiteten Lösungen. Die Spielleitung geht Angriffsvektor um Angriffsvektor durch und bezieht die Teams in die Diskussion mit ein. In dieser Bewertung finden drei Kriterien Anwendung: (Technische) Machbarkeit (1), Plausibilität (2) und Erfolg im Hinblick auf Schutzmaßnahmen, die von Team Blau festgelegt wurden (3). Für Fälle, in denen keine eindeutige Entscheidung in der Diskussion getroffen werden kann, hilft „der Zufall“, implementiert als Spielkarten.

Die Teams erhalten einen Ordner mit Informationen über den Spielablauf und den Spielregeln. Diese legen beispielsweise fest, dass außerhalb der Spielzeiten nicht an der Weiterentwicklung der Strategie im Team gearbeitet werden darf. Zudem dürfen die Teams keine IT-Unterstützung in Form von Laptops, Smartphones o.ä. nutzen.

4.4 Das Debriefing

Ein Debriefing gibt den Teilnehmern die Möglichkeit, ihre persönlichen Erkenntnisse zu reflektieren und gibt Anregungen, das im Spiel Erfahrene in den Arbeitsalltag zu übernehmen. Hier folgt das Spiel den Anregungen von Kriz [33]. Wesentliche Ergebnisse, die im Rahmen dieser Debriefings gewonnen wurden, werden im nächsten Abschnitt vorgestellt.

5 Ergebnisse der „Operation Digitales Chamäleon“

Der nachfolgende Abschnitt stellt wesentliche Ergebnisse der gespielten Serious Games „Operation Digitales Chamäleon“ vor. Hierbei stützt sich die Empirie auf sieben Spiele, die in Tabelle 1 gelistet sind.

Tabelle 1. Durchgeführte Spiele „Operation Digitales Chamäleon"

#	Datum	Dauer Training	Dauer Spiel	Teil-nehmer	Anzahl rote Teams	Anzahl blaue Teams	Sektor	Länder-code
1	10/2015	3d	6h	11	1	1	Staat und Verwaltung (Polizei, Justiz)	DEU
2	01/2016	5d	9h	9	1	1	Transport und Verkehr (Luftfahrt)	FRA
3	03/2016	2d	6h	10	1	1	Staat und Verwaltung (Polizei)	DEU
4	03/2016	2d	10.5h	19	3	1	Staat und Verwaltung (Militär)	DEU
5	05/2016	2d	10h	18	2	1	Staat und Verwaltung (Militär)	DEU
6	05/2016	2d	10h	20	3	1	Staat und Verwaltung (Militär)	DEU
7	07/2016	2d	10.5h	17	3	1	Staat und Verwaltung (Militär)	DEU

Es ist zu beachten, dass in dem iterativen Vorgehen beim Design des Serious Games auch die Evaluation weiterentwickelt wird. So wurde der Fragebogen zur Evaluation des Spiels erst ab Spiel #4 eingesetzt. Ergebnisse wurden in den Spielen #2 und #3 mittels Post-Its im Rahmen einer moderierten Gruppendiskussion erhoben. Spiel #1 diente als Pretest mit Fokus auf die Spieldurchführung – hier wurden Notizen des Spielleiters während des Debriefings angefertigt.

5.1 Spielerlebnis

Spielerisches Lernen wird mit Spaß assoziiert und eine positive, angstfreie Atmosphäre ist entsprechend den Empfehlungen des BSI und den empirischen Resultaten (vgl. Kap. 2.1 und 2.2) wichtig für den Erfolg von Schulungen und speziell Sensibilisierungsmaßnahmen. Dies steht in Einklang mit den Empfehlungen zur Entwicklung von Serious Games (z.B. [34]). Gemäß McConigal ist Spaß während des Spielens eine wichtige Voraussetzung zur Steigerung der Motivation der Teilnehmer und der Qualität der Spielergebnisse [35]. Killmeyer definiert den Faktor Spaß ebenfalls als wichtige Voraussetzung für eine erfolgreiche IT-Sicherheitssensibilisierung [36]. Tabelle 2 zeigt die Ergebnisse der Spielevaluation per Fragebogen zur Aussage „Das Cyberwargame hat mir Spaß gemacht".

Tabelle 2. Spaßfaktor in Spiel #4 bis #7

Aussage	*Trifft nicht zu*	*Trifft eher nicht zu*	*Neutral*	*Trifft teilweise zu*	*Trifft voll zu*
Das Cyberwargame hat mir Spaß gemacht.	0	3	4	41	26

„Operation Digitales Chamäleon" hat den meisten Spielteilnehmern Spaß gemacht. Beobachtungen seitens des Spielleiters bestätigen dieses Ergebnis: Während der Durchführungen konnten des Öfteren Reaktionen wie „lautes Lachen" beobachtet werden. In allen Spielen herrschte eine konzentrierte, aber lockere Atmosphäre – keiner der 104 Spielteilnehmer der ersten sieben Spiele ist vorzeitig ausgestiegen. Eine positive Arbeitsstimmung ist wesentliche Voraussetzung für den (langfristigen) Erfolg der Sensibilisierungsmaßnahme und damit für die Verbesserung der IT-Sicherheit wie in den folgenden Kapiteln dargestellt.

5.2 Wahrnehmung

IT-Security Awareness beinhaltet die Wahrnehmung (Definitionen Awareness Kap. 2.2) von Gefahren und Risiken. Im Debriefing von Spiel #4 bis #7 wurde ermittelt, ob „Operation Digitales Chamäleon“ die Wahrnehmung verbessert.

Tabelle 3. Risikobewusstsein / Bedrohungseinschätzung in Spiel #4 bis #7

Aussage	*Trifft nicht zu*	*Trifft eher nicht zu*	*Neutral*	*Trifft teilweise zu*	*Trifft voll zu*
Ich stelle für mich eine Steigerung meines IT-Risikobewusstseins fest.	1	3	9	34	27
Ich kann die Komplexität von Bedrohungen auf die IT-Infrastruktur besser einschätzen.	0	4	9	46	15

Tabelle 3 stellt dar, dass „Operation Digitales Chamäleon“ sowohl das IT-Risikobewusstsein, als auch die Fähigkeit, die Komplexität von Bedrohungen auf die IT-Infrastruktur einschätzen zu können, positiv beeinflusst. Der Selbsteinschätzung der Teilnehmer nach, ist das Spiel nicht nur geeignet (Fakten-) Wissen zu vermitteln, sondern schlägt die Brücke zu Wahrnehmung und richtigem Handeln (vgl. Kap. 2.2).

5.3 Wissensgewinn

Im Debriefing von Spiel #4 bis #7 wird im Fragebogen nach dem Wissenszuwachs gefragt und die Mehrheit stellt einen Wissenszuwachs für sich fest (vgl. Tabelle 4).

Tabelle 4. Wissensgewinn in Spiel #4 bis #7

Aussage	*Trifft nicht zu*	*Trifft eher nicht zu*	*Neutral*	*Trifft teilweise zu*	*Trifft voll zu*
Ich stelle für mich einen Wissenszuwachs am Ende der Veranstaltung fest.	0	1	4	28	41

In einer zweiten, offenen Frage (Durchführung #4 bis #7) oder in einem Debriefing über Post-Its werden die Spielteilnehmer nach dem Wissensgewinn gefragt. Nach sieben Durchführungen stehen 144 Aussagen zur Auswertung zur Verfügung. In einer qualitativen Inhaltsanalyse nach Mayring [37] werden diese 144 Aussagen in die drei Hauptkategorien „Wissen über Angriffe“, „Wissen über Schutzmaßnahmen“ und „Sonstiges Wissen“ einsortiert.

Die beiden Kategorien „Wissen über Angriffe“ mit 57 Aussagen sowie „Wissen über Schutzmaßnahmen“ mit 66 Aussagen sind in etwa gleich stark ausgeprägt („Sonstiges Wissen“ mit 21 Aussagen). Dieses Ergebnis ist bemerkenswert: Die „böse Seite“ – also das rote Team – hat die kreativere Rolle und so wäre eine intensivere Auseinandersetzung mit Angriffen, also mehr Nennungen in der Kategorie „Wissen über Angriffe“ zu erwarten. Zudem sind in den sieben Spielen mehr rote als blaue Teams angetreten und zusätzlich werden in der Wissensvermittlung bspw. in Live-Hackings Angriffe plastischer behandelt als Schutzmaßnahmen. Dies illustriert, dass

„Operation Digitales Chamäleon“ zur Auseinandersetzung mit Schutzmaßnahmen anregt – entsprechend dem Forschungsziel, IT-Sicherheit für KRITIS zu verbessern.

Eine zweite Inhaltsanalyse der Aussagen zu „Technik“, „Organisation“, „Mensch“, und „Übergreifend“ lässt erkennen, dass die Spielteilnehmer auf Angreiferseite mehr „übergreifendes Wissen“ gewinnen konnten. Exemplarisch ist hier die Aussage „Arbeitsweise von Nation States“ zu nennen. Auf der Seite der Schutzmaßnahmen werden mehr spezifische Einzelmaßnahmen genannt. Genannte Beispiele sind das PAP-Prinzip des BSI (vgl. [38]) oder die Funktionsweise einer Datendiode (vgl. [39]).

Spielteilnehmer stellen interessanterweise nicht nur neueste Bedrohungen oder Schutztechnologien sondern auch ältere Angriffsvektoren oder etablierte Sicherheitstechnologien als Wissenszuwachs dar. So wurden als „Neues Wissen“ referernziert: der seit Jahrzehnten bekannte Angriffsvektor „Man-in-the-Middle“, der „Unterschied zwischen IDS / IPS“ , Angriffsvektoren wie „Man-in-the-Cloud“ [40] aus dem Jahr 2015 oder „Watering hole attack“ [41] von 2012. Das illustriert die Notwendigkeit für Sensibilisierungsmaßnahmen – auch für Funktionsträger.

„Operation Digitales Chamäleon“ vermag also neues Wissen zu vermitteln und sensibilisiert besonders im Themenfeld der Schutzmaßnahmen.

5.4 Verhaltensänderung

Im Debriefing reflektieren die Teilnehmer ihre Erfahrungen der Spielphase und leiten daraus individuell Vorsätze für ihre berufliche Tätigkeit ab. Die empirische Basis umfasst 208 Vorsätze (aus Spiel #1-#7), die mittels Fragebogen und in Diskussionen erhoben und in qualitativer Inhaltsanalyse nach Mayring [37] analysiert wurden. Jeder Vorsatz wird einer Kategorie (Individuum, Organisation, IT-Infrastruktur) zugeordnet, abhängig worauf sich ein Vorsatz auswirkt (siehe Tabelle 5).

Tabelle 5. Ausgewählte Vorsätze der Spielteilnehmer im Hinblick auf eine Verhaltensänderung

Individuum	*Organisation*	*IT-Infrastruktur*
Büros nicht unverschlossen lassen; Mehr Berichte / TecBlogs zum Thema IT-Sicherheit / Cyberwar lesen; Mehr Zeit in IT-Sicherheit investieren; Bewusster auf potentielle Gefahren achten;	Transparenz in der IT-Sicherheit; Sensibilisierung der Mitarbeiter intensivieren; Mit den anderen Administratoren Angriffsszenarien ausdenken und dann checken, ob man safe ist; Kompetenzen auf mehrere Schultern verteilen;	Öfter eigenes Netzwerk penetrieren; Regelmäßige Schwachstellenanalyse; Datenabfluss über Web-Schnittstellen (Cloud, Email, …) verhindern / eindämmen; Testumgebung für kommende Updates nutzen (Office, Windows 7, Java etc.);

Auffällig ist, dass viele Vorsätze genannt werden, die die Organisation betreffen: Organisation (117 Vorsätze), Individuum (78 Vorsätze), IT-Infrastruktur (13 Vorsätze). Das zeigt, dass „Operation Digitales Chamäleon“ eher organisatorische IT-Sicherheit als technischen Schutz der IT-Infrastruktur adressiert. Gerade vor dem Hintergrund, dass sich im Themenfeld IT-Sicherheit Kritischer Infrastrukturen IT-Professionals um die Sicherheit von bspw. Industrieanlagen Gedanken machen müssen, die bisher nicht als IT-Sicherheitsrisiko eingeschätzt wurden, kann ein solcher Impuls die notwendigen organisatorischen Änderungen anregen.

Tabelle 6. Kategorien und Anzahl der Vorsätze für Verhaltensänderung

Kategorie	*Anzahl der Vorsätze*
(Organisatorisches) IT-Security Awarenesstraining	55
(Individuelles) IT-Security Awarenesstraining	27
Operative IT-Security-Vorgänge	19
Monitoring	18
Bestehende IT-Security-Konzepte	15
Aufgeschlossene Denkansätze	14
Cross-Functional IT-Security-Teams	13
Aufmerksamkeit	11
Informationsverteilung	10
Informationsbeschaffung	6
Auditing	5
Penetration Testing	5
Abschreckung	3
Personalmanagement	3
Resignation	2
Keine Verhaltensänderung	1
Keine Auswertung möglich	1

In einer qualitativen Inhaltsanalyse wurden die 208 Vorsätze in 17 Kategorien systematisiert (vgl. Tabelle 6). 55 Vorsätze werden der Kategorie „(Organisatorisches) IT-Security Awarenesstraining“ zugeordnet: Spielteilnehmer möchten die Mitarbeiter der Organisation besser sensibilisieren. 27 Vorsätze umfasst die Kategorie „(Individuelles) IT-Security Awarenesstraining“, mit Vorsätzen wie „Erhöhte Weiterbildung im Bereich IT-Sicherheit“. Kategorie „Operative IT-Security-Vorgänge“ beinhaltet 19 Vorsätze – ein Beispiel ist, zu prüfen, „Dass keine unbekannte Person sich alleine im Raum aufhält“. Auch dies illustriert, dass das Spiel Impulse setzt, IT-Sicherheit als Organisationsaufgabe zu begreifen.

In den Spieldurchführungen konnte beobachtet werden, dass interdisziplinäre Teams gute Resultate erzielen, also Teams mit Mitgliedern entweder verschiedener Hierarchiestufen von der strategischen bis hin zur operativen Ebene oder mit Mitgliedern aus den Kernthemen der IT-Sicherheit zusammen mit Vertretern angrenzender Domänen wie Arbeitsschutz oder bauliche Sicherheit. So nutzte bspw. ein blaues (interdisziplinäres) Team Motivatoren zur Steigerung der Mitarbeiterzufriedenheit um die Bereitschaft der Mitarbeiter, Innentäter zu werden zu reduzieren. Die Notwendigkeit für Interdisziplinarität spiegelt sich auch in den Vorsätzen wieder. So beinhaltet Kategorie „Cross-Functional IT-Security-Teams“ 13 Vorsätze, von denen ein Vorsatz lautet: „Zusammenarbeit mit anderen (Admins, User, SiBe, Brandschutzbeauftragter)“.

Nur vergleichsweise wenige Spielteilnehmer planen als Vorsatz die IT-Sicherheitstechnologie zu verbessern oder zu erneuern. Spielteilnehmer gaben an, sie wollen bspw. häufiger nach Schwachstellen oder Fehlkonfigurationen in der IT-Infrastruktur suchen und diese beheben („Penetration Testing“ (5 Vorsätze)).

Zusammenfassend lässt sich feststellen, dass „Operation Digitales Chamäleon“ zu Verhaltensänderungen motiviert, also nicht alleine Faktenwissen vermittelt und vor allem zur Auseinandersetzung mit organisatorischen Aspekten anregt.

6 Zusammenfassung und Ausblick

In diesem Artikel präsentierten wir unsere IT-Security Awarenessmaßnahme „Operation Digitales Chamäleon“ mit ausgewählten Ergebnissen der ersten sieben Durchführungen. Die APTs als Spielergebnisse zeigen, dass die Spielteilnehmer APTs und IT-Sicherheitsmaßnahmen realistischer Komplexität erarbeiten und so „Operation Digitales Chamäleon“ geeignet ist, als IT-Security Awarenessmaßnahme für IT-Sicherheitsverantwortliche und IT-Sicherheitsprofessionals im KRITIS Kontext eingesetzt zu werden (vgl. [5] [6]). Die Auswahl der Ergebnisse liegt in diesem Beitrag auf dem Spielerlebnis, der Wahrnehmung, dem Wissensgewinn und der Verhaltensänderung. Das Spiel macht Spaß und erfüllt damit ein wichtiges Erfolgsmerkmal von Serious Games. „Operation Digitales Chamäleon“ motiviert die Spielteilnehmer zu Verhaltensänderungen, und vermittelt nicht alleine Faktenwissen. Diese Verhaltensänderungen betreffen eher organisatorische als individuelle oder technische Aspekte. „Operation Digitales Chamäleon“ adressiert also die wichtigen Themen der IT-Sicherheit Kritischer Infrastrukturen. Das deckt sich mit den Empfehlungen des BSI: Langfristige Verhaltensänderungen sind wesentlich für ein langfristig erfolgreiches IT-Sicherheitsmanagement – neue IT-Sicherheitstechnologie anzuschaffen genügt nicht. Die Evaluation des Erfolgs solcher IT-Sicherheitsawarenessmaßnahmen ist inhärent schwierig zu evaluieren – das zeigen der State of the Art von Praxis und wissenschaftlicher Literatur und so ist die Evaluation des Spieles dem Spielgegenstand angemessen.

„Operation Digitale Schlange“ und „Operation Digitale Eule“ sind zusammen mit „Operation Digitales Chamäleon“ die ersten Spielformate der IT-Security Matchplay Serie. Für alle drei Formate sind weitere Spiele und Weiterentwicklungen geplant.

7 Danksagung

Hiermit bedanken wir uns beim BMBF als Fördergeber des Projekts „Vernetzte IT-Sicherheit Kritischer Infrastrukturen“ (FKZ 16KIS0213). Ebenso möchten wir allen Spielteilnehmern für die guten Spielergebnisse und das Engagement danken. Dem Associate Editor und den Gutachtern sind wir für hilfreiche und konstruktive Kommentare dankbar.

Entwurf eines cloud-basierten Geschäftsmodells für die kontinuierliche Prüfung

Andreas Kiesow[1], Oliver Thomas[1]

[1] Universität Osnabrück, Fachgebiet für Informationsmanagement und Wirtschaftsinformatik, Osnabrück, Deutschland
{andreas.kiesow,oliver.thomas}@uni-osnabrueck.de

Abstract. Die zunehmende Digitalisierung und Komplexität der Abschlussprüfung als daten- und wissensintensive Dienstleistung externer Prüfungsgesellschaften verändert bestehende Geschäftsabläufe der Mandanten-Prüfer-Beziehung. Dabei ist ein Wandel von einer jährlichen Prüfung auf Basis historischer Daten zu einer unterjährigen, kontinuierlichen Prüfung zu beobachten. Daraus ergibt sich, insbesondere für kleine und mittelständische Prüfungsgesellschaften, der Bedarf an technologischer Unterstützung, um ihre Stellung am Abschlussprüfermarkt zu behaupten. Ein innovativer Lösungsansatz ist in diesem Zusammenhang die Auslagerung kontinuierlicher Prüfungsdienstleistungen an einen spezialisierten Informationsdienstleister, der Prüfungsresultate über eine Cloud-Architektur bedarfsorientiert zur Verfügung stellt (Audit-as-a-Service). Zur Umsetzung dieses Ansatzes wird in dem vorliegenden Artikel ein Geschäftsmodell nach dem Business Model Canvas entworfen. Dazu wurde ein konzeptionell-deduktives Verfahren angewendet. Die Autoren dieses Artikels adressieren mit der Vorstellung dieses Geschäftsmodellentwurfs eine Forschungslücke in der Fachliteratur und eröffnen damit eine neue Forschungsrichtung zur Umsetzung und Verbreitung von kontinuierlichen Prüfungsdienstleistungen.

Keywords: Continuous Auditing, Audit-as-a-Service, Business Model, Cloud-Computing, Digitalisierung

1 Einleitung

Geschäftsmodelle (engl. business models) können als Werkzeuge verstanden werden, die die Beschreibung, Erneuerung und Bewertung von Geschäftsabläufen ermöglichen. Geschäftsmodelle werden als *digital* bezeichnet, wenn eine Veränderung der genutzten Informations- und Kommunikationstechnik (IKT) fundamentale Veränderungen für die Durchführung des Geschäfts und die Umsatzentstehung nach sich ziehen [1]. Eine zunehmende Digitalisierung der Geschäftsabläufe ist bei der Prüfung von Rechnungslegungsprozessen im Rahmen der Jahresabschlussprüfung zu beobachten. Die Verschärfung regulatorischer Rahmenbedingungen und steigende technische Komplexität der Rechnungslegung erfordern einen erheblichen Bedarf zur Weiterentwicklung traditioneller Geschäftsabläufe in der Abschlussprüfung [2], [3].

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Kiesow, A.; Thomas, O. (2017): Entwurf eines cloud-basierten Geschäftsmodells für die kontinuierliche Prüfung, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 882-896

Dieser Wandel ist vorrangig durch eine Veränderung von einer traditionellen Jahresabschlussprüfung mit Prüfungshandlungen auf Basis historischer Daten in Stichproben [4] zu einer unterjährigen, automatisierten Prüfung in (quasi-)Echtzeit, gekennzeichnet [5]. Diese kontinuierliche Prüfung (engl. continuous auditing) basiert auf dem Einsatz innovativer Technologien und der Entwicklung betrieblicher Informationssysteme (IS), deren Untersuchung einen Kernbereich der Wirtschaftsinformatik (WI) darstellt [6]. Trotz der Implementierung von Prototypen in individualisierten Einzelszenarien, wie z. B. [7], [8], haben sich kontinuierliche Prüfungsansätze in der Praxis bislang nicht verbreitet [9]. Als Gründe werden dafür technische und organisatorische Barrieren [10] sowie mangelnde fachliche Expertise [11] genannt. In der Fachliteratur existieren in diesem Kontext Überlegungen hinsichtlich der Auslagerung von kontinuierlichen Prüfungsdienstleistungen an spezialisierte Informationsdienstleister, um insbesondere kleinen und mittelständischen Wirtschaftsprüfungsgesellschaften (WPG) Prüfungsergebnisse auf kontinuierlicher Basis zugänglich zu machen [12], [13].

Durch die mittlerweile nahezu durchgängige Digitalisierung der Rechnungslegung durch Enterprise-Resource-Planning-, und Buchhaltungssysteme [14] sowie die jederzeitige Verfügbarkeit und Flexibilität von Ressourcen durch Virtualisierung sind wesentliche technische Voraussetzungen zur Auslagerung kontinuierlicher Prüfungsdienstleistungen erfüllt. In dem vorliegenden Artikel wird eine solche Auslagerung von Prüfungshandlungen und den damit verbundenen vor- und nachgelagerten Tätigkeiten an einen externen Informationsdienstleister, der als Bindeglied zwischen Mandanten und Prüfungsgesellschaft fungiert, betrachtet.

Zur Umsetzung dieses Auslagerungsvorhabens bedarf es allerdings Geschäftsmodelle als Werkzeug zur Repräsentation und Analyse der angestrebten Geschäftslogik [15], [1]. Der vorliegende Beitrag greift diesen Bedarf an Geschäftsmodellen für die kontinuierliche Prüfung auf. Dazu werden die Eigenschaften des Cloud-Computings (CC) zu Entwicklung einer Geschäftsmodellinnovation *Audit-as-a-Service* genutzt. Da diese Umsetzung die Entwicklung eines digitalen Geschäftsmodells erfordert [16], lautet die Forschungsfrage dieses Artikels daher: *Wie muss das cloud-basierte Geschäftsmodell eines externen Dienstleisters für die kontinuierliche Prüfung von Rechnungslegungsprozessen gestaltet werden, um die Verbreitung der kontinuierlichen Prüfung in der Praxis zu ermöglichen?*

Zur Beantwortung dieser Frage wird auf Grundlage des Business Model Canvas nach Osterwalder (2004) und Osterwalder und Pigneur (2010) ein Geschäftsmodell entworfen und unter Anwendung des Ordnungsrahmens nach Labes et al. (2014) hinsichtlich cloud-spezifischer Bewertungskriterien analysiert. Der vorliegende Artikel stellt erstmalig in der Fachliteratur den Entwurf eines vollständigen Geschäftsmodells für die kontinuierliche Prüfung vor. Damit werden die bislang vorrangig technologischen Betrachtungen der digitalen Transformation der Abschlussprüfung um Aspekte der Geschäftsmodellentwicklung erweitert. Das entworfene Geschäftsmodell kann sowohl von Wissenschaftlern als auch Praktikern als Werkzeug zur Analyse der Voraussetzungen und Aktivitäten, die für die Umsetzung und Verbreitung der kontinuierlicher Prüfung erforderlich sind, genutzt werden.

Dazu wurde der Artikel wie folgt gegliedert: In Abschnitt 2 werden relevante theoretische Grundlagen zur kontinuierlichen Prüfung und zur Geschäftsmodellentwicklung erläutert. In Abschnitt 3 wird das durchgeführte Forschungsvorgehen begründet. In Abschnitt 4 werden die Ergebnisse zur Geschäftsmodellentwicklung und -analyse gezeigt. Die Ergebnisse und Limitationen des Artikels werden in Abschnitt 5 kritisch reflektiert.

2 Theoretische Grundlagen

2.1 Kontinuierliche Prüfung

Um eine fundierte Grundlage über den Forschungsstand der kontinuierlichen Prüfung zu bilden, wurde eine strukturierte Literaturanalyse nach Webster und Watson (2002) durchgeführt [17]. Bei der Suche in sechs Literaturdatenbanken (EbscoHost, SpringerLink, ISI Web of Knowledge, ACM Digital Library, ScienceDirect und Wiley) nach den Suchbegriffen {Continuous Assurance}, {Continuous Auditing} und {Continuous Monitoring + Audit} wurden 52 relevante Artikel identifiziert, die durch Rückwärts- und Vorwärtssuche um weitere 42 Artikel ergänzt wurden. Die Relevanzkriterien waren dabei englische Sprache, Qualität des Publikationsorgans, die Anwendung im Kontext der Jahresabschlussprüfung (engl. financial auditing) und Verfügbarkeit des Artikels. Die Kriterien zur Analyse und Charakterisierung der 94 Papiere waren der grundlegende wissenschaftliche Ansatz, die betrachteten technischen Konzepte zur Umsetzung der kontinuierlichen Prüfung, die Zuordnung zur internen und/oder externen Revision sowie das Artefakt des Papiers, wie z. B. Methoden oder Modelle. Die detaillierte Beschreibung und zentralen Ergebnisse dieser Literaturanalyse wurden als Vorarbeiten in einem separaten Papier [18] veröffentlicht. Für den vorliegenden Artikel wurde die Analyse um die Suche nach dem Begriff „business model“ erweitert und die so identifizierten acht Artikel ausgewertet.

Nachweise zu Überlegungen, digitale Geschäftsmodelle der Mandanten für eine kontinuierliche Prüfung der Rechnungslegungsdaten zu nutzen, lassen sich in der Fachliteratur seit Verbreitung des Internets zu Beginn der 2000er Jahre. Kneer (2003) stellt dazu die Frage: „Has the change in the business model/environment rendered look-back financial attestations valueless?“ [19]. Greenstein und Ray (2002) stellen in diesem Kontext ein Modell zur Integration von Prüfungsleistungen in die Geschäftsprozesse der Mandanten vor: „This model is based on accounting firms' need to respond quickly to evolving e-business models employed by their information-age clients“ [20]. Murthy und Groomer (2004) sehen in der kontinuierlichen Prüfung die Möglichkeit zur Entwicklung eines innovativen Geschäftsmodells und stellen ein Modell vor, das den bedarfsorientierten Zugriff auf Prüfungsergebnisse und -urteile gegen eine Gebühr, vorsieht [21]. Yeh und Shen (2010) erweitern dieses Modell um technologische Aspekte und kommen zu dem Ergebnis, dass darauf ein neues Geschäftsmodell für Wirtschaftsprüfer und die externe Revision aufgebaut werden könnte [22]. Gehrke und Wolf (2010) stellen das Konzept einer Web 2.0 Kooperationsplattform für Abschlussprüfer vor und skizzieren in diesem Zusammenhang ein Geschäftsmodell für die kontinuierliche Prüfung.

Bei allen vorgenannten Autoren wird stets von einer Prüfer-Mandanten-Beziehung ausgegangen. Ein alternativer Ansatz ist die Auslagerung von Prüfungshandlungen und den damit verbundenen vor- und nachgelagerten Tätigkeiten an einen externen Informationsdienstleister, der als Bindeglied zwischen Mandanten und WPG fungiert [12]. Der Vorteil für die WPG liegen darin, dass sie nicht selbst die personellen Kapazitäten, die für die Umsetzung der kontinuierlichen Prüfung erforderlich sind, aufbauen müssen, da der Informationsdienstleister diese als temporäre Leistung der WPG zur Verfügung stellt. Die WPG profitiert zudem von den Erfahrungen, die ein Informationsdienstleister aufbauen wird, dessen Tagesgeschäft die kontinuierliche Prüfung ist. Begünstigt durch Erfahrungskurven- und Skaleneffekte ist davon auszugehen, dass die Kosten der Auslagerung niedriger sind als im eigenen Kompetenzaufbau. Der Informationsdienstleister wird langfristig Standards bei den Anbindungen, Extraktion und Auswertung der Rechnungslegungsdaten entwickeln, so dass eine zeitnahe Anpassung der Extraktions- und Auswertungsmechanismen an heterogene Systemlandschaften angenommen werden kann.

Allerdings wurden im Rahmen der durchgeführten Literaturanalyse keine detaillierten Ausführungen zu Geschäftsmodellinhalten eines solchen Ansatzes gefunden. Zusammengefasst werden zwar die Notwendigkeit und die technische Machbarkeit von Geschäftsmodellen zur Verbreitung kontinuierlicher Prüfung gesehen [15], jedoch keine fundierten Untersuchungen über die Gestaltung, Elemente und die Wertschöpfung der kontinuierlichen Prüfung durchgeführt. Diese Forschungslücke wird mit dem vorliegenden Artikel adressiert.

2.2 Geschäftsmodelle

In der Fachliteratur existieren unterschiedliche Definitionen des Begriffs Geschäftsmodell [23]. Morris et al. (2005) definieren das Geschäftsmodell als prägnante Darstellung von untereinander verbundenen Variablen, deren Verbesserung einen nachhaltigen Wettbewerbsvorteil implizieren [24]. Osterwalder (2004) sehen im Geschäftsmodell eine vereinfachte Darstellung der Aktivitäten eines Unternehmens. Dabei wird das Geschäftsmodell als Werkzeug oder Instrument charakterisiert. Der Zweck eines Geschäftsmodells besteht demnach darin, die Kombination der benötigten Elemente und deren Beziehungen untereinander aufzuzeigen [25]. Nach Amit und Zott (2001) sind diese Elemente die Gestaltung der Inhalte, des Aufbaus und der Steuerung von Geschäftsvorgängen [26]. Nach Bieger und Reinhold (2011) sowie Chesbrough und Rosenbloom (2002) kann der Inhalt eines Geschäftsmodells auch als Logik des Unternehmens verstanden werden [27], [28]. Alle Definitionen teilen das Verständnis, dass die zentrale Funktion des Geschäftsmodells die Darstellung des Nutzens oder Wertes, der von der Organisation vermittelt wird, beschreibt [25–28]. Dieser Nutzen fließt dabei an Kunden, Partner und an das Unternehmen selbst [26], [25]. Auf Basis dieser Beschreibungen wird in diesem Artikel das Geschäftsmodell definiert, wie folgt: Ein Geschäftsmodell ist ein Instrument zur präzisen Darstellung der Logik, bzw. der interagierenden Elemente einer Unternehmung, um Nutzen für Kunden, Partner und sich selbst zu schaffen und dabei einen dauerhaften Wettbewerbsvorteil zu erlangen.

Das Geschäftsmodell dient in diesem Zusammenhang als Medium zwischen Geschäftsstrategie und den Geschäftsprozessen des Unternehmens [1].

In der Fachliteratur werden unterschiedliche Konzepte zur Erstellung von Geschäftsmodellen diskutiert, die sich insbesondere hinsichtlich der zu berücksichtigenden Elemente unterscheiden [23], [29]. Auf Basis vergleichender Literatur wurden für die Untersuchungen zu diesem Artikel ausschließlich Konzepte betrachtet, die ihre jeweiligen Elemente explizit benennen [23, 30]. In den Vorarbeiten für den vorliegenden Artikel, die sich hier nicht darstellen lassen, wurden insgesamt sieben Konzepten hinsichtlich relevanter Elemente analysiert. Die Geschäftsmodell-konzepte nach Osterwalder (2004), Bieger und Reinhold (2011) sowie Hamel (2002) wurden dabei als die geeignetsten Konzepte hinsichtlich Abdeckungsrad relevanter Elemente bewertet. Diese drei Konzepte sind zudem allgemeingültig und unabhängig einer bestimmten Industrie anwendbar [31], [30].

Die Autoren dieses Papiers entschieden sich für die Anwendung des Business Models Canvas nach Osterwalder (2004) sowie Osterwalder und Pigneur (2010). Dieser Ansatz ist dem strategischen Management und dem Informationsmanagement zuzuordnen, sowohl in der Praxis als auch in der Wissenschaft etabliert und durch eine intuitive Vorgehensweise gekennzeichnet [30]. Anders als bei Hamel (2002) und Bieger und Reinhold (2011) beginnt bei Business Model Canvas der Prozess eines innovativen Geschäftsmodells bei der Recherche, Gestaltung und Implementierung eines neuen Geschäftsmodells, welches anhand der Marktreaktionen weiterentwickelt wird. Aus Sicht der Autoren ist dieser Ansatz für eine gestaltungsorientierte Entwicklung eines Geschäftsmodells gegenüber den anderen Ansätzen zu bevorzugen.

3 Forschungsansatz

Nach Magretta (2002) kann das Geschäftsmodell als praktisches Äquivalent einer Forschungsmethode verstanden werden: “Business modeling is the managerial equivalent of the scientific method–you start with a hypothesis, which you then test in action and revise when necessary” [32]. Dies impliziert das Vorhandensein eines Geschäftsmodells, das in anknüpfenden Forschungsarbeiten zum Test, d. h. zur empirischen Evaluation, verwendet und zukünftig verbessert werden kann. Die Gestaltung eines Geschäftsmodells für die kontinuierliche Prüfung erfordert aus Sicht der Autoren daher ein konstruktivistisches Vorgehen. Diese Notwendigkeit begründet sich aus dem grundsätzlichen Verständnis des Geschäftsmodells als Artefakt, mit dem die kontinuierliche Prüfung effektiv und effizient umgesetzt werden kann [33].

Bei der Abwägung von Methoden sind aus Sicht der Autoren wirtschaftliche und zeitliche Einschränkungen zu berücksichtigen. Simulationen, prototypische Umsetzungen und Methoden der Aktionsforschung erfordern kapitalintensive Vorarbeiten, die aufgrund der Komplexität der Abschlussprüfung und den dabei involvierten Akteuren nur unter hohem Kapitaleinsatz zu entwickeln sind. Zum gegenwärtigen Zeitpunkt ist aus Sicht der Autoren der initiale Entwurf eines Geschäftsmodells für die Auslagerung von Prüfungsleistungen einzig durch die deduktive Ableitung eines Konzepts mit Referenzeigenschaft auf Planniveau möglich

[34]. Dieser initiale Entwurf kann für die Entwicklung zukünftiger IKT in der Wirtschaftsprüfung verwendet werden, um, wie von Magretta gefordert, einen empirischen Nachweis über die Nützlichkeit der kontinuierlichen Prüfung in der Praxis zu erbringen.

Gestaltungsorientierte Forschung (engl. design science research) erfordert die rigorose Evaluation der entwickelten Artefakte [33]. Aufgrund der komplexen, praktischen Umsetzung des in diesem Artikel diskutierten, neuartigen Prüfungsansatzes als kapitalintensive Innovationen ist die Durchführung von Evaluationsmethoden höherer Wertigkeit, wie z. B. Fallstudien oder Simulationen, zum gegenwärtigen Zeitpunkt nicht möglich. Entsprechend der konzeptionellen Ausrichtung des vorliegenden Artikels, kann die Evaluation des vorgestellten Geschäftsmodells derzeit ausschließlich rein deskriptiv erfolgen. Dazu wurde eine argumentativ-deduktive Analyse unter Verwendung des morphologischen Kastens nach Labes et al. 2014 durchgeführt [16]. Zusammengefasst wurde in der vorliegenden Forschungsarbeit ein konstruktivistisch-qualitatives Vorgehen angewendet.

4 Geschäftsmodell Audit-as-a-Service

4.1 Kurzbeschreibung Audit-as-a-Service

Audit-as-a-Service (AaaS) umfasst die Integration eines spezialisierten Informationsdienstleisters als Bindeglied zwischen Wirtschaftsprüfungsgesellschaften (WPG) und deren Mandanten und stellt somit eine vertikale Erweiterung der Wertschöpfungskette in der Wirtschaftsprüfung dar (siehe Abbildung 1). Die Dienstleistung des Informationsdienstleisters ist ein Leistungsbündel aus einmaliger Implementierung von Extraktionsroutinen in den Rechnungslegungssystemen des Mandanten, z. B. Buchhaltungssystemen, und der kontinuierlichen Übertragung und Auswertung der daraus extrahierten Daten. Kerngedanke ist somit, dass die WPG die kontinuierliche Prüfung und die dazu erforderlichen Aktivitäten an den Informationsdienstleister auslagert [35]. Der WPG soll die Möglichkeit gegeben werden, die Ergebnisse dieser Prüfung bedarfsgerecht, d. h. in eigens vordefinierten Intervallen und nach individualisierten Auswertungsregeln, zu beziehen. An diese besondere Form der Auslagerung werden verschiedene Anforderungen hinsichtlich Bedarfs- und Serviceorientierung gestellt. Die Eigenschaften des Cloud-Computings (CC), maßgeblich das bedarfsgerechte und flexible Angebot von IT-Leistungen in Echtzeit, bieten anerkanntermaßen ein hohes Potenzial zur Entwicklung disruptiver Geschäftsmodellinnovationen [36].

Nachfolgend wird der initiale Entwurf eines Geschäftsmodells vorgestellt, das die Eigenschaften des Cloud-Computings mit dem Prinzip der kontinuierlichen Prüfung zu einem Geschäftsmodell „as-a-Service" vereint. Diese Ausführungen basieren auf Vorarbeiten, die die Untersuchung von Erfolgsfaktoren für die kontinuierliche Prüfung auf Basis einer Literaturstudie [10], die Entwicklung eines Rahmenwerks zur Gestaltung von IS für die kontinuierliche Prüfung auf Basis von Fokusgruppeninterviews mit Experten aus der IT-gestützten Abschlussprüfung und dem Enterprise Architecture Management [35] sowie ein im Anschluss erstelltes Prozessmodell für Audit-as-a-Service, das auf Basis von Eins-zu-Eins-Diskussionen mit Experten aus der Praxis erstellt wurde [37].

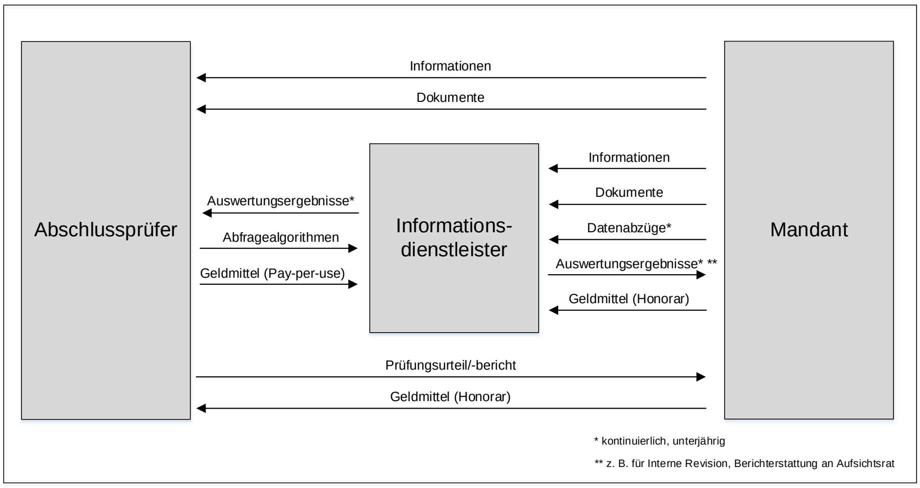

Abbildung 1. Wertschöpfungskette von Audit-as-a-Service [13]

4.2 Geschäftsmodellkonzeption

Das Business Model Canvas nach Osterwalder (2004) besteht aus neun unterschiedlichen Elementen [25]. Nachfolgend werden diese neun Elemente für AaaS beschrieben. Eine zusammenfassende Darstellung dieser neun Elemente ist entsprechend des Business Models Canvas [38] in Abbildung 2 enthalten.

(1) Kundensegmente. Die Kundensegmente sind der erste Teil der Kundenschnittstelle und legen fest, an welche Zielkundengruppe sich das Wertversprechen richtet [25]. Kunden von AaaS sind sowohl Organisationen, die eine Rechnungslegung betreiben und ein Interesse an einem kontinuierlichen Nachweis über die Vollständigkeit und Richtigkeit der verarbeiteten Rechnungslegungsdaten haben als auch Organisationen, die im Auftrag die Rechnungslegung einer anderen Organisation prüfen. Dabei werden vorrangig kleine und mittelständische WPG adressiert, deren personellen und technischen Kapazitäten häufig nicht ausreichen, um selbst eine kontinuierliche Prüfung umzusetzen. Zum erweiterten Kundenkreis zählen Abteilungen der Internen Revision, Controlling und Business Intelligence von Großunternehmen sowie Start-Ups und Organisationen im öffentlichen Sektor.

(2) Wertversprechen. Das Wertversprechen ist das zentrale Element des Geschäftsmodells und repräsentiert das Wertangebot des Unternehmens. Dabei handelt es sich um ein Bündel aus Produkten oder Dienstleistungen, die einen Nutzen für die Kunden schaffen und auf den Ressourcen des Unternehmens basieren [25]. Nach

Osterwalder und Pigneur (2010) schaffen verschiedene qualitative und quantitative Faktoren einen Wert für Kunden [38]. Zielsetzung von AaaS ist die Befähigung der Kunden zur kontinuierlichen Prüfung von Rechnungslegungsprozessen. Das Attribut kontinuierlich bedeutet dabei *unterjährig* und *zeitnah*, was die Automatisierung und Digitalisierung von Prüfungshandlungen erfordert. Die *Prüfung* beschreibt den Vorgang der Beurteilung, ob die Daten der Rechnungslegung einer Organisation ein den tatsächlichen Verhältnissen entsprechendes Bild der Vermögens-, Finanz- und Ertragslage wiedergeben. Damit soll der Zeitverzug zwischen Entstehung und Aufdeckung eines inkorrekten oder betrügerischen Sachverhaltes reduziert werden. Zudem sollen die üblichen Belastungsspitzen in den Jahresabschlüssen reduziert und die Qualität der Rechnungslegungsdaten der Organisation erhöht werden. Betriebszweck von AaaS ist es, den Kunden diesen Nutzen zu bieten, ohne dass diese eigenen, kapitalintensiven Anschaffungen, wie z. B. Hard- und Software sowie personelle Kapazitäten, aufbauen müssen. Dieses Wertversprechen wird durch den Aufbau einer Programmier- und Software-Umgebung (Platform-as-a-Service, Software-as-a-Service) in einer privaten Cloud-Umgebung angeboten.

(3) Kanäle. Die Kanäle eines Geschäftsmodells beschreiben, wie das Unternehmen mit seinen Kunden in Kontakt tritt und ihnen das Wertangebot unterbreitet [25]. Der zentrale Vertriebskanal des AaaS-Anbieters ist das Internet. Der AaaS-Dienstleister wirbt darüber sowohl durch die eigene Webseite als auch über soziale Netzwerke für das Wertangebot. Darüber hinaus findet die Ansprache potenzieller Kunden auf Konferenzen und Prüfertagungen statt. Der Einsatz von Print-Medien ist grundsätzlich möglich, widerspricht allerdings der angestrebten Digitalisierungsstrategie.

(4) Kundenbeziehungen. Die Kundenbeziehungen beschreiben die Beziehungen, die mit dem Zielkundensegment eingegangen werden [25]. Dabei werden dem Unternehmen die Kundengewinnung, die Kundenpflege und die Verkaufssteigerung als Motivation unterstellt. Zu Beginn umfasst die Beziehung zu den Kunden, d. h. WPG und Mandanten, die Unterstützung bei der Einrichtung der Extraktionsroutinen. Langfristiger Bestandteil der Kundenbeziehungen von AaaS ist der on-demand self-service, der es den Kunden ermöglicht den Umfang und die Bestandteile des Wertangebots zusammenzustellen, ohne im direkten Kontakt mit dem Informationsdienstleister zu stehen. Zusätzlich werden jedem Kunden im Bedarfsfall eine persönliche Betreuung zugesichert. Als Kommunikationsinstrument dienen in diesem Zusammenhang auch die Service Level Agreements (SLAs), in denen der Umfang und die Leistung definiert sind.

(5) Umsatzmodell. Das Umsatzmodell beschreibt, wie dem Unternehmen die monetären Mittel durch die Bereitstellung des Wertangebots zufließen [25]. Die Nutzung der kontinuierlichen Prüfungsleistungen wird über eine Nutzungsgebühr abgerechnet. Die Höhe der Gebühr ergibt sich durch die tatsächlich genutzten Leistungen (engl. measured service). Eine Abrechnung entsprechend des für das CC typische pay-per-use-Prinzip kann z. B. pro Nutzer und Monat erfolgen. Darüber hinaus wäre die Abrechnung in periodischen Raten als Flatrate möglich, was den Nutzern einen unbegrenzten Zugang zu allen Funktionen der Plattform ermöglicht.

(6) Schlüsselressourcen. Die Schlüsselressourcen beschreiben die Fähigkeit, einen wiederkehrenden Prozess auf Basis interner und externer Ressourcen auszuführen [25]. Der Betrieb von AaaS erfordert ein Data-Center, in dem die IT-Infrastruktur, u. a. Hard- und Software, betrieben wird. Menschliche Expertise wird in den Bereichen der Softwareentwicklung, Marketing und Vertrieb sowie Wirtschaftsprüfung und IT-Revision benötigt.

(7) Schlüsselaktivitäten. Die Schlüsselaktivitäten und die Wertkonfiguration beschreiben die wichtigsten Aktivitäten zur Wertschaffung [25]. Die Schlüsselaktivitäten bei AaaS umfassen drei Kategorien: Die operativen Schlüsselaktivitäten umfassen die Implementierung von Extraktionsroutinen in den Systemen der Mandanten und Schnittstellen an das Audit-Datawarehouse. Zusätzlich werden Auswertungsskripte entwickelt und implementiert, die über den Datenbestand im Datawarehouse laufen. Weitere Aktivitäten betreffen Aufbau und Verwaltung der Infrastruktur sowie die Weiterentwicklung der eingesetzten Software. Spezielle Problemlösungsaktivitäten dienen zur Lösung spezifischer Kundenprobleme. Personalwirtschaftliche Aktivitäten sowie Marketing und Vertrieb deinen der Unterstützung des Betriebszwecks.

(8) Schlüsselpartner. Die Schlüsselpartnerschaften werden mit mindestens einem weiteren Unternehmen eingegangen, um den eigenen Wertschöpfungsprozess durch externe Ressourcen und Fähigkeiten zu ergänzen [25]. Für AaaS besteht die besondere Situation, dass die Kunden Wirtschaftsprüfer und Mandanten, auch als Partner fungieren, da sie Auswertungsregeln bzw. die Rechnungslegungsdaten liefern, die für die Erstellung des Wertangebots unerlässlich sind. AaaS kann daher als eine besondere Form des Co-Creation betrachtet werden. Weitere Schlüsselpartner sind andere Anbieter von Cloud-Services, von denen kurzfristig Speicherressourcen bezogen werden können, sowie externe Softwareentwickler. Darüber hinaus sind berufsständische Organisationen und Branchenverbände weitere Schlüsselpartner.

(9) Kostenstruktur. Die Kostenstruktur beinhaltet alle Kosten, die im Unternehmen durch die Erzeugung des Wertversprechens entstehen [25]. Kosten entstehen zum einen durch die Anschaffung und den Betrieb der technischen Infrastruktur, insb. durch ein Data-Center, die dem die Hardware betrieben wird. Zum anderen entstehen Kosten durch die Anstellung von Beschäftigten in den Bereichen Softwareentwicklung, Marketing und Vertrieb sowie der persönlichen Kundenbetreuung. Variable Kosten können zudem durch die Nutzung externer Ressourcen (engl. third-party-services), die sich ebenfalls nach dem pay-per-use-Modell berechnen, entstehen. Je mehr Kunden der AaaS-Dienstleister hat, desto mehr Infrastruktur muss extern bezogen werden. Weitere Kosten für Telekommunikation, elektrische Versorgung und Büroräume werden hier nicht weiterbetrachtet.

Abbildung 2. Audit-as-a-Service Business Model Canvas

4.3 Geschäftsmodellanalyse

Technologischer Fortschritt, insbesondere das als „Basisinnovation“ [39] charakterisierte CC, verändert die Geschäftsmodelle von IT-Dienstleistern [1]. Daraus ergibt sich die Notwendigkeit, Geschäftsmodelle hinsichtlich der cloud-charakteristischen Umsetzbarkeit zu beurteilen. Labes et al. (2014) vereinen dazu bestehende Geschäftsmodellelemente und cloud-spezifische Gestaltungsmerkmale zu einem morphologischen Kasten, der als Ordnungsrahmen für die Analyse cloud-basierter Geschäftsmodelle genutzt werden kann [16]. Das im vorherigen Abschnitt vorgestellte, auf einer Cloud-Architektur basierende Geschäftsmodell für die kontinuierliche Prüfung wurde anhand dieses Ordnungsrahmens analysiert (siehe Abbildung 3). Wie nachfolgend erläutert, konnten dabei kritische Elemente identifiziert werden, die bei der Anwendung des Business Models Canvas bislang nicht berücksichtigt wurden.

Strategie. Bei der Erstellung des Geschäftsmodells wurden bislang keine strategischen Aspekte betrachtet. Mit AaaS wird vorrangig eine Differenzierungs-strategie angestrebt, da sich der Betriebszweck, nämlich die kontinuierliche, unterjährige Prüfung von Rechnungslegungsprozessen, vom traditionellen, jährlichen Vorgehen anderer Marktteilnehmer maßgeblich unterscheidet. Zu Teil ist die Strategie als Nischenstrategie zu begreifen, weil AaaS hauptsächlich kleine und mittlere WPG unterstützt. Durch die Gestaltung (engl. design) eines innovativen Prüfungsansatzes kann AaaS als Markterweiterung betrachtet werden. Durch die unternehmensübergreifende Zusammenführung von Daten des Mandanten und Auswertungsregeln der WPG wird letztendlich auch eine Marktdurchdringung (engl. diffusion) im Sinne einer Steuerung von Akteuren angestrebt. Als Bindeglied zwischen WPG und Mandanten fokussiert Audit-as-Service eine vertikale Integration.

Wertversprechen. Die bei der Geschäftsmodellerstellung angestellten Überlegungen zum Wertversprechen konnten durch die Analyse erweitert werden. Die cloud-spezifischen Leistungen sind durch die Bereitstellung eines Audit-Datawarehouses als zentralen Speicherort für die Rechnungslegungsdaten gekennzeichnet. In dem Audit-Datawarehouse werden Auswertungsregeln ausgeführt (engl. computing). Zusätzlich werden den Kunden eine Entwicklungsumgebung mit eigenen Werkzeugen angeboten, mit denen individuelle Auswertungsregeln erstellt werden können. Gesetzliche Vorgaben an die Auslagerung von Rechnungslegungsdaten erfordern den Betrieb einer privaten Cloud-Infrastruktur, bei der der physische Speicherort der Daten jederzeit bestimmt werden kann. Dadurch ist der Standort der Leistung beschränkt ist. Darüber hinaus skaliert der Leistungsumfang vom Speichervolumen der Rechnungslegungsdaten und den gewählten Auswertungsregeln, die durch den Benutzer individualisiert werden können.

Wert generieren. Durch die Analyse des Geschäftsmodells konnten weitere Entwicklungspotenziale in Bezug auf die Generierung des Werts identifiziert werden. Ziel des Ansatzes ist die Errichtung eines strategischen Netzwerks, das die Unterstützung weiterer Partner mit fachlichem und technischem Wissen benötigt. Neben umfangreichen technischen Ressourcen müssen dazu auch Aktivitäten zum Aufbau und Verwaltung einer sachgerechten Infrastruktur durchgeführt werden. Eine besondere Schwierigkeit stellt die Abschätzung der Kostenstruktur dar. Neben klassischen, variablen Komponenten, wie z. B. Gehältern, könnten durch eine Überauslastung der Systeme kurzfristig weitere Speicherkapazitäten notwendig werden. Dadurch müssten Speicherkapazitäten bei externen Technologiepartnern eingekauft werden, womit erhebliche variable Kosten verbunden wären.

Wert vertreiben. Das Geschäftsmodell sieht eine variable Generierung von Erlösen als pay-per-use-Modell vor. Ebenso ist jedoch auch die Buchung eines Basispakets denkbar, das über periodische Zahlungen, entsprechend der eingestellten Prüfungsintervalle, abgerechnet wird. Wie im Geschäftsmodell beschrieben, ist der maßgebliche Vertriebsweg von AaaS eine Netzwerk-Infrastruktur, auf die Benutzer über das Internet zugreifen können. Um das Wertversprechen einer ortsunabhängigen Prüfung sicherzustellen, muss eine Darstellung von Ergebnissen auf mobilen Endgeräten unterstützt werden. Darüber hinaus erfordert die Implementierung von Extraktionsschnittstellen die Erbringung von Services beim Mandanten vor Ort. AaaS kann vorwiegend als Unterstützungsleistung (eng. support) betrachtet werden. Da es sich bei Rechnungslegungsdaten um sensible, hochkritische Daten handelt, die durch gesetzliche Vorgaben geschützt werden, müssen Informationen über deren Auswertung und Speicherung über transparente SLAs kommuniziert werden. Der Zielmarkt wurde durch das Business Model Canvas ausreichend adressiert. Der Markt- und Kundenfokus liegen auf einer klar abgrenzbaren Branche (Wirtschaftsprüfung) und zum Teil in der Nische der kleinen und mittleren WPG sowie internen Revisionseinheiten von Großunternehmen.

	Kategorie	Unterkategorie	Gestaltungsmerkmale						
	Strategie	Generische Strategie	Kostenführerschaft	Differenzierungsstrategie	Nischenstrategie				
		Marktstrategie	Market Adaption	Market Design	Market Diffusion	Market Co-construction			
		Markteintritt	Neueintritt	Markterweiterung	Know-how-Transfer	Vorherige Markterfahrung

Abbildung 3. Morphologischer Kasten von Audit-as-a-Service in Anlehnung an [16]

5 Kritische Würdigung

Ausgangspunkt der durchgeführten Untersuchung war die mangelnde Verbreitung von kontinuierlichen Prüfungsansätzen in der Praxis. Wesentliche Ursachen dafür sind der umfangreiche Personal- und Wissensbedarf sowie zahlreiche technische und organisatorische Barrieren, die vor allem kleine und mittlere WPG an einer Umsetzung kontinuierlicher Prüfung hindert. Ein Lösungsansatz ist die Auslagerung der Aktivitäten zur Umsetzung und Durchführung der kontinuierlichen Prüfung an einen spezialisierten Informationsdienstleister. In Hinblick auf die eingangs formulierte Forschungsfrage wurde in diesem Artikel die Repräsentation eines auf einer cloud-Architektur basierenden, innovativen Geschäftsmodell in der Wirtschaftsprüfung entworfen. Dazu wurde das Business Model Canvas nach Osterwalder (2004) und Osterwalder und Pigneur (2010) verwendet.

Das vorgestellte Geschäftsmodell ist lediglich als erster, aber notwendiger Entwurf zu verstehen. Je nach Ausgestaltung der einzelnen Bausteine können unterschiedliche Geschäftsmodelle generiert werden. Es ist festzuhalten, dass es keine einzig richtige Lösung für ein Geschäftsmodell zu Audit-as-a-Service geben kann, sondern verschiedene, nützliche Geschäftsmodelle in Abhängigkeit von den beteiligten Parteien und der angebotenen Leistung möglich sind. Wir gehen davon aus, dass eine besonders nützliche Lösung, d.h. ein sehr geeignetes Geschäftsmodell, erst näherungsweise durch mehrere Evaluationszyklen und schließlich erst bei einer Umsetzung unter realistischen Bedingungen entstehen wird.

Ein zweiter, wesentlicher Kritikpunkt ist, dass vermutlich nicht alle technischen und organisatorischen Barrieren durch die die Auslagerung und das entworfene Geschäftsmodell überwunden werden können. Vielmehr findet eine Verlagerung der Umsetzungsrisiken auf den spezialisierten Informationsdienstleister statt. Dem kann entgegengehalten werden, dass sich der Informationsdienstleister das Risiko durch die gezahlten Tantiemen entschädigen lassen und im Laufe der Zeit durch die Generierung von Erfahrungskurveneffekte die Leistung günstiger anbieten können wird.

Aus methodischer Sicht kann der Vergleich von lediglich sieben Konzepten und die Anwendung eines einzigen Ansatzes kritisch betrachtet werden. Eine weitere Limitation dieses Artikels kann daher in den theoretischen Ausführungen zur Auswahl und Begründung der betrachteten Geschäftsmodellkonzepte gesehen werden. Allerdings konnte festgestellt werden, dass wesentliche inhaltliche Überschneidungen zwischen den betrachteten Geschäftsmodellkonzepten bestehen.

Eine weitere Limitation liegt in den Ausführungen zu den Gestaltungsmerkmalen des CC im Business Model Canvas. In der Literatur werden für das CC zahlreiche Aspekte diskutiert, die im Rahmen dieses Artikels nicht betrachtet wurden. Durch Vorstudien konnte jedoch festgestellt werden, dass die Kerneigenschaften in der Literatur sehr ähnlich beschrieben und zum Teil standardisiert sind [40].

6 Fazit und Ausblick

Zusammengefasst kann das vorgestellte Geschäftsmodell als erste, konzeptionelle Repräsentation einer neuartigen Geschäftslogik verstanden werden, die durch einen iterativen Prozess verbessert werden muss. Damit werden die bislang vorrangig technologischen Betrachtungen der digitalen Transformation der Abschlussprüfung um Aspekte der Geschäftsmodellentwicklung erweitert. Zudem werden mit dem Geschäftsmodell erstmalig die Möglichkeiten aufgezeigt, wie Eigenschaften die Cloud-Computings für die Umsetzung der kontinuierlichen Prüfung genutzt werden können. Der Beitragt zeigt somit, wie IKT das bestehende Geschäftsmodell der traditionellen Jahresabschlussprüfung verändert und zu einem neuen, disruptiven Ansatz weiterentwickelt. Dadurch können analoge Vorgehensweisen für die digitale Transformation anderer klassischer Dienstleistungen abgeleitet werden.

Die Autoren dieses Artikels erwarten mit den vorgestellten Ergebnissen neue Impulse für die digitale Transformation der Abschlussprüfung und die, insbesondere im deutschsprachigen Raum, stagnierte Debatte über die kontinuierliche Prüfung geben zu können. Gegenstand geplanter Forschungsarbeiten ist die Evaluation des erstellten Geschäftsmodells durch Experten aus der IKT-Branche und die prototypische Umsetzung der Kernkomponenten um auf dieser Basis parallele Simulationen zur traditionellen Abschlussprüfung durchzuführen. Zukünftige Arbeiten sollten zudem die Preisbereitschaft für die Nutzung von AaaS über einen quantitativen Querschnitt der Kundensegmente untersuchen. Fernziel ist die Ausgründung einer Gesellschaft, die die wirtschaftliche Verwertung der vorgestellten Geschäftsmodellinnovation anstrebt.

Abstract. When improving human-centered service systems (HCSSs) with information and communications technology (ICT), financial aspects are important but challenging for companies with established business models (BMs). The use of ICT and changes in value creation reflect business needs, but commercial success requires modifications and extensions of the BMs. However, prevailing approaches do not take account of these requirements. In this paper, we present a BM design process that fosters the extension of BMs for ICT-enabled HCSSs to support service innovations. Using an action research project in the field of volunteering, we iterated and revised the BM design process in a project collaboration with three end-user companies having similar objectives. The process guides those responsible for service innovation in structuring, analyzing, and the decision-making of alternative BM extensions. Thus, the presented approach contributes to ICT-related service innovation projects by describing systematic and repeatable activities that are the first step for commercial success.

Keywords: Business Model Design, Service Design, Service Innovation, ICT, Action Research

1 Introduction

From a business perspective, leveraging information and communications technology (ICT) to improve human-centered service systems (HCSSs) makes sense as it enables productivity improvements, cost reductions, and innovation [1, 2]. Visionary companies take advantage of this and put established competitors under pressure to respond to new trends and rethink their value creation [3, 4]. While it appears that not all of the ICT-enabled service innovations solely focus on the strategic competitive advantages, the commercial success of the innovations is important [5]. Here, ICT has to generate value in the corresponding business model (BM) [1]. While companies have problems to generate successful and sustainable BMs [6], neither general approaches that foster BM extensions for ICT-enabled HCSSs exist [7] nor do existing BM approaches cover the required activities of BM design [8].

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Kleinschmidt, S.; Peters, C. (2017): Fostering Business Model Extensions for ICT-Enabled Human-Centered Service Systems, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 897-911

Both research and business practices have recognized the potential of BMs for ICT-enabled HCSSs. In research, the influence of ICT on service innovations and the development of corresponding BMs are named as top research priorities [9, 10]. The connection between the two concepts is seen as important because digital BMs can change the way value is created in ICT-enabled services [7, 11]. Moreover, design knowledge for BMs includes an explicit contribution answering these strategic business questions [12]. In business practice, the commercialization of ICT-enabled HCSSs can have profound economic consequences within an emerging market [2].

Given the importance of the systematic extension of BMs for ICT-enabled service innovations in HCSSs, it is surprising that little research has been done on this topic. Therefore, the research question that is to be answered in this paper is:

How can business models be adapted to commercialize ICT-enabled service innovations in human-centered service systems?

We use an action research project in the field of volunteering to derive a systematic and repeatable BM design process. This process can foster the extension of BMs for supporting ICT-enabled service innovations in HCSSs and facilitating their commercial success. We derive the process based on the existing literature on BM design and test and iterate it in three different project settings. We use the learnings from each case to improve the BM design process that aims at structuring, analyzing, and the decision-making of alternative BM extensions. In conclusion, this paper contributes to the existing literature with an explicit and systematic approach to BM design in HCSSs that considers previous theoretical findings and solves real-world problems.

The paper is structured as follows. After this introduction, the next section provides the theoretical backgrounds of ICT-enabled HCSSs and BM design, which define the key terms and concepts relevant to these related fields. The third section justifies and describes the action research approach used in this paper. The fourth and fifth section contain the derivation of the BM design process from the literature and learnings from the three use cases in our project. The application of this process is described in the sixth section before we then discuss it with regard to its improvements and limitations in the seventh section. In the end, the findings are summarized and a proposal for further work is presented.

2 Theoretical Background

2.1 ICT-Enabled Human-Centered Service Systems

Service and service systems are essential concepts for the understanding of HCSSs. In line with the service-dominant logic, we understand service as a process cocreating context-specific value [13]. It takes place in service systems as it includes several participants, with one of them being the beneficiary. These service systems are "configurations of people, information, organizations, and technologies that operate together for mutual benefit" [2]. Put simply, services are problem-solving based on the capabilities and interaction between the different actors. The various parts are connected via coordination and cooperation to create services [13].

HCSSs, which are service systems with a focus on human interaction and personal services, require particular attention [2]. They differ from other service systems because personal interaction is essential for the value creation [14]. These properties are present in diverse industries such as hospitality, healthcare, and retail, but not limited to these [1, 2]. In this paper, we base our findings on the field of volunteering. Volunteers are part of HCSSs as volunteering can be defined as “giving time or skills during a planned activity for a volunteer group or organization” [15], which implies interaction and personal engagement.

Based on emerging trends such as an increase in digital innovation, there is an expansion of ICT in service systems [1]. ICT is fundamental to many HCSSs [4, 16]. Here, ICT and people are an integral part of the ICT-enabled value creation [17]. As coordination and cooperation are critical to value creation, the leveraging of ICT for HCSSs influences how HCSSs work. Furthermore, ICT enables service innovation that helps to improve and expand the service systems [1, 9]. On the one hand, ICT can enhance the efficiency of current services by simplifying coordination and cooperation. On the other hand, ICT offers possibilities to come up with new services when integrating customers and employees into the service process and substituting them [9].

The presented properties produce a number of challenges. Service innovation, a service system reconfiguration to increase the value for the involved actors [18], is important to remain successful [9]. This is difficult to implement as HCSSs resist traditional optimization solutions and their economic contribution is hard to measure [2]. Also, the dependency on knowledge and customization, as it is the case in volunteering, increases customer involvement in value creation [19]. The support of ICT could solve these challenges [17]. Here, ICT-enabled HCSSs have to prove their benefit over traditional service systems and require mechanisms to build synergies with existing systems [5]. For the systematic design of service systems, concepts of service engineering have been expanded to the system’s perspective, which are coined under the term service systems engineering [20]. So far, none of these concepts, methods, or design processes cover a BM perspective.

2.2 Business Model Design

BMs and their components cover the essential functions of service systems. A BM is a “simplified and aggregated representation of the relevant activities of a company. It describes how marketable information, products and/or services are generated by means of a company's value-added component” [10]. The objective of BM design is to expose business opportunities by defining a value for the participants involved in the service system [3]. The customer value proposition that “describes the benefits customers can expect from products and services” reflects this purpose [21]. Thus, it also shows how a client's problem is solved [22]. This approach is related to how a service is designed and can therefore not be considered separately [6, 23]. A BM refers mostly to a particular product or service with an associated value to the customer [21]. This value to the customer is the basis for the financial return of the product or service [22]. BM design is a critical task for managers and represents a challenge when established BMs are reconsidered and revised [3].

The result of BM design is a set of relevant and individual activities that represent the positioning of the company to customers and competitors. The process of the design is similar in many cases although there is no uniform approach [8]. What is challenging to BM design is that contrary to partial optimization, system-level design is important [3]. A BM that only focuses on value creation and/or delivery without simultaneously considering revenue streams from that value will likely be economically unsustainable [24]. Additionally, when reconsidering existing BMs, there are forces of inertia and resistance to change that represent a challenge [3].

The activities in BM design are supported by different concepts. These concepts represent interfaces to BM design [10]. They help in the development and commercialization of service systems and their corresponding BMs. Thus, we searched for research streams that follow these objectives. To verify the completeness of our findings, we asked two experts of the field for input on such concepts. Table 1 lists the concepts including their objectives and the connection they have with BM design.

Table 1. Concepts Related to Business Model Design

Concept	*Objective*	*Interfaces*
Customer Development [25]	Align product development with customer needs and market	Service ideation, revenue model
Lean Startup Approach [26]	Service development with shortened development cycles	Service development and implementation
Service Design [27]	Design service according to the needs of customers or participants	Service ideation and development
Service Innovation [1]	Reconfiguration to increase the value for the involved actors	Service ideation and development
Value Proposition Design [21]	Define the functionality of services and customer needs	Service ideation, development, and visualization

3 Research Method

Canonical action research combines the generation of scientific knowledge with researcher intervention to solve immediate real-world problems in a formalized form [28, 29]. Here, the fundamental assumption is that an understanding of complex processes can be achieved by changing these processes as well as observing and reflecting the effects. Good results can be expected when the goals of the researchers coincide with those of the field partners and the researchers are actively involved in the process of problem solving [28]. As action research runs in iterations, the cycles of diagnosing, action planning, action taking, evaluating, and specifying learning are repeated until the problem is solved [30]. IS research and HCSS settings such as education have successfully used this research approach in the past [29].

The research presented in this paper was embedded in a research project that aimed at developing and introducing online matchmaking platforms for volunteers. The platforms support organizations to coordinate the placement of volunteers and people or nonprofits in need of help. The research project contained a technical part including the development and testing of the matchmaking software and a business part including the design and implementation of the service system. The project collaboration consisted of researchers, technical developers, and the future operators of the platform. During the project, it became apparent that a BM design was needed based on existing services that had not been available in the prevailing approaches. The objective of the BM extension was to help those responsible for the service financing, improvement, and further operation.

The data collection was initiated in a joint problem analysis with all project partners. Based on the problem description, we conducted a literature review with keywords of "business model design", "customer development", lean startup", "service design", "service innovation", and "value proposition design". High-quality literature was searched for processes that guide the BM extensions for ICT-enabled service innovations in HCSSs. Qualitative data analysis [31] was applied to the found literature to search where the design process starts and ends and what the different steps in between are. Based on the results and with the method of collaboration engineering [32], we planned workshops in three organizational settings (Table 2). We had the chance to develop a BM for every company. Therefore, the three settings represented the research cycles in the action research project. The BM design process took place in seven workshops. The analysis was done in one workshop with all partners. In company A and C, the remaining process was completed in one workshop with a larger group of experts. In company B, the BM design was performed in four internal workshops. Based on the learnings from the previous workshops, we revised the BM design and reapplied it to the next setting. A documentation of the actions was made in the form of protocols.

Table 2. Organizational Settings (anonymized company profiles)

Company	A	B	C
Industry	Regional Development	Volunteering	Care Service
Country	Germany	Switzerland	Germany
Staff	15	75	940
Project Owner	General Manager	Product Manager	Project Manager
Participants	14 (8 external experts)	4	9 (5 external experts)

4 Knowledge Base

4.1 Literature Review

The BM design process is intended to help those responsible for the HCSSs in financing their existing and ICT-enabled service processes by guiding the extension of the BMs. Therefore, the process steps should focus on design including commercialization. We found ten publications that specifically deal with the design and extension of service systems and BMs. Table 3 includes the findings regarding the found publications and their coverage of the phases in the order of their publication date.

Table 3. Results of the Literature Review

Publication	*Steps of the Business Model Design Process*			
	Analysis	Idea Generation	Evaluation & Selection	Implementation
[33]	○	○	◐	○
[3]	○	●	◐	○
[23]	●	●	◐	●
[24]	●	●	◐	◐
[34]	○	●	●	◐
[35]	○	●	○	●
[36]	●	●	○	●
[37]	◐	●	○	○
[8]	◐	●	○	●
[38]	●	●	○	●
● = Covered ◐ = Partially Covered ○ = Not Covered				

Different steps in the process that could be identified include the analysis, idea generation, evaluation and selection, and implementation. None of the publications covers the full BM design process. First, the analysis is mostly a preparatory activity that enables an effective and efficient design of the BM extensions. Because the BM is to be built on an existing service enabled by ICT, the analysis should include a particular business service. A previous analysis of the environment is therefore not necessary. The result could include a visualization of the current service design and BM including ICT [23]. This is used to challenge the individual activities of the service [8]. Second, the idea generation contains the conception of the BM extension. This is most of the time the essential part of the design process. Here, the possible BMs are developed in terms of the definition of activities that generate value for a particular customer segment, specify the service provider, and link the activities with each other [3]. The objective is to conceptualize value creation for the customer and derive revenues for the service provider. The result could be a collection of possible and realistic ideas [23]. Nearly all publications cover this step. Third, the evaluation and selection aim at assessing the developed BM extension and choosing the most promising option(s). This could include the critical questioning of the BM design decisions and the financial contribution [34]. The evaluation outcome depends on the impact on the customer value, the sustainability of the investment and innovation, and the ability to compete with competitors [33]. The result could be a clear idea of which options are available, particularly for quick and long-term successes, and a selection of the most promising BM extension [35]. Fourth, the implementation builds a starting point for a functioning BM as it integrates the transition from concept to operationalization. Therefore, the necessary steps for an implementation are defined including the associated risks [24]. The initiation of quick wins is an integral part of this action [23]. After that, the implemented BM is influenced by a revision and reconfiguration based on external feedback and learnings [8]. This revision ensures a design according to the customer needs.

In summary, the literature reviews show that none of the publications depicts the complete BM design process. Findings were derived with regard to the steps of the BM design process. An explicit application to the service system that focuses on human interaction and personal services is not included. Therefore, this adaptation is part of the workshop preparation and follow-up.

4.2 Workshop Insights

Table 4. Results from the Workshops

Company	A	B	C
Diagnosing	Needs more users so that it is profitable.	Needs further use cases for continuous funding.	Introduced and needs cross-financing.
Action Planning	Definition of possible users of the platform.	Definition of extended users and use.	Definition of additional use with revenue.
Action Taking	Focus on the development of BMs via exploitation of existing resources.	Focus on BMs with new customers through new use cases.	Focus on the definition of customer groups with associated values and revenues.
Evaluating	BM extensions were developed for other age groups and a supply service.	BM extensions were developed for municipalities and companies including implementation steps.	BM extensions were developed for other service providers, local care facilities, and city authorities including a financial concept.
Specifying Learning	More focus on concrete customer values with associated revenues.	Further steps are necessary to implement the design.	Extensions including customer groups, value propositions, and revenue streams.

Following the action research cycles introduced in the method section, the different stages to improve and iterate the findings were completed. Table 4 includes the results from the workshops. The results from the diagnosing phase show that the objective of the BM extension is similar in all cases of the project. The primary problem throughout the cases was that the service was improved by ICT to support the offline service system with a value proposition that remains constant. As this is a platform business and primary customers are not willing to pay (they are volunteers), this challenge included the expansion of the use of ICT-enabled service systems to add additional customers who cover the costs. On this basis, the action planning and action taking for each workshop that describe the purpose of the workshop sessions were defined. The objective was to find new users, new uses, and new revenue opportunities. The learnings from the previous workshops initiated the changes in the workshop. While the first workshop focused on the entire BM with its activities, the second focused on specific customer groups, which was more effective. Based on these customer groups, the associated value proposition, and corresponding revenue opportunities were defined. The learning from the second case was that the design includes the definition of implementation steps. The evaluation of the BM extensions was done in the form of a workup of the workshop results. The experts who participated in the workshops commented on the quality of the BMs. In all companies, BM extensions could be triggered successfully.

5 Result

The result of the iteration and revision is the BM design process depicted in Figure 1. The process includes all activities that are necessary to create BM extensions for ICT-enabled HCSSs. The first three steps, depicted in gray, include activities that are directly related to the design process. The activities in the fourth step, the implementation, affect the BM design retrospectively and guarantee the desired service and BM design.

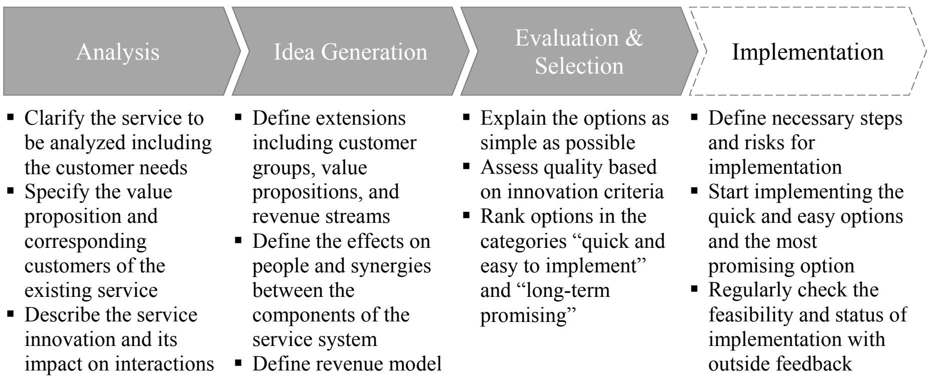

Figure 1. Business Model Design Process

The first step is the analysis of the existing service. Here, the service and the BM that is to be extended are identified and clarified. The value of the service to stakeholders and the activities in the form of a value proposition are an important part thereof [36]. The value proposition canvas [21] can be used to describe the service and specify the customer needs and corresponding values. Moreover, for a shared understanding of the purpose and service output, the effects of innovations from ICT are described. This provides the opportunity to show all results, constraints, and interrelationships of the service system [3]. The analysis challenges the individual activities of the service system [8] with a particular focus on the customers and their value proposition [21]. In HCSSs, the identification of capabilities and interaction is important as they constitute the value cocreation [2]. For a description of all other activities included in the BM and service innovation, the business model canvas [23] can be used.

The second and most important step in BM design is the idea generation. Here, the BM extensions are defined in a structured manner including a customer segment, a matching value proposition, and the value capture expected for the service provider

[24]. There are different starting points for the collection of ideas [23, 24]. The basis for the considerations of BM extensions in HCSSs are the ICT-enabled service innovations that include some new BMs [17]. Desirable are innovations originating from an enhanced customer value that put the customer at the center of service innovation and innovations where the technology is the driver for the BM extension [35]. Here, it is important to know which parts are visible and desirable to the customer [24]. A funding model complements a BM design [3, 23]. It is the result of the division of investments, costs, and revenues. In the end, the options must be assessable regarding the effects and synergies [34].

The third step is the evaluation and selection of alternative BM extensions. Here, the options that have been developed in the previous step are presented to increase a shared understanding. Based on this outline, the quality of the extensions is assessed regarding the BM design decisions and their financial contribution [34]. There are assessment criteria that help to evaluate the quality of the extensions [23, 33]. The evaluation criteria include the customer value offered in the BM, the sustainability of the investment, the stability of the innovation, and the ability to compete with competitors [33]. Moreover, part of the evaluation is whether resources are available or acquisition is possible for the extended BM [24] and whether changes in the relationships and interactions in the service system are needed. The selection will provide the most promising BM extension alternatives and a guide for decision-making [35]. Quick improvements are an important component as well as long-term oriented and promising options [35]. The evaluation is the basis for incremental improvements [23].

The fourth step is associated with the implementation. The process steps include preparatory actions as the actual implementation is not part of the BM design process. Nonetheless, decisions that are made here have an influence on the final design of the BM extensions. Therefore, Figure 1 shows this step by dashed lines. To prepare the implementation, the steps necessary need to be defined. In human-centered design, customer integration should be part of the implementation. Therefore, it should be part of the planning [35]. Results of these activities are documents that specify milestones, structures, finances, and the project plan [23]. Furthermore, the risks of changing the service system associated with the implementation should be documented [24]. In particular, this includes the substitution of humans by ICT [9]. After that, it is possible to follow change management protocols to implement the BM and review the efficacy and any further improvements [37]. The implementation can be monitored by the design parameters and the decision-making and evaluation criteria [34].

6 Application

The developed BM design process was applied in all partner companies. For illustration and better understanding, we demonstrate the use of the process in company C step by step. The partner offers care services that help aged people or persons in other difficult situations to cope with everyday life as independently as possible. Due to the limitation of public and private funding, the care services cannot be applied unlimitedly. When there is little help needed or the need for assistance is at an initial stage, it is not possible to take advantage of these services. To cover this gap and to identify any further demand, the care service company and a housing association started organizing neighborhood assistance in one of their residential properties. To reach more volunteers outside the residential property and to cross-finance the service, the care service company decided to organize the placement of volunteers online.

In the analysis, the existing service has been formally defined for the first time. The results show that the residents are people who usually live alone and have little money from their pension. Some of the people may feel social isolation, loss of importance, and physical decline. They want to experience joy, meet other people, have a structure in their lives, learn, and have the feeling of being needed. The placement service helps older people with early physical handicaps to deal with their everyday life with the assistance of their neighbors. This, including social contacts, helps with simple daily tasks and allows participation in various activities. Neighbors that accompany elderly people can thereby expand their competencies and receive cost compensations due to legal regulations. The ICT-enabled innovation changed the service with the result that the offers and requests can be published and arranged online. Thus, it expanded the group of volunteers to the neighborhood.

In the idea generation of possible BM extensions, options were discussed based on the existing service visualized in a BM canvas. Here, employees of the care service, from the housing association, and representatives of the city authorities discussed ideas and their consequences based on their experiences. Sources for reflections were the needs of the residents and other possible uses of the platform. Obstacles consisted in the clear definition of the users and their needs. Therefore, the prerequisite for adding a new idea was a specified customer group and a corresponding value customers are willing to pay for. In addition, the scalability of the platform was important.

Table 5. Selected Business Model Extensions

Customer	*Value Proposition*	*Revenue Stream*	*Consequences*
Professional service provider	Service platform	Placement fee	Supplementary offering
Local facilities for elderly people	Advertising platform for future customers	Advertising fee	Advertisements for users
City authorities	Execution of municipal tasks	Participation of retirement benefits	Need assessment may be outsourced

In the evaluation and selection, the workshop participants presented the initial idea and summarized the generated BM extensions. Here, a clear definition of the evaluation criteria is crucial for the success. Evaluation criteria were the benchmark from the other volunteering services and the revenue potential. Because competitors already offer similar but specialized services, the BM extensions were evaluated and discussed considering switching costs and a differentiation from competitors. Because the cross-financing of the service was the primary objective, the recurring revenues depicted crucial quality criteria. At the end of the workshop, participants had the opportunity to place their vote for a quick win and a promising long-term solution. For company C, the three BM extensions from Table 5 were selected. These include offers to professional service providers, local facilities for elderly people, and the city authorities. Professional service providers could offer services such as care or medical services for direct booking on the platform. Other local companies that target elderly people could promote their offers on the platform. Also, due to the fact that the platform supports the city authorities in assessing the needs in the neighborhood, the platform provides help for social tasks.

After the workshops, the implementation started with the definition of the steps for each BM extension. Here, this task included the acquisition of the appropriate partners that meet the quality standards, definition of the necessary technical adjustments in the system, and activation of a test group that can provide feedback on the developments. The usage as an advertising platform was a quick win and starting point as the technical adjustments were the smallest and the potential customers easy to reach. Since each placement on the platform also poses a threat to individual privacy, the protection against fraud was a significant risk aspect that needed to be considered for all options. The selected business model extensions enable the care provider to use different revenue streams that can together ensure long-term financing. Commercial success can be achieved even though the main objective has a social and voluntary background.

7 Discussion

Several different approaches aim at generating successful and sustainable HCSSs and corresponding BMs. However, how business models can be adapted to commercialize ICT-enabled service innovations in HCSSs remains unclear. Consolidating contributions from different approaches and considering properties of ICT-enabled HCSSs, we were able to answer the research question of this paper by deriving and testing a BM design process. The objective of the four-step process is enabling those responsible for service innovation in structuring, analyzing, and the decision-making of alternative BM extensions. Although prevailing approaches offer the possibility to design BM extensions, our proposed BM design process provides operationalized steps that allow for the integration of HCSSs, can be used for established service systems, and enable a combination of BM design and service innovations. The value of the method combination is thus included in the in the prescriptive knowledge of the BM design process and its steps.

BM design is a distinctive activity that requires a systematic approach [3]. Nevertheless, present approaches do not comprise the entire process and do not include any operationalization in form of a step-by-step instruction of activities that have to be done. What they offer are, on the one hand, rules that help to find the right design for the right market [24, 33, 35, 38]. These are useful because they make generally accepted statements that are valid for all product and service systems. In addition, they are useful to verify the BM design in terms of strategic fit and competition. They do not have a specific character and do not refer to any specific domain. On the other hand, present approaches offer a high-level process in which BM design represents only a part [8, 34, 37]. These approaches are important in order to consider all of the steps. This does not define a concrete result and does not specify when, what, and how something has to happen in the design process. Other approaches include the right steps but are difficult to use because of their large coverage [23]. Our approach is a guide that includes all steps with specific activities. This is associated with a specific beginning and end of the design process. This allows for an application in different domains and a clear adaptation to the respective needs. In our case, there is a special consideration of HCSSs in the form of an analysis of the interaction and the impact on the people in the service system. The workshops showed that these points were important in the discussion about the suitability and sustainability of the BM design alternatives.

Although BM design is particularly difficult for managers of established service systems [3], no approach provides a guide for this situation. Some approaches are assumed to be able to be applied to already established service systems [23], but they offer no distinction between their actions. The analysis of the environment and competitors [8, 23, 36] provide knowledge that exists in an established service system. These activities focus primarily on gaining competitive advantages, contrary to the focus on commercial success of the ICT-enabled service system [5]. Our proposed BM design process starts with the analysis of the existing service system to promote a shared understanding of the existing service system and its value proposition. In addition, the aspiration of the previous approaches to create new markets [33] is not always practical. Starting with service innovation as a system reconfiguration [18], the ICT-enabled extension of the service system usually aimed at improving existing services. A commercialization on new markets is afflicted with risks [24] and the acquisition of new resources [23], which may not be desirable. Our approach is based on existing technical innovations and/or their ability to create a new value for customers. It turns out that the adaptation of the service system offers the possibility for compliance with restrictions, for example, the focus on interaction, as it is the case in HCSSs.

The development of the process shows that BM design is interdisciplinary as it covers both the design of the service itself as well as related BMs. This is relevant because a service is a process cocreating a context-specific value [13] and HCSSs depend on human interaction and personal services [2]. The value creation and thus the commercialization can only happen with the connection of both. Correspondingly, the literature used in this context comes from various directions. It should be noted that most of the existing approaches focus on the BMs or service. Contributions that include a combination of both are usually of theoretical nature [37]. Our solution provides a BM design that includes the interrelationships between service process and BM innovation, as it has been requested [9]. Different aspects are considered. The process aims at both the customer and the technical innovation. Thus, it covers the most likely drivers of innovation [23]. In addition, BM design provides the possibility to do system-level design and the design of service components [3]. Overall, our approach thus includes different aspects of BM design and service innovation.

The presented research is not without limitations. As BM design is an iterative process [22, 24], the development of the BM extensions with the help of the BM design process is just the first step in achieving a sustainable financing for the ICT-enabled service innovations. We developed and iterated the process with our partners based on a theoretical background. In doing so, new activities were tested in different settings to improve the results. The process presented here includes all activities that have been found useful. Thereby, completeness is not claimed. Nonetheless, we showed that the proposed design process generates several possible and realistic BM extensions that are a good starting point for an iteration with customers and partners. In addition, the acquired knowledge provides an understanding for and from a particular domain with a specific problem. The action research method used to develop the BM design process provides the possibility to learn from joint problem solving, but does not allow an overall generalization of the findings. An abstraction of the findings is only acceptable if the situation and domain are similar to that presented in this paper. To counter this, we based the development of the BM design process on prevailing approaches and iterated the findings in different companies. This allows a comparison with these approaches and expands the application to the presented theoretical background. Therefore, our findings on BM design can be helpful for situations in which service innovation is enabled by ICT and value creation is changed.

8 Conclusion

BM design for ICT-enabled HCSSs focuses on creating value for companies and customers. To capture this value, we derived a BM design process that guides the development of BM extensions. Building on previous contributions from this field, the process was iterated and revised in our action design research project. We used the learnings from three organizational settings to create a systematic and repeatable approach. The result is a BM design process that allows for the revision of the service systems and the corresponding BMs in synergies with and with respect to the existing ICT-enabled HCSSs. The resulting BM extensions foster the commercial success and the long-term financing of the service systems.

With this paper, we offer several contributions. First, the BM design process guides those responsible for service innovation in structuring, analyzing, and the decision-making of alternative BM extensions. The BM design process provides concrete steps and activities and is designed for an application in ICT-enabled HCSSs. Thus, it provides an approach that is relevant to all ICT-related service innovation projects. This process is the first step for the commercial success of ICT-enabled HCSSs. Second, we contribute to the body of knowledge as we provide insights into the combination of the two research streams that have mostly been tackled independently so far, that is, BM design and service innovation. We promote a further understanding of the steps and activities in the design of BM extensions and enable a systematic support of both. Third, by enabling the funding for three volunteer platforms, we solve real-world problems with our research. This confirms the relevance of BM design and shows other objectives besides sustainably competitive advantages.

Future work can build on the developed BM design process. The documentation of the successful application can extend the discussion on BM design and produce suggestions for further improvement. The process can be adapted to other application areas to support the digital transformation. In addition, the long-term success of the developed BM extensions can be examined.

Abstract. Because of its potentially disruptive influence on business models (BMs), blockchain technology has sparked a lively debate among researchers. Our Delphi study sets out to explore the impact of blockchain in payments, which represents a major cornerstone of banking and the cradle of this technology. The results, grouped around four areas of thoughts, indicate that blockchain allows the offering of new services and renders some of the current ones obsolete. This consequently impacts the financial structure of firms in the payments industry and further generates great potential for new BMs while making some existing ones obsolete. Eventually, new players, which are better able to leverage the potential of blockchain, will give a strong impulse to this development. Our findings contribute to the literature by providing new insights about the impact of innovative technologies on BMs and have further practical implications by presenting a better understanding of future BMs in payments.

Keywords: *blockchain, business model, Delphi method, innovation, payments industry*

1 Introduction

Technological changes pose new challenges and generate further opportunities for firms. In particular, innovative technologies have the potential to modify the equilibrium among the firms in an industry. Leading firms consistently fail to stay at the top of their industry when technological discontinuities occur [1]. Not promptly identifying their impact on the business model (BM) may even result in a ruinous error [2]. Examples are the introduction of digital cameras, smartphones, and online streaming. Companies such as Eastman Kodak, Nokia, and Blockbuster had to leave the market because of their inability to adapt their BMs to a changed technological environment. Hence, it is extremely important to clearly assess the consequences that the introduction of new technologies for the BMs in the affected industry can have.

During the last years, the financial services sector has gone through far-reaching changes partly due to the recent financial market crisis. Nowadays, the move toward digitalization of processes and products is further pushing banks and other financial institutions to rethink their strategies, BMs, and operations. The advent of new technologies, combined with a decline in margins and the rise of new competitors, are pressuring incumbent companies to find viable solutions that would allow them to cope with

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Holotiuk, F.; Pisani, F.; Moormann, J. (2017): The Impact of Blockchain Technology on Business Models in the Payments Industry, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 912-926

the new environment. It is under this scenario that especially a technology named blockchain is attracting the attention of the actors in the financial sector for its potentially revolutionary enhancements of operations and financials. Following [3], blockchain technology stands for a radical shift to direct transactions between end parties without current intermediary services building on a consensus mechanism to verify new transactions, and a decentralized record keeping of all transactions.

Although the misuse of bitcoins has aroused some skepticism in the payments industry, the technology behind this early form of new digital currency has gradually imposed its evocative presence. Over recent years, blockchain-based applications have multiplied and use cases that cross over the boundaries of the payments field have been envisioned. Blockchain is thought to have an extraordinary potential [4,5] and its adoption in the payments industry is believed to be groundbreaking [6].

Nevertheless, even if preliminary predictions about the effects of blockchain for specific parts of the financial sector have been made, a clear delineation of the consequences that it might have for the overall payments industry has yet to be identified. To address this point and contribute to the literature related to BMs and technological innovations, this article answers the following research questions: *How does blockchain technology impact current and new business models in the payments industry?*

The results are based on a Delphi study among experts in the payments industry knowledgeable about blockchain technology. The study is composed of three rounds. In total, 45 experts from several European countries have agreed to take part in the study. The results, grouped around four areas of thoughts, indicate that blockchain technology will affect the BMs in the payments industry by (1) allowing new services and making some of the current services obsolete. (2) Through this change in services, a subsequent impact on the financial structure of firms in the payments industry is realized. (3) This generates a great potential for new BMs in the market while some existing ones become obsolete. (4) Eventually, the industry is impacted by new players that are better able to leverage the potential of the technology. Our contribution lies in the analysis of the impact of new technologies on BMs using the example of blockchain technology.

The remaining part of this article is organized as follows. Section 2 outlines the conceptual background of the paper. In particular, it covers cornerstones of BMs as well as blockchain technology and delineates the current situation of the payments industry. Section 3 explains the methodology of our study, whereas section 4 presents the results of the Delphi analysis. Section 5 discusses the implications and limitations of the study. Section 6 concludes the paper.

2 Background

2.1 Business Models

BMs are a relatively new concept in management studies [7]. The first apparition of the term can be dated back to 1957, but it is not until the end of the twentieth century that it has broadly attracted the attention of researchers [8]. Although a specific definition has still to be found [9], a BM has been identified as the "story that explains how an enterprise works" [10] or also as the way firms do business. Further definitions of the term have been proposed in the past. Nevertheless, the concept of value represented a central aspect in many of the descriptions given by researchers since the early studies published around the topic [9–13]. Therefore, the definition of BM adopted in this paper follows this approach established around the concept of value by Osterwalder and Pigneur [12], which identifies a BM as "the rationale of how an organization creates, delivers, and captures value".

Next to the concepts of value, strategies, and processes, research on BMs has also delineated a strong link with technology. In particular, the design of IT systems able to support BMs has been one the most cited issues in the early 2000s [14]. BMs represent an intermediate layer – the link between a firm's strategy [8], processes [15], and information technology (IT) [7,16]. This relationship between IT and BMs is fundamental to understand, design and leverage organizations [16]. Technological innovations alone do not assure the success of a firm [17]. A BM is important to secure a competitive advantage [18] and to mediate between the development of technologies and the creation of economic value [13] as well as firm performance [19]. It is essential to capture the value from an innovation and assure its commercial success [11].

The link between BMs and technology further assumes a particular relevance when analyzing the introduction of technological innovations in a specific industry. Inertly maintaining longstanding beliefs and not adapting a company's BM to technological discontinuities has proven to carry fatal consequences [2]. Evidence from the drug industry suggests that in order to have such an effect, new technologies should "create new dependency ties and reshape collaboration patterns" [20]. Therefore, it is imperative to assess opportunities and challenges engendering from technological changes. This article uses the blockchain in payments to evaluate the impact that a new technology has on the BMs of firms in this specific field.

2.2 Blockchain Technology

Blockchain has been initially launched as an approach to payment transactions based on cryptography to provide an alternative mechanism for the trust between two transacting parties [21]. This technology enables a collective bookkeeping system (ledger), which, by means of a mathematical function (hash function), allows participants to reach an agreement on the approval of a transaction. The information concerning single transactions is gathered in 'blocks'. These blocks are reviewed and verified by the network and added in a chronological order on the computers of all participants of the network. A distributed ledger of verified transactions of a particular unit is then provided to the network. As such, the traditional role played by financial institutions as trusted third party, able to mitigate the risk behind a transaction, is under scrutiny.

Bitcoin was the first digital currency and remains the largest until now [22]. Furthermore, it represents one of the most famous applications of blockchain technology. Nowadays, blockchain is being proposed as a solution for a broad spectrum of transactions, which range from real-time payments between two parties (rapid settlement and without requiring a bank account) to transferring funds across currencies (micro payments, remittances), and digital assets (digitally stored records of ownership).

The impact of blockchain technology might go much further than some modified processes and a few new products and services. A number of authors expect that the consequences might be much further reaching in that entire BMs will be affected [4,5]. In this sense, the impact on BMs through blockchain technology might be a good example for the far-reaching potential of IT [23].

Accordingly, blockchain technology or the more general term of distributed ledger technology (DLT) has raised huge interest in the Information Systems (IS) community, e.g. with regard to trust and cryptographic aspects [24], to the procedure and implications [3], as well as to diverse issues of virtual currencies [25]. Hence, this paper aims to further contribute to this literature by providing an enhanced understanding of the implications that the introduction of this technology might have on BMs.

2.3 Payments Industry

The payments industry represents one of the major business fields of financial institutions. In effect, payments are not only a lucrative source of revenues, but they are the anchor product for various other services and, furthermore, a critical element in terms of customer data. For banks, payment information is a source of knowledge about the customer and, further, is an opportunity to generate points of reference to integrate business processes into the processes of their customers. Thus, losing stakes in payment transactions would cause disastrous consequences for banks.

Currently, the payments industry in Europe finds itself in a state of great upheaval triggered by regulatory as well as political initiatives. Among them it is worth mentioning the creation of the Single Euro Payments Area (SEPA), the establishment of instant payments, which is already decided and on the way, the revised payment services directive (PSD2), which will become effective in 2017 in all EU member states, and the regulation on interchange fees (EU 2015/751). Most of the current projects serve the goal to harmonize the euro payments market in Europe, as well as to encourage more competition and open the market to new entrants.

Globally, the emergence of smartphones has allowed new players, such as large technology and telecommunication enterprises, entering the market. Furthermore, numerous companies from the fintechs arena (start-up companies in the financial services sector relying heavily on IT) have emerged.

Squeezed in between the need for investments in compliance and IT, the erosion of income from traditional sources, and increased competition, the BM of many financial institutions is already under pressure. Therefore, any further attempt to make the current payment infrastructure obsolete or to pull away payment transactions from banks and other financial institutions strongly contributes to deteriorating their BMs. In this regard, blockchain technology represents a fearful threat, especially since it might switch off the third-party function of financial institutions in payments. At the same time, however, the reduction of costs that could be realized by the use of blockchain in payments induces financial institutions to closely look at its development.

This promising potential of blockchain technology has roused large attention at existing payment infrastructure operators such as SWIFT, providers of international payment transactions as well as regulators. Enterprises from both technology as well as the financial services sector are considering and launching prototypes of blockchain-based solutions. In particular, incumbent companies try to defend their BMs by applying a range of strategies from developing in-house platforms to directly investing in blockchain companies, partnering with them, or offering accelerator services to explore blockchain applications.

Large banks have started to participate in worldwide collaborations (e.g. R3, among them Citibank, Credit Suisse, Deutsche Bank), and almost all major consultancies as well as auditing firms offer their expertise and try to position themselves as the leading knowledge carriers.

3 Research Method

The analysis at the center of this paper is based on a Delphi study conducted among experts from the payments industry knowledgeable of the blockchain technology. Given the lack of existing research and the exploratory nature of our study, open qualitative interviews would have been an option. However, the industry still shows a high degree of uncertainty on the study's topic. Furthermore, based on our industry insight, specific expertise could clearly be located. This advised a multi-stage study in a more formalized and group-oriented approach. Therefore, the Delphi approach was the method of choice [26]. The Delphi method was developed in the 1950s [27] and has become a common tool for measuring and aiding forecasting and decision-making [26]. It is especially appropriate for exploratory theory building on interdisciplinary issues, which often involves new or future trends [28,29]. Hence, the method is highly recognized in research concerning technology forecasting [30,31] and has been used extensively in IS research to identify and rank key issues for management action [32].

The Delphi method allows for the discussion of a complex issue through a structured communication process [33]. Dakey and Helmer [27] define Delphi as a method that attempts to obtain the most reliable consensus of a group of anonymous experts. Four distinct characteristics are presented by von der Gracht [34]: anonymity, iteration, controlled feedback, and statistical group response. With respect to our research aim and as suggested by Murry and Hammons [35] we chose a 3-round procedure. In this regard, we follow Fan and Cheng [36], who suggest three rounds as being sufficient to reach consensus and borne in mind time constraints which might influence the method [34].

Round one (R1) aimed to derive panelists' insights and opinions. In round two (R2) panelists evaluated the results of R1. Round three (R3) asked panelists to reevaluate the results in light of the group feedback. Although we recognize that the Delphi method has been widely reviewed [31,33,37], we briefly outline the identification of experts, data collection as well as analysis, and explain the specifics of our study.

3.1 Identifying the Panel of Experts

The most important criterion when selecting panelists is the individual expertise on the issue under study [38]. Therefore, we took the requirements described by Hill and Fowles [39] as well as Adler and Ziglio [31] into account. Accordingly, we selected qualified experts depending on their work experience in payments and/or blockchain technology, their professional position, and the role and background of the company they work with. A key requirement for experts to be selected was a thorough understanding of blockchain technology to assess its implications on payments. In addition, a deep understanding of payments was needed to assess industry-specific consequences for BMs. For the identification and validation of experts, we used web search, talks with practitioners, and databases of professional networks. Hence, the Delphi panel was composed to be a representative mix of experts [3] and included 45 panelists: 16 (35%) from consulting, 11 (24%) from fintechs, 6 (13%) from banks, 4 (9%) from academia, 3 (7%) from public institutions, 3 (7%) from payment service providers, and 2 (4%) technology providers. The high number of consultants is explained by their current leading role in collaborative projects with banks and technology companies with regard to blockchain technology. The panel has not changed throughout the study, but size reduced due to minor dropouts. The stable core enabled us to deduce a broad range of answers from a wide spectrum of organizations while still staying with a clearly focused evaluation and consensus process [40].

3.2 Data Collection and Analysis

Due to the iterative and multi-stage nature of Delphi studies, data collection and analysis are presented jointly. In R1, we sent out 45 emails to the panelists where we asked them to independently provide ideas, thoughts, and opinions on the development of blockchain technology. According to Linstone and Turoff [33], we designed R1 with an open-end format, suggesting starting points around BMs. This was done to elicit individual perspectives, judgments, and opinions from each panelist. In order to develop a general framework in the direction of our research question, the starting points were created by the researchers as suggested by Schmidt [32]. Hence, to stimulate answers in R1, broad questions (e.g. future scenarios, products, and technology) were provided where panelist could deliver their input. All answers were submitted via an online form.

We received 38 responses. For easier reading and analysis the responses were collected in one document resulting in 20,000 words of qualitative data. In order to distil the most relevant statements, the input was coded by three independent researchers with a moderator coordinating the coding activities. First, the researchers went through all answers and developed their own code list. Second, the moderator guided the discussion among the researchers to generate one code list which reflected all relevant input. Finally, the researchers translated all codes into better readable and easily understandable statements. As an example, the code “new business models” was translated to “With the blockchain technology new business models in payments will develop”. All statements relevant to our research are presented in section 4. By means of the coding in R1, an initial set of 45 statements was produced describing the implications of blockchain technology in payments.

In this paper, we analyze and discuss those statements which are relevant for BM research in relation to blockchain technology. The researchers identified 17 out of the 45 statements as being relevant to the objectives of this research. The statement selection was based on the following criteria: threats and opportunities for existing BMs, need for revising current BMs, implications for designing new BMs, and new service offerings in the industry with substantial potential for new BMs.

For the subsequent evaluation of the statements in R2 and R3, we had to take into account that the expert panel consists of practitioners with limited time as well as relatively low methodical understanding. Hence, to better facilitate the evaluation, the statements were presented through the use of an online tool (Qualtrics) with a strong focus on intuitive readability. In R2, we exclusively considered the 38 panelists who completed R1. These experts were presented with the statements generated in R1 and asked to provide an evaluation of each statement on a six-point Likert scale ranging from "Strongly agree" to "Strongly disagree". Six points were chosen to encourage clear decisions toward agreement or disagreement but at the same time to offer enough options for a differentiated evaluation. At the end of R2, the evaluation of each statement was received from 36 out of the 38 panelists.

This group of 36 experts was further considered in R3, where the identical statements from R2 were presented to the panelists, along with the group's responses from R2 combined with each panelist's own evaluation. Since we required a high degree of clarity to present the responses we adopted intuitively usable measurements. Hence, solely graphical representations of the evaluations were shown. This approach exceeds the standard Delphi method, but assures the correct interpretation, as Argyrous [41] stresses that the mean of ordinal data is misleading and incorrect. In the end, panelists were asked to provide their individual evaluations in light of the group evaluations in R2. In total, 34 responses were collected from R3 (Table 1).

Table 1. Response rates within the Delphi panel

Round 1		*Round 2*		*Round 3*	
Sent out	Complete responses	Sent out	Complete responses	Sent out	Complete responses
45	38 (84.4%)	38	36 (94.7%)	36	34 (94.4%)

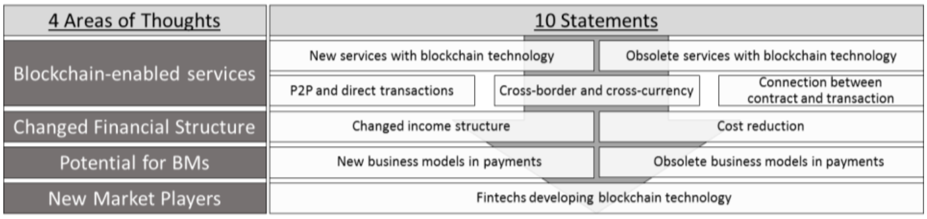
After finishing R3 we checked group stability, as defined by Dajani et al. [42] and Linstone and Turoff [33], with the majority of panelists agreeing to the statements. Across all statements, the average for agreement was 87% and only 13% for disagreement.

Next, we compared two statistical measures, variance and variation, of R2 and R3 to determine if consensus was achieved. The average variance was reduced from 1.23 in R2 to 0.96 in R3. Furthermore, the average variation decreased from 47% in R2 to 43% in R3. Finally, we selected those statements of the initial 17 with the highest consensus values. First, we used a predefined level of agreement of 75% on our 6-point Likert scale. This seems reasonable as similar research uses percentages between 60% [43] and 80% on a 5-point Likert scale [44]. Second, we required a variation score below 50% as suggested by English and Keran [45]. Third, statements were excluded when the variance was above 1.0 [34]. As a result, we were able to identify ten statements meeting the before mentioned criteria.

4 Results

The ten statements are the result of the Delphi method and best summarize the implications of blockchain technology on BMs in the payments industry based on the expert panel. Figure 1 illustrates how the ten statements are synthesized into four areas of thoughts: (1) Blockchain-enabled services as a first cluster indicate how new services around peer-to-peer (P2P) and direct transactions, cross-border and cross-currency transactions, as well as the connection between contracts and transactions are being introduced. At the same time some existing services are rendered obsolete. (2) This change in services causes a change in the financial structure of firms in the payments industry. (3) As a consequence, there is a great potential for new BMs in the market while some existing ones become obsolete. (4) A strong impulse to new BMs is given by new players like fintechs, which are better able to leverage the potential of blockchain technology. Details on the opinions of the panelists are provided in the following.

Figure 1. Implications of Blockchain Technology for BMs in the Payments Industry



We see a strong consensus around the impact on payment services due to the introduction of blockchain, and we argue that there are direct implications at the BM level as the design of BMs involves the definition of services a firm delivers [11].

On the one hand, panelists stress that the development of blockchain technology allows new service offerings to be brought to the market. In more detail, experts mention three service areas, which play a major role in the further development. These services are shaping the development of BMs and are forerunners of the change to come in payments: (1) Blockchain technology is expected to make direct transactions possible without any third party acting as "*trust agent*"[1]. Hence, "*transaction can be executed peer-to-peer*" directly between two contractual parties (peers). P2P transactions can occur between identified parties such as firms or customers; but also between unidentified parties like machines (cars etc.) or even unbanked customers. Furthermore, "*transactions without a middle man*" are paving the way for decentralized trading markets. (2) Blockchain technology is thought to improve international transactions in

[1] All direct citations in this section are taken from the answers panelists provided in R1 and are formatted italic.

cross-currency and cross-border context. The huge potential of these improvements become obvious when looking at globalized trade and the high inefficiency of the current global payment infrastructure. Today, cross-border transactions are time-consuming, lengthy, and expensive. Blockchain technology will make these payments "*faster and cheaper*", i.e. faster by providing a solid, common infrastructure across borders for transactions, and cheaper by removing expensive intermediaries, thus overcoming today's "*lack of trust*". If blockchain technology allows easy international transactions based on digital currencies, currency exchange will erode as a service and remove pricey currency exchange offices. Furthermore, due to the inclusive nature of the technology, global and permissionless accessibility, current high charges for remittances by third parties will fade and erode the respective BMs as individuals can participate directly in remittances abroad. These improvements will be some of the "*biggest impacts*" of blockchain technology. (3) A completely new service blockchain technology will allow is the connection between contracts and transactions. Hence, the technology can be used to keep records of "*contracts of purchase and passing of property*" in addition to the actual transaction. Thereby, contracts of purchase can be directly linked to payment transactions, which is referred to as smart contracts. As a result, blockchain technology can be used as a "*proof of ownership*" as well as a proof of payment. The development of smart contracts will allow the "*automated execution of transactions*". Hence, smart contracts prove to be a critical cornerstone in the current advancements around the internet of things. Finally, the connection between contracts and transactions allows 'programmable' money flows and automation of transactions, which leads to decentralized autonomous organizations, where business rules are coded in the organization and executed automatically under certain conditions [46]. Further, extended service offerings mentioned in several answers, touch upon the relevance of "*making money out of data intelligence*" and data in general. The future for market players will be around payment services enhancing the traditional transaction services. Data can be used to offer "*data analytics*" to deliver deeper insights into payments, which contributes to enhanced "*fraud detection and prevention*". Other important services, which will be needed, are the conversion between traditional payments and blockchain payments as well as personal financial management.

On the other hand, blockchain technology is expected to render obsolete current payment services like third-party trust service, clearing and settlement, as well as reconciliation. As a starting point, most panelists mentioned that today's processes are "*inefficient and slow"*. They particularly refer to the current payment infrastructure (SWIFT and SEPA transactions), which require a lot of manual steps and, hence, *"transfers at a relatively high cost"*. Due to the unified record keeping in the blocks, clearing and settlement services will no longer be needed for payments based on blockchain which rather leads to the implementation of "*fully automated reconciliation*". As a result, the omission of entire process steps is expected to eliminate core services of existing BMs, questioning their existence. Ultimately, blockchain technology *"will allow equal access"* for market players, making payments a commodity.

As a consequence of new services, the financial structure of the BMs changes. The implications are twofold: On the one hand, the revenue structure resulting from payment transactions changes substantially, which means that traditional sources of revenue die out. Yet, at the same time new ones emerge. There is consensus that "*payments will be a commodity*" resulting in very low margins. Furthermore, the currently mainly margin-based revenue structure will erode with transaction fees dropping to "*even less than cents*". Current margins benefit from high complexity and artificially created boundaries between payment networks, which will vanish with blockchain technology. Revenue streams of BMs have to be shifted away from transaction-based margins and have to focus on the provision of "*user-friendly and secure platforms*" or the management of smart contracts. On the other hand, blockchain technology allows cost reductions. For example, the replacement of the currently inefficient payment infrastructure by blockchain technology will free up capital. Also the costs for processing transactions drop, making the transfer of money cheaper. "*The opening of formerly closed systems*" provides great potential to reduce costs. Overall, the increase of efficiency will "*address the rising costs*" of regulation and allow more efficient compliance due to increased transparency. For instance, "*know-your-customer processes will be streamlined*", which results in decreased costs. Furthermore, the faster execution of transactions leads to a reduced risk of default and, hence, to lower costs.

Building on the blockchain-enabled services and the changed financial structure, strong effects on BMs are observable and play a major role when discussing blockchain technology. Nonetheless, the perception is double-edged. On the one hand, we see a strong consensus that new BMs with regard to payments will emerge. For example, panelists stress the importance of data by underlying "*data analytics and further data-related services*". This is in accordance with the trend in our research, that payments-related BMs will only survive if new services are added like "*payments-extending services and products*" and thus BMs are enhanced. Only the creation of "*value-added service*", complementing current BMs, will allow financial institutions to keep their customer base stable. For example, panelists point out that future BMs will no longer build on account service fees but "*hosting and data security fees*" and will be able to "*monetize interfaces*", not just services.

Quite contrary to the great potential of blockchain technology for payments, we see, on the other hand, an equally strong consensus that some BMs in payments will become obsolete. Examples are the traditional margin-based, intermediary or trusted party BMs. The role of a trustworthy broker ("man in the middle*") "will be redundant with blockchains*". Intermediaries face the problem of complete eradication as they are going to be "*extinct because their BM is being replaced with a more efficient mechanism*". Margins cannot provide a source of revenue, as the mere execution of transactions will lose importance in blockchain systems. Blockchain features, like direct transactions, speak against the current structure of the market. This phenomenon is also recently discussed in academic research [3]. Furthermore, it is questionable if financial institutions can maintain their current function as trusted party as advancements with blockchain will enable features like direct transactions and equal access to the market for all participants. It is noteworthy that participants compare the "*future role of payment service providers to the letter mail in the age of the internet*".

Finally, the described changes and implications give rise to new market players. As new players, and particularly fintechs, enter the market, new BMs are expected. Following the panelists, fintechs will play an important role in the context of blockchain technology application in payments. Panelists see fintechs as an "*enabler for market infrastructure*" and as "*specialized providers from outside with a catalytic role*". The increasing number of fintechs like Ethereum and Ripple supports this view. Moreover, there are certain structural and technological boundaries in existing financial institutions that make it hard to change the underlying technology the business is running on (e.g. back office software, inter-organizational payment networks, supra-authority infrastructure). In contrast, fintechs have the advantage of being able to decide for a new technology with fewer dependencies and, hence, adopt blockchain technology considerably quicker. They will play out their advantage to occupy parts of the value chain and offer services industry-wide, which will force existing players to "*acquire white label blockchain solutions*" from fintechs to stay in the market.

5 Discussion

This paper is motivated by the debate on the influence of blockchain technology [24,47] and the growing body of literature on cryptocurrencies [25], combined with the necessity to assess how this would impact BMs in the payments industry.

Our findings indicate that changes due to the introduction of blockchain are reflected in new services as well as new revenue structures and eventually new BMs. Following the definition by Christensen et al. [1], blockchain technology exemplifies disruptive market capabilities, as it currently offers features, which seem uncommon or less convenient, but will change and impact the industry in the long run. The disruptive power of blockchain is further supported by previous literature on the topic [47]. Our findings add a new perspective to the literature on BMs by showing how a new technology could actually impact the BMs of firms in those industries where it is introduced. In this regard, we extend the insights provided by Sabatier et al. [20] and suggest that new technologies have the potential to disrupt the equilibria within an industry especially by undermining the service logic and the revenue structures established within this industry. To better address these situations, banks and other financial institutions in the payments industry have to rethink their current BMs and allow for experimentation. Based on the ongoing development of the technology, these firms have to better assess implications on their current services and products to prepare for the arrival of blockchains. Through cooperation with fintechs, incumbent financial institutions could be better able to benefit from the fintechs' dynamism while limiting the need for large and risky investments until a clear path for the development of the technology has emerged. As first cross-currency transaction conducted by some international banks and the fintech Ripple indicates, a couple of financial institutions have already adopted such an approach.

With the elimination of process steps, the impact of technology will also be reflected in the firms' business processes. Furthermore, we acknowledge the transformative power the technology also poses on society. The inclusive character of blockchain, equal access for all participants and almost zero participants costs, allows addressing the unbanked customer in the developed as well as developing part of the world and new BMs can offer a wide range of services to those customers [48].

The technology is still developing and a lot of try-outs, prototypes and experiments are needed. Nonetheless, the technology receives a lot of attention and was recently added to Gartner's hype cycle of emerging technologies in 2016. Interestingly, blockchain is placed at the peak of the cycle, which shows the attention it has raised as well as the inflated expectations it faces. Still, moving along the hype cycle does not mean that the technology is a temporary hype as some critics raised in the academic literature might suggest [49]. Instead, the development shows the different stages technologies are going through and our findings do not refer to temporary effects. Nonetheless, the full potential of the technology is still not completely foreseeable and the application of blockchain is still highly context-specific. Not every setting in the payments industry is suitable and a number of questions remain unanswered [3]. Questions raised by our panel of experts such as "*For how long shall systems work in parallel?*" or "*Will the technology prove successful and actually make things better?*" still remain open.

Limitations of our research include the reporting of primarily positive aspects of blockchain technology by the experts in R1. Hence, positive aspects seem to outweigh, which can be explained by the fact that people naturally tend to report aspects they are aware of or agree with. Thus the statements focus less on possible drawbacks. Experts were asked for their opinions and judgments on blockchain technology, which might sometimes be far from real use cases or first prototypes. Not every expert necessarily has gathered personal experience with the technology. Furthermore, the expertise on this new technology is still immature and uncertainty remains.

Blockchain technology is at a young age and research on the matter is still scarce. Future research should deepen the findings of this paper in two directions. First, as described by Al-Debei et al. [15], we see implications from BMs to the underlying business processes. Hence, an analysis of business processes at an intra-firm level is promising and allows studying implementations of blockchain technology within fintechs or first prototypes developed by incumbents. This could also be deepened with a case study analysis and/or interviews with founders of fintechs with the focus on blockchain. Second, there are interactions between the BM and the overlying business strategy [15]. Therefore blockchain technology, as it impacts BMs, also yields strategic implications. Strategy has to include digital technology and to establish a closer link between business and IT [50]. Therefore, studying the impact of blockchain technology on BMs and corporate strategy will provide a better understanding of the fusion of business and IT strategy [50].

Our results led to a research agenda in the field of blockchain technology. First of all, it appears to be decisive to better understand new, customer-centered services enabled by blockchain technology and how these services could be used in existing and new BMs in the field of payments. An analysis of the services will also allow to investigate the interplay between new and existing players. Next, it is fundamental to analyze the changes in the cost structure and, hence, the financial benefits of blockchain as costs represent a major driver for the adoption of new technology and changes to the BM. From the adoption and integration of blockchain technology, researchers can deduce the adaptions needed for existing BMs and the potential for new BMs.

6 Conclusion

Blockchain is a new technology with potentially disruptive power, which yields implications for a number of industries [47]. First applications arose in the financial services sector with bitcoins [21], which puts the payments industry at the center of innovations around blockchain technology. Our study is the first of its kind to gather a high number of experts and gain a better understanding of the implications on BMs in the payments industry. Our paper outlines the changes due to blockchain technology, which are clustered in four areas of thoughts. First, new services are introduced, which foster P2P transactions, cross-border and cross-currency transactions, as well as the connection between contracts and transactions, and, hence, make current services obsolete. As a consequence, financial structures of existing BM will change. Third, these changes will be reflected in the development of new BMs, making some existing BMs obsolete. Finally, these changes create a potential for fintechs to enter the market by leveraging blockchain technology.

Summarized, our research delivers insights into how changes in payments, due to blockchain technology, progress and in what directions firms have to think to overhaul their BMs. Our research contributes to BM literature by analyzing the impact of new technologies. Furthermore, the findings yield new research avenues, which are promising to further explore the topic of blockchain. In the end, the saying "one secret to maintaining a thriving business is recognizing when it needs a fundamental change" [18] might prove right once again with BMs in payments.

Abstract. Self-checkout terminals allow integrating customers as active co-producers into a retailer's business processes. They have enjoyed increasing popularity in the past years since they allow saving costs and increasing customer satisfaction. Yet, they cannot be implemented in many retail settings, as the technology relies on retailer provided terminals and does not yet fully utilize the possibilities provided by mobile smartphones, which until recently have mostly served as decision or shopping aids. This paper presents steps towards and results from a field study of a purely mobile self-checkout solution that provides a more time efficient shopping experience to time-constrained users. We show that the time performance of app users is independent of store rush and that the time for a transaction is significantly lower for app users compared to regular shoppers during peak periods.

Keywords: shopping aids, mobile payments, self service technologies, retail, lost sales

1 Introduction

Recent implementations of self-service technologies (SST) such as self-checkout terminals enable users to scan and pay groceries without interaction with the store personal [1]. By skipping the waiting queues of regular registers, SST have been effective at increasing consumers' satisfaction and convenience [2, 3]. Self-checkout solutions today are usually implemented through large physical terminals that include barcode scanners and payment facilities [4]. Some solutions also provide the ability to scan items already during the shopping journey with dedicated handheld scanning devices or the user's mobile phones. However, even in these scenarios the digital shopping basket is transferred to a self-checkout terminal where the actual payment and integration of transaction data take place, creating new, unnecessary bottlenecks. As a consequence, capacity constraints remain during peak times [2]. While current self-checkout solutions are well suited for the digital transformation of regular grocery stores and have become well adopted among these [4], they are not easily applicable to

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Vuckovac, D.; Fritzen, P.; Fuchs, K.L.; Ilic, A. (2017): From Shopping Aids to Fully Autonomous Mobile Self-checkouts - A Field Study in Retail, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 927-941

a convenience store context. Unlike regular grocery stores, convenience formats typically have a high share of customers that only purchase very few items. In Europe, convenience stores are often located at train stations where space is highly constrained and expensive [5] and train schedules often generate significant peak loads of customers. During these high peak hours, convenience stores often experience a high share of lost sales as customers not willing or able to wait decide to abort their purchase or frequent competing stores [6, 7]. Due to the space requirements of traditional self-checkout solutions, it is often not feasible to dedicate the space needed to physical terminals to handle these peak loads more efficiently. While retailers have historically differentiated from competitors mainly through price, assortment and location [8], recent technologic advancements enable increasing differentiation through the use of interactive technologies [9]. We therefore develop a fully autonomous self-checkout solution suited for the fast-paced environment that combines self-scanning and mobile payments. We report findings from a digital transformation project including a field study conducted jointly with one of Europe's leading convenience store operators. Our contributions include a thorough analysis of the pre-transformation situation, critical aspects of the design and implementation of such an information system and results from an evaluation in a real-world pilot deployment with 46 buying users and 129 transactions in a period of 12 weeks. Our results provide valuable insights that are potentially applicable to other cases of digital transformation where end-users are involved in core business processes with own mobile devices. In addition to mitigating the lost sales problem, we open possibilities for forming a digital relationship between consumers and retailers.

The paper is structured as follows. We first study and summarize the relevant literature and illustrate our research context, questions and methodology. We illustrate the current situation and based on this we design a target shopping process adapted to our research context and provide an overview of our system architecture. We then discuss results from our field study and finish with a conclusion and outlook.

2 Related Work

2.1 Shopping aids

Many retailers have deployed technology solutions traditionally known as shopping or decision aids to assist shoppers in their shopping journey [11]. Common shopping aids, both online and in-store, can either help screen and narrow down available products or allow for the in-depth comparison of selected products [12]. While shopping aids in the form of in-store kiosks have been around in physical retail for a longer time [10], they have been used and studied much more in detail in online settings [11–13]. Online shopping aids have been shown to reduce search costs and increase convenience and the quality of purchase decisions [11, 12]. They can help enhance store loyalty but can also increase consumers' price and promotion sensitivity [13]. Furthermore, implementations of shopping aids in physical retailing besides in-store kiosks, such as smart shopping carts, can increase spending and re-patronage intentions as well as satisfaction and loyalty of users [14, 15]. Yet, such solutions require high up-front investments. However, the increasing ubiquity of smartphones paired with their mobile and personal nature, has made the operationalization of personalized shopping aids economically and technologically feasible in physical retailing on a much greater scale [16]. Thus, consumers are beginning to increasingly utilize mobile phones in the shopping process–currently mostly for information search in the pre-purchase phase and less for actual purchase transactions [17]. However, research has also shown that consumers shop differently online compared to offline [13] and that mobile shopping aids are overwhelming shoppers with information instead of providing key functionalities [18].

2.2 Mobile Payments

Mobile payments can be defined as all transactions in which consumers use a mobile phone to transfer money or funds from one party to another in exchange for goods or services [19–22]. In general, one can distinguish between *remote mobile payment applications*, in which transactions are made independently of the location of the user and *proximity mobile payment applications* in which a user's mobile phone communicates locally with the point-of-sales (PoS) [20]. While the former resemble online payment systems known from e-commerce settings, the latter require a solution to link the digital and physical economy [23]. Such solutions include utilization of short-range wireless communication protocols such as the Bluetooth protocol or near frequency communication (NFC) technology [23] or the scanning of a 2D barcode [24]. Mobile payments are frequently considered the "killer" application of mobile communication networks [25] and seen as the most critical driver for the success of mobile commerce [21]. Yet, the adoption and usage of mobile payments remains sobering and below expectations [20, 26–28]. Nevertheless, expectations are currently rising again due to increasing penetration of the NFC technology [26].

Several studies have highlighted the security and trust as prerequisites for the adoption of mobile payments [22, 27]. Research on mobile ticketing systems, where the transaction itself happens remotely and independently of the location, yet the ticket verification happens locally, show that convenience and speed have a big impact on perceived usefulness and the use of mobile ticketing systems [29, 30]. In such manner, people are willing to use even more complex ticketing systems when they are in a hurry or try to avoid queues [30]. Hence, the relative advantage of mobile payments is among others driven by possible queue avoidance and situational factors such as the presence of queues, support the adoption of mobile payment solutions [19]. Yet, current mobile payment solutions require mobile devices to interact with the same established PoS [20, 28] and thus require users to queue at the same register, offsetting potential advantages.

2.3 Self-service technologies

Self-service technologies (SST) can be defined as technological interfaces that allow customers to coproduce a service without employee interaction [1, 31–33]. Retailers mainly offer SST to reduce costs and improve customer experience [3]. The most frequently mentioned advantages of SST are convenience and speed [2]. Negative experiences include forced experiences of self-checkout uses, instances when self-checkout terminals have been closed at certain times of the day (i.e. night) and the fact that these terminals happen to be slower when there is a queue [2]. In accordance with this, researchers find complementary reasons for the use of self-checkout terminals and traditional checkouts at traditional retailers and advice practitioners to offer both in addition to another [34]: With respect to this, researchers have found evidence that SST customers tend to use self-checkout terminals for smaller baskets and might avoid items that require additional steps in the checkout process (e.g. fruits, vegetables etc.) [32]. In fact, small shopping baskets turn out to be a key reason for self-checkout usage and are only topped by long lines at traditional PoS [35].

The service quality of SST is mainly determined by functionality, enjoyment, design, assurance and convenience and has a positive impact on customer loyalty through customer satisfaction [3]. However, while the first trial and adoption of SST constitutes the most prominent obstacle since it usually involves significant behavior change [36], actual waiting time at regular checkout terminals acts as an important determinant for actual use [37]. From an industry perspective the main concern regarding self-checkout solutions is the potential increased risk of theft. While there is little evidence regarding the impact on retail shrinkage, the studies available suggest that there is no increase [38, 39]. To the best of our knowledge, there exists no implementation or analysis of a fully mobile self-checkout solution in grocery retailing.

3 Research Framework

3.1 Research Context

Our study is carried out in collaboration with a leading European convenience store retailer with a physical store network of over 1000 stores–most of them located at public transport transit points such as train stations. For a pilot study, we have selected three stores at Zurich main station. None of the stores currently have a self-checkout solution in place. In fact, traditional self-checkout solutions have been evaluated as unprofitable due to high place requirements and investment needs. Also, there is no mobile application or shopping aid offered by the retailer at the time of the pilot start and mobile payment support was introduced just shortly before the pilot start. Due to the fast paced nature of the business at the pilot store locations, there is no loyalty card system in place either. The retailer suspects and has anecdotal evidence that a high share of sales is lost due to long queues and time pressure of customers during peak hours.

3.2 Research Question and Methodology

The key challenge is to enable a self-checkout system that allows consumers to fully autonomously purchase products in a grocery store even under time pressure. To address this complex problem, we follow a design science approach [40]. First, we aim to leverage insights from store workers and managers as well as quantitative data from the three existing stores to get a better understanding of the extent and nature of the problem. Second, we translate the learnings in an iterative system design and implement a corresponding artefact consisting of a mobile application, an instore feedback component, and a backend system. Our development process focuses on previously outlined constructs from SST and mobile payments research, namely functionality, relative advantage, complexity and convenience [3, 36] and perceived risk, assurance, security and trust [3, 22, 27, 36]. We optimize these constructs over multiple test phases and iterations with various users. Finally, we evaluate the artifact in a 12 week pilot deployment. The corresponding research question we hereby aim to address is whether such an implemented artifact provides added benefit to users. We operationalize this by ultimately measuring its repeated use [41] and quantifying time performance during more and less busy periods of the day [42], as well as the difference to the regular shopping time during busy periods, as waiting time has been revealed to be a key issue for our industry partner and was shown to impact the satisfaction-loyalty relationship of retailers [6, 7].

4 Design and Evaluation

4.1 Analysis of Status Quo

The following analysis is based on one year transaction data for two stores and half a year for one of the three pilot stores with more than 1.2 Million receipts in total. The highest frequented store has on average about 2,300 transactions per day, followed by 1,500 transactions by the second and about 700 from the smallest of the three stores.

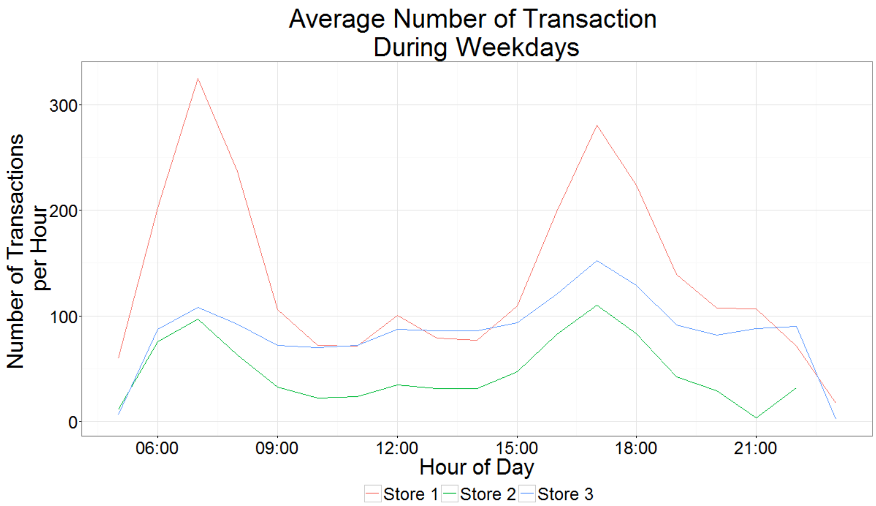

Figure 1. Distribution of average number of transactions per hour throughout weekdays

All of the three stores are characterized by very small shopping baskets with on average 1.5 to 1.8 items per transaction and an average basket value between 6 and 10 CHF. None of the stores currently have a self-checkout solution in place. The share of baskets that include alcohol, tobacco or services (ultimately, products that cannot be purchased through the mobile application), lies between 18 and 36%. The most popular products include soft drinks, beer, (self-service) coffee, tobacco, newspapers, magazines and bread and pastries. Our research partner does not offer a loyalty program and has thus no clear insight into consumption patterns of consumers. Due to the central location of our pilot stores and the high share of commuters, two of the three stores are characterized by high peak demand before and after working hours. Figure 1 illustrates the average daily pattern during weekdays for the three different stores. All of the three stores have their highest number of transactions either between 7 a.m. and 9 a.m. or between 5 p.m. and 7 p.m. Store 1, also the biggest in size, is characterized by the highest increase during peak hours of more than three times the average demand during. Especially this store exhibits very long queues during rush hours and customers are faced with long waiting times. We therefore argue that it is critical that a mobile self-checkout application minimizes the required time and effort for customers even during peak hours in the presence of long queues. Furthermore, it is important to mention that all the stores in our pilot are part of a chain and thus not stand alone stores, yet the mobile self-checkout application is only supported in the respective pilot stores.

4.2 Target shopping process

The key functionality of our mobile application is to buy physical products from a brick-and-mortar retailer without interaction with the PoS. The shopping process is composed of four main operations: A user has to check into the respective store before choosing products in order to see the correct price information. Users then select products by scanning the barcode printed on the product or shelf. After scanning the barcode, the user can adjust the desired quantity and then add the product to his (virtual) shopping basket. The user can then review his basket and start the checkout and payment process. The process is completed once the user confirms his transaction and the due amount is charged to the credit card information stored on the user's mobile device (Figure 2).

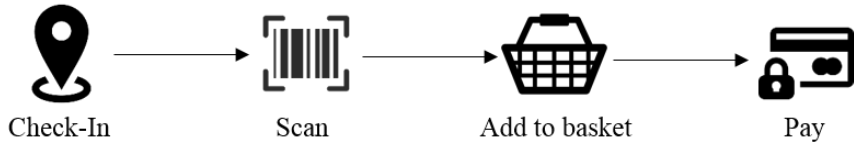

Figure 2. Illustration of target shopping process

The system was developed in several design iterations. The first iteration was conducted together with store workers and managers in order to come up with a first initial implementation which also allows store workers to track and identify valid transactions of users and thus emerged as a key requirement. The second design iteration took place in a lab setting where students used a first proof of concept and were faced with a typical shopping assignment. Based on feedback from seven testers, the design was refined. Eventually, it emerged that the testers favored a version of the self-checkout application that included a physical touch point (a QR code) within the retail store. The third design iteration took place in a real store setting where eight testers used the mobile self-checkout application executing real transactions in order to buy a product of their choice in one of the pilot stores. We again collected user feedback and use this to improve the mobile application's usability, mainly focusing on in app communication and the in-store feedback system.

4.3 System Design

Our system illustrated in Figure 3 consists of three components, the backend, an iOS application which allows users to self-scan and pay products with their smartphone and an in-store information system which provides feedback for successful transactions.

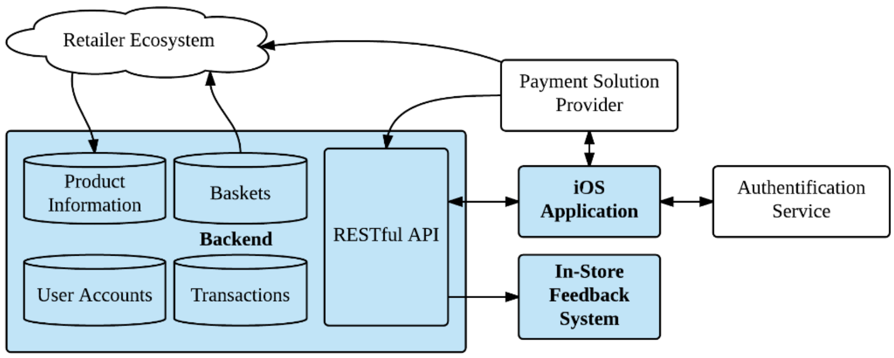

Figure 3. Overview of system architecture, developed artefact marked blue

The backend is responsible for storing all the information and communicating with the two clients. As our research partner's infrastructure relies highly on information systems that currently do not support application programming interfaces (APIs) that would allow the mobile application and the in-store feedback system to retrieve and store information, we mirror the retailer's product database and build our own backend. Product information is exported daily from our industry partner in order to account for changing prices. By predefining a specific data format we ensure a frictionless and correct re-integration of all transactions back into the retailer's information systems. The mobile self-checkout application "Scan&Go" is implemented for iOS systems and can be downloaded freely from the Apple App Store. The app features a short optional tutorial that outlines the steps to be performed in order to purchase a product. After registering with a phone number, a user has to fill out a short screening survey (six questions). Among others, users are asked about their motivation, demographics and average train station frequency. Since the service provided by our mobile application is highly location based, only at least multiple times per month at Zurich train station can participate in our pilot study[1]. Once registered and screened, a customer can use the mobile self-checkout application–if eligible.

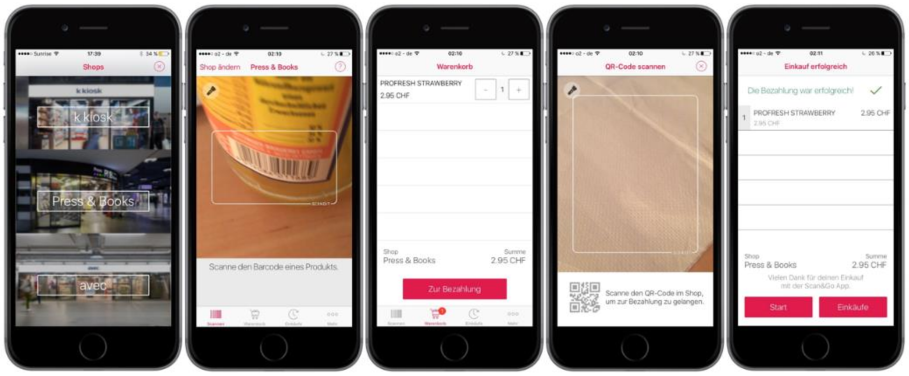

Figure 4. Screenshots of in-app view of 1) check-in, 2) barcode scanning, 3) virtual shopping basket summary, 4) QR-code scan and 5) confirmation and digital receipt

The in-store feedback system serves two purposes, theft prevention and public information signaling for successful purchases. It consists of a tablet that is mounted to a chipboard and features a poster with the QR which the user has to scan to confirm his payment. Although from a technologic perspective not required, the QR code serves three purposes: 1) it ensures that the user is in a pilot store, 2) it ensures that the user is in the right pilot store and did not accidentally check-into a wrong one and 3) guarantees that the user is located right in front of the tablet and store workers and other shoppers are able to match transaction feedback with a user[2]. The tablet constantly checks against the backend's API whether a transaction was successfully executed and approved by the payment service provider. In this case, the tablet, which is also visible from further away, turns green, features a confirmatory message and plays a positive, *cashregisterlike* sound. Based on user feedback, we believe, that a well designed and implemented in-store feedback system is key to support adoption and usage of such a purely mobile self-checkout application.

1 Since this train station is relatively big and features many stores of the same banner, even on several levels, this allows us to confirm a user's eligibility only to some extent.

2 While the first two purposes can be replaced with beacon technology the last cannot without compromising easy matching and/ or usability.

5 Results

5.1 User Recruitment

Users are recruited through three distinct channels. First, we email about 60 colleagues and friends. Furthermore, we distribute flyers to current customers either through the cashier or a dedicated student. Finally, we launch a small Facebook campaign targeted at people at the train station during the illustrated commuting hours.

5.2 User Statistics

The evaluation study ran in all three stores during 12 weeks from July to September 2016. We recruit 200 eligible users of our mobile application (out of 229 total registrations). 29 registered users were not eligible for participation either due to no supported payment method (11), age (11) and/ or a too low train station frequency (20). Users involved in the development of the mobile application are already excluded from this sample. 81% of all registered users are male and the majority is between 25 and 34 years old (35%) followed by 35 to 44 years (27%) and 18 to 24 years (22%). The majority (45%) of registered users states curiosity as their main motivation, followed by 38% that state time saving as the most important driver behind trying the mobile self-checkout application (convenience, 11%). 39% of all users are multiple times per week at the train station while slightly less, 36% of all registered users, visit the train station daily. 13% each state to be once a week or multiple times per month at the train station. In order to illustrate the consequences of long queues and waiting times during peak hours and quantify the previously hypothesized lost sales problem, we additionally ask users how often on average they have aborted or not even started a purchase due to long waiting times. In total, almost half of our sample state that this happens on average at least once a week, with about 10% claiming that this is even a daily problem. These statistics support our initial hypothesis and anecdotal evidence from store workers and managers. Although there is obviously self-selection involved in the acquisition of users for such a mobile self-checkout application, we conclude that there is great benefit for users and opportunity for retailers to differentiate – with a potentially highly lucrative business case for retailers able to address this issue by providing a faster shopping experience.

5.3 Conversion and Usage

Out of 200 eligible users 83 have scanned at least one product, either playing around with random products of other retailers or testing the app’s functionality with actual products from our research partner. The detailed user funnel is illustrated in Figure 5. No financial incentive for using the app has been given to users. In total 46 users (23% of all eligible users) have carried out at least one transaction through the app and in total 26 users have used the self-checkout application more than once for a product purchase. Thus, about 56% of all buying users have made more than one transaction.

While these numbers itself are above industry benchmarks of similar e- and m-commerce implementations [43, 44], conversion and usage numbers are even greater when accounting for the recruitment channel of customers. We distinguish between proximity recruitment (in-store through flyers) or distance recruitment (Email to colleagues and friends and Facebook campaign). The cohort type can be assigned to users based on the date of their respective registration. All of the relative conversion numbers of proximity recruited users are higher than for distance recruited ones.

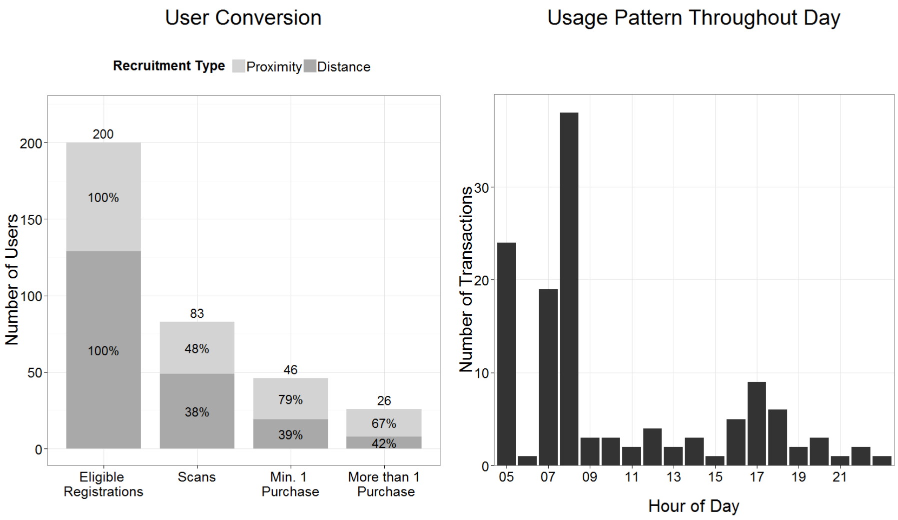

Figure 5. User conversion with number of users per action for proximity (flyer) and distance (Email, Facebook) recruited users (percentage numbers illustrating share of users relative to previous action for same recruitment type) and number of total transactions per hour

Out of all proximity recruited users, 48% have scanned an item using the app and 79% of these have ultimately also purchased something. In fact, about 38% of all proximity recruited users have made a purchase using the app, compared to 15% in the distance recruited group. Even more impressively, 46% of proximity recruited users stating "time saving" as their main motivation have made a purchase, and if stating to be at the train station "daily", the share of users making a purchase with the app is even 57% - with all of these (8) making at least one more purchase through the app. We report a total of 129 transactions issued through the mobile application with about 85% of all transactions made in Store 1. The most active user has a total number of transactions of 23, followed by one user with 16 and one with eight transactions. Figure 5 shows that most of the transactions through the app are made in the morning hours, specifically between 8 a.m. and 9 a.m. Compared to the overall sample, relative app usage is even greater during the morning peak.

5.4 Time Performance

In order to analyze the impact of increasing store rush and queues on the mobile app users, we measure the time required from 1) opening the app and 2) a first product scan to a successful transaction and its respective distribution throughout time and during peak and non-peak hours for all of the 129 transactions. For the first metric, 12 transactions (4 morning peak, 6 nonpeak, 2 afternoon peak) had to be excluded, as an instance of opening the app was either not reported or the app was obviously already opened much prior to entering the store (more than 10 minutes before the purchase). We find that the mean purchase time from app opening is about 99 seconds (st. deviation 86 seconds) with a median of 64 seconds. While our first metric has a relatively wide distribution, the purchasing time from a first scan is on average 40 seconds (st. deviation 38 seconds) with a median of 28 seconds and is thus more concentrated.

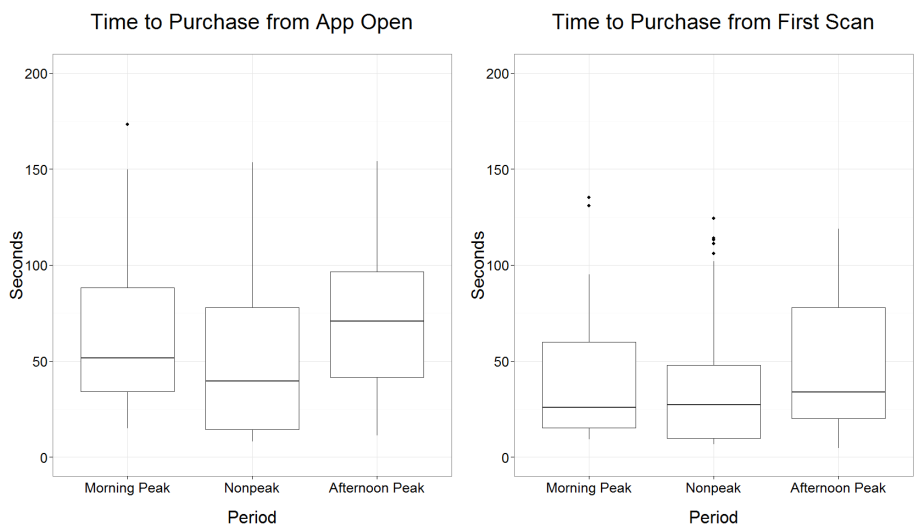

Figure 6. Standard boxplots (1st, 2nd and 3rd Quartile) of time to purchase from app open and first scan during peak (morning and afternoon) and nonpeak periods ($N_{morning\ peak}$ = 57, $N_{nonpeak}$ = 57, $N_{afternoon\ peak}$ = 15)

In order to compare our two measures throughout the day, we categorize the transactions into three different time intervals according to regular transaction data from the three pilot stores, with a morning peak period from 7 a.m. to 9 a.m., an afternoon peak period from 5 p.m. to 7 p.m. and a remaining nonpeak period. Our results in Figure 6 show almost equal or equal means and medians for both measures between the different periods of the day. We hypothesize that the somewhat higher median shopping time during the afternoon and evening period is due to less time pressure and more of a “strolling” shopping behavior of users. We attribute the wider distribution of our first metric to the differences in time needed to buy certain products (i.e. coffee from a self-service coffee machine – users could scan the barcodes before, after or while making the coffee) and also to the fact that some people already open the app before entering the target store. Due to the noisier distribution of the first metric, we argue that the purchase time from first scan is a more accurate measure of the actual shopping time required, as products bought have to be scanned in store whereas an instance of opening the app can occur outside of the store. In order to evaluate the performance of app users we derive a baseline by taking the shopping time for all regular shoppers during the morning peak period and compare this to app users during the same morning hours. For each users we measure the time from picking a first product from the shelf as this should correspond to a first scan of a product within the app. We collect a sample of 95 observations. The mean purchasing time for regular shoppers is 99 seconds (st. deviation 46 seconds) compared to 39 seconds (st. deviation 31 seconds) for app users during the morning peak.

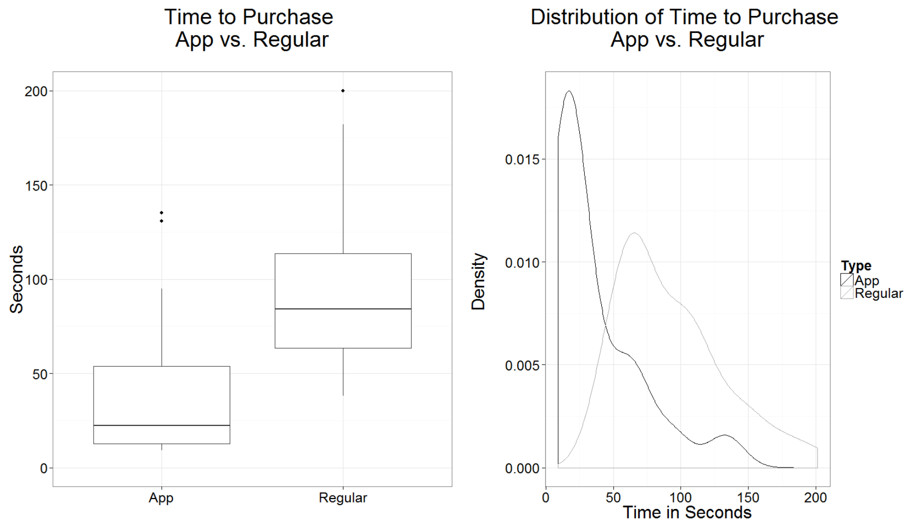

Figure 7. Standard boxplots (1st, 2nd and 3rd Quartile) and kernel density plots of purchase times for app users and regular shoppers during peak hours (N_{App} = 57, $N_{Regular}$ = 95)

Figure 7 shows the distribution of purchasing times for both app users and regular shoppers during the morning peak. We conduct a Wilcoxon-Mann-Whitney-Test [45] for non-normally distributed data and find statistically significant evidence that the time to purchase is smaller for app users (p = 8.56e-12).

6 Conclusion and Outlook

We have designed and implemented a mobile self-checkout application and tested its acceptance and usage in a first pilot at three stores at the central train station in Zurich. Learnings from the usage logs of 46 purchasing users, of which 26 are repeated purchasing users, illustrate positive value and consumer acceptance from such an application. An onboarding survey has provided additional insights into the demographics and motivation of our study participants and illustrated that almost half of all users regularly (at least once a week) fail to make purchases because of time pressure and long queues. With respect to this, we compare with the baseline time performance of regular shoppers during peak hours and show that app users on average save 60 seconds. Furthermore, we are able to show that the required purchasing time for app users is stable throughout the day, even in the presence of queues during morning and afternoon rush hours. Our study is a first step in understanding how to design a fully autonomous mobile self-checkout solution and transition from stationary to mobile retailing. In order to gain more insights into app adoption and usage and learn more about general consumption patterns of mobile app users, we aim to extend our study further with more participants over a longer time period and collect additional data on satisfaction of mobile app users. Furthermore, besides technical obstacles one obvious reason for retailers not implementing a purely mobile self-checkout solution is easier control of actual product purchases when using self-checkout terminals. Consequently, we aim to measure changes in inventory shrinkage at the end of our extended study in order to evaluate the impact of such an application on theft and inventory shrinkage. A self-checkout application as presented in our study allows retailers to offer valuable information systems based services to consumers beyond only the provisioning of additional product information and allows retailers to pursue new digital business models. It can help retailers differentiate from competitors in an increasingly crowded market place. Thereby, consumers profit from a faster and more convenient shopping experience. Furthermore, in the absence of existing loyalty programs, such a mobile app provides more sophisticated insights into individual shopping patterns.

Abstract. Open innovation has been and remains to be a rapidly changing field of research in Information Systems and various other disciplines. With the rise of professional open innovation platforms and the emergence of crowdsourcing as well as employee-driven innovation, studies on the front-end of open innovation – namely idea generation, collaboration and evaluation – are facing new challenges. In this structured literature review, we analyze a large body of prior research in order to derive a framework, which is able to classify and reflect the lively debate on open innovation. In addition, we identify important implications for practitioners with advise on the design of open innovation systems. Moreover, our study identifies several promising areas for future research.

Keywords: open innovation, literature review, generation, collaboration, evaluation

1 Introduction

More than a decade after its conceptual inception by Chesbrough [12], open innovation (OI) still receives remarkable attention by scholars. It developed into an established research field in Technology and Innovation Management as well as Information Systems [17]. Many organizations, including public and corporate agents, have established OI platforms to solicit innovative ideas from a broad base of users. OI is an important means to create disruptive business innovations, rapidly changing existing and shaping new business models, processes and products [2]. For instance, Dell's ongoing "IdeaStorm" generated more than 20,000 suggestions for product improvements from thousands of registered users [6]. Because of such vast numbers of participants and proposals, an OI contest is likely to produce superior ideas and solutions that are able to compete with experts and innovators from corporate research and development (R&D) units – a proposition in line with the "wisdom of the crowds" theory [2, 31, 45, 47]. However, previous research suggests that these large idea collections in OI processes also tend to produce a number of highly redundant ideas and suggestions that greatly vary in terms of quality [8, 45, 46]. While about a third of

Wirtschaftsinformatik (WI 2017), St. Gallen, S. 942-956

the ideas might be great, a majority is either mediocre or of low quality and is hence discarded as scrap [46, 28]. This is one reason why organizations often refrain from having their own experts evaluate each proposal, and resort to ask all users in an OI engagement to collectively evaluate and develop ideas further.

The environment for OI platforms is rapidly changing. At the beginning, many firms tried to set up proprietary OI systems, but with the rise of crowdsourcing [23] and professional OI platform providers (e.g., Hyve, Exago), OI might turn into a common form of R&D in leading corporations, as well as being more easily accessible to small and medium-sized enterprises (SMEs) and even individuals [17]. Moreover, with the emergence of topics such as employee-driven innovation [21, 13] and computer-supported organizational participation [57], OI might face new requirements within firms. Moreover, while process facilitators of OI engagements were able to profit from its novel character for a long time, they might face the problem of engaging less technology-savvy users and keep users engaged and active over a longer period of time going forward – both inside and outside the company. Considering the recent surge in research publications on OI and the changing environment for it, there is a need for a unified and structured framework that is able to both classify prior studies and guide future research.

In this paper, we therefore explore how extant research has analyzed the determinants for idea generation, collaboration and evaluation in OI – representing the key elements of the OI front-end [24] – to derive lessons on how OI systems need to be designed in the future in order to produce innovative solutions. In effect, we can also highlight areas for future research.

To do so, we analyzed 50 articles identified by means of a structured literature review [60]. In order to support researchers and practitioners in identifying well-studied and under-researched areas, we provide a concept matrix and a related framework that illustrate the flow of typical OI processes with the most relevant components. Both classify and summarize the studies along the sphere and sources the OI system addresses, the type of IT artifact, as well as the subject, testable propositions and methodology of the research. Our findings illustrate that idea generation and idea evaluation were almost equally often considered by the literature, mostly analyzing the collaboration processes. We find that researchers often recommend interactive ideation processes to increase the proposals' potential. Moreover, using multi-attributive rating scales was regularly found to strengthen decision quality. We criticize that many researchers developed OI systems on their own, rather than adopting prior development. Finally, we highlight areas for future research, including researching phenomena such as information cascades as well as the difference in idea generation and evaluation by internal versus external crowds.

In what follows, we explore the background and set the boundaries of our research in Section 2. We then introduce our methodology in Section 3 and describe the literature review process in detail. In Section 4, we report our results and discuss implications for practitioners as well as future research in Section 5. Section 6 draws a conclusion.

2 Background

For more than a decade, research on OI has been and continues to be a rapidly emerging and developing field of study in Information Systems and various other disciplines, such as Economics and Management Science [24, 2, 61]. Unsurprisingly, scholars have proposed a number of definitions and models that aim to describe OI. For the purpose of this literature review, we use a broad approach by Chesbrough [12], who defined OI as the use of purposeful inflows and outflows of knowledge to stimulate internal innovation, and expand the markets for the external use of innovation.

In practice, OI is often implemented using an idea contest. Adamcyzk et al. [2] referred to this as IT-based and time-limited competitions by organizations calling on the general public or a specific target group to propose innovative solutions. In doing so, the organizers make use of the expertise, skills and creativity of a crowd of users.

Hrastinski et al. [24] classified OI systems as technologies for idea management, problem solving and innovation (analysis). Their front-end typically comprises features and processes that support users in generating proposals and, consequently, developing and evaluating them. The systems might include sophisticated measurement tools to enable the evaluation process. Users might also be incentivized by rewards and recognition to participate in OI engagements. We will refer to these two common functionalities of OI systems as idea generation and evaluation, which can both happen with or without collaboration amongst users of the system [24].

Usually OI systems are implemented in the public sphere on one hand, by actors such as governments and non-governmental organizations. On the other hand, OI systems are especially popular with firms. Moreover, Gassmann et al. [17] suggested that universities and other academic organizations are engaging in OI too. These three broad spheres already hint at the possible target groups of OI processes. These are typically crowds that are either internal to the facilitating organization (e.g., employees, members) or external (e.g., customers, general public). In addition, OI facilitators often involve an (independent) expert committee to evaluate user-generated content [2]. Thus, considering these three broad spheres and target groups, research on OI is able to investigate various factors and their effects. Reviewing studies in Economics and Management Science, Adamczyk et al. [2] suggested that scholars are mainly concerned with assessing (1) the quality of idea generation processes, (2) the efficient design of OI processes, as well as (3) the users' motives to participate in OI engagements.

3 Research Method

In what follows, we describe our method for data collection, which builds the basis for the subsequent analysis. First, in order to provide a clear scope for this literature review, we need to set the boundaries of research [60]. We focus on what Hratinski et al. [24] referred to as the front-end of OI systems; that is, studies on computer-supported tools for the generation and evaluation of creative and valuable ideas and solutions in OI, including their collaborative development and rating. Thus, we consider the process from the point at which a facilitator opted to use an OI system until the point at which it comes to the decision of whether and how an idea shall be implemented. Hratinski et al. [24] referred to the latter as the back-end of OI. Also, research on new product development that does not explicitly refer to an OI process (e.g., by using data from an OI platform) is hence beyond the scope of our study. Furthermore, as we expect to find a large number of research articles on OI, we need to focus on studies that contribute most to the cumulative building of knowledge in the Information Systems literature by providing an advance to previous propositions and models [20]. Thus, we only include research that proposes the design of a solution for a pre-defined problem along with some form of demonstration and/or evaluation [43, 20].

3.1 Data Collection

Following the principles of Webster and Watson [60], we conducted an in-depth topic-based literature review focusing on idea generation, collaboration and evaluation in OI systems.

As OI represents an interdisciplinary and emerging research field, we included all relevant research published in journals listed in the ABS Academic Journal Guide 2015 [1] in the research subject areas of (1) Economics, Econometrics and Statistics, (2) Information Management, (3) Marketing, (4) Innovation and (5) Operations Research and Management. As we focus on Information Systems in particular, we also included full papers published in the seven leading generic Information Systems conference proceedings as recognized by ACPHIS [3]. To this list of conferences, we added CHI as the leading conference on Human-Computer-Interaction [67].

To investigate the literature base, we concentrated on the following databases: ProQuest (ABI/INFORM), Elsevier, IEEE, ACM, JSTOR, Web of Science, and EBSCOhost. Furthermore, AIS electronic library was accessed to review relevant conference proceedings.

For the research database search, we used a set of keyword combinations. In order to cover the broader literature on OI, we paired “open innovation” with “process”, “system”, “engagement” and “design”. Additionally, we combined “innovation” with “contest” and “tournaments” as these words are sometimes used as quasi-synonyms for OI engagements. Moreover, we wanted to cover more detailed studies on the sub-processes of OI activities. Therefore, we used a broad set of words we combined with “idea”, namely “generation”, “collaboration”, “evaluation”, along with a number of synonyms such as “assessment”, “voting”, “rating”, “ranking”, “screening”, and “filtering”, as well as “competition” and “management”.

Articles published before the year 2000 were excluded from our research, since computer-supported ideation and evaluation in OI was not properly defined in the last century.

Our literature search was conducted in three steps from April to May 2016. First, keyword search resulted in 212 articles being selected based on their title and abstract. We then removed duplicates and irrelevant articles. For instance, many articles investigated creativity or evaluation techniques in closed innovation environments. Other scholars analyzed managerial consequences or the implementation process of new ideas gained from OI, which is also beyond the scope of our study. Moreover, articles from publications other than those listed in the ABS Academic Journal Guide 2015 and conference proceedings recognized by ACPHIS were excluded to ensure a high level of quality. Second, the remaining 88 articles were analyzed in more detail focusing on their methodology and findings. Articles not satisfying the conditions set in our boundaries of research in Section 2 were excluded from our subsequent analysis. For instance, some studies implemented a system and refrained from evaluating it properly.

Articles satisfying the conditions introduced in Section 2 formed the basis of our third and last step. There, we conducted backward and forward searches, leading to 13 additional articles. In total, this structured review process resulted in a sample of 29 journal and 21 conference articles.

3.2 Data Analysis

Following Webster and Watson [60], we categorized the literature according to topic-related concepts as motivated in Section 2. First, we classified the articles based on the sphere that the study was conducted in, meaning public, corporate or academic [17]. Second, we extended our literature review by categorizing the type of source the research examined. On the basis of typical OI target groups, a source is either an external or internal crowd developing and/or evaluating ideas. Besides these crowds, an independent expert committee can also serve as a source of information [2]. Third, we also analyzed whether the research in our literature review proposed and evaluated an IT artifact of some sort. The definition of IT artifacts is subject to debate in the Information Systems literature [20]. Yet, we followed the definition by Peffers et al. [43], describing an artifact as something artificial, constructed by humans, which can be “any designed object in which a research contribution is embedded in the design” (p. 55). Furthermore, we adopted Gregor and Jones’ [20] classification of artifacts in terms of models, principles and methods. We also added the category of full system, which describes whether an artifact includes models, principles and methods to enable idea generation, collaboration and evaluation. Fourth, we categorized each study by its main research subject. As we focus on the front-end of OI as defined by Hratinski et al. [24], the three categories are idea generation, collaboration and evaluation. Moreover, each article investigated OI with regards to some form of testable proposition by introducing a quantitative, statistical analysis or through heuristic propositions [20, 56]. With regard to research on OI, we categorized the studies according to whether they (1) perform quality assessment, (2) analyze the efficiency of a process or (3) investigate user motivation [2]. Additionally, we analyzed in which sphere each study was conducted in. Finally, we categorized the identified literature according to the methodology used. Building on Palvia et al. [40], we limited these categories to frameworks/models, literature reviews, case studies, surveys, mathematical models and interviews. Two researchers classified the literature independently. Few inconsistencies were discussed and re-evaluated in order to reach a common understanding and resolve discrepancies.

4 Results

Our results point out that OI in general and idea generation, collaboration and evaluation in particular, recently received increased attention by researchers (see

Table 1). Most studies were published in conference proceedings, followed by research published in leading journals (see Table 2). Moreover, retrieving 19 articles in research fields such as Technology and Innovation Management as well as Marketing, confirms that OI is a constantly evolving, interdisciplinary field of research.

Publications	15	8	6	21

We developed a concept matrix that categorizes each study (see Table 3). The concept matrix follows the outline of our data analysis in that it is structured in terms of the sphere and source, the type of IT artifact as well as the subject of the study, its testable propositions and methodology. In terms of idea generation we found 11 articles, compared to 16 articles investigating idea evaluation exclusively, whereas 21 articles covered both subjects at least partially. Interestingly, we found that researchers covered collaboration only in conjunction with either idea generation or evaluation, but never as a stand-alone research subject. Collaboration was investigated almost equally for generation and evaluation (39 vs. 33). This arises from the fact that many articles investigate OI systems that rely on collaboration.

With regard to the testable proposition, the vast majority of all articles covered at least some kind of quality assessment. In many cases, studies analyzed the quality of user-generated ideas through evaluations by experts committees [e.g., 46, 8, 28, 27, 32]. Thus, the propositions were both quantitative as well as heuristic in nature [56], as the experts used standardized rating methods to express their personal evaluation. Some studies took a more quantifiable approach, for instance, by evaluating the degree of user participation and activity (e.g., based on the number of executed trades or submitted ideas) on an idea market platform [51]. Two other studies conducted social network analyses [25, 7], which assessed both quality and quantity of user interactions. Moreover, 12 studies were concerned with evaluating efficiency of the processes of an OI engagement. Most often, this was the case for research on rating scales, where scholars tested how fast and accurate participants were able to conduct an evaluation task [e.g., 46, 8, 28, 14, 5]. Only one article (despite the

ME: Method, FS: Full system, PR: Principle, MO: Model literature reviews) examined efficiency in collaborative idea generation; in this case by analyzing the redundancy of idea proposals [29]. Also user motivation was measured by many scholars, mostly by means of surveys or interviews. These studies asked for users' motives to participate and their satisfaction with the OI system. However, user motivation was often covered as an additional topic rather than being the main research question.

The majority of extant research investigated OI in the context of the sphere of the firm. Many papers also included an academic perspective, while only a fifth of the studies addressed the public sphere.

Many studies did not propose and evaluate an IT artifact. Surprisingly though, those that did often proposed a full OI system, which covered all the features described by Hratinski et al. [24] as the front-end of OI systems. Among them, many were studies in the domain of gamification, which focused on topics of user involvement through gamified reward systems and rankings to provide a gripping user experience [49, 66, 16, 54].

Most studies dealt with an external crowd as its source for idea generation, collaboration and/or evaluation. Other studies contributed to the overall trend of employee-driven innovation by sourcing ideas or evaluation from an internal crowd of employees [4, 13]. Moreover, some studies asked experts to assess the quality of user-

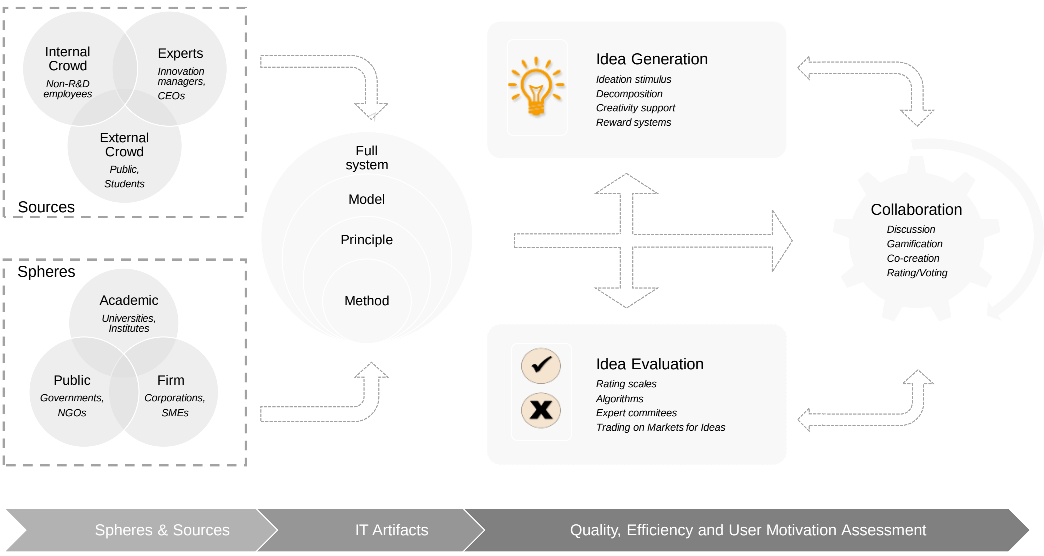

Figure 1. Framework for idea generation, collaboration and evaluation in OI

generated ideas or ratings. Magnusson et al. [36] was the only study to solely focus on experts as a source of information. The study analyzed different idea screening procedures by asking experts to rate ideas retrieved from an OI contest.

In terms of the methodologies, we find a rather clear picture. Despite the variety of research areas covered in our literature review, the vast majority of articles employed case studies [4, 5, 6, 7, 8, 9, 10, 11, 16, 19, 22, 25, 26, 27, 28, 29, 30, 32, 33, 34, 35, 36, 37, 44, 45, 46, 47, 48, 49, 50, 51, 52, 54, 55, 58, 59, 62, 63, 64]. Scholars either set up their own OI systems and applied them in practice – collaborating with firms, students or the general public – or extracted data from existing OI platforms (e.g., Dell's IdeaStorm [6] or Starbuck's MyStarbucksIdeas.com [4]). These case studies were sometimes supported by surveys [9, 11, 22, 25, 34, 35, 47, 49, 50, 62, 66] and/or interviews [4, 7, 11, 13, 44, 49, 66] in order to explore users' motives to engage in and perception of OI engagements. Seven studies developed frameworks and models of OI [13, 14, 24, 34, 41, 58, 59]. Moreover, six studies developed mathematical models in order to investigate the optimal design of OI processes [19, 22, 53, 55, 63, 65]. Furthermore, we found five literature reviews [2, 24, 38, 42, 61]. They were at least two years old and examined distinctively different research questions than our study. For instance, they examined literature on boundary areas of OI, such as markets for ideas [38] or crowdsourcing [42].

Investigating lessons for the design of OI systems, we find that idea generation and idea evaluation were almost equally often considered by the literature. Most studies did so by also analyzing the collaboration processes. Both Bullinger et al. [11] and Blohm et al. [8] suggest that collaborative ideation outperforms non-collaborative approaches. Moreover, research [18] established that the point in time when users are involved in collaborative processes is crucial. Moreover, Luo and Toubia [35] also emphasized that decomposing an idea and providing stimulus ideas can significantly change the outcome of an idea generation phase. Several studies highlight that the decomposition of the evaluation task by providing multi-attributive rating scales for the user also increases the accuracy of decisions [8, 9, 13, 34, 46, 47]. Moreover, Klein and Garcia [28] suggest that crowd evaluation is very helpful in detecting bad ideas, but less so when it comes to distinguishing medium or good ideas from really excellent proposals. Research also finds that facilitators of OI processes need to consider an appropriate level for users' cognitive load [9, 19]. Particularly looking at idea evaluation, there seems to occur a trade-off between accuracy and the effort users have to put into idea evaluation [60, 36]. Moreover, many studies stress the importance of the provision of rewards, incentives and other motivating elements for users [16, 34, 49, 54, 66]. For instance, users might already be inclined to participate because they can gain access to the knowledge of experts and peers [34].

Based on the results of our study, we propose a framework that reflects the current state of research (see Figure 1). The framework is based on our concept matrix (see Table 3) and includes all columns except for the study methodology, which is common across the IS discipline. The framework provides readers with a model that describes a typical OI process flow, allowing researchers to locate prior studies and structure future work more easily. It illustrates that both the sphere for the application as well as the sources of information provide the basis for an OI system. The sphere describes whether an academic, public or corporate agent is the facilitator of the OI process. This facilitator decides which source to address. Sources can either be coming from an internal crowd (such as employees) or external crowd (e.g., customers) or experts, like innovation managers or board members. The OI system itself represents an IT artifact. Researchers have to decide whether they seek to investigate full OI systems or only some parts (i.e., models, principles or methods [20, 43]). Facilitators engage their users in idea generation and/or evaluation processes. In many cases, these processes are interactive and involve user collaboration. Research investigating OI analyzes the above mentioned processes by assessing the quality, efficiency or user motivation. In what follows, we will use this framework and our concept matrix as the basis to discuss prior and identify promising areas for future research.

5 Discussion and Future Research

The finding that research on OI has most recently gained new traction underlines the timely importance of our research. Considering the vast amount of studies from various backgrounds – including many case studies –OI can arguably be considered as an important and well established means to create business innovations. In terms of idea evaluation, our study points out that researchers mostly measured the accuracy of user ratings in comparison to the evaluation of an expert committee. Though very practical, this method is also highly subjective as it depends on the expert selection and might be biased due their predispositions (e.g., having managers of a company evaluate suggestions for improvement by employees [28]). This makes the reproduction of research very difficult. Despite this disadvantage, it is a fairly common method and very suitable as many studies were case-specific and, thus, might depend on inside-knowledge from selected experts to better grasp the value of proposals.

Moreover, our literature review includes only one study that focused on the efficiency of the idea generation process [29]. However, as many firms use OI engagements, it is their employees who use the platforms for ideation. Thus, managers need to be aware of an efficient process structure in order to save valuable resources. Accordingly, one area for future research could be the efficiency of processes in idea generation. For instance, the researched we reviewed stressed that proposals are often redundant [9, 28, 46-47]. Thus, finding methods to limit similarity of ideas – for instance, through issue-based information systems – might be an interesting starting point.

Furthermore, we did not find any study that evaluated whether an internal crowd might be more accurate and efficient in delivering innovative solutions than an external crowd and vice versa. This might be another avenue for future research.

We find a number of studies analyzing idea evaluation process efficiency [e.g., 46, 8, 28, 14, 5]. However, we notice that studies on rating scales and voting techniques often decided to isolate effects triggered by social influence. For instance, both Riedl et al. [47] as well as Klein and Garcia [28] asked participants to evaluate ideas in settings where they were unable to see previous ratings by other users in order to avoid information cascades. However, in practice, users' decisions could be swayed by peer opinions [46-47, 67]. This is intuitive when looking at information sharing in social networks and, even more so, in idea markets, where facilitators explicitly build on the users' collaborative exchange of evaluations (i.e., trading activity) to derive the best ideas [32, 51, 38]. Thus, future research could investigate the robustness of different rating scales against information cascades and related effects in order to reflect more realistic conditions of OI systems.

While many studies evaluated users' motivation to participate in an OI contest, analyzing motivation was often more of a by-product rather than the main focus of any study. However, as OI becomes more professionalized, on one hand, and more of a standing, long-term process, on the other, Gassmann [17] note that motivating users becomes more challenging. Thus, future research could focus on this area as well. For instance, some studies were conducted using gamified systems, which builds on rewards, badges and other attributions to drive user motivation [49, 66, 16, 54]. However, as gamification does not necessarily lead to long-term motivation [16], future research could focus on longitude studies.

Finally, our literature review finds that extant research produced numerous models and systems for OI. However, they have rarely been adopted by other researchers. This might be related to the highly specific context to which OI processes are used for, making it difficult to generalize models and associated findings. On the other hand, idea generation, collaboration and evaluation represents a common theme in Information Systems research. There are also a number of professional OI platform providers (e.g., Hyve, Exago). Although we acknowledge the holistic approach undertaken by many studies developing a complete OI system from the ground up, we encourage future research to focus on more specific areas by contributing to the cumulative building of design theories. Gregor and Jones [20] criticized the constant re-invention of artifacts and methods under new labels, which we see happening in the literature of OI as well. The concept matrix and framework of our literature review can help to guide these approaches by providing a unified, structured approach.

This study needs to be considered against its limitations. We set strict research boundaries, following Weber and Watson [60]. Yet, this led to the exclusion of some studies from our final analysis. We might have missed some studies because they did not include the specific keywords in their title or meta-data and were not referenced by the studies we analyzed. For instance, idea evaluation can be framed as a group decision, which is a large area of IS research but is not necessarily conducted within an OI context. Furthermore, we found only few studies framing OI in the public sphere. However, as modern governments begin to involve their citizens more often in processes such as participatory budgeting [39], future research could investigate how such engagements resemble OI.

6 Conclusion

In summary, this study developed a model for research on idea generation, collaboration and evaluation in OI processes by conducting a structured literature review. We demonstrated that OI remains an emerging interdisciplinary research field, which is gaining new attention in the scientific community. Our analysis suggested that the majority of prior research investigated OI by means of case studies, often proposing an IT artifact. Our study contributes to the Information Systems literature by providing a unified, structured framework that can help to reflect and classify past research and guide future studies on OI. We also contribute to the IS literature by identifying several research gaps, which could build the basis for future research. This includes comparisons between internal and external crowds, a call for the investigation of phenomena such as information cascades, and our critique of a very limited cumulative knowledge building.

Considering the recent changes in the OI environment (e.g., accessibility for SMEs, employee-driven innovation, and professional OI platform providers), OI will most likely remain a rapidly emerging field for research. Our literature review also includes some implications for practitioners, guiding the design of future OI systems. For instance, we highlight the well-proven efficiency of multi-attributive rating scales, the acknowledgement of the users' cognitive load and the emphasis on rewards, incentives and other motivating components.

Going forward, it will be interesting to see, which mechanisms will yield the most creative and valuable ideas while still ensuring appropriate levels of effectiveness and user motivation in the long-run.

Abstract. Due to permanent changes, companies constantly need to contend with new challenges. Developing and improving business models can help to adapt to constantly changing environmental conditions and to achieve competitiveness. Because most innovative developments are not the result of a single inventor, we used Collaboration Engineering to elaborate a systematic process design for business model development. To ensure an effective process design, we turned to existing knowledge by including theoretical and practical requirements of business model development. Additionally, in order to guarantee the high quality of the process, we evaluated the systematic process on the basis of a multilevel and iterative evaluation. Our evaluation clearly indicates results equivalent to expert-based business model development. Accordingly, the process design enables a continuous and recurring business model development without the ongoing support of professional facilitators.

Keywords: Business Model Development, Collaboration Engineering, Requirements of Business Model Development, Systematic Process Design

1 Introduction

Due to permanent changes, companies constantly need to contend with new challenges. Globalization and the corresponding development of the global economy bring increased transparency to the markets through new and innovative technologies. Customers have more options than ever to choose the right offer for themselves [1]. This development, in conjunction with increasingly homogenous products and services, results in an increase in the intensity of competition. Consequently, the differentiation from competitors plays an essential role for companies [2].

In this context, business models can represent an important factor to ensure competitiveness [3] and thus help to commercialize products and services [4]. Well-functioning business models can be regarded as the underlying structure for the desired

(Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 957-971

economic success of ideas, products, and services [1] and help in differentiating from competitors. Accordingly, companies can use the positive influence of business models on their performance [5].

Due to the fast changing environment of companies and the intense competition, it is necessary to develop and continually innovate the appropriate business models [3, 6]. Such a continuous refinement of its business model represents a challenging task for companies [7] and increased interest in the phenomenon [8]. In the course of the development of their business, many companies rely on established processes in the development of product innovations [9]. An empirical study from 2009 shows that business model innovation can have a greater potential for success than comparable product and process innovations [10]. With respect to these challenges, it is no longer sufficient to rely only on process and product innovation [11].

Consequently, the question arises how companies can develop business models continuously and in consistently high quality. The literature shows that the number of approaches to the development of business models has increased in recent years. Nonetheless, appropriate approaches for business model development vary greatly in relation to their procedure, their level of detail, and the techniques applied [2]. Good examples in this context are the common approaches of Osterwalder [12], Gassmann, Frankenberger, and Csik [6], Grasl [13], and Wirtz [14]. Moreover, Ebel, Bretschneider and Leimeister [15], Köster [16] and Pelzl [17] describe methods, tools, and techniques in the field of business model development. However, these approaches tend to provide higher-level concepts because of largely neglected detailed instructions and systematic process models, for example in the form of an agenda, enabling a direct implementation to the company. Against this background, the application of these approaches and tools represents a difficult task for companies, especially without the support of consultants, professional facilitators, and business model experts. Approaches that meet these criteria and provide detailed instructions and an explicit selection of methods, tools, and techniques have only been merely addressed in the existing literature. According to this reasoning, the elaboration of a systematic process design to the development of business models including detailed instructions can be seen as the next logical step in the strategic handling of business models in companies [18].

In this paper, we close the above indicated research gap and elaborate a systematic process design for business model development, which can be applied directly in companies. Because most innovations are not the result of a single person, the focus is particularly on cooperation in groups and therefore the combination of knowledge, skills, and experience [19, 20]. Against this background, we use Collaboration Engineering (CE) to elaborate a reusable collaborative group process for business model development. Collaboration Engineering offers a structured process for systematically elaborating collaborative processes [21]. With the help of this structured approach, a detailed process design for business model development will be created.

To achieve these objectives and to address the indicated research gap, we chose a tripartite research procedure. First, we deal with the question of which requirements for business model development can be identified in literature and practice. Second, we deal with the question of how to transfer the identified requirements into a systematic process design, which allows repeatability and a direct implementation. Third, we address the question of how to evaluate the effects of the application of the process design.

To answer these questions, we structured our paper as follows: We first give an overview of the existing knowledge of business model development including a working definition of the term business model. Afterwards, we explain the use of Collaboration Engineering and its applicability to business model development. To ensure an effective process design, we turned to existing knowledge by including theoretical and practical requirements of business model development derived from a literature review and an interview study. In order to elaborate the collaborative group process, we apply the central design process collaboration process design approach for Collaboration Engineering (CoPDA) [21]. In addition, we conduct a multilevel and iterative evaluation of the process design. Finally, we discuss limitations and future research and complete the paper with a conclusion.

2 Related Work

In the scientific literature, the focus has been on business models since the mid-90s. In the last 20 years, the number of scientific publications on this subject has significantly increased [5]. However, this attention is not limited to people with a scientific background. Equally, entrepreneurs, managers, investors, IT professionals, and journalists dedicated their attention to topics around business models [22]. Shafer, Smith, and Linder [23] consequently mention an anchoring of the term business model in management vocabulary.

Despite the intense debate on this issue, research in business model field is still highly active [24] and there are still different approaches, concepts, and definitions of the term business model. Accordingly, there is no universally accepted definition of the term business model [2, 5, 23, 25]. Against this backdrop, we want to introduce the definition by Wirtz [14] as a working definition.

“A business model is a simplified and aggregated representation of the relevant activities of a company. It describes how marketable information, products and/or services are generated by means of a company’s value-added component.“

The chosen definition by Wirtz is based on the value-added activities of the companies mentioned in many definitions and additionally shows which areas of value are involved in business models.

According to the rising interest on business model topics, the number of methods and approaches to the development of business models has increased [2]. Schallmo [2] notes that the level of detail in business model development approaches varies from simple descriptions to detailed process procedures. Furthermore, Rudtsch et al. [26] note that certain approaches relate to specific applications of business models (e.g., E-business models). For this reason, universal applicability is hardly feasible. Moreover, it can be stated that many approaches lack a clear connection between tools and techniques used and corresponding organizational process models for business model development [4]. This reasoning describes the need for directly implementable process designs for business model development with clear links to the tools and techniques used.

To focus on the needs of business model development and the innovativeness of groups, a detailed approach to create collaborative processes is necessary. To ensure the direct applicability of the process design, the chosen approach should provide support for the implementation of collaborative group work with appropriate tools. Collaboration Engineering meets these requirements and deals with the design and implementation of collaborative processes in order to fulfill recurring and high-value tasks. In this connection, group members combine their knowledge and skills in order to achieve a defined goal [27]. Practitioners execute the tasks of professional facilitators. In this way, there is no need for an ongoing support of professional facilitators [28].

To apply Collaboration Engineering, two important conditions, the repeatability of the task and the high quality of the task, have to be fulfilled [28]. As already mentioned, companies have to adapt to continuously changing influences. The continuous and recurring development of new business models represents an important factor for the creation of an economically successful company [3, 6]. Based on this reasoning, it can be concluded that the development of business models is a recurring task. In relation to the high quality of business model development, it is important to consider the creation of economic value through business models. In relation to the influence of business models on the performance of companies [5] and the respective strategic positioning of the business logic in the strategy of companies [29], business model development can be regarded as a high-quality task.

3 Methodology

The elaboration of the systematic process design can be divided into three sections. In order to build up the process design on existing knowledge, we first identify theoretical requirements in a literature review and practical requirements in an interview study. Based on these identified requirements of and insights into business model development, we apply the collaboration process design approach of Collaboration Engineering to elaborate the process design in a systematic manner. Additionally, in order to guarantee the high quality of the process, we evaluate the process design on the basis of a multilevel and iterative evaluation using design simulations, walk-throughs, and pilot tests. The following chapter describes the evaluation steps in detail.

3.1 Identification of Theoretical and Practical Requirements

In order to ensure an effective process design, we turned to existing knowledge by including theoretical and practical requirements of business model development. In this context, we identified theoretical requirements by means of a systematic literature review. To analyze the identified sources in a systematic manner, a category system based on the CoPDA was created. This category system reflects the CoPDA and focuses on the goals, group products, and basic conditions of the collaborative process.

As part of the systematic literature review, we looked for current journal articles that deal with the requirements of business model development in the period between 2000 and 2015. The search was conducted in the databases of EBSCOhost, SpringerLink, IEEE, and Science Direct. We used broad-based keywords (Business Model *Design, *Development, *Engineering, *Framework, *Innovation, *Process, *Tools) and eventually identified 1,256 papers. Based on a structured review process of title, keyword, and abstract search including forward and backward search, 55 relevant sources including referenced books, conference articles, and dissertations were identified. The identified conference articles had to meet the same requirements that were defined for the search of journal articles. Afterwards, the identified sources were analyzed with the help of the established category system in relation to the requirements of business model development. The corresponding results of the systematic literature review are visualized in Table 1.

Table 1: Theoretical and Practical Requirements of Business Model Development

Category	***Requirements (RQs)***	***Source***
Goals	Developing the current business model (G1)	I
	Fast and easy application of the process design (G2)	L; I
	Continuous documentation of the results (G3)	I
	Structural procedure (G4)	L; I
	Creating awareness for the need for change (G5)	L; I
Group Products	Created team spirit in the group (P1)	L; I
	Shared knowledge of basics of business model development (P2)	L; I
	Analysis of existing business model (P3)	I
	Shared knowledge about the existing business model (P4)	L; I
	Executed environmental analysis of the existing business model (P5)	L; I
	Elaborated tool/framework for business model development (P6)	I
Basic conditions	Achieve commitment (Bc1)	I
	Use a wide range of tools (post-its, index cards, mind maps) (Bc2)	L; I
	Visual representation of operating steps and results (Bc3)	L; I
	Use technical options for storing the results (Bc4)	I
	Design simple procedures (Bc5)	I
	Enable cross-divisional communication (Bc6)	I
	Convince doubters (Bc7)	I
	Arrange enough time (Bc8)	I
	Despite technology, use face-to-face approaches (Bc9)	I
	Use interdisciplinary teams (Bc10)	L; I
	Facilitators should have skills and experiences in facilitation (Bc11)	I
	Facilitators should have strong social skills (Bc12)	I
	Practitioners should have the ability for abstraction (Bc13)	L; I
	Practitioners should have strong social skills (Bc14)	I

Source: L = Literature; I = Interview study

Looking at the results in detail, it becomes apparent that the theoretical requirements identified in the literature are not sufficient to build a systematic process. First, not enough theoretical requirements were identified. Second, the theoretical requirements were not formulated with sufficient precision. To complement the theoretical requirements and to provide a more substantive basis, an interview study was carried out to identify practical requirements for business model development. Against this backdrop, eleven interviews in the context of business model development were conducted. The semi-structured interviews with experts of business model development (consultants, enterprise architects, business developers, and entrepreneurs from different industries with a minimum of three years of experience in business model development) had a duration of 30-55 minutes and were transcribed for analysis. The categories for the evaluation were deductively specified by the category system, which was also used in the literature review. By using a standardized category system, both analyses are comparable. In this context, one author defined the respective requirements with the help of an iterative and detailed coding based on a 15-step process, which was inspired by the qualitative content analysis according to Mayring [30]. Then, the results were examined and improved by the other authors with the help of a joint vote. The results of the interview study are presented in Table 1. By including theoretical and practical requirements, a detailed basis to elaborate a systematic process design for business model development is created.

3.2 Elaboration of the Process Design Using the CoPDA

In order to elaborate a systematic process design for business model development, we used the collaboration process design approach as a central design process in Collaboration Engineering. The CoPDA consists of five steps. The task diagnosis represents the first step. In this step, an analysis of required tasks, stakeholders, resources, facilitators, and practitioners is conducted. The results of this step represent defined goals and group products (outcomes) of the collaboration process. The second step addresses the task decomposition and deals with the determination of the individual activities of the process. These activities are derived from the group products of the first step. In the third step, thinkLet choice, thinkLets are assigned to each activity that has previously been identified. ThinkLets are defined as a design pattern of Collaboration Engineering. Subsequently, in the fourth step, agenda building, activities and thinkLets are transferred into an executable sequence using an agenda. The last step of the CoPDA, design validation, represents the evaluation of the developed collaborative process [21].

The elaboration of the process and the application of the CoPDA are based on the identified theoretical and practical requirements (G1-G5). In the first step, task diagnosis, the identified goals, the group products, and the basic conditions are used to define the objective of the collaborative process. The objective can subsequently be defined as follows: *"The purpose of the process design is a structured development of a business model for an observed enterprise with a heterogeneous experience and cross-functional group of up to six people in a one-day-workshop. In addition, the* *compiled results of the workshop are continuously documented. Furthermore, an awareness of the need for change is created within the group (G1-G5).”*

Based on the defined goals, group products, and basic requirements, the further steps of the CoPDA can be applied in order to elaborate the systematic process design. Thus, in the second step, the identified group products were decomposed into activities. In the third step of the CoPDA, the corresponding tasks were allocated to thinkLets, which contribute to a structured implementation of the activities. Based on this, in the fourth step, a facilitation process model (FPM) of the process was created (see Figure 2). The FPM provides an overview of the process flow. Therefore, the FPM combines the activities and the collaborative thinkLets. Thus, the elaborated process design consists of 11 activities. It should be noted that the activities of A8 to A10 are created in a loop repeating to the final drafting of the business model. To ensure the mentioned direct applicability of the process in practice, an internal agenda of the collaborative process was created in the fourth step of the CoPDA. The internal agenda shown in Table 3 offers action-guiding instructions to implement the business model development.

3.3 Evaluation of the Process Design

In order to guarantee the high quality of the process, we evaluated the systematic process design in the fifth step of the CoPDA, the so-called design validation. To perform a detailed evaluation and refinement of the process design, we chose a multilevel and iterative procedure that provides a revision of the process design according to each stage of the evaluation. Referring to this procedure, we validated the process design in four iteration loops. After each iteration loop, the process design was revised and adjusted.

To uncover hidden weaknesses, we used design simulations, walk-throughs, and pilot tests as a set of three evaluation methods. In this manner, our aim was to improve the process design continuously. Figure 1 depicts the evaluation process including the evaluation methods and the corresponding iteration loops. In the following, the evaluation is described in detail.

First, we started with a design simulation of the process design initially created. In Collaboration Engineering, design simulations represent a detailed step-by-step review of the process design by the collaboration engineer [31]. In this way, stumbling blocks in the process were identified and the formal correctness and consistency of the process were tested [21]. These improvements were directly implemented in the design simulation.

Walk-throughs are an evaluation method based on a detailed step-by-step review of the process design with experts. Walk-throughs represent the second evaluation method. In the context of walk-throughs, valuable ideas and alternative solutions are collected and discussed [32, 33]. First, we conducted two walk-throughs with experts of Collaboration Engineering. By doing so, the correct application of Collaboration Engineering was ensured and valuable suggestions for the implementation of individual activities were collected. The resulting findings were included in the process design and the second version of the process design (V2) was created. Second, we conducted two walk-throughs with business model development experts. In this way, we achieved additional insights into the facilitation of workshops on business model development. The third iteration loop was also completed by a design simulation. In this way, we created the version V3 of the process design.

As a final iteration loop and in order to check the successful application of the process design without the ongoing support of a professional facilitator, we conducted three pilot tests. The pilot tests were applied in an experimental setting in an IS master's course. In these pilot tests, the participants redeveloped an existing business model of an energy consultant platform. In this context, two of the pilot tests used the guidelines and instructions of the process design. The first pilot test was conducted by the collaboration engineer. The second pilot test was conducted by a practitioner. To compare the quality of the process design, the third pilot test was conducted by an expert of business model development. This expert did not use the guidelines and instructions of the process design. Initially, by using a questionnaire, the participants were interviewed about their previous experiences and skills in the field of business model development. Based on their experiences, the participants were randomly allocated to three groups. The pilot tests were analyzed using a questionnaire to evaluate the process design from the perspective of the practitioner. In this way "satisfaction with process", "tool difficulty", "process difficulty", "satisfaction with outcome", and the "effectiveness of the satisfaction with outcome" were examined [34–36]. The findings obtained could subsequently also be incorporated in the process. In addition, the facilitators of the pilot tests documented their experiences in a protocol. Following a final design simulation, the final version V4 of the process design was created.

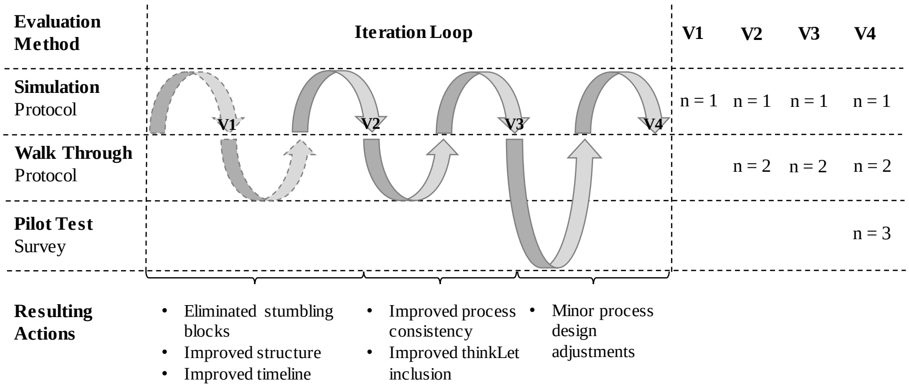

Figure 1: Iterative Evaluation of the Process Design (adapted from [37])

In the first and second iteration loop, according to V1 and V2 of the process design, mainly stumbling stones were eliminated. In the early stage, the structure of the process design was especially very fragmented. In addition, the timelines for each activity were adjusted. In this connection, CE experts highlighted the need for sufficient time for each activity. In the third iteration loop, according to V3, the focus was on the consistency of the process. In this context, thinkLets and their adoption to business model development were especially considered. Against this background, the involvement of thinkLets was increased.

The fourth iteration loop focused on the pilot test. Table 2 depicts the results and insights of the analysis of the survey. In order to fulfill the aim of CE, enabling collaborative group processes conducted by practitioners who are better or equivalent result in the comparison to professional facilitators and experts. All in all, we asked five blocks of questions. Each block consisted of five questions. In relation to the answer on a 5-point Likert scale, all groups achieved high average scores across all categories. The differences between the results are minimal and can be considered substantially equivalent. In this context, we used a simple t-test to examine if significant differences existed between the two test groups with the collaboration engineer and practitioner and the group with the business model expert. First, it should be mentioned that with exception of "satisfaction with process" of the practitioner's group and "satisfaction with outcome" of the collaboration engineer's group, the various results are not statistically significant. Considering the lack of the significance of the results (with exception of the two results mentioned), we can assume that the elaborated process design delivers results comparable to those of a professional business model expert. Thus, we can assume that the elaborated process design results in sufficiently good results, as embedded in the CE objective. In addition, the category "tool difficulty" shows especially high results. This suggests that the selection and application of the techniques used in the elaborated process design had been purposefully designed.

Table 2: Results of the Survey

Category	**Collaboration Engineer Mean (SD)**	**Practitioner Mean (SD)**	**BM Expert Mean (SD)**
Satisfaction with Process	4.51 (0,50) ^{ns}	4.31 (0,36)**	4,77 (0,21)
Tool Difficulty	4.23 (0,69) ^{ns}	4.40 (0,61) ^{ns}	4,42 (0,45)
Process Difficulty	4.25 (0,45) ^{ns}	4.06 (0,43) ^{ns}	4,11 (0,23)
Satisfaction with Outcome	3.92 (0,52)**	4.37 (0,56) ^{ns}	4,48 (0,40)
Effectiveness	4.06 (0,46) ^{ns}	4.11 (0,62) ^{ns}	4,10 (0,74)

Note: n=7 participants per group; ns = not significant, *** p<0.01, ** p<0,05, * p<0,1

Furthermore, the approximately similar results indicate that the process can also be autonomously performed by practitioners. In conclusion, we can assume that the process can be universally and directly applied in organizations without the ongoing support of a collaboration engineer or a professional facilitator. All in all, the participants of the pilot tests were satisfied with the development of the business models as well as with the results of the process.

4 Results

In this chapter, the elaborated process design is depicted and explained. As already mentioned in the part on the conceptual development, we created a facilitation process model (see Figure 2). The FPM visualizes the structured procedure with the number and name of the activity, the pattern of the collaboration, the respective thinkLets, and the suggested time of the systematic process design.

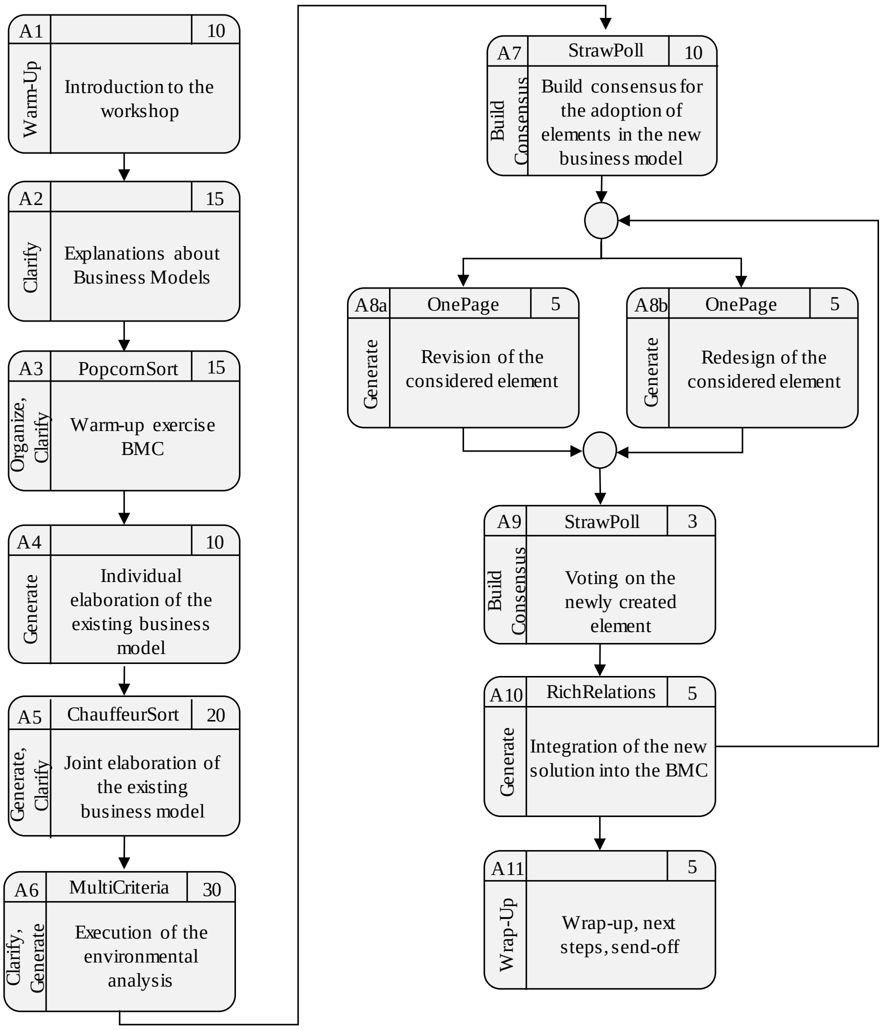

Figure 2: FPM - Systematic Process Design of Business Model Development

The internal agenda, visualized in Table 3, enables the direct implementation of the process design by providing instructions, group formations, and tools. Moreover, the internal agenda indicates how identified group products and basic conditions are incorporated into the systematic process design.

Nonetheless, not all procedures and basic conditions can be displayed in the internal agenda. In this context, the following sequence shows the respective conditions of the systematic process design.

Table 3: Internal Agenda of the Systematic Process Design

Act.	Instructions and Group Formation (PG = plenary group, SB = subgroup, I = individual)		Tools	RQs
A1	PG: Facilitator and practitioners introduce themselves. Facilitator presents the agenda and goals of the workshop. Achieve commitment to the goals from practitioners.		Presentation	P1; Bc1
A2	PG: Emphasize the relevance of BMs and explain the basic knowledge about BMs and the BMC. Ask: Do you understand the basics of business model development?		Presentation	P2; Bc1
A3	SG: Practitioners create the business model in subgroups based on content predefined in the BMC. GP: Discuss the solutions in the plenary group.		Presentation, BMC (DIN A3), prepared post-its	P2; Bc2; Bc3
A4	I: Practitioners individually elaborate the existing BM in the BMC.		Presentation, BMC (DIN A3), small post-its, pens	P3; Bc2
A5	PG: Prepare the post-its of the existing BM for the BMC. Present the post-its and discuss which field is addressed. Stick the post-its to the right place as soon as consensus has been reached. Achieve commitment and perform these steps for all predefined post-its. Summarize the existing BM and take a picture of the elaborated BMC.		Predefined post-its of existing BMC, BMC (DIN A0)	P3; P4; Bc1; Bc2; Bc3;Bc4
A6	PG: Prepare the environmental analysis questionnaire for each practitioner and introduce the practitioners to the environmental analysis (EA). I: Each participant answers the EA questionnaire (20 min.). PG: Consolidate and present the results of the EA questionnaire with the help of the EA tool. Take a picture of the results of the EA tool.		Presentation, EA questionnaire, EA tool	P5; Bc2; Bc3; Bc4
A7	PG: Facilitate the (optional) transfer of the existing elements in the new BMC. Stick the transferred elements (post-its) to a new BMC. Take a picture of the new BMC.		EA tool, BMC (DIN A0)	P5; Bc2; Bc3; Bc4
A8	PG: **Yes**: Revision of the considered element Ask: How can the considered element be revised for our business model? Orient yourself to the key questions of the respective element. The practitioners can add the existing solution and stick post-its with suggestions to the BMC.	PG: **No**: Redesign of the considered element Ask: How can the considered element be redesigned for our business model? Orient yourself to the key questions of the respective element. The practitioners are intended to stick post-its with suggestions to the BMC.	Presentation with guiding questions, BMC (DIN A0)	P6; Bc2; Bc3
A9	PG: Read each post-it of the element concerned in the BMC and ask for commitment. In case of objections, facilitate a discussion and ensure a solution (majority decision).			P6; Bc1; Bc2
A10	PG: In order to adapt the interrelations between the elements in the BMC, the facilitator gives an overview of each relationship of each element and asks for necessary additions or objections. Facilitate the discussion and ensure a solution (majority decision). Activity is performed for each element according to the order of the BMC.		Presentation with interrelation-ships, post-its, pens	P6; Bc2; Bc3
A11	PG: Summarize the workshop and the newly elaborated BM. Check if you have achieved the goals of the workshop and take a picture of the final BMC.			Bc3; Bc4

The process was consequently designed for facilitators with skills and experiences in the field of workshop facilitation (Bc11). In addition, strong social skills should be considered in practitioner and facilitator selection (Bc12; Bc14). Furthermore, the process was designed for interdisciplinary teams (Bc10). In this way, cross-divisional communication also plays an important role (Bc6). Regarding the 232 minutes of workshop time, sufficient time should be given to business model development (Bc8). Despite the ongoing technological transformation, a face-to-face approach should also be considered (Bc9). Due to the continuous obtaining of commitment, doubters could be convinced (Bc7). Altogether, the process was designed as simple as possible (Bc5).

In addition to the illustrated internal agenda, the elaborated process design contains tools and content requiring an additional explanation. Thus, the process makes use of basic knowledge of business development in general and the Business Model Canvas (BMC). In this context, it is important to prepare the basic knowledge as well as the guiding questions and the interrelationships of the BMC. Prior to the workshop, it is furthermore necessary to draw up the existing business model of the considered company. The environmental analysis plays a central role in the process design because of the consolidation of the answers to the environmental analysis questionnaire.

5 Contributions, Limitations, and Future Research

Using Collaboration Engineering and a multilevel evaluation including iteration loops, we created a recurring and directly implementable process design that contributes to business model research. As part of the elaboration of the systematic process design, we bundled theoretical and practical requirements into a systematic process design. In this way, the process design is based on the current knowledge about business model development and cooperation in collaborative processes. Consequently, we consolidated the level of knowledge in science and practice.

The innovative combination of Collaboration Engineering and business model development enables new and interesting application opportunities in the research fields of Collaboration Engineering and business model development. Moreover, this new link enables organizations to systematically develop their own existing business model by means of clearly structured instructions.

Furthermore, the individual activities in the process design represent sophisticated procedural patterns for the use and development of the Business Model Canvas. Consequently, the design process of elaborating the Business Model Canvas was transferred into a clear and structured approach.

As a result, it is possible to work up the existing business model in a structured manner and beyond represent the entire revision process using Collaboration Engineering. In summary, it is possible to adapt the business model to constantly changing environmental conditions at any time with correspondingly less preparation time. With regard to the aim of the paper, a process design that offers direct applicability and explicitly describes the use of technology has been created. Moreover, the process design enables a continuous and recurring business model development without the ongoing support of professional facilitators.

Despite these contributions, this study is not without limitations. In this context, the elaborated hypotheses of the business model are not tested in the process design. Against the background of the sample of the evaluation, additional evaluations in various contexts could confirm the effectiveness of the process design and further improve the process design itself. Accordingly, with regard to future research, the process design could be extended by a validation phase or a complementary workshop for transferring the assumptions into testable hypotheses. Another important aspect in the context of future research is the ability to create a toolbox for an individual and tailored adaptation to the needs of individual organizations. Thus, the process design can be converted into structured patterns, allowing the targeted use of individual parts of the process according to organizations' needs.

While the process is based on collaborative cooperation, the use of IT is so far underrepresented. The developed systematic process design thus serves as a basis for the further inclusion of IT in order to allow for the additional flexibility of the process design and the fast adoption of small changes. The next logical step should consider the inclusion of IT and online collaboration in the process design. The aim is to observe the underlying process design principles and to leverage the strengths of IT and online collaboration. The environmental analysis offers potential for the use of IT. In this connection, the analysis can be conducted by mobile apps or online collaboration tools to improve the process design. Moreover, additional mechanisms to combine several business models should be implemented with the help of IT.

6 Conclusion

The aim of the present paper was to create a continuous and recurring process design for business model development. In this regard, Collaboration Engineering was used to elaborate the process design. CE deals with the design and implementation of collaborative processes for the implementation of recurring and high-value tasks. The direct applicability without the ongoing support of professional facilitators characterizes the elaborated process design. In this context, theoretical and practical requirements of business model development have been identified. Based on these requirements, the systematic process design was elaborated with the help of the CoPDA. The evaluation represents another important aspect of the elaboration of the process design. Against this background, the process design was tested and improved using a multilevel and iterative evaluation. The evaluation clearly indicates results equivalent to expert-based business model development. Accordingly, the process design enables continuous and recurring business model development without the ongoing support of professional facilitators. In this context, the process design provides a detailed elaboration of the procedure steps, materials, and documents that are necessary for the facilitation and implementation. All in all, the elaborated process design created with CE can be regarded as novel way to continuously develop business models.

Abstract. This paper explores the concept of business model management, defined as a generic process covering all phases of the business model life-cycle. In contrast to previous business model literature, which is mainly focused on the design of business models, we argue that the successful exploitation of the business model concept requires a dedicated management approach. Due to the lack of extant research in the domain, we build on multiple, exploratory case studies of large organizations, based on 20 expert interviews. This paper contributes to a better understanding of the current practices and needs in business model management and the multifaceted role of the business model concept in each of its phases. Moreover, we suggest roles of IT in the business model management process.

Keywords: Business model management, business model design, business model implementation, case study

1 Introduction

A business model (BM) is an abstract representation of business logic [1]. Serving as a reference framework, it supports practitioners in conceiving, designing and communicating business ideas [2–4]. The academic literature provides analyses of how organizations design and innovate their BMs [5–7]. However, although the BM can be understood as a structured management tool [8], there is still no clear understanding of its roles beyond design and innovation, also seen as the transition from BM *plan* to its *execution* [9].

"A 'strong' business model can be managed badly and fail, just as much as a 'weak' business model may succeed because of strong management and implementation skills" [9]. For instance, Ryanair's BM "creates several virtuous cycles that maximize its profits through increasingly low costs and prices" [10]. Its competitive advantage keeps growing as long as managers make these virtuous cycles spin. Being designed in a dynamic environment, as a reaction for instance to market changes, increasing competition, or technological innovation, BMs thus require active management [11]. Although recent research indicates that the BM life-cycle should embrace more phases than just design [12], these phases and a holistic management

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Terrenghi, N.; Schwarz, J.; Legner, C.; Eisert, U. (2017): Business Model Management: Current Practices, Required Activities and IT Support, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 972-986

approach have seen very little attention in academia and practice [13] – wrongly, in our view, because the BM concept can be leveraged by decision makers for implementation and management of a successful business, [9] and shifts "from a conceptual and theoretical focus to tooling and practical usability" [14]. We address this gap by answering the following research questions: (RQ1) *What is the current state of practice in business model management?* (RQ2) *What are the roles of the business model concept in each phase of this process?* If BMs are found to be relevant from a management perspective [15], decision makers also need IT-based BM tools to support their management. To address this aspect, we ask a third question: (RQ3) *What are IT's roles in supporting the business model management process?* Building on a qualitative research design and insights from 20 case studies, our findings confirm that companies mostly use the BM concept for analysis and design, but have not fully embraced it as management instrument in the implementation and control phases. Our study provides a baseline for future research by providing conceptual foundations and developing avenues for practice and future research.

The remainder of this paper is structured as follows: We start by reviewing the literature to derive an analysis framework for BM management (Section 2). We then present our qualitative research design (Section 3). Our empirical insights shed light on the current practices and required activities in 20 cases (Section 4). We conclude by developing avenues for practice and future research (Section 5).

2 Theoretical Background

In this chapter, we review the BM literature and elaborate on the emerging theme of BM management. Building on our literature review, we suggest an analysis framework that will guide our empirical study.

2.1 Business Model Concept

Although every company adopts a BM, either explicitly or implicitly, it remains an open question what exactly is understood by BM, that is, how it should be conceptualized [16]. At a fundamental level, scholars and practitioners agree that the BM is crucial for the success of today's organizations, especially concerning growth potential [17], competitive advantage [18, 19], long-term performance [20], and as a new source of innovation [21]. The academic community has recognized BM's potential, leading to a rapidly growing number of publications across management, IT, strategy, and other disciplines [8, 22].

In practice, the growing interest in the concept was catalyzed by the popularity of representations of the BM such as the so called Business Model Canvas [3], e3-value ontology [2], or St.Gallen Business Model Navigator [23], which have become reference tools for business innovation in both entrepreneurial and large organizations [14]. The main benefits of these BM conceptualizations are the systemic and abstract representations of the core business logic [9, 1, 24], which can serve as a useful device to analyze and communicate a company's value creation, delivery, and capture mechanisms [16].

2.2 Business Model Management

Recently, scholars have begun to investigate the phases of BM management beyond design, such as analysis [25], implementation [26], and management [27]. However, the literature provides very limited and inconsistent conceptual or empirical evidence on the practices and characteristics of BM management as a holistic process [17, 28]. For instance, [35] identifies design, implementation, operation, change, and controlling phases within the so-called business model life-cycle. [30] document an experimentation and exploration phase, followed by an implementation stage, and [23] distinguish between the phases of mobilizing, understanding, designing, implementing, and managing BMs.

Generally, the BM concept can be considered either as a static *blueprint* or as transformational, "using the concept as a tool to address change and innovation in the organization, or the model itself" [29]. The latter view reflects a management context, because it considers the BM as a tool to support the analysis, planning, and transformation of organizations [30]. It also comprises the transformation of the BM itself. Specifically, a business model "is typically a complex set of interdependent routines that is discovered, adjusted, and fine-tuned by 'doing' " [29]. Given how crucial it is to sustain the BM in volatile ecosystems, all tasks should be managed deliberately and its "conception, introduction into the marketplace, and ongoing management should not be left to chance" [31].

2.3 IT Support

Software and tools that support BM management have already been developed but are still in the earliest state of immaturity and are largely restricted to the design phase, by supporting the visualization of a BM [15]. However, recent research highlights that such "computer-aided business modelling tools should go beyond simple design tools and evolve into an own class of high-level decision support tools" [27]. This implies that software tools not only support design, but also the overall process.

2.4 Towards a Framework of Analysis for Business Model Management

Building on the literature, we develop an analysis framework to guide our empirical research on BM management (Figure 1). We suggest defining BM management as *an generic management process, building on the business model as the central unit of analysis.* The overarching element of our framework is the BM conceptualization employed in practice. Through this element, we account for a better understanding of the relevant aspects of the BM concept in the different BM life-cycle phases. We refer to specific BM conceptualization and operationalization as well as the general mindset and perception of practitioners toward the BM concept. For BM management, we rely on four generic phases of strategic management: analysis, design, implementation, and control [32].

Analysis. Given that the development of new BMs or the improvement of existing ones is a complex challenge for managers [33], understanding when changes in the BM are needed is essential [34]. During this phase, relevant aspects such as technological innovations in the external and internal environment are identified to assess the urgency of and opportunities to alter the BM [34].

Design. "Designing a new business model requires creativity, insight, and a good deal of customer, competitor and supplier information and intelligence" [17]. Design could include activities such as brainstorming, prototyping, testing, and selection [3] and could be theoretically guided by dedicated frameworks [24].

Implementation. Design and implementation phases are distinct but strongly related: a 'good' BM design can lack the expected value owing to its ineffective implementation [9]. Thus, in this phase, project management could become relevant [12] in order to operationalize the BM [26].

Control. Although the BM may have been rigorously designed and implemented, its de facto performance and effectiveness are subject to emerging events and needs being continuously controlled, for instance, in relation to financial, process, or growth performance [35] and associated risks [16].

These phases can be mapped to the ones mentioned in [3, 9, 12] and reflect the more generic phases of strategic management. However, these four phases cannot be considered as exact, given the early stage of BM management. They should be considered as 'idealized' rather than 'ideal'. In line with the literature, phases could be carried out in parallel, iteratively, or ad-hoc [3, 9, 12].

The underlying element is IT support (similarly to [15]), because each BM management phase can be expected to be supported by one or more software tools [15].

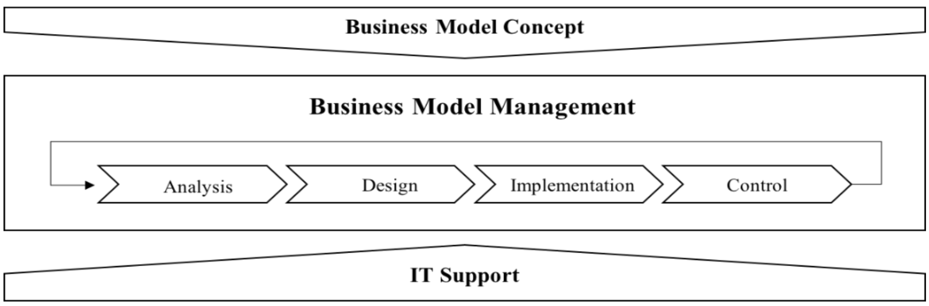

Figure 1. Framework of Analysis for Business Model Management

3 Methodology

To better understand the current situation and roles of BM management in practice, we applied a qualitative and exploratory research design by conducting multiple case studies [36]. A case study method is commonly defined as "empirical inquiries that investigate a contemporary phenomenon within its real-life context"; it is particularly useful to understanding the emerging topic of BM management [36]. We performed multiple case studies because this approach reinforces the generalizability of results [37]. We conducted a series of 20 cross-industry cases of large organizations. For each case, we collected data through semi-structured interviews with experts in different managerial roles.

3.1 Case and Expert Selection

To gain insights into BM management in organizations, we had to identify suitable case sites, as well as experts as key informants. Our goal was to cover a broad variety of organizations from different industries and with different levels of expertise in BM management in our case sample.

Table 1. Characteristics of Interviewees and Their Organizations

Roles	Managers (18), Director (1), CEO (1)
Divisions	Innovation (12), corporate strategy (6), business development (2)
Industries (code)	Automotive (AUT) (2), financial services (FIN) (2), energy (ENE) (3), chemicals (CHE) (3), conglomerate (CON) (3), information technology (INF) (2), logistics (LOG) (1), high-technology (HIG) (3), research (RES) (1)
Countries	Germany (11), Switzerland (3), France (2), U.S. (2), Italy (1), Norway (1)
Revenues (avg.)	$40B
Size (avg.)	98K employees

Before approaching a wider number of companies, we conducted four knowledge-sharing sessions with affiliated practitioners who have experience in BMs in their organizations and were willing to share their insights. Based on the results of the knowledge-sharing sessions, we learnt that the topic is particularly relevant for large organizations (> 250 employees) across industries: compared to small- medium-enterprises, they tend to assign more resources to BM-related initiatives (e.g,. dedicated teams or organizational units). Further, decision makers in large organizations are usually aware of the BM concept, but struggle to manage it. The knowledge-sharing sessions have been also crucial to spot roles of 'BM experts' in an organization: we identified experts in several areas such as new business development, innovation management, general management, and strategic management. Finally, we approached potential candidates at conferences, events and through personal contacts of the authors and seven colleagues. We invited decision makers in large organizations who have BM knowledge and have adopted or intend to adopt it in the management of one or more phases. Of the 34 experts we invited, 24 agreed to be interviewed; all had managerial or executive roles in large organizations. Four could not provide any relevant insight on BM management phases and were excluded, resulting in 20 eligible cases. Table 1 summarizes the characteristics of the organizations and interviewees. To guarantee anonymity, we refer to each expert with a code (e.g., AUT1 = the industry of the organization s/he belongs to: Automotive 1).

3.2 Data Collection and Analysis

Between January and May 2016, we conducted 20 semi-structured interviews by the authors or one of their seven colleagues. The interviews were done face-to-face (18 of 20) or via telephone (2 of 20) and lasted between one and four hours. In some cases, a first brief telephone interview was followed by a meet-up. Usually, between one and three interviewees participated, often from very different organizational units, reinforcing the topic's relevance across divisions. At least two interviewers participated; one leading the conversation and the other(s) taking notes. Owing to confidentiality, we did not audio-record any session; statements in quotation marks can therefore not be considered as direct citations. During the interview process, we presented our current understanding of BM management to interviewees, followed by questions about their previous experience with and use of BMs, the topic's general relevance, IT's potential roles, and general feedback, followed by an open discussion.

For data analysis, the interview notes (between pp. 2 to 5 per interview) were consolidated and analyzed by two authors, individually, along the process of constant comparison and iterative conceptualization [38]. Some interviews were done in German or Italian and had to be translated into English. In the analysis process, we categorized the codes into the elements of the theoretical framework before identifying emerging themes in each group. In case of disagreement, a third author was involved in the discussion until we had clarification. Finally, each author reviewed the coding, and we achieved agreement in a round table session.

4 Results

4.1 The Business Model Concept

Regarding the BM concept, we highlight two important findings: its operationalization and its relevance across BM management phases. While some academics argue about the 'best' BM conceptualizations, our results suggest that certain organizations are able to leverage the BM concept without specific templates (AUT1, FIN1, FIN2, CHE3), while others operationalize the concept through existing BM frameworks, such as Osterwalder's Business Model Canvas (CON2, INF2, CHE2). However, there appears to be consensus that, sooner or later, organizations adapt these frameworks to their specific needs and/or integrate them with other templates (e.g., SWOT). As CHE1 notes, "*we need flexible canvases and tools, because each company develops and uses their own.*" CON3 confirms that "*every company has its own specifications, which must be represented.*"

Regardless of its specific conceptualization, the relevance of the BM concept differs significantly across the BM management phases. Organizations strongly apply a BM perspective during the design phase and highlight its importance, such as "*visual representations*" (CHE2), "*spot and rank the most critical elements of a BM through the eyes of the customers*" (AUT2) or "*represent alternative BM designs*" (CON3). However, they report additional issues during implementation. Some companies report that "*other divisions do not speak this language*" (AUT2), "*some colleagues don't want to think creatively*" (CHE1), and "*management looks at ROI*" (INF2). Since more stakeholders are increasingly affected in advancement throughout the phases (RES1, CHE3), conflicts with the core business must be avoided (AUT1).

4.2 Business Model Management

Table 2. Results Per and Across BM Management Phases (insight recurrence)

	Analysis	*Design*	*Implementation*	*Control*
Current practices	Environment analysis (7)	Iterative testing (6)	Accountability management (3)	Financial performance (2)
	Partnerships (3)	Customer centricity (4)		
Required activities	Prevention of disruption (5)	Stimulation of scenarios (6)	Stakeholder management (4)	Holistic dashboard (6)
	Portfolio analysis (3)	Enhanced visualization (4)	BM portfolio management (2)	Prompt notification (4)
	Idea management (2)			
IT support	Key value to current practices and required activities (6) Creativity and communications are enabler, not inhibitors (4) Integrated with other tools (3)			

Analysis. *Current practices.* The analysis phase is mostly described as the process of collecting relevant information from the external environment, which refers not only to customers (CON1) but also competitors (AUT1, LOG1), other industries (ENE2), new market entrants that "*might intervene and disrupt the market*" (CHE1), and digital trends (CHE1, INF1, ENE2). Some organizations proactively analyze their environment, adopting an "*intensive collaboration with startups*" (ENE1) to "*help them grow and to change [their] business model based on their insights*" (CHE1). Similarly, CHE2 mentions that her organization constantly runs internal workshops and "intrapreneurship" programs to help employees generate and collect business ideas.

Required activities. The lens on the external environment is primarily based on the question "*how could my business model be disrupted?*" (CHE3). This dilemma concerns the experts' hope, and fear, that "*digital transformation might change things or open new opportunities*" (ENE2). Thus, interviewees highlight the need for a prompt signal that can spot a disruption threat, or opportunity, in advance, because "*it is […] important to find the right timing for business model innovation.*"

Among the organizations that trigger BM design based on the analysis of internal capabilities (HIG2, CHE2, CON3), the primary activities concern the "*understanding of portfolio of [existing] business models*" (CON3). The same expert highlights that "*Not every product must be a financial performer, because it could complement services. It is important to map these dependencies. We would always start on the portfolio layer.*" The collected information is often unstructured and lacks a filtering process that leads to the design phase. For this reason, CHE2 suggests that an "*idea management tool*" is needed. Thus, the crucial activities needed in the analysis phase concern the identification of possible changes in the industry, systematic management of insights for BM design or adaptation, and the acknowledgment of internal constraints relating to existing BMs.

Design. *Current practices.* BM design should use the customer as starting point for value creation. Experts tend to validate their assumptions through market analysis and product test (e.g., prototypes). For instance, CHE3 states that they "*test different elements of the [business model] canvas with customers (e.g., willingness to pay).*" In this sense, the customer is perceived as a co-innovator. AUT1 highlights the relevance and urgency of customer centricity owing to digital transformation, suggesting that design "*needs to anticipate the digital expectations of customers three years ahead.*" However, although most organizations highlight customer centricity, an expert in the oil and gas industry (ENE3) states that in their commoditized market, this is not relevant, since "*we just need to find resources and sell them.*"

A second recurrent – and expected – insight is that the BM design is typically iterative. Experts highlight the essential, repetitive validation of their assumptions, which can take place through the adoption of specific tests (CHE1, CON3) and through prototyping (CHE3, HIG1, CHE3). Tests are considered particularly valuable for generating multiple BM designs, also known as *versioning* (CHE2). Prototyping is a practice that, according to CHE3, helps to "*avoid long-term investments upfront.*" However, two experts mention feasibility regarding testing and prototyping: ENE3 and RES1 highlight that constraints such as time, legislation, and infrastructure often prevent testing and prototyping.

Required activities. Although testing and prototyping are currently common practices for several organizations, such as minimum viable propositions and surveys, interviewees mentioned the need for further support in the validation of BM design. In particular, "*business model simulation*" is a recurrent term (e.g., AUT2, INF1). CHE1 describes it as the assessment of "*internal and external requirements, so that the business model can work in particular situation[s] or market[s].*" Similarly, INF1 focuses on the relevance of simulations to predict "*the best customer channel, sales and distribution.*" Such activity is also highlighted as an IT solution to support managers in creating multiple scenarios or *versions* of a BM (CHE2) and to identify the critical elements of a BM (AUT2).

To support BM simulation and validation, experts suggest that a detailed visualization of a BM and its elements is needed: CHE2 states the "*need to get more* *details in the business model canvas to actually use it and communicate ideas.*" AUT2 also supports the urgency for a "*granular*" representation that "*avoids ping-pong in the communication between departments*," while FIN2 focuses on a BM visualization that enables better customer segmentation and description.

Implementation. *Current practices.* The implementation phase holds unique characteristics, particularly compared to the design phase. Generally, it appears to be "*a challenge at a large company*" (HIG1), perhaps even "*the biggest hurdle*" (HIG2). Specifically, the first important characteristic noted by several interviewees is the increasingly significant role of stakeholders. Employees who are directly responsible for BM implementation and execution are a primary stakeholder group. CON3 describes this group as the "*entrepreneurial team*" and asks "*what are the ideal characteristics of the members of this team?"*

Required activities. Concerning stakeholders, ENE3 addresses the "*need to have a business model owner, who pushes the execution with the implementation team.*" As several other respondents highlighted the need for general stakeholder management, we see a second stakeholders group beyond the BM owner. These stakeholders could be the implementation team (ENE3), sponsors (CHE3, HIG1), or coaches (CON3). Stakeholder management's role is also emphasized by the need for "*approval management*" (HIG1, CH1, FIN1) or "*stage-gate processes*" (RES1). ENE3 suggests employing a "*power couple*" – two managers accountable for BM design and implementation respectively, and who strongly depend on each other.

While the previous phase indicated a focus on finding the right BM and assessing customer needs, implementation is concerned with finding the right organizational set-up. Several companies mentioned potential conflicts between the traditional core business and new BMs. For instance, AUT1 noted that "*the central question is how the traditional core business can be combined with new, digital businesses*," facing major challenges such as self-cannibalization, which must be avoided, because "*there is no willingness to give up existing business for new ones*" (CON1).

Control. *Current practices.* Only two interviewees addressed the regular control of one or more implemented and 'running' BMs (INF1, FIN2). They highlight continuous monitoring of financial performance, referring to specific BM elements, such as revenues and costs. Both INF1 and FIN2 suggest that there is currently no control tool besides financial reports and, when necessary, ad hoc analysis of specific reports' insights.

Required activities. CON3 argues that "*business models are never stable.*" To control a BM, experts suggest that data and IT systems are necessary. Here, INF2 comments that "*[they] need to make a dashboard*" to visualize and leverage quantitative data for BM improvement. Similarly, CHE2 states the "*need to look at environment data*" to monitor and prevent threats and seize opportunities, while CON1 asks "*if the customer has an input, how [can we] leverage this input in the business model in the best way?*" INF1, also owing to his industry, suggests that such a dashboard should provide "*real-time monitoring*" of the BM.

The regular controlling of a BM and its visualization as a dashboard form the basis for working as "*early warning*". CON3 explains that "*alerts must notify business model owners if crucial parameters deflect. Thus, these parameters must be captured (for instance, financial indicators, regulations, or other requirements).*" FIN2 argues that his organization needs to enhance reporting practices in order to enable more complex queries. RES1 and CHE3 discuss how alerts should also help managers to distinguish between the need for incremental change and the need for disruptive change.

4.3 IT Support for Business Model Management

While most respondents reported the need for general software support of BM management, only CON3 is already systematically working with a mix of "*predefined Excel files for evaluation and risk management, as well as PowerPoint, and one tool to describe processes.*" With two exceptions (ENE2, HIG1), most companies argue – similarly to CHE1 – that "*software support would be a key additional value*" (CON1, CHE1, CHE2, RES1, CON2, FIN1). For instance, CON1 states that "*no tools are used, which is a big problem*," while CON2 notes that "*we need situation-specific and iterative tools.*" However, a major requirement of those tools is that they could be helpful by providing a pre-structured process that "*moderates the process, colleagues, and process sequence*" (FIN1) yet maintains the agility and flexibility, particularly during the design phase. "*We need […] iterative tools to avoid fixed step-by-step processes with unnecessary steps*" (CON2).

While some firms are concerned about creativity and agility during design, the results show that the implementation phase could strongly benefit from software support. The primary reasons are that implementation requires support for "*identifying experts in the network*" (CHE1) and "*identifying organizational units that could provide knowledge or support the business model to implement it faster*" (CON3). From the interviews, we also learnt that BM representation should "*provide deep dives into certain elements*" (CON3), an "*ecosystem view*" (RES1), and be "*integrated with other conceptual tools, such as strategy-maps or balanced scorecard*" (FIN1). We can also report two significant relationships with existing software systems (CON1): "*a BM perspective could be integrated into existing tools, such as CRM*" and "*how can business models be derived from the ERP?*"

5 Discussion

Our study contributes to the BM literature by suggesting a comprehensive conceptualization of BM management. Based on empirical insights from 20 cases, we assessed current practices and required activities in BM management. Our results reveal that organizations still concentrate on BM analysis and design, but also confirm the need for a structured management process. The above mentioned empirical findings outline future avenues for research and practice, laying the groundwork for further studies.

5.1 Business Model Management

In response to research question 1, our results suggest that current BM practices in large organizations mainly relate to analysis and design, and that BM management, as a holistic management approach, is highly relevant to companies across different industries. In this sense, it empirically confirms previous theoretical arguments [3, 13], which hold that the BM concept is widely accepted for designing and innovating new BMs but that there is a significant need to focus on the BM management as a whole, including implementation and control (Table 3).

Our study is also one of the first to explore the details of such a holistic process in terms of current practices, required activities, and IT's roles. The results show that organizations have an expressed need for a general process to manage the entire life-cycle of BMs and provide a first rich picture of the current situation in practice. Further, the maturity level, which could be considered as experience with BMs and the level of adoption of the concept in different phases, varies widely. Very few organizations have already adopted a fairly structured BM management process (CON3, CHE1), while most either begin with small BM-related projects or have integrated the BM perspective into their existing innovation processes (e.g., product innovation).

5.2 The Roles of the Business Model Concept

Regarding research question 2, we found that the BM concept is in fact important during all phases. Interestingly, its role and application appears to change along the phases, pointing at a multi-faceted conceptualization (Table 3). Our results show for instance that the *working mode* changes along these phases. During analysis and design, frequent iterations, agility, simulations, and customer centricity are key. During implementation and control, a fairly sequential procedure with "*approval management*" (CHE1) and "*milestones*" (CON3) was indicated. In addition, the main sources of knowledge also differ among the phases: during the analysis, the environment is crucial; in the design phase, the focus is on products and customers; the implementation phase depends strongly on the contribution of internal experts and on the integration with other internal BMs; the control phase requires data acquired from enterprise systems and other data sources. Irrespective of the phases, some authors even go beyond the management of a single or multiple BMs; they state that the BM concept is a crucial perspective to manage the entire corporation, irrespective of the company's size. Such "*evolution*" of the BM concept has been recently coined by [39] as *business model-based management*.

A primary obstacle to the further adoption of the concept, particularly during implementation and control phases, could be the "*lack of business model mindset*" (INF1, AUT1, CHE2, ENE1, ENE3, FIN2). Here, many divisions such as corporate strategy become involved. According to the experts' insights, these stakeholders may have a short-term perspective (FIN2), looking solely at financial performance and ROI (CHE3, INF2) and may feel threatened by changes to the traditional BM (AUT2).

Table 3. Overview of the Characteristics of Business Model Concept and Management

	Analysis	*Design*	*Implementation*	*Control*
Maturity level (current practices)	High (10)	High (10)	Low (3)	Low (2)
Working mode	Explorative, open	Agile, iterative	Gateways, sequential	Structured, regular
Key knowledge source	Environment	Offer, customers	Internal experts, other internal BMs	Internal data source
Obstacles to the adoption of BM management	Lack of BM mindset; focus on short-term results; fear of cannibalizing the traditional BM			

5.3 IT's Roles

Consistent support of the entire BM life-cycle raises the need for adequate IT solutions, not only as digital visualization of BMs, where pen-and-paper seems to be sufficient for most practitioners. We respond therefore to the quest for research on "*IT support for developing and managing business models*" [15] by providing first insights into requirements of the prospective research stream on software systems that "clearly go beyond simple design tools […] and evolve into an own class of high-level decision support tools" [15]. IT must support a structured management process, but should not constrain agility in and the iterative nature of the early phases of BM development. Handling this paradox could be a fundamental aspect of IT support to drive the adoption of systems and to ensure their sustained use throughout the life-cycle. In other words, paying attention to the above mentioned characteristics of the different phases may contradict the over-simplistic assumptions of BM software tools, which mainly focus on visualization. Further, a selection of specific features was highlighted, namely simulation, collaboration, knowledge management, reporting, and the fact that IT support should include additional strategy tools such as strategy-maps that are easy to adapt.

We also contribute to the broader IS literature by building on [27]'s argument about IS's key roles in "informing strategic disciplines and in contributing to increase understanding of the essence of BMs and other strategic notions." While [27] suggest three primary contributions of IS to strategic management (modeling at a strategic level, strategizing as designing, considering computer-aided design), we added an additional role of IS. Given the high relevance of implementation for any BM's success, a fruitful future research area could be to investigate to what extent the existing IT-landscape is a barrier to successful BM management. For instance, CON1 notes that not all BM ideas can be implemented, owing to the rigidity of the IT-landscape, and that it should be examined how existing IT systems (e.g., ERP, CRM) can support BM management, providing data or integrating a BM perspective.

6 Conclusions

This study investigates the current practices and required activities associated with BM management. Drawing on empirical insights from 20 case studies, we found evidence that managers in large organizations acknowledge the BM concept's relevance, not only for the purpose of design, as already established in the literature, but also for analysis, implementation, and control. We have shown the increasing relevance of the BM concept throughout all phases and, although companies report different maturity and adoption levels, it affects different activities and multiple stakeholders.

Our study provides a baseline of BM management from a practitioner perspective, and we trust that it will inspire other researchers to contribute to this emerging research stream. Specifically, we identified three primary limitations that could trigger future studies. First, we approached practitioners interested in the topic, rather than those who would deliberately not manage BMs (e.g., managers in controlling, who have all the tools they need in place). Interviewing such a group could provide useful insights into the barriers to BM management adoption and could therefore sharpen BM management's value proposition.

Second, BM management is still in its infancy. Organizations use the concept mainly for design and creativity purposes (e.g., during workshops) or to complement other innovation processes and therefore have little experience with BM implementation and control. It follows that our findings on these two phases need for further validation. In particular, corporate spinoffs or recently introduced BMs might be interesting subjects for case studies.

Finally, in this study, we sought to obtain a broad overview of the state-of-the-art in BM management. Thus, we approached a fairly large number of organizations. Future research could build on our findings to conduct in-depth research into selected organizations that adopt BM management in each phase.

Abstract. The Internet of Things (IoT), in which virtually all physical things become connected to the internet, promises enormous economic potential. The IoT might disrupt entire industries and it forces companies to rethink their current business activities. In light of these challenges, research on business model innovation (BMI) can offer promising insights. This research paper aims to contribute to the emerging BMI literature by identifying innovation barriers in an IoT context. 16 barriers are identified based on ten expert interviews that were conducted with employees from five multinational companies. The contributions of our study might lay a fruitful ground for future research.

Keywords: Business Model Innovation, Internet of Things, IoT BMI Barriers.

1 Introduction

General Electric (GE) has been well-known for selling industrial hardware and maintenance services. However, recently the company got under pressure in new fields of competition facing non-traditional competitors such as SAP, IBM as well as big data and analytics startups [7]. Instead of offering reliable industrial equipment, these new competitors shift the customer value proposition towards the Internet of Things (IoT) and "deriving new efficiencies and other benefits through advanced analytics and algorithms based on the data generated by that equipment" [7, p. 91]. To meet the new competition and to address the challenges arising from IoT solutions, GE is currently transforming its entire business model [7]. In this respect, GE faces severe challenges, similar to many traditional manufacturing companies across industries [3, 7].

Little is known about how the IoT will change business models and even less about what IoT specific barriers hamper business model innovation (BMI) [cf. 14]. In fact, first studies already investigate general barriers to BMI [3, 6]. In addition, there is a large literature stream on technical IoT challenges [e.g. 4, 12]. However, to the best of our knowledge, there are no empirical studies that investigate IoT-specific BMI barriers in detail. Previous studies on IoT BMI provide anecdotal evidence and do not base their findings on empirical data [cf. 13]. To shed more light on the depicted research gap, this study identifies barriers to IoT BMI and can be seen as a first explorative step towards a better understanding of IoT adoption. Thereby, the study focuses on large

Bilgeri, D.; Wortmann, F. (2017): Barriers to IoT Business Model Innovation, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 987-990

multinational companies that conduct technology-driven BMI in an IoT context. More specifically, our research aims to address the following research question (RQ):

What are specific barriers to technology-driven IoT business model innovation?

2 Background

The *Internet of Things* describes a broader vision that all sorts of objects become smart, able to gather data and communicate both with each other and the internet [5]. Porter and Heppelmann argue that the key novelty of IoT solutions lies in "[the changed] nature of the 'things'" [13], including their connectivity and the digital services that they facilitate [5]. Such offerings, spanning the digital and the physical world, require a broad array of enabling technologies [12], which is reflected in various value creation layers inherent to IoT solutions [5].

Despite the lack of an agreed business model definition [15], a common high-level understanding emerged that business models explain a focal firms' value creation and value capture [17]. Taking a transformational perspective on business models is the essence of *business model innovation* [4]. In the light of a missing conceptualization, business model innovation is used as an umbrella term describing companies' efforts connected to "the search for new business logics of the firm and new ways to create and capture value for its stakeholders" [2, 9]. So far, little is known about BMI processes [14]. In fact, scholars agree that the related literature on new product development (NPD), with its much richer record, is most suitable as a starting point for BMI process research [3, 6, 14]. Latest research on NPD identifies four key innovation stages: idea generation and screening (ideas are gathered and the most promising opportunities selected); concept development and evaluation (business model components, such as revenue mechanics, are elaborated); technical implementation (technical realization of the offering and introduction of the business model throughout the organization) as well as commercialization (business model is scaled successfully in the market) [10].

The complexity of emerging IoT solutions brings along some severe *new challenges* [cf. 12]. A rich field of research exists, investigating IoT barriers from a very technical viewpoint. Among the most critical problems identified in this type of literature are a lack of protocol standardization, scalability limitations, energy supply and security issues [cf. 4, 12]. Besides this technical stream, various studies, including the seminal article of Chesbrough, investigate what might generally hinder organizations to innovate their business models [cf. 3]. Amit and Zott [1], for instance, identify the four characteristics novelty, lock-in, complementarities as well as efficiency and elaborate how these aspects might be contradicting to "traditional configurations of firm assets" [3, p. 358]. Several early studies also elaborate on more operational challenges managers face when attempting to innovate their companies' business models, such as overcoming internal resistance, financial hurdles, setup of value networks and the successful management of the applied implementation approach [6].

3 Methodology

Ten in-depth expert interviews were conducted with employees from five leading multinational corporations across the IoT ecosystem. The interviewee selection followed a heterogeneous purposive sample approach applying three pre-defined criteria [16]: (1) interviewees have either been actively involved in or closely guided IoT related BMI projects; (2) they possess more than two years of IoT BMI experience to ensure that they can sufficiently inform the research; (3) they are employees, partners or consultants to manufacturing companies across the IoT ecosystem. Interviews lasted between 30 and 60 minutes, followed the same case protocol, were audio-recorded and additional secondary data about the companies in general or mentioned IoT BMI projects in particular were collected for data triangulation purposes [16].

4 Findings and conclusion

The paper at hand identifies 16 barriers to IoT business model innovation, which are structured along four high-level innovation stages (cf. Table 1) [10].

Table 1. Identified IoT BMI barriers structured along stages adapted from Luchs et al. [10])

I. Idea generation and screening	*II. Concept development and evaluation*	*III. (Technical) implementation*	*IV. Commercialization*
1. Process ownership 2. Product-centric focus 3. Immediate profit thinking 4. Uncertainty	5. Innovation-driven R&D vs. reliability-focused IT 6. Collaborate with various partners 7. Data privacy 8. IoT value propositions	9. Clash of cultures 10. Data analysis 11. Legacy systems 12. Efficient operations	13. IoT revenue mechanics 14. After-sales commercialization 15. Customer analytics 16. Ambidexterity

Thus, this study can be seen as a first explorative step towards a better understanding of IoT adoption. The findings contribute to the ongoing debate on BMI by strengthening scholars' and practitioners' understanding of IoT specific hurdles to business model innovation. Some of the identified barriers build upon well-known BMI barriers, such as *legacy systems* or *ambidexterity* [8, 11]. But, when analyzed in an IoT context these barriers gain unexpected new facets and thus relevance. Others are IoT specific and have not yet been discussed in the BMI literature at all, including barriers such as *data analysis* or *customer analytics*. The results of this study should be assessed in the light of their limitations. One general limitation of qualitative research is generalization of results [16]. More specifically, our research is limited by the number and selection of interviews conducted. Further work in different empirical settings will be required to enhance the validity of the research. Taking these aspects into account, we hope that the contributions of our study lay a fruitful ground for future research. Promising research avenues might include a more in-depth analysis of the identified IoT BMI barriers with regard to their impact on BMI success.

The presented work is supported by the Bosch IoT Lab at the University of St. Gallen.

Critical Success Factors of Digital Business Strategy

Friedrich Holotiuk[1] and Daniel Beimborn[1]

[1] Frankfurt School of Finance & Management, Frankfurt, Germany
{f.holotiuk,d.beimborn}@fs.de

Abstract. Digitalization does fundamentally impact firms' strategy development. With the fusion of IT and business strategy, Digital Business Strategy (DBS) creates the foundation for digital business models [1]. In this paper, we develop a DBS framework, based on a structured review of 21 industry reports. From this analysis, we yield 8 generic dimensions with a total of 40 critical success factors (CSFs) for DBS. The CSFs represent a rich set of actions specific to DBS and to the design of business models in the digital business environment. The discussion shows that academic research is lagging behind in contributing to DBS. Future research is suggested to further formalize the concept of DBS and to create a better understanding about how firms can successfully establish DBS.

Keywords: Digital Business Strategy, Business Model, IT Strategy, Industry Reports, Meta-Analysis

1 Introduction

Digital Business Strategy (DBS) is an emerging concept at the intersection of Information Systems (IS) and Strategic Management [2], which calls for contributions from academic research [3]. DBS describes the fusion of business and IT strategy [1] and the incorporation of digital technologies in business strategy [4]. With DBS, the separate and subordinate role of IT strategy to business strategy is given up for a joint approach to both, thereby leveraging internal, e.g. IT, instead of externally focused actions to create competitive advantage [2]. Recently, this trend has got into the focus of IS journals, like the MISQ special issue 2013 or the research agenda proposed in Business and Information Systems Engineering (BISE) in 2014 [5]. The combination of different scientific perspectives as intended by Veit et al. [5] is a cornerstone of DBS. However, guidelines for the development of DBS along with effective implications for the design of digital business models (BMs) are still scarce in the academic literature [6].

Contrary, DBS has found strong support in practice in form of numerous industry reports of research centers like the MIT Center for Digital Business [7], research firms like Gartner [8], technology advisory firms like Accenture [9] or Capgemini [10], and strategy consultancies such as McKinsey [11], BCG [12], and Bain [13]. In practice, the advancement of digital technologies and the rethinking of strategy are linked to "strategic principles" [14 pg. 5], a "digital strategy process" [9 pg. 10], or "strategic

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Holotiuk, F.; Beimborn, D. (2017): Critical Success Factors of Digital Business Strategy,
in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung
Wirtschaftsinformatik (WI 2017), St. Gallen, S. 991-1005

challenges" [15 pg. 9]. The use of digital technologies to "achieve strategic end" [16 pg. 6], leverage of data to create customer insight [8], and develop a digital mindset [17], are among the clearly identified actions of DBS in practice. Interlinks between practice and academia are observable with the new line of thinking on the role of IS executives, inspired by John F. Rockart, developing from "technically oriented" to "managerially oriented" [18 pg. 3]. IS executives are now developing more 'strategically oriented' skills along with greater digital literacy [19], as digital technologies become of strategic importance [20]. These technologies are summarized under digitalization, which stands for the emergence of "rapid Internet and technological advancements" [21 pg. 48] and "a sociotechnical process of applying digitizing techniques to a broader social and institutional contexts that render digital technologies infrastructural" [22 pg. 2]. As a result, strategic implications for the design of BMs from digitalization are observable, justifying the current research on DBS in academia and mainly practice. Nonetheless, good practices for implementing DBS or insights into strategic actions of DBS are few [6]. The development of the related academic research stream is still in its infancy. Hence, it is worthwhile to study what industry reports are suggesting firms to do in terms of Critical Success Factors (CSFs), i.e., in order to "ensure successful competitive performance" [23 pg. 12]. CSFs define a few actions and areas of a firm which are of critical importance to the firm's success [23]. They are not focused on achieving competitive advantage but lead to competitive failure if not met [24]. Hence, they can be used to answer currently open questions on effective strategy development of DBS and the successful translation of DBS into BMs. Moreover, CSFs help us to gain a better understanding of DBS in practice and provide helpful insights for academia. In the end, we deducted our research question directly from the outlined shortcomings of academic research as well as from the profound calls for new insights to DBS: *What are the CSFs of DBS in today's business environment?*

Consequently, our research is motivated by the quest for a new, holistic, approach to strategy development in the digital business environment and the identification of CSFs of DBS. Thus providing new academic input and the needed theoretical grounding. The goal is to derive a set of CSFs of DBS, which can be synthesized in a framework for DBS and the design of digital BMs. As academic research findings on DBS are scarce, this paper provides a review of, particularly, industry reports to include findings and advancements on DBS from practice. We consolidate the current state of industry research on the nature and success of DBS as well as contribute a framework for DBS, which is structured along 8 dimensions with 40 CSFs. The dimensions of the framework provide managerial implications for designing BMs in the digital business environment and outline future research avenues. Also, implications from strategy to BMs further to business processes can be derived [25].

The remainder is structured as follows: First, the background provides a literature summary of the origin of DBS and its implications for the design of BMs. Next, the research methodology explains the detailed procedures to extract CSFs of DBS via a structured analysis of industry reports. Afterward, findings are synthesized in the DBS framework and the CSFs are explained. Finally, the discussion puts the framework in perspective to the literature and highlights implications and limitations of our research.

2 Background and Related Research

IT has been on the management agenda for a long time, it was first focused on data processing and technical problems, developed to be more functional-oriented and focused on Management Information Systems, later focused on first strategic implications and the competitive use of IT, and last to the alignment of business and IT [26]. Consequently, IT and business strategy were characterized by a distinction, such as how IT could support to achieve business goals. This distinction has been coined 'strategic alignment', describing the parallel development of IT and business strategy as well as the support function of IT to business [27]. As a result, an "aligned but essentially subordinate" [1 pg. 472] role of IT to business strategy dominates strategy development. This differentiation is inadequate for a time where digital technologies are disrupting products, industries, and markets. Where firms have to entrench digital capabilities to stay competitive. Hence, with digitalization a gap between what is required and the traditional thinking of strategic alignment developed.

DBS aims at addressing this gap by taking a broader and more inclusive view on IT strategy and recognizing changes due to the digitalization. Statements, like "digitalization transforms our society like only the industrial revolution did before in recent history" [28 pg. 10] and society is undergoing "remarkable change because of digital technology" [29 pg. 734] support the ongoing transformation. The fusion of the digital and physical worlds fundamentally impacts firms' operations and industry boundaries. In this transformation, it is not a matter of whether or not firms will be digital, but a matter of how and when they become digital [9]. Strategy plays a superior role in this transformation; Catlin et al. [30] show that strategy-related factors cause the biggest variance between 'digital leaders' and average performers when comparing competitiveness. However, the transformation of strategy is lagging quite behind the transformation of the business environment.

As a result of digitalization, IT strategy is seen today "as essential to the framing of overall business strategy, that is, a fusion of IT and business strategy" [2 pg. 513]. The implied constant interlocking of business and IT strategy with DBS can deliver competitive advantage [31,32] and underlines the contrast to the traditional view of IT strategy. However, the current state of research on DBS unveils blank spots in IS as well as Strategic Management with only a few academic articles having been published. While IS research has analyzed how digital technologies are influencing a firm's strategy, structures, and processes [32,33] and how business value is shifting [34], the fusion of business and IT strategy has not yet been a clear focus – the question of "how to build a competitive advantage in turbulence with digital IT systems" [35 pg. 443] remains.

However, it should not be neglected that, academia needs naturally more time than practice to establish a new research stream. Consequently, the overall research on DBS has remained largely atheoretical and dominated by industry reports [16] and practitioner guidelines [36]. Research in practice shows that "conventional business strategy is not the best fit for meeting the demands of digital growth" [9 pg. 8] and affirms that "companies [are] competing in a fundamentally new way" [14 pg. 2], due to digitalization. Practice research recognizes that DBS "it is not about changing the way we do technology, but changing the way we do business" [7 pg. 22] by rethinking strategy.

Although implications on strategy are discussed, BM-related considerations are few, but should be considered, as these two concepts, strategy and BM, although they are distinct, are connected [5]. Strategy is about “deliberately choosing a different set of activities to deliver a unique mix of value” [37 pg. 64] whereas the BM is “an abstract representation of an organization […], of all core interrelated architectural, co-operational, and financial arrangements […], as well as core products and/or services […] needed to achieve strategic goals” [25 pg. 8]. BMs are one way to translate strategic actions from DBS into value architectures for the business [38]. Hence, they have undergone tremendous change as value creation has shifted, due to redefined product and service offerings [39]. New BMs are needed as traditional products and industries are disrupted by digitalization. “The digitalization of the book is fundamentally reshaping the structure that has underpinned the book publishing for 200 years […], changing the very idea of books” [29 pg. 724]; illustrates how value shifts away from products, where it is unclear if industries or markets stay the same or have to adapt.

So far, there is little research about how firms design DBS to develop new BMs as a way to create opportunities and stand out from the industry norm [2]. Nevertheless, the expectations of the research community are high, such as the hope for “DBS to explain why some [strategic implications of digitalization on the business environment] […] are observed instead of others” [40 pg. 553]. Our research connects the consequences of digitalization with implications on strategy as we see “digital technologies are fundamentally reshaping traditional business processes” [1 pg. 472], provides insights into DBS in practice from industry reports, and synthesizes findings into a DBS framework.

3 Research Methodology

Insights from industry reports with a focus on strategic aspects due to digitalization promise to help to develop a better understanding of DBS in academia. However, so far the reports fail to put their research within a theoretical framework and to provide significant insights for academic research, which we aim to overcome. The following review and analysis of industry reports will derive CSFs of DBS, which deliver the input from practice for the development of the DBS framework. Our approach extends current academic research with a profound understanding of the nature of the concept in practice, which is specifically suggested for DBS research [1] and also applied for similar emerging IS concepts [41]. For the review of industry reports, we followed the guidelines for scientific literature reviews as specified by Webster and Watson [42]:

Data collection started with the identification of relevant industry reports. Reports from, among others, analyst and consulting firms were identified by an online search via public internet search engines for the term ‘digital business strategy’ and slight variations of it (e.g. digitalization strategy). The search was restricted to reports published between January 2011 and July 2015 for the following reasons: First, insights and themes in industry reports are extremely fast-moving and the publishing rate is high, with around five new reports per month. Second, the strategy focus of digitalization is new and it was not until recently that reports focused on strategic implications and DBS [43]. Third, our research should build on a fairly mature stock of insights, which is rather true for more recent reports, as they are building on the knowledge gained from previous ones. Next, from the online search results, the first 200 hits were reviewed to find out whether they included an industry report relevant to our research goal. Reports had to specifically address strategic aspects in response to digitalization. After deletion of duplicates, the search delivered a total of 64 industry reports.

These reports were then scanned for their strategic implications (e.g. the design of new organizational structures, the long-term orientation of the firm), relevance for strategy in general (the development of new strategies, involvement in the strategy making), as well as usefulness to develop a framework for DBS (e.g. first indications for possible dimensions). Industry reports fulfilling these requirements hold the most potential to deliver input for the framework and were therefore included. We included, for example, a report focusing on strategy over technology [16] or a study on growth strategies [9].

Industry reports not fulfilling these specifications were excluded when they met at least one of the following criteria: (1) focusing on only one singular organizational function like sales or digital marketing; (2) focusing purely on new leadership roles (e.g. only discussing responsibilities of employees or managers); (3) associated with DBS but not providing any strategic implications like an analysis of German ‘Industry 4.0’ initiatives in the production; (4) too small deltas to other reports (due to subsequent reports from the same authors/institutions) (5) specific industry focus and no implications for strategy (e.g. focused on technological vision). Finally, 21 industry reports were selected as input for the subsequent analysis [7–17,20,30,36,43–49].

For analyzing these 21 reports, we applied the ‘critical success factor method’ [23]. It aims to identify and determine information and actions (CSFs) which are most needed to reach a defined outcome or goal [23]. Although the original version of the CSF method builds on interviews with top-level executives, it could be modified for our research by replacing the interview data source with the identified industry reports. We used a simplified coding method to identify the specific CSFs in each report [50]. The original aim to make CSFs explicit and encapsulate them to management priorities, allowing management to act on a more knowledgeable and [23], remained true.

Subsequently, the coding of the 21 industry reports assisted our research by “organize[ing] and make[ing] sense of the qualitative data” [50 pg. 152]. To obtain our framework we followed a staged process: First, we coded CSFs which explicitly focus on strategic actions undertaken by firms or identify potential for firms to improve strategy development to address digitalization. Identified CSFs were recorded in an Excel spreadsheet. The coding delivered an initial, cumulative, and duplicate-free set of 89 CSFs, which occurred in the sample. The second step was a repeated analysis of the 21 reports for the mentioning of the previously determined set of 89 CSFs, which created a result matrix with information on which CSF was mentioned in which report. As a result, the analysis delivered a total of 500 entries with an average of 23.8 different CSFs per report and 5.6 reports per CSF. Counts for each CSF ranged from 1, the lowest (CSF found in only one report), to 21, the highest (CSF found in all reports). This comprehensive set of weighted CSFs provided rich insights but was still distorted by CSFs that were raised to be ‘critical’ by only very few reports. Therefore, we followed Sproull [51] and reduced the set of CSFs to only those that were identified in more than 15% of the reports (i.e. 3 reports) to gain a more robust set of CSFs. The eliminated 30% of

CSFs explained less than 11%; contrary, the final set of 62 CSFs explain 90% of all entries. Ultimately, we consolidated CSFs with overlapping content as well as grouped similar CSFs together. In the end, 40 CSFs provided the final input for the framework.

Finally, we screened the CSFs to identify dominant themes. Applying an iterative procedure starting with rather broad themes and trying to further condense them to most relevant, led to the creation of 8 dimensions forming our DBS framework. These dominant themes are comparable to themes in academic research, as used by Kohli and Grover in their article, describing themes as “not mutually exclusive, nor are they exhaustive; rather they are meant to initiate a discussion of how the IT community must rethink […] and expand the agenda for research.” [34 pg. 28]. Analogously, the themes were used to structure the CSFs in practice and the dimensions of our DBS framework.

4 Findings

The layout of the DBS framework (Figure 1) is inspired by similar frameworks in adjacent research, like a framework synthesizing the literature on agile manufacturing [52], and is oriented towards the ‘business model canvas’, which structures relevant areas for new BMs [53], to provide the same clarity and guidance for DBS and to support the translation of strategy into BM by a corresponding structuration. Our framework comprises the 8 dimensions, identified as dominant themes, and the 40 CSFs.

Figure 1. The DBS framework

The first two dimensions, <u>*Sales and Customer Experience*</u> and <u>*Organization*</u>, are the two largest subsets of CSFs; hence and due to their fundamental role, they are pictured as the two ‘pillars’ of the framework. All other dimensions are placed in a descending order with regard to their strength (i.e. count of entries) between the pillars. Table 1 shows all dimensions, the assigned CSFs, and the count of entries. The CSFs provide actions for DBS development and the design of new BMs. They are introduced in detail in the following, while only explaining the strongest CSFs for each dimension:

<u>*Sales and Customer Experience*</u> focuses on *seamless integrated offline (physical) and online (digital) channels* [8,16]. The seamless customer experience across all channels with an integration of channels is a decisive action [13,49]. Mobile, as the most significant sales channels in future, requires a coherent presence across all channels. DBS builds on blending physical and digital worlds by a greater integration of online and offline experiences. Experiences around the product, mostly digital and intangible, are superior to the physical utilization of the product [13,36].

Table 1. The dimensions and CSFs as identified by the analysis of industry reports

#	*Count*	*Dimensions / CSFs*	*#*	*Count*	*Dimensions / CSFs*
	84	*Sales and Customer Experience*		*76*	*Organization*
1	20	Seamlessly integrated offline(physical) and online (digital) channels	7	15	Agility to reallocate resources and reorganize rapidly
2	15	Digitalization of customer interaction and products&services	8	13	Change management for radical and rapid change
3	14	Analytics to customize and create products&services	9	12	Multi-level and multi-speed organization for faster reaction
4	13	Direct contact for customer centricity			
5	12	Customer integration with open innovation	10	11	Organizational alignment towards digital
6	10	Outstanding customer experience and satisfaction	11	10	Long-term orientation but short, intense sprints to change
			12	8	Organizational separation → Spin-off
			13	7	Lean decision-making
	66	*Culture and Leadership*		*57*	*Capabilities and HR Competencies*
14	15	Create and foster digital mindset with a digital agenda	20	13	Capability to reinvent value chain and to challenge status quo
15	15	Common set of values with digital as value creation			
16	12	Accept failure and encourage new to grow success	21	11	Digital skills, know-how, and talent
17	10	Innovation and adaptive culture with evolvable goals	22	10	Capability to design new business models
18	8	Commitment to transformation in strategy and culture	23	9	New assets and capabilities
19	6	Rethinking of C-level roles (CDO, CIO)	24	7	Leaders have to identify new HR potentials
			25	7	Acquire, retain, and attract new talents
	56	*Foresight and Vision*		*48*	*Data and IT*
26	13	Establish a clear vision with future positioning	31	19	Use data and information from central source
27	13	Tight feedback loops and aspiration to improvements			
28	12	Foster faster innovation / rapid prototyping	32	11	Fundamentally different role of IT with two-speed IT
29	10	Look what is laying left and right			
30	8	Bold experimentation	33	10	Real-time and large-scale data processing
			34	8	Modular IT platform
	31	*Operations*		*25*	*Partners*
35	17	Data-driven and digitally automated process	39	14	Network effects with open systems and partner integration
36	5	Not just business but operating models change			
37	5	Blending human and digital resources	40	11	External partners
38	4	Provide financial resources			

Augmented reality, customer-focused technology, and digital customer decision journeys lead to a *digitalization of customer interaction and products&services*, allowing firms to develop data-rich insights about customers [16]. As products and services are being digitalized firms are required to enhance them with digital extensions like a permanent access to them via a digital channel. As a result, BMs have to allow for every (physical) product being augmented with a digital service [8]. The increased availability of customer makes *analytics to customize and create products&services* an absolute necessity with DBS where customer messages are individualized to preferences and enriched with contextual data. Products are constantly adjusted to better reflect the customer needs. With *direct contact for customer centricity*, firms build deeper connections between brands and customers as well as execute customer care from all business units via digital channels [36]. Firms have to avoid third parties and disintermediate customer relationships to establish a long-lasting tangible and emotionally affected brand connection [15]. Firms take on an 'outside-in' perspective, internalize the customer viewpoint, and customers become the central hub of digital service delivery [49].

Organization focuses on *agility to reallocate resources and reorganize rapidly*. Agility is an integral part, or, 'in the DNA' of DBS, requiring firms to self-tune the organization to changing circumstances. DBS builds on organizational agility to allow for fast adaptation [16] by collaboration across foregone organizational boundaries. Organizational liquidity allows firms to shift businesses as customer needs shift, requiring new BMs, agile operating models, and the ability to scale fast and learn quickly [43].

Proper *change management for radical and rapid change* prepares employees for imminent changes and sets the organization on a new course. Story-telling can be used to convey the ‘digital story’ and to gain employee buy-in, stimulate pride, and entrench the digital transformation [16]. A *multi-level and multi-speed organization for faster reaction* is needed to enable ambidextrous organizations which renovate the core and innovating the outside. As a result, firms are able to quickly respond to customers’ demand while balancing internal constraints with needed speed for faster reaction. *Organizational alignment towards digital* is used to establish a dedicated team to support digital business opportunities and build up digital governance to align fragmented digital activities [30]. Digital transformations by individual units need to be aligned to the organization, culture, and technology of the firm [47]. *Organizational separation, such as spin-offs,* enable digitally centered sub-businesses with separate competitive advantage. Corporate venturing is a catalyst for digital platforms and growth of divisions without constraints by utilizing variable business architectures [12,17].

Next, *Culture and Leadership* aims to *create and foster a digital mindset with a digital agenda* where the culture takes on an exploratory and adaptive character [14], is open for change, and “conducive to the digital transformation” [16 pg. 9]. Collaboration and cross-functional work are encouraged to generate new ideas and drive innovation. Firms are breaking free of silo-thinking [30]. With it, firms have to establish *a common set of values with digital as value creation* and integrate digital technologies in the transformation as well as the way people work. Leaders have to entrench digital values for the culture, such as forward-thinking, openness, technology acceptance, entrepreneurial spirit, and a startup way of working [43]. The value of digital innovation has to be understood, recognized, and cherished to be successful [16]. This goes along with a new culture which supports to *accept failure and encourage new to grow success.* It is necessary to establish a common appreciation that risk taking involves failure and failure is embraced “as a prerequisite for success” [16 pg. 4]. The culture must encourage risk-taking and tolerate failures to succeed [14]. A *commitment to transformation in strategy and culture* is needed by the leadership team to set DBS on the right course and lead the digital transformation by example from the top of the organization [7,16]. It is important to understand that leaders drive the transformation, address technologies that bring change, and trigger the connected change of culture.

The *Capabilities and HR Competencies* dimension strongly builds on a *capability to reinvent value chain and challenge status quo* where employees identify where value is now and in the future as well as lift value to the next level by moving it from the traditional world of value chains to the world of platforms, ecosystems, and stacks [12]. Disaggregated value chains are caused by a reduction of transaction costs and firms need to analyze the value chains to detect points which are best for possible digitalization [13]. The need for *digital skills, know-how, and talent* stands on top of the list for almost all firms [47]. In order to design and execute DBS, firms have to train employees for the needed digital skills, align incentive systems, and provide financial resources for human capital development [7,16]. Beyond the clear technical IT skills, also non-IT skills, such as visioning, collaboration, and organizational change management, are required with DBS. New talents are attracted by a commitment to the digital transformation, leaders' digital literacy, and a firm-wide understanding of the power of digital technologies [16,43]. In particular, the *capability to design new business models* becomes a strategic capability with DBS. As BMs change from 'inside-out' to 'outside-in', they become more customer focused. "This shift is the essence of adopting a digital BM" [9 pg. 6]. Firms innovate their BMs more often and incorporate small-scale as well as fundamental disruptions of traditional BMs [16]. Hence, BMs are shorter lasting and adapted more frequently when aligned to DBS [8]. The knowledge-driven digital business environment requires *new assets and capabilities*, such as, in the form of state-of-the-art infrastructure to enable the digitalization of products, as well as digital capabilities to design digital product extensions [49]. Firms digitally transform their core capabilities by building up complex and cross-functional combinations of assets and capabilities in their BM, e.g. people, processes, and expertise, to withstand competition [17]. However, not everybody is able to learn required digital skills, so *leaders have to identify new HR potentials*. Hence, the assessment of required skills and the identification of people, which can be trained to support the transformation, are needed [8,30].

<u>*Foresight and Vision*</u> is about *establishing a clear vision with future positioning* for the digital transformation [20]. With DBS, firms are required to have a transformative vision of the future and still provide the needed clarity and to achieve it [7]. The vision is characterized by *tight feedback loops and aspiration to improvements*, where firms learn from customer, employee, and partner interactions to further develop the vision and, hence, update services and products. Frequent feedback loops and the reaction to feedback are an iterative process which determines the success with DBS [47]. *Fostering faster innovation/ rapid prototyping* enables 'learn-track-react' behavior and 'test-and-learn' approaches, where firms model new products quickly, put them into the market promptly, and test them constantly [49]. For the continuous delivery of new products, minimum viable products are sufficient which increase the speed of product development [49] to allow firms to "fail, fast, and inexpensive" [8 pg. 24]. As the environment is changing quickly, firms need to *look what is laying left and right*. Scanning the environment helps to identify digital opportunities, disruptions, and potential threats [30]. Sensing and anticipating of technology-driven transformations are needed [12] as traditional industry barriers disappear and allow asymmetrical rivals and unlike allies.

The <u>*Data and IT*</u> dimension puts the CSF to *use data and information from a central source* in focus. It is one of the most often occurring CSFs in our findings, which underlines that (big) data analytics and sense-making of structured and unstructured, as well as inside and outside data from different sources channeled in a central data source, are vital [30]. DBS leverages data and analytical methods to use data-driven decision making, make data-assisted economic decisions, learn about the customer, and turn data into insights. Data is a competitive advantage as information is at the core of BMs in the digital business environment. As a result, the *fundamentally different role of IT with two-speed IT* is no longer about enabling, but creating the business. IT takes on a new thinking by harnessing digital technologies to create business value [20]. *Two-speed IT* lets firms operate IT at two different speeds with rapid results, high reaction times, and extreme flexibility towards the customer facing side, and a strong internal backbone on the other [30,47]. This bimodal approach supports digitalization with rapid front-end changes while fulfilling backend requirements. Moreover, *real-time and large-scale data processing* is a key action allowing firms to "track and communicate digital key performance indicators frequently” [30 pg. 11]. Additionally, real-time contextual information and analytics are combined to rapidly develop actionable insights from data for DBS [49]. A *modular IT platform* with “agile technology delivery skills” [30 pg. 5] builds on speedy but flexible services, and integrated functions with shared solutions. Firms utilize an orchestration of services along with a ‘continuous delivery model’, which allows them to release and iterate quickly [48].

Operations is infused with data to create *data-driven and digitally automated process* for higher automation. This allows supply chains to react quickly and anticipate customer demand. The further automated handling of services and completely automated customer interactions in BMs, such as Zipcar or car2go, increase speed and efficiency [11]. *Blending human and digital resources* creates human-centric designs for businesses with individual solutions by interlocked human and digital channels [49]. DBS focuses on efficiency in the interaction between people and technology, with digital technologies adding velocity to processes and services.

The main goal of the *Partners* dimension is to utilize *network effects with open systems and partner integration*. There is an increase in value with each new customer added, hence digitally-enabled firms tend to form natural monopolies and create “winner-takes-all dynamics”, e.g. Google and Facebook [15]. Firms have to open their services and products to a community as well as allow for an easy integration of new connected devices, objects, and people via open standards, allowing products in a network to be more powerful. With *external partners,* firms form strong and collaboratively partnerships. Additionally, extensive external orientation supports learning and innovation [8]. The collaboration goes beyond boundaries of the firm and extends to customers, technology providers, and suppliers. Firms allow partners to collaborate for specialized expertise [49] and utilize partnerships for specific innovations.

In summary, all 40 CSFs allow better strategy development and help to advance the understanding of DBS, but only some have received academic mentioning.

5 Discussion

We advance the literature on business and IT strategy by identifying CSFs of the content and development of Digital Business Strategy. Specifically, we presented a comprehensive overview of CSFs, as raised by industry reports, consolidated in our DBS framework. The framework provides actions for the development of DBS with 40 CSFs, divided into 8 dimensions. As the framework is derived from industry research, its CSFs should be discussed by reflecting it with scientific work, where available.

First, the academic literature exhibits a strong focus on the customer side of DBS and on building customer-centric organizations [4], which supports the strong customer orientation in our framework, as represented by the pillar ‘sales and customer experience’. We observe a growing number of digital BMs, redefining customer interfaces with digital technologies and putting customer service capabilities to the next level. As a consequence, BMs have to ‘integrate physical and digital worlds’ by blurring boundaries between online shops and physical stores (e.g., order online and pick up offline).

Furthermore, as IT systems become core elements of firms, there is evidence of firms 'digitalizing products&services' for competitive advantage [29,54]. With it, the 'digitalization of customer interaction' leverages customer data to improve in-store customer satisfaction by working with value-adding service from online, like access to customer profiles to provide individualized services. Recent examples are the BMs in the sports gear industry, which focus on integrated fitness trackers for all apparels.

Next, there is a growing body of literature on new leadership roles due to the digitalization. For instance, Bennis, in line with the 'culture and leadership' dimension of our framework, focuses on the change of leadership roles with DBS as he discusses how leaders must "understand the power" of digitalization [19 pg. 635]. In practice, as in our framework, the role of the Chief Digital Officer (CDO) pays respect to this development and ensures the needed attention. As a consequence of DBS, we see the appointment of CDOs to head new BMs and addressing digital services. Contrary, academic research remains at stressing skills like transparency and adaptive capacity [19].

Nonetheless, changes due to DBS should not stop at the top level, but have to be translated further into the entire organization. Hence, firms have to establish 'organizational alignment towards digital', which has not been mentioned in the DBS literature, yet. The scarce literature on DBS stresses to increase the firm's strategic capability to adapt to dynamic changes in the business environment [1]. Indeed, 'agility' becomes a strategic action and goal, as we were able to identify it as a CSFs of our framework.

Further, developing two organizational speeds is a way for creating organizational agility; it is equally discussed in practice as well as academia. The so-called 'multi-speed organization' is a CSF and fundamental tension of DBS. It is supported by Woodard et al. [40], who stress dynamic adaption to changing market conditions while providing a stable environment for value generation, and the recent bimodal IT concept, describing "different architectures, processes, and organization parts" [41 pg. 1418].

Also, other CSFs, outlined in our framework, yield opportunities for digital BMs like to 'use of data and information' (e.g. 'real-time and large-scale data processing'), or integrating niche players to access highly-specialized services in value networks.

In conclusion, academic articles on DBS fall short with regard to some aspects of the DBS framework but show first insights into DBS from academia. The discussed aspects of the DBS literature present only a subset of the CSFs identified in our framework. The DBS framework with its 8 dimensions and 40 CSFs, presenting the nature of DBS in practice research, goes beyond currently scientifically addressed topics, offers a broad perspective on the strategic implications due to digitalization, and provides guidelines for strategy development and BM design. Therefore, DBS focuses on the utilization of digital technologies and how they can be applied to create business value, hence, changes the way of business and revenues, ultimately leading to digital BMs [5].

Limitations and future research: Our research is limited by a focus on DBS relevant aspects, but the high number of CSFs shows the different facets of the concept and the diverse research areas. Hence, a deeper analysis of singular CSFs will be promising. Methodologically, the combination of a literature review approach and a modified critical success factor method to analyze industry reports is quite unique to IS research, so far; accordingly, the value and plausibility of such an approach might be less clear as for well-established research methods. Furthermore, the selection of industry reports is intended to provide a clear strategic focus for the DBS framework. Still, selection criteria can vary and are not free from subjective influences. The same applies to the subsequent elimination of minor CSFs, which was chosen according to the research set-up [51]. The CSFs were grouped into 8 different dimensions, using the dominant themes identified by the researchers. The themes are not free of overlap nor indisputable, a deeper analysis should look at relationships among them (e.g., interaction effects or causalities, preconditions etc.), since their impact on long-term firm success is of course highly inter-related (e.g., the tight interconnection between the dimensions of organization and culture). Further, the dimensions could be validated by a Delphi study, which could also refine a ranking of the most important CSFs, not provided by our framework so far. Hence, future research could add to our research with more quantitative measurement scales and statistical metrics for the CSFs. Finally, two limitations were identified by interviewees[1]: firstly, the framework lacks a finance dimension, which would pay respect to the huge investments firms make to advance the digital transformation; secondly, a dimension considering the influence of regulation on emerging topics and developments in the digital business environment is missing.

In summary, the understanding of adequate strategy development is essential to design BMs [25]. As we know that BMs are an extension of DBS, we discuss how BMs can add causal relations between the components of DBS to generate value.

6 Conclusion

DBS, an emerging concept for strategy development, has caught high attention by practitioners and scholars. It presents a further advancement of IT strategy and the traditional alignment view. Our research explores the current state of industry research on DBS, identifies CSFs of DBS, and synthesizes them into a framework. Our framework addresses outlined challenges of traditional strategy development, where IT strategy is "aligned but essentially subordinate to business strategy" [1 pg. 472], by presenting 40 CSFs. Led by these CSFs, our framework allows better strategy development and a more integrated approach to the challenges raised by digitalization. The dimensions of the framework are stable as they are conceptually rooted as well as remain generic to allow for changes of single CSFs over time.

DBS puts firms in a superior position, when it comes to the digital transformation and evolving to digital maturity. Evidence for the success of DBS is found since the majority (~ 80%) of digitally mature firms have a DBS; by contrast, among digital immature firms only 15% do [16]. By translating DBS into digital BMs above-average results regarding revenue [9], cost efficiency, and capital productivity can be expected. The CSFs of our framework will help practitioners advance DBS and present starting points for further research, as outlined above. In the end, our framework enriches the body of knowledge on DBS, but shows also that more insights are required.

[1] We started discussing the findings of our analysis with experts from the industry who brought up these thoughts. We thank for their intellectual support.

Abstract. Business models have gained much interest in the last decade to analyze the potential of new business ventures or possible innovation paths of existing businesses. However, the business model concept has only rarely been used as basis for quantitative empirical studies.
This paper suggests the concept of a Business Model DNA to describe the characteristics of specific business models. This concept allows to analyze business models in order to identify clusters of business models that outperform others and calculate future prospects of specific business models.
We used 181 startups from the USA and Germany and applied data mining techniques, i.e. cluster analysis and Support Vector Machines, to classify different business models in regards to their performance.
Our findings show that 12 distinct business model clusters with different growth expectations and chances of survival exist. We can predict the survival of a venture with an accuracy of 83.6 %.

Keywords: Business Model; Success Prediction; Data Mining; Cluster Analysis; Support Vector Machine

1 Introduction

Business models (BMs) have established in different research communities, like management science and information systems, whereas in practice they are seen as vital for business success [1, 2]. Furthermore, a shift from traditional BMs to electronic ones took place in the last three decades [3, 4]. There are many definitions and frameworks available on the concept today [1].

Business modelling gained significant importance in startup communities, too [2]. Startup firms are a driver of economic growth, innovation and employment opportunities [5]. Unfortunately the failure rate of startups is very high, with estimates ranging from 50% to more than 83% [6, 7]. Why some new ventures fail, while others succeed, is one of the central questions not only for entrepreneurship research, but also for possible entrepreneurs [2, 8]. Scholars agree that current research is still lacking methods to predict firm success [2, 9-11]. Additionally, most of the previous studies

(Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1006-1020

are based on qualitative research [2, 9]. This study proposes a new method for predicting firm success taking into account quantitative measures.

Through the emergence of more powerful data analysis tools and the growing amount of available data, it is possible to use data mining to find meaningful patterns in datasets [12]. Data mining is concerned with making sense of large amounts of data and finding patterns that are difficult to find manually [13].

The goal of this paper is to combine data mining approaches (i.e. cluster analysis and Support Vector Machines (SVM)) with the BM concept to predict the chances of success for startups. This allows better informed, empirically backed strategic and investment decisions [14]. To operationalize this approach, we suggest the BM DNA – in analogy with the human genome – as a concept to describe the characteristics of a specific BM based on various factors. The proposed instance of the BM DNA has been drawn from the 55 BM patterns based on Gassmann, Frankenberger and Csik [15].

The remaining paper is structured as follows. The second chapter describes related work including relevant BM literature. The third chapter elaborates the method that is applied in order to evaluate BMs of startup firms. The fourth chapter illustrates the dataset that has been used. Results of the cluster analysis and the different models of a SVM for classifying BMs are shown in the fifths chapter. The sixth chapter discusses these results and limitations of the study. The final chapter concludes with a short summary, contributions and aspects for future research.

2 Related Work

More than 60 years ago, Drucker [16] defined the term BM as the answer to “who is the customer, what does he value and how can you make money from it”. With the rise of the internet and digital firms the concept has gained more attention in research and practice [1, 10, 17]. This has led to various definitions of BMs in different research streams [18, 19].

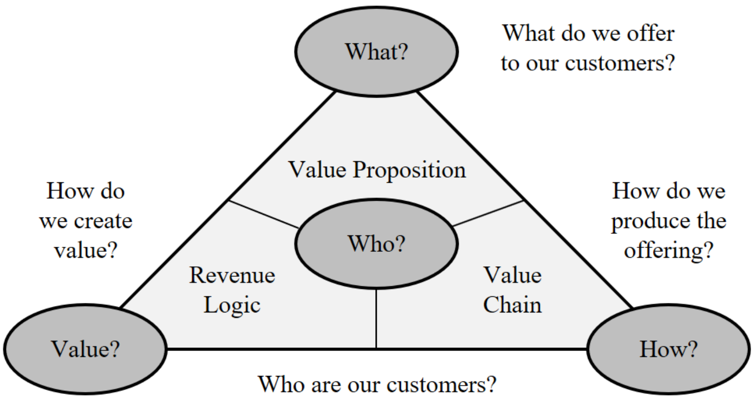

Figure 1. The magic triangle of business models [15]

Drawing from common BM definitions, Gassmann, Frankenberger and Csik [15] have developed a BM framework that consists of four central dimensions: the *Who*, the *Wha*t, the *How*, and the *Value* (see Figure 1). This framework builds the foundation of their 55 BM patterns, which they have identified by analyzing 250 BMs along the four dimensions of the framework. These 55 patterns describe the core of how a BM works. Gassmann, Frankenberger and Csik [15] assume that 90% of the BMs that exist today can be broken down into the same 55 patterns.

Classification of BMs has a long history in entrepreneurship and e-commerce research [20]. Previous studies have used classifications of BMs in empirical research to analyze the influence of BMs on enterprise performance [9]. Lambert and Davidson [9] reviewed research from 1996 to 2010 and found 40 papers that investigate this relationship. Studies that focused on e-commerce conclude that firms should concentrate on interaction platforms for facilitating online transactions and advertising as major revenue stream to be successful. Other studies show that a strategical focus on BM innovation leads to a higher profitability. Additionally, the usage of novelty-centered BMs is related to enterprise success. Moreover, some studies demonstrate that if a BM can easily be transferred to other markets, the firm will more likely be successful [9].

Weill, Malone and Apel [21] distinguish BMs along two dimensions, asset types (financial, physical, intangible, human) and asset rights (creator, distributor, landlord, broker). This leads to a matrix of 16 theoretically possible BM clusters, of which 14 are legal. This framework was used to classify more than 10'000 firms, publically traded on U.S. stock exchanges in order to perform a stock market analysis. They discovered that innovative manufactures are most valued by the stock market. These manufactures are defined as organizations that invest more in research and development than the industry average [21].

Spiegel, Abbassi, Zylka, Schlagwein, Fischbach and Schoder [2] focused on the success of early stage startups using empirical qualitative research. They found that the founders' social capital is crucial to receive funding in this situation. Founders with a better professional social network are able to develop a better BM using their contacts for information and status benefits [2].

However, only few of these studies have focused on quantitative empirical research to quantitatively analyze whether some BMs perform better than others [2, 9]. Scholars agree that future work should aim for the better understanding of relationship of BMs and firm performance [2, 9-11].

3 Research Method

To analyze BM patterns of successful startups, we rely on the Mattermark dataset which is a collection of information about startup firms. In order to avoid a bias towards US or German firms, we drew a random sample of 75 US and 75 German startup firms. For this sample we collected additional information to describe the BM by manually searching the web. Additional information sources included firm websites, press reports and interviews with founders that were publically available.

As the Mattermark dataset is strongly biased towards successful startups we identified additional failed ventures from Crunchbase-Insights, Deadpool and autopsy.io. We sent out a survey to a total of 210 firms and 309 founders asking for additional information to match the data available in the Mattermark dataset. In this way, we were able to include 31 failed startups with sufficient information on financing, revenues, competition and innovativeness of the product.

In the first step of the analysis the BM DNA is built for each of the 181 firms. Similar to the DNA as a molecule that carries most of the genetic information of living organisms, the BM DNA should be a representation of a BMs characteristics. Hence, it should describe the essence of a business in a precise way that allows comparison to other BMs.

In order to build a BM DNA, we draw on the 55 BM patterns developed by Gassmann, Frankenberger and Csik [15]. As 90% of the BMs that exist today can be broken down into the same 55 patterns [15], these BM patterns serve as a sufficient basis for describing the BM DNA. For each of the 55 patterns we used a binary variable to indicate whether a firm uses this pattern or not. In this sense, the BM DNA is a vector that indicates the patterns a certain BM applies. Figure 2 is an exemplary visual representation of the BM DNA. We manually evaluated each firm with regards to the BM patterns it applies. This evaluation and coding process was solely done by one person to ensure a consistent coding of the BM DNAs.

1	2	3	4	5	6		49	50	51	52	53	54	55
0	1	1	0	0	1	...	1	0	1	1	0	0	1

Figure 2. Representation of an exemplary BM DNA

The second step of the data analysis is a cluster analysis based on the BM DNAs. This is not only done to result in meaningful clusters of BMs with different growth perspectives, but also to improve the results of the SVM [22]. We applied the k-means clustering algorithm according to Jain, Murty and Flynn [23] with squared Euclidean distances. The algorithm was used in an iterative process with different numbers of clusters (k) as input factor. The final number of clusters has then been determined with regards to two criteria, the maximum distance between the clusters (I) and the meaningfulness of the clusters (II).

In the third step we developed a metric to evaluate the success of a venture. Therefore, we used both the survival of a firm and its revenue growth. In order to have a comparative metric for revenue growth, we measure the growth relative to the actual revenue (see Figure 4 in the next chapter). The less revenue a firm generates the more revenue growth it needs to generate in order to be evaluated successful.

As a fourth step a SVM is used to classify BMs according to their growth perspectives and whether they are successful or unsuccessful. SVMs use a nonlinear mapping to transform input data (training data) into high dimensional data. The method searches for an optimal, maximum marginal separating hyperplane [24]. This hyperplane is based on support vectors which can be seen as a small subset of the training data [22]. The SVM has been chosen since both neural networks and SVMs have shown to deliver satisfying results in similar studies [25]. An initial comparison of these two techniques using our data indicated better results for SVMs. Thus, SMVs are used in this study with the following information as input:

- BM Information: BM DNA, cluster, scope, focus (B2C or B2B), industry, physical assets, firm age
- Involved people: industry/ foundation experts, investors, founding team size, education of founders, location (Country & City)
- Startup idea: closeness to science and patents, competition and innovativeness

The dataset is randomly split into 80% of the data for training and 20% for testing since this often leads to optimal results [26]. The training data is used to produce the model. This model is then fed with the test data.

The performance of the model is measured by an accuracy, kappa and area under the curve (AUC). The kappa value shows the difference between the calculated solution and a random solution. A kappa value of 0 would indicate a random classification whereas a kappa value of 1 stands for a perfect solution [27]. The AUC measure indicates as well how the model performs in comparison to a random model. The random model would have an AUC of 0.5, whereas an AUC of 1 would indicate a perfect classifier [28].

4 Dataset

The dataset includes 181 firms in total, 31 failed firms resulting from the survey and 150 active firms from the Mattermark dataset. Eighteen of the 31 failed firms were founded in the USA. The databases have been accessed in Mai 2015. The majority of firms is founded between 1999 and 2015. The initial coverage of BM patterns resulting from the manual coding is shown in Figure 3. Almost all firms apply the BM pattern *Digitalization* (11) which stands for digital products or services [15]. However, the dataset is not focused on digital industries.

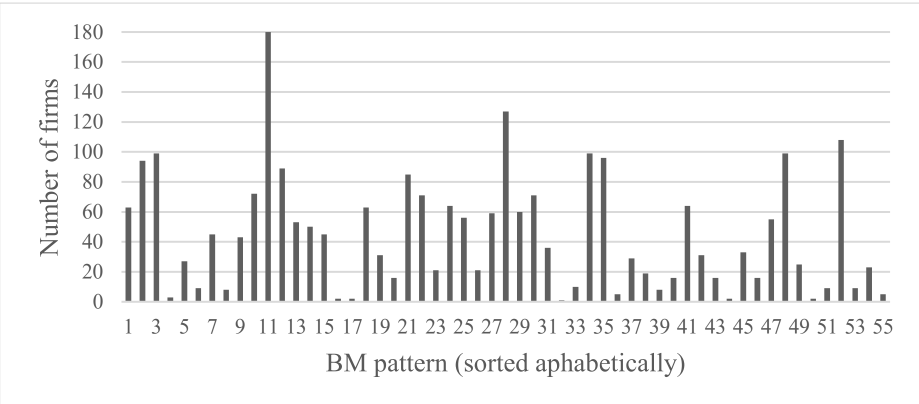

Figure 3. Initial coverage of BM pattern

To get to a meaningful result for the success measure, the data for the USA and Germany had to be treated differently due to the fact that the German firms did not satisfy the same growth criteria than the US firms. This can be linked to the smaller number of average investors and funding the German firms had. Average funding of US startups (238.2 $ M) is more than 3 times higher than the funding German startups received (58.2 $ M). Additionally, German startups had three investors on average while startups from the USA had almost 9 on average.

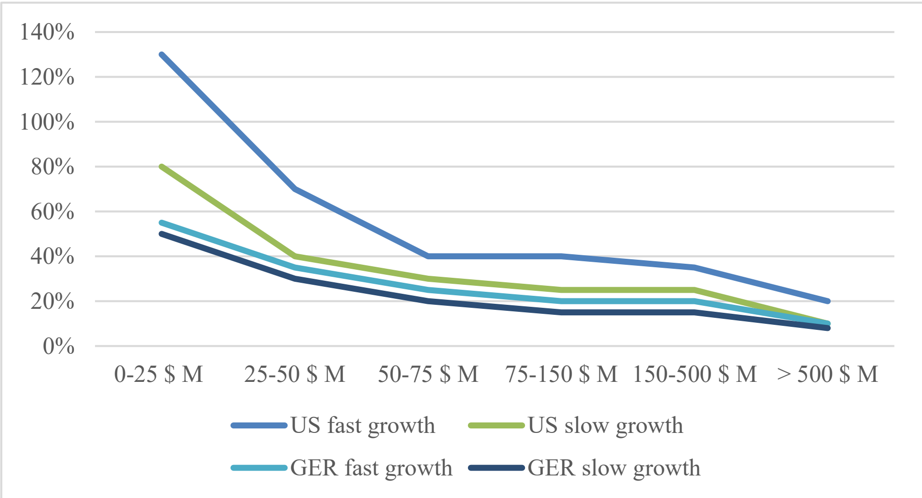

Figure 4. Revenue growth thresholds adapted from [29]

Less funding means fewer possibilities to invest in rapid growth and, therefore, the two regions are not comparable with the same growth percentages. The thresholds were determined in accordance to Maltz and Saljoughian [29] and adjusted for German firms. Figure 4 shows the thresholds that separate the different firms into fast growing and slow growing firms.

5 Predicting Business Model Success

5.1 Business Model Clusters

In the following the characteristics of each of the 12 identified clusters are elaborated. One cluster resembles firms that have a similar combination of BM patterns (BM DNA). Table 1 shows which BM patters are mainly applied by the firms in the respective cluster.

Table 1. Mainly applied business model patterns by cluster

Cluster	*Mainly applied BM patterns*
Freemium Platforms	Freemium and Platforms (Orchestrator, Two-Sided Market or Long Tail)
Experience Crowd Users	Experience Selling, Crowdsourcing and Leverage Customer Data
Long Tail Subscribers	Long Tail and Subscription
Affiliate Markets	Aikido, Affiliation and Platforms (Two-Sided Market, Orchestrator or Long Tail)
Mass Customizing Orchestrators	Mass Customization, Layer Player, Orchestrator and Two-Sided Market
Innovative Platforms	Aikido, Two-Sided Market, Orchestrator and Revenue Sharing
E-Commercer	E-Commerce and Direct Selling
E-Commerce Affiliates	E-Commerce, Affiliate and Long Tail
Add-On Layers	Add-On, Layer Player and Subscription
Crowdsourcing Platforms	Aikido, Crowdsourcing, Customer Loyalty and Platforms (Two-Sided Market or Orchestrator)
Customized Layers	Subscription and Mass Customization
Hidden Revenue Markets	Hidden Revenue, Two-Sided Market, Affiliation and Long Tail

Table 2 indicates the clusters, the number of startup firms in a cluster (n) and their chances of success in terms of survival, fast growth and slow growth. The numbers are to be interpreted as the percentage of firms in the cluster that met the success criteria described in section 3. Thus, firms in the category slow growth also include those firms that managed to grow fast and survival category also includes those firms that managed to grow slowly or fast. The number of members per cluster is well balanced with the fewest members in cluster 0 and 5 with 6. Cluster 7 has the most members with 29.

The *Freemium Platform* cluster mostly includes firms that are using a *Freemium* model or a platform (e.g. *Orchestrator*, *Two-Sided Market* or *Long Tail*). The former offers a free basic service to attract a broad customer base. Revenues are generated by additional chargeable offers. *Orchestrator* coordinate value activities of various firms to offer their customers an aggregated product. The BM of the *Two-Sided Market* serves different customer groups with one platform. The platform is only interesting for any of the two customer groups if the other one is present in a sufficient number as well. For this reason, free services are usually offered to one group of customers. The basis of both BM patterns is a mediation platform. The *Long Tail* pattern is used when the profits for many small payments are achieved by a small margin. Concluding, this cluster includes firms that aggregate the services of different providers and offer a free basic service on their platform as well as a supplementary service. The number of firms in this cluster is rather low (n=6). While all the firms in the sample survive, only half of the firms exhibit strong sales growth. Thus, it is assumed that only a few customers are willing to pay for additional services.

Table 2. Successful business models by cluster

Cluster	*n*	*Fast Growth*	*Slow Growth*	*Survival*
Freemium Platforms	6	50%	50%	100%
Experience Crowd Users	11	18%	27%	64%
Long Tail Subscribers	16	75%	75%	94%
Affiliate Markets	23	52%	65%	78%
Mass Customizing Orchestrators	12	50%	67%	83%
Innovative Platforms	6	67%	67%	100%
E-Commercer	14	43%	57%	57%
E-Commerce Affiliates	29	45%	45%	76%
Add-On Layers	20	45%	60%	90%
Crowdsourcing Platforms	11	73%	91%	91%
Customized Layers	13	54%	62%	69%
Hidden Revenue Markets	20	25%	25%	75%

The *Experience Crowd Users* cluster includes firms that pursue *Experience Selling* and *Crowdsourcing*. In addition, firms in this cluster *Leverage Customer Data*. As part of the *Experience Selling* BM, experience of customers is the key part of the customer value proposition. The goal of the offer is a unique experience. As part of the *Crowdsourcing*, central activities of the value creation are transferred to the crowd, either to the general public or a selected group. This makes it possible to use the potential of large user groups for the firm. The *Leverage Customer Data* pattern is characterized by drawing advantage from customer data. This can be achieved by offering tailored advertising, for example. However, this cluster has the second worst survival rate (64%) and the worst success rate (18%). Our findings suggest that it is very difficult to survive with this BM. Even if startups survive, the growth opportunities are poor. Thus, this cluster is more suitable for niche markets.

The *Long Tail Subscriber* cluster mainly relies on the *Long Tail* and the *Subscription* pattern as an integral part of its strategy. The latter refers to a contractually fixed periodic payment of the user to the provider. In return, the customer can use the offering during a certain period of time. This combination in digital goods is very successful, as duplication of information or provision of software solutions cause almost no additional costs. Therefore, products can be offered very cheap and greater profits can be achieved by many smaller payments over a longer period. Since 94% in this cluster survived and 75% of firms experienced a fast growth, it can be seen as a very successful one.

In addition to the affiliate model, entities within the *Affiliate Markets* cluster utilize the classic patterns of platforms (i.e. *Two-Sided Market*, *Orchestrator* and *Long Tail*). In addition, the *Aikido* pattern is employed. Under the *Affiliation* BM, client referrals to third parties are rewarded with commissions. Price comparison portals are an example of the combination of the affiliate model with a platform. *Aikido* comprises BMs that concentrate on something different than competitors in the same industry. An example is a transfer of BMs that have proven to be successful in other industries. The survival rate of this cluster is average.

The *Mass Customizing Orchestrators* connect the *Mass Customization* pattern with *Layer Player*, the *Orchestrator* and the *Two-Sided Market* pattern. *Mass Customization* means that products, although produced in mass production can be individualized to a certain degree though a variety of options. If a solution for a particular part of the value chain is offered in various industries the *Layer Player* pattern is used. This cluster combines an individual offer with a platform on which the partial offers are available for individual partners. It has a survival rate of 83% and a fast growth rate of 50%. Thus this cluster is quite convenient to grow rapidly.

The next cluster, *Innovative Platforms* focuses besides the classic patterns of a platform such as *Two-Sided Market*, *Orchestrator* and *Revenue Sharing*, mainly on the *Aikido* pattern. Thus, firms of this cluster are trying to integrate new ideas in the BM of platforms. This can be seen as quite successful because all of the firms of the sample have survived until now and two-thirds are also growing fast.

The *E-Commercer* cluster is characterized by the pattern of *E-Commerce* and *Direct Selling*. Entities in *E-Eommerce* offer products or services through the internet. *Direct Selling* means that no intermediaries are used to sell products. This cluster has the lowest survival rate and the second lowest rate of success. This is because the e-commerce market is already saturated. Entering the market is very difficult for young firms without innovative BMs due to strong price competition. An example firm of this cluster is Zalando.

The cluster *E-Commerce Affiliates* performs slightly better than the *E-Commercer* cluster. Besides *E-Commerce* patterns, it follows the *Affiliation* and *Long Tail* pattern. About 3 out of 4 firms survive in this cluster. Only 45% can generate strong growth. By aggregating the offers of many suppliers, a wide selection is created for the customer. Money is generated through links to websites of actual shops.

The *Add-On Layer* uses the *Add-On* pattern, *Layer Player* and *Subscription*. Here, a basic offer is provided relatively cheap. A surcharge must be paid to use more options. This pattern is often used in software as a service (SaaS) products. 90% of firms that use this BM have survived so far. However, only 45% grow fast. This can be attributed to the fact that for many services, the majority of the users just employ basic versions.

Aikido, *Crowdsourcing*, *Customer Loyalty* and the aforementioned platform patterns are used by the cluster *Crowdsourcing Platforms*. *Customer Loyalty* tries to lock-in the customer through incentives such as a bonus scheme or rewards for repeated use. Especially for crowdsourcing, it is extremely important to develop an active community. Therefore, the combination of these two patterns is quite useful. Likewise, a platform for exchange is required for crowdsourcing. The success ensures that users of this BM are right. Nine out of ten firms survive and nearly three out of four grow fast. One potential reason could be that a strong transformation from a pure consumer to dialogue with firms has taken place in recent years. For this reason, many customers are willing to invest time and energy in crowdsourcing campaigns.

The *Customized Layers* also use the *Subscription* and the *Mass Customization* model. The combination of *Layer Player* and *Mass Customization* is very common, especially in the SaaS industry. In this cluster, a hull software is used in many industries but tailored to every firm. We find that slightly less than 75% of the firms survive in this cluster. Additionally, only 54% exhibit strong growth.

The *Hidden Revenue Markets* rely on the *Hidden Revenue* and the *Two-Sided Market* pattern. In addition, *Affiliation* and *Long Tail* are included. In the *Hidden Revenue* pattern there is usually one offer free of charge for one side of a two-sided market. The other group of customers have to pay. The combination of *Long Tail* and *Hidden Revenue* suggests a high volume of transactions. Otherwise it would not be possible to sustain the offer with low payments. A famous example firm of this cluster is the Telegram Messenger. The cluster with this BM does not perform very well. Although three out of four firms survive, only one out of four grows fast.

The 12 clusters show some significant differences. Even though some clusters like the *Freemium Platforms* had a high survival rate, the rate of success was considerably lower compared to other clusters. The same can be seen in regards to the *Innovative Platforms* cluster as well as the *Add-On Layers* cluster. The most consistent cluster was the *Crowdsourcing Platform* cluster which had a survival rate of 91% and a fast growth rate of 73%. This means firms of this cluster that survive tend to grow fast and strong. The *Experience Crowdusers* cluster has a low survival rate of 64% as well as a low success rate of 18%. This cluster can be seen as a niche market. The *E-Commercer* cluster also shows that this is a market with strong competition as most firms do not make it. The few ones that survive grow fast and big. This observation can be seen in the e-commerce market which is dominated by a few big players. The *Long Tail Subscribers* use an interesting BM that combine a big customer base paying a relative low price with a subscription model. In this way the firms are able to attract enough customers to survive and to grow fast. This is as well shown by their survival and success rate of 94% and 75%. Overall it can be seen, that of the 12 clusters 7 are above the 50% survival threshold and only the *Experience Crowdusers* and the *Hidden Revenue Markets* clusters are well below this threshold.

5.2 Success Classification Models

Table 3. Accuracy of success classification

	Model	*calculated*	*true*		*class*	*Kappa*	*Accuracy*	*AUC*
			yes	*no*	*precision*			
1	Fast growth	yes	21	6	77.78%	0.312	66.59%[1]	0.744
		no	12	15	53.57%			
2	Slow growth	yes	26	9	74.29%	0.339	66.8%[1]	0.734
		no	8	12	60.00%			
3	Survival	yes	46	2	95.83%	0.673	83.6%[1]	0.899
		no	2	5	71.43%			
4	Fast growth only BM	yes	17	7	70.83%	0.153	58.4%[1]	0.629
		no	17	14	45.16%			

The SVM is used with different models to classify ventures according to their growth perspectives and survival. Table 3 shows the results of the different classification models. The first model separates firms between fast growing and not fast growing. For example, the model claims that 27 firms are fast growing. However, only 21 of these

[1] Based on 50-50 weighted sample

27 firms are actually classified as fast growing. In other words, their growth relative to their revenue lies above the threshold depicted in Figure 3. The model is able to correctly classify two thirds of the given test data.

The second model takes into account whether a firm is slowly growing or not slowly growing. Hereby, it shows a similar accuracy like the first model. The third model, however, is able to correctly classify 83.6% of given startups in regards to their survival or not. The fourth model is as well concerned with the separation of fast growing firms and not fast growing ones. However, the fourth model uses only information about the BM DNA as an input.

The accuracy considerably varies in the different models. The survival model is the most accurate one as it has a high accuracy as well as a high Kappa measure of 0.673 which is classified as substantial. The AUC measure is also promising with a value of 0.899. The other models lack in accuracy. Furthermore, the success models, models one and two, have Kappa values of around 0.3, which is classified as fair [27]. The AUC values were respectable for both success models though as they were 0.744 and 0.734 respectively.

The fourth model proved that BM information by itself has only very weak classification ability. This means that it is not possible to achieve a high classification accuracy without a combined approach. The low kappa value of 0.153 and AUC value of around 0.6 underlines this statement.

6 Discussion

The paper discusses two data mining approaches for classifying startup BMs in terms of their success by building on a new concept called BM DNA. The first result, arising from a cluster analysis, shows currently promising or not promising BM clusters. As part of the second result a SVM is introduced for classifying BMs as successful or unsuccessful.

The k-means clustering algorithm is used in this study since it has shown to be very efficient [23]. However, the algorithm shows some downsides. The number of clusters is an input factor, the outcome is depended on the initial solution, it is sensitive to outliers and can end up in local optimal solutions instead of global ones [23, 30]. In addition, the Euclidian distance used with binary data can be seen as problematic [23]. The iterative usage mitigates these disadvantages. Alternatively, a hieratical agglomerative clustering algorithm can be used and is seen as future research.

The clusters achieved a satisfactory result even though some similar patterns correlate with different clusters. These patterns are applied in many companies. On the other hand, some patterns, like *Cash Machine*, *Trash-to-Cash*, *Target the Poor*, *White Label* or *Ultimate Luxury*, do not show a strong correlation with any pattern. There were not enough firms that use these patterns in the sample.

There are different models in the literature aiming to classify BMs in regards to survival and not survival (Table 3). The survival model (3) correctly predicts 95.83% of the successful firms and 71.43% of the unsuccessful firms without considering economic anomalies. This accuracy is as good as or even better than most studies of

Business Failure Prediction (BFP) for new ventures. Lussier [31] was able to match 73% of the failed and 65% of the successful firms by using logistic regression.

This study used SVM as classification method. Different methods are used in literature. Gartner, Starr and Bhat [32] used multiple discriminant analysis and were able to correctly classify 85% of the firms which is similar to this approach. Marom and Lussier [33] achieved an accuracy of 85.4% which is also comparable. However, our model is superior in classifying successful businesses as Marom and Lussier [33] were only able to classify the successful ones with an accuracy of 84%. Ciampi and Gordini [34] were able to correctly classify 68.4% of their firms. Ecer achieved results of 91.18% and 88.24% for neural networks and SVMs respectively. Hence, both techniques have a high prediction ability [25]. Ecer [25] achieved a better accuracy using neural networks while Olson, Delen and Meng [24] had the best result with decision trees. Wilson and Sharda [35] used the same financial ratios as Altman since they wanted to compare neural networks and multiple discriminant analysis. Here, multiple discriminant analysis was outperformed by neural networks in every test. However, in this study, the prediction ability of the SVM proved to be superior for the survival model in comparison to other methods in literature.

There are some limitations of SVMs. Information about the founders and their prior knowledge of the industry and founding, the degree of innovativeness of the new firm as well as competition, founding team size, and patents improved the model accuracy [7, 31, 36-38]. While the variables did produce a satisfactory model, the problem of transparency and transportability, the inherent issue of all SVMs, still exists [24]. With SVMs, it is not possible to show how much each variable is influencing the outcome in a numerical way like with a logistic regression. Unfortunately, it is also not possible to visualize the model since it has too many dimensions for producing a graphical representation. Other authors used techniques like ANOVA, principal component analysis (PCA) or correlation matrices to preselect the variables they used in their models [39, 40]. However, these approaches neglect the interaction of the independent variables among themselves and can lead to a worse selection of variables. Thus, SVM has been used in this study and delivers very good results compared to other studies.

While the survival model was able to deliver a good prediction accuracy, models used on mature firms that include profound financial ratios are superior in accuracy. The model by Altman was able to correctly classify 95% of the cases. Edminster also used a number of financial ratios in his multiple discriminant analysis model and had a 92% classification success rate on small firms [41].

However, the focus of this paper is on startup firms. The rate of failure in startups is considerably higher than in mature firms [2]. Additionally, in early stage startups, it might be difficult to get profound financial numbers. Thus, a success model with an accuracy of almost 85% is a very good classification model for startups.

The proposed model in this paper is a considerable contribution for startup classification and success prediction. However, this study is a proof of concept only. Our study showed that the used method is able to correctly classify startups concerning their overall success. More data is needed to clearly verify, enhance and refine the model.

7 Conclusion

This paper suggests a BM DNA as means to describe the specific characteristics of certain BMs. It demonstrated the applicability of this concept by drawing from the 55 BM patterns based on Gassmann, Frankenberger and Csik [15] to describe the characteristics of a sample of 181 firms.

The BM DNA was then used in a cluster analysis. 12 different BM cluster were created including their chances for survival, for slow growth and for fast growth. These 12 cluster can be used in practice to make an assumption for growth perspectives of an actual startup. Some BM clusters seem to have better future prospects than others.

In a next step a SVM has been used to estimate a BMs survival and growth perspectives. The classification of survival worked fairly well. It is a major contribution for research since comparable studies do not achieve similar accuracies. Furthermore, an advanced model should be used in practice by entrepreneurs and investors as a step of business model evaluation.

However, the classification of slow and fast growth as a means to evaluate the success of a BM was not very reliable. Future research should investigate in additional classification algorithms (1), apply the model on a larger dataset (2) and extend the BM DNA with additional information (3). Our fourth model shows that this is needed to correctly classify BMs concerning their growth perspectives.

While future versions of the BM DNA serve as a good predictor of BM success, it is still a reflection of data from the past and, thus, past success factors. Innovation and consequently the chances for exceptional success will remain a creative process of identifying new approaches and promising re-combinations. However, predictions based on the BM DNA may serve as a sounding board for entrepreneurs and investors to critically reflect on specific BMs and make purposeful decisions.

“I did use it!” - Assessing subjective vs objective cognitive artifact usage

Abstract. For decades, IS researchers have discussed the reliability of subjective measurements to assess actual artifact usage. Especially in experimental settings, as in the design science context for instance, the participants’ usage data of the evaluated artifact represents an important point of analysis. However, collecting objective usage data, (i.e. logfiles) is often not feasible depending on the artifact. In this paper, we present the theoretical grounding of collecting cognitive artifact usage data using eye-tracking technology. Grounded in immediacy and eye-mind assumption the participants’ artifact fixations are used as objective usage measurement. The question remains if in comparison, the collection of subjective (e.g. perceptual) usage data is sufficient and reliable for such experiments. The results of our comparative analysis indicate that researchers could use subjective measurements when comparing different artifact designs and should rely on objective measurements when testing the effect of an artifact compared to a control group without artifacts.

Keywords: Artifact, eye-tracking technology, laboratory experiments, objective usage, subjective usage.

1 Introduction

The use of information technology (IT) by individuals remains the variable of interest in the information systems (IS) field and has been recognized as a key element of the *missing link* from IT investments to business value [1, 2]. The question if a certain IT artifact is used or not and which outcomes are related to the IT usage, has been subject of investigation in numerous experiments in IS research. In general, there are two possible approaches for measuring usage: subjective or objective measurements [3]. Already in 1989, Fred Davis concluded that “n*ot enough is currently known about how accurately self-reports reflect actual behavior*” [4: p. 334] and still, more than 25 years later, there is an ongoing debate on the reliability of self-reported, subjective usage measurements.

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Morana, S.; Kroenung, J.; Maedche, A. (2017): "I did use it!" - Assessing subjective vs objective cognitive artifact usage, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1021-1035

Overall, there is a strong tendency that subjective data is no fully reliable approximation of objective data in the research discourse [5]. Still, there are inconsistent results that argue for the reliability of subjective usage [6, 7].

The primary objective of experiments in the design science research (DSR) [8] context is the investigation if certain effects occur while participants use an IT artifact (we use the term artifact to subsume the terms artifact / treatment / intervention) [9]. In DSR, the usage of the evaluated artifact in the experiment is an important information that requires special attention [10]. Within an experimental setting, researchers can collect subjective data (e.g. by asking the participants on their artifact's usage in a questionnaire) or objective data (e.g. by recording the participants' interaction with the artifact using a screen cam). In most experimental settings, the participants actively use the artifact, from a human-computer interaction (HCI) point of view, for example, by clicking on a button or scrolling on a website. In such experimental settings, assessing the participants' objective usage is easy. For an overview on objective use measurements in experiments see Eckhardt et al. [3].

In contrast to this, there are experimental settings in which the participants do not actively use the artifact (e.g. clicking a button) during the experiment, but use it from a cognitive point of view. One example is the provision of a textual explanation [11] (as the actual artifact) in an experimental application. The participants can read these explanations during the experiment and use the provided textual information without any active interactions with the computer. Rather, the participants read the information, store it in their memory, and use it, for example, to process the experimental task. We define this as cognitive artifact usage; the user interacts with the artifact only by viewing at it and processing the provided information, for example, text or images, cognitively. Due to missing direct human-computer interactions with the artifact (e.g. by counting click rates), the logging of such objective usage data is more difficult. However, in most cases, it is important to know if and to which extent the participants used the artifact during the experiment to assess its effect or impact. In such experimental settings, researchers often rely on subjective usage data, because objectively measuring such cognitive artifact usage is difficult.

A possibility to address this shortcoming is the utilization of eye-tracking technology. Eye-tracking technology enables researchers to measure the participants' eye movements on the screen and thus, allow an objective measurement of the users' cognitive artifact usage. According to the immediacy assumption and the eye-mind assumption [12], researchers can infer the participants' current cognitive activity based on their current glance on the computer. The following example shall illustrate this assumption: While looking at a picture in a gallery, the individual most likely also thinks about the picture and thus, cognitive processes take place. Consequently, eye-tracking technology enables researchers to derive the participants' current cognitive activity by recording their eye fixations during the experiment. However, the utilization of eye-tracking technology in experiments today is still rather expensive from both, a financial and an effort point of view, compared to gathering subjective data using a survey. Thus, gathering subjective usage data is less effort. Considering the ongoing debate on subjective vs. objective measurement, the question remains if subjective measurement data is reliable for assessing cognitive artifact usage in laboratory experiments as formulated:

Do subjective measurements reliably approximate objective measurements with respect to cognitive artifact usage in laboratory experiments?

Our research contributes to the ongoing debate if subjective usage measurements are a reliable approximation for objective usage measurements in laboratory experiments. We provide insights from our DSR laboratory experiment and discuss under which conditions the application of subjective measurements is sufficient and when objective measurements are required based on our experiment data. From a methodological point of view, we present the theoretical baseline for objectively measuring cognitive artifact usage in laboratory experiments with eye-tracking technology, grounded in the immediacy assumption and the eye-mind assumption [12]. We demonstrate how to apply eye-tracking technology for measuring and analyzing objective artifact usage. In addition, our findings contribute to the IT usage research stream as they provide an example under which conditions subjective usage measurements can be applied.

2 Theoretical Foundations and Related Work

2.1 Information Systems

Researchers conduct experiments to evaluate if the usage of a certain artifact results in the proposed effect or not. There are two types of usage measurements within experimental setting, participants report their subjective usage, or researchers measure the usage objectively during the experiment. Wu and Du [13], based on a comprehensive literature review on IS usage research, discuss two different types of subjective usage types: reported usage and assessed usage. The researchers argue that the key difference between reported usage and assessed usage is the application of ordinal scales for the measurement. Reported usage indicates the "*users-reported amount of time or number of times of using a system*." [13: p. 683] In contrast to this, assessed usage "*refers to the ordinal-scale-measured intensity and extent of using a system*." [13: p. 683] For the remainder of the paper, we refer to subjective usage for both type of usage types.

Using subjective (reported and assessed) usage measurements can result in non-reliable data and distorted results, due to possible common method biases [7, 14]. There is an ongoing debate whether subjective usage is a reliable approximation for objective usage. When talking about artifact usage in experiments, the whole stream on IS usage research is important to consider. Before summarizing a selection of findings on the subjective vs. objective usage debate, we shortly address the construct system usage itself. In decades of IS usage research there is few "*in-depth, theoretical assessment of the construct*" [15: p. 228], until it was re-conceptualized by Burton-Jones and Straub [15]. The researchers propose six measures for system usage ranging from very lean to very rich, enabling researchers to provide more insights in the applied usage construct. Straub et al. [7] also discuss the assessment of system usage and the comparability of subjective and objective system usage. They found, in contrast to their expectations, that both types of usage measurements are not strongly correlated to each other [7].

In a repetition of the study by Straub et al. [7], Barnett et al. [6] found a stronger relationship between the subjective and objective system usage. Their analysis reveals a correlation between the perceived and objective usage, ranging from $r = 0.38$ to 0.43 [6]. The researchers conclude their article with a suggestion to consider the context of the study when deciding which type of usage measurements to apply. Barnett et al. [6] suggest to apply objective data when the actual usage is connected to the dependent variable (such as performance) and subjective data when general insights are required [6: p. 81]. In the discussion of their empirical results, Burton-Jones and Straub [15] also shortly address the question when to use subjective and objective measures. They suggest objective usage "*to measure the system and task aspects of usage*" and subjective usage (such as questionnaires) "*to measure user states such as cognitions or emotions during usage*". [15: p. 243]

2.2 Psychology

Investigating the discrepancy between self-reported and actual behavior has a tradition in experimental psychology and is related to the debate on usage behavior in IS research. There is evidence that participants are unaware of many biases in their choices resulting in questioning the reliability of subjective behavior compared to objective behavior [16]. One stream of research in this discipline further addresses introspective information and the reliability of such subjective data for decades. The reliability of subjective data measurements depends on the applied methods. Verbal reports for instance, can be accurate and a significant reflection of the objective behavior, if the introspective information is relevant to the current task and available in the participants' short-term memory [17, 18]. Thus, introspection can only access cognitive representation kept in the participants' working memory [17]. Other information influences the participants' introspective information. Studies revealed, the participants subjective measurements can be influenced by the perceived difficulty of the task [19] or subjects' own motor responses [20].

2.3 Human-Computer Interaction

In contrast to these supportive findings on a correlation between subjective and objective usage data in psychology, there are also non-supportive results. Analyzing participants' mobile application usage, Reuver and Bouwman [5] found no correlation between subjective and objective usage measurements. Moreover, they discuss the possibility of type I and type II errors when relying on subjective measurements alone [5]. All in common, in the aforementioned usage studies is the participants' active interaction with the system, for example, Straub et al. [7] investigate voice mail usage and Reuver and Bouwman [5] investigate mobile applications use. In such settings, the objective artifact's usage measurement is possible, for example, by using logging functionality within the applications.

This is not possible for assessing the artifacts' usage without some sort of direct human-computer interaction, for example, clicking on a certain button. An example of such a setting is the provision of an explanation within the experiment's application, which is always present and there is no activity by the participants required to make the explanation visible. The participant can read the explanation or not, there is no possibility to log this reading process within the experiment's application. The participant is looking at the explanation, reading it, and cognitively processing the provided information. Eye-tracking technology enables researchers to capture this reading or looking process by recording the participants' eye movements on the screen [21, 22]. This is grounded in the immediacy assumption and the eye-mind assumption proposed by Just and Carpenter [12, 22]. The immediacy assumption "*is that a reader tries to interpret each content word of a text as it is encountered.*" [12: p. 330] The eye-mind assumption "*is that the eye remains fixated on a word as long as the word is being processed.*" [12: p. 330]

Eye-tracking technology is also used for quite some years in HCI research [23] and psychological research [21, 24–26]. Several studies showed the linkage between the humans' eye movements and their attention [22, 24]. With respect to this research, we focus on this very link between eye fixations and attention, since the link between fixations and cognitive processing lies beyond the scope of this article. Although research in the field of cognitive psychology regards eye-fixations also as approximation for cognitive processing [24]. Eye-tracking technology is, for example, used to investigate eye movements in reading and information processing research [24, 25]. In a recent study, the participants' subjective report of eye fixations was compared to the objectively measured fixations using eye-tracking technology [27]. In this study, the participants were able to report at least a subset of their eye movements. Nevertheless, the researchers also identified false reported eye movements [27]. In line with the results on subjective vs. objective usage measurements [6], there is the potential for subjective measurements to be a reliable approximation for objective measurements, but it depends on the study context and applied methods. The eye-tracking technology provides researchers "*quantitative and qualitative measures of observers' subjective reports and reveal experimental effects of visual search that would otherwise be inaccessible." [27: p. 1]* Depending on the experimental setting, participants might not be able to provide a justification for their own decisions [28] and thus, eye-tracking technology can be used to obtain objective data [21].

3 Hypothesis development

Summarizing the brief presentation of the ongoing discussion on subjective vs. objective usage measurement, there are findings supporting a correlation [6, 7] and findings rejecting a correlation [5]. In line with the supportive findings, we assume that a reliable rating of the participants' cognitive artifact usage in a laboratory experiment is possible. In such a setting, the participants use the artifact cognitively, for example, by reading or viewing at it, based on the eye-mind assumption [12]. We assume these cognitive processes are stored within their short-term memory. According to the immediacy assumption [12], participants should be able to recall their recently conducted activities. Thus, when asking the participants immediately after the experiment, their activities during the course of the experiment should be available in their short-term memory. This relationship is additionally grounded in research on introspective information [17, 18]. Thus, we argue the participants' perception of their artifact usage should be possible. We propose that the subjective artifact usage is a reliable measurement in experimental settings with cognitive artifact use. Summarizing our assumptions, we propose the following hypothesis:

Hypothesis*: Subjective measurements are positively related to objective measurements of cognitive artifact usage in laboratory experiments.*

For testing this hypothesis, we consider the objective artifact usage as the reliable measurement. We test if there is a significant positive relationship between the subjective perceptions of artifact usage and its objective measurements. This would indicate that the perceived usage measurements are a reliable approximation for the objective usage measurements as tested in several other studies [5–7]. In order to prevent possible type I and II errors [5], we also test for a relationship between the perceived artifact's usage and the objective usage of other applications used in the experiment. This test is required in order to ensure that the participants' subjective measurement, their introspective information, only reflects the artifact's usage and not the usage of other applications. Next, we describe the experimental setup for testing our hypothesis.

4 Experimental setup

We test our hypothesis in the context of an experiment on the effect of providing textual and visual explanations [11] to support individuals' process execution. The experiment itself is part of a DSR project aiming to design an assistance system [29] to support users' process knowledge and process execution performance [30]. In the experiment, we simulated an IT ticketing process and tested if the explanations' provision by the assistance system has the intended effects on the users. The participants had to handle eight IT requests (e.g. create a new user account or purchase of hardware) provided by a simulated email client in a simulated ticketing system according to the specified ticketing process. This ticketing process is a simplified version of a real-world organizational ticketing process adapted from the DSR project's case company. The applications used in the experiment (see **Figure 2**) are simplified versions of the case company's applications used to handle their ticketing processes. One week before the experiment, the participants received a training on the experimental ticketing process and applications. They also received the documentation and we asked them to study it in detail.

The participants in the experiment are students (bachelor and master level) from a large German university and we randomly assigned them to one of three groups. We developed two versions of the assistance system as treatments. In both versions, the assistance system is depicting the sequence of the ticketing process steps supporting the participants with its execution. Moreover, the "advanced treatment" additionally provides textual explanations [11] for each of the process steps. In the following, the group “advanced treatment” refers to the group receiving the advanced assistance system, the group “basic treatment” refers to the group receiving the basic version of the assistance system (without the additional textual explanations). We decided to test two assistant systems with varying amount of text to control for possible differences in the participants usage behavior. The control group received an empty assistance system only stating that the participants should process the emails according to the process specifications. The usage of the assistance systems was voluntary for the participants, but the provided information supported the execution of the experiment’s tasks. We refer to the email client, ticket system, and service catalog as the “experiment’s applications” in the reminder of the paper.

To anonymize the paper, we renamed the assistance system to “ARTIFACTNAME”. In the experiment, the training upfront, and in the survey afterwards, the assistance system had a dedicated name enabling the participants to identify, distinguish, and remember it when reporting their subjective usage. We measured the subjective usage perceptions by two self-developed questions on 7-point Likert scale (intervals in arrow brackets), adapted from the subjective usage measures applied by Davis [4]:

Question use 1: *I used the* ARTIFACTNAME *in the experiment*
<strongly disagree – strongly agree>

Question use 2: *In the experiment, I used the* ARTIFACTNAME
<never – very frequently>

We used Tobii X2-30 eye tracker and the software Tobii Studio for recording the experiment’s sessions. Eye-trackers by Tobii are used in many research domains and Tobii is one of the market leaders of eye-tracking technology world-wide [31]. The eye-tracker recorded the participants’ eye movements with a frequency of 30 Hz. Thus, every 33ms the participants’ eye fixation and position on the screen, for example, was measured and stored with the timestamp by Tobii Studio. In addition, the experiment’s sessions were screen-recorded. The resulting videos as well as the collected data was analyzed subsequently. Following Figure 1 depicts a screenshots of the recorded sessions and the highlighted eye movements of the participants (red dots and lines) based on the collected data by Tobii Studio. The diameter of the red dot indicates the duration of the participants’ eye fixation at the certain point on the screen and the red lines indicate the movement of the participants’ eyes on the screen. Such a visualization of the participants’ eye movements and fixation durations supports researchers to reconstruct the participants’ behavior during the experiment. The screenshot shows a participant with the “advanced treatment” providing the sequence of the ticketing process and the additional explanations for each process step. Please note, to anonymize this paper, the artifact name (top right) and the image of the participant (top left) was blurred.

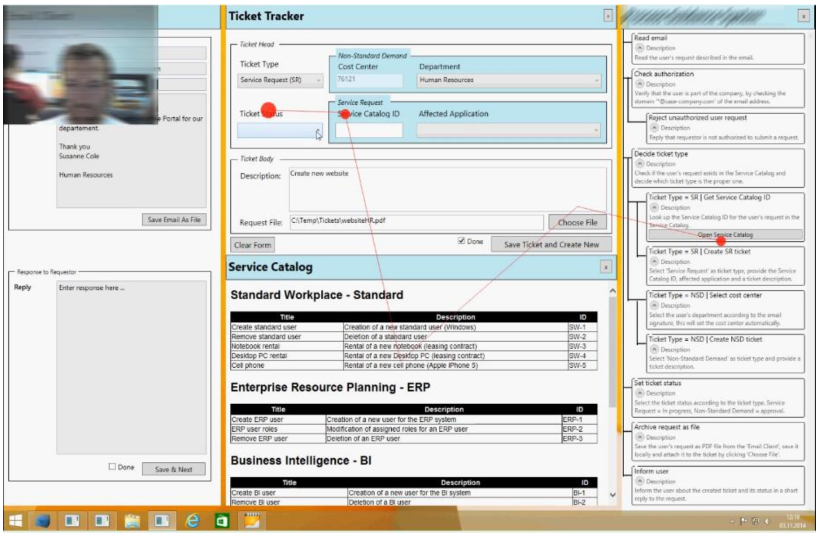

Figure 1: Screenshots of experiment recordings

Within Tobii Studio, we defined four areas of interest (AoI), for the experimental applications (see **Figure 2**). The software analyzes the recordings and provides the participants' fixation counts for each AoI. We used these fixation counts as objective usage measurements grounded by the immediacy assumption and the eye-mind assumption [12].

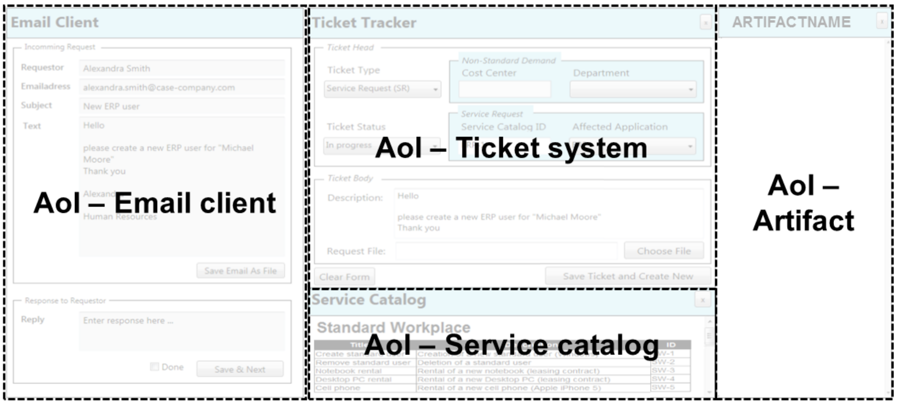

Figure 2: Experimental applications and AoIs

Following Burton-Jones and Straub [15], both usage measurements address the "extent of use" and refer to the second type of measurement richness [15]. Please note we do not discuss the experiment's actual measurements and results here, as we focus on the question whether subjective usage measurements are a reliable approximation of objective usage measurements. However, during the experiment we controlled for the intended effect of the assistance systems and the results indicate a positive effect of both assistance systems compared to the control group. Next, we present the analysis of the participants' subjective and objective usage in the experiment.

5 Analysis

In total, 118 students participated in the experiment, 29 females and 89 males with an average age of 21.81 years (standard deviation = 2.31 years). Table 1 contains the mean values and standard deviations of the total fixations, time, and the survey data for the three experimental groups.

We applied a Shapiro-Wilk test [32] to test if our data follow a normal distribution. All measurements, except for three measures, are not normally distributed, thus referred to non-parametric statistical tests for the data analysis. The mean values of the total fixations indicate a similar usage of the email client, ticket system, and service catalog among the three groups. The artifact's usage varied strongly between the three groups. The highest mean usage, both subjective and objective, has the "advanced treatment" group with a mean count of 2417.97 fixations that equals to 80.59s compared to a mean fixation count of 356.80 fixations or 11.89s of the control group.

Table 1. Mean values and standard deviation of the total fixations, time, and survey data

			Objective measurement					Subjective measurement	
Group	n		AoI – Artifact[1]	AoI - Email client[1]	AoI - Ticket system[1]	AoI - Service catalog[1]	Time[2]	Survey - Use 1[3]	Survey - Use 2[3]
Advanced treatment	39	mean	2417.97	6221.92	5634.18	2520.97	715.90	4.41	4.03
		SD	3141.65	1991.18	1905.30	1107.07	288.61	1.85	1.91
Basic treatment	38	mean	1148.60	6357.26	6176.66	2637.37	753.41	3.97	3.50
		SD	1071.33	2598.87	2363.80	1704.95	307.86	2.11	2.01
Control	41	mean	356.80	6899.10	6115.24	2238.24	684.96	2.76	2.54
		SD	297.07	2101.68	2188.53	1312.69	195.76	1.98	1.91
[1] measured in fixations | [2] measured in seconds | [3] measured on a 7-point Likert scale from 1 to 7									

As expected, the treatment groups' usage is higher than the control group's usage. In order to gain deeper insights, we calculated the fixations per minutes for the four AoI and visualized them in boxplots (see Figure 3). The results indicate a similar usage of the ticket system and the service catalog among the three groups. Surprisingly, we found a significant difference for the email client usage (measured in fixations per minute) between the "advanced treatment" group and the control group (p-value = 0.016) as well as between the "basic treatment" group and the control group (p-value = 0.012).

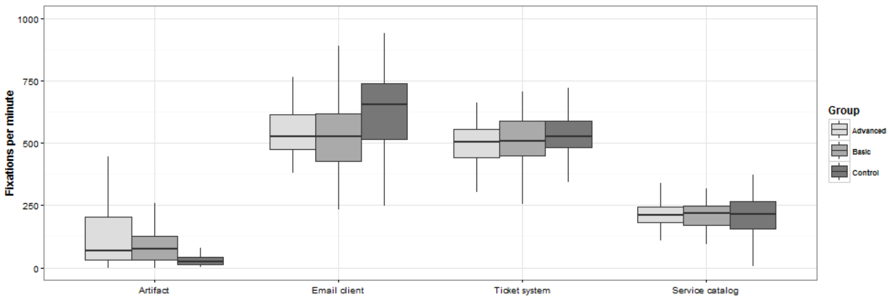

Figure 3. Participants' fixations per minute

The analysis of the artifact's fixations per minute reveals a similar result. For both treatment groups there is a significant difference compared to the control group (both p-values < 0.001). Next, we test for the positive correlation between the objective usage and the subjective usage with the Spearman Rho test [33, 34]. Table 2 contains the Rho values of the correlation tests and the correlations' significance.

Table 2. Correlations between objective and subjective usage (means)

	Complete dataset				**Advanced treatment group**			
	AoI-A	AoI-E	AoI-T	AoI-S	AoI-A	AoI-E	AoI-T	AoI-S
AoI Artifact	1.00 ***	0.46 ***	0.59 ***	0.30 **	1.00 ***	0.66 ***	0.78 ***	0.43 **
Survey - Use 1	0.52 ***	0.24 **	0.28 **	0.19 *	0.68 ***	0.49 **	0.62 ***	0.44 **
Survey - Use 2	0.48 ***	0.24 **	0.26 **	0.21 *	0.60 ***	0.45 **	0.50 **	0.46 **
	Basic treatment group				**Control group**			
	AoI-A	AoI-E	AoI-T	AoI-S	AoI-A	AoI-E	AoI-T	AoI-S
AoI Artifact	1.00 ***	0.57 ***	0.60 ***	0.45 **	1.00 ***	0.40 **	0.60 ***	0.07 n.s.
Survey - Use 1	0.64 ***	0.44 **	0.36 *	0.25 n.s.	0.00 n.s.	0.02 n.s.	0.07 n.s.	-0.08 n.s.
Survey - Use 2	0.59 ***	0.38 *	0.36 *	0.21 n.s.	0.03 n.s.	0.13 n.s.	0.12 n.s.	0.01 n.s.

AoI-A = AoI artifact | AoI-E = AoI email client | AoI-T = AoI ticket system |
AoI-S = AoI service catalog
*** p < 0.001 | ** p < 0.01 | * p < 0.05 | n.s. p > 0.05

The test reveals a correlation between the treatments' objective usage (AoI-Treatment) and the subjective usage measurements (Use1 and Use2) for the complete dataset, the "advanced treatment" group, and the "basic treatment" group. The correlation test for the control group reveals no correlation between the perceived and objective usage measurements. In addition, we tested for a correlation between the subjective usage and the objective usage of the experimental applications. In line with the first correlation test, we found a positive correlation for the complete data set and both treatment groups (except for the "basic treatment" group's service catalog usage).

There is no correlation for the control group. As last step, we tested for a correlation between the objective artifact usage and objective usage of the experimental applications. Here, we found a positive correlation for the complete dataset as well as all three experimental groups (except for the control group's service catalog usage).

6 Discussion

The analysis of the complete data set reveals a positive correlation between the subjective usage perceptions and the objective artifact usage. Moreover, we identified a correlation between the subjective artifact usage and the objective experimental applications usage. This could indicate a type II error, as the participants might not only have assessed their artifact usage, but the overall usage of the experiment's applications. Therefore, we tested for a correlation between the objective artifact's and experimental application's usage. Again, we found a positive correlation. The experiment's setup and task could explain these correlations. The participants used the experimental applications in order to fulfill their experimental tasks and the assistance system supported their process execution. Therefore, there is a correlation between all four objective usage measurements. This fact could also explain the correlation between the subjective artifact's usage and objective usage of the experiments applications. Based on the introspection theory [17], we assume the participants are able to assess their artifact usage, as their cognitive artifact usage is stored in their short-term memory. The objective usage measurements' reliability is based on the immediacy assumption and the eye-mind assumption [12]. Therefore, we can conclude both measurements as reliable and confirm our hypothesis for the entire dataset.

However, the distinct analysis for the three groups reveals contradictious results. Both treatment groups show similar results compared to the complete dataset. However, the control group reveals a different result. There is no correlation between the subjective and objective artifact usage. The control group participants had no information about how to execute the ticketing process provided in their artifact. Thus, we expected that they do not use it (cognitively) in the experiment as their artifact contained only a blank space. Thus, we assume they have the information on "no artifact usage" in their short-term memory. Accordingly, the control group's participants should not report any usage. Nevertheless, the control group reported a low subjective artifact usage (mean value of 2.76 and 2.54).

There are some possible explanations, for example common method biases such as the social desirability bias [14, 35]. The control group participants may had the tendency or need to report some artifact usage in order to "*present themselves in a favorable light*" [14: p. 881], despite the fact they actually did not use it. The participants of the control group could have over-reported their usage because they viewed this behavior as appropriate [35]. Another explanation could be the control group participants were confused and reported their subjective usage of the experimental applications. However, the analysis showed there is no such correlation and therefore, we assume there was no confusion among the participants. Summed up, we can confirm the hypothesis for both treatment groups and reject the hypothesis for the control group.

7 Summary and Future Work

In this paper, we present our research addressing the ongoing debate on subjective vs. objective usage measurements. More specifically, we address experimental settings with cognitive artifact usage, e.g. in the context of DSR projects. In our experiment, we measure the objective usage with eye-tracking technology and the participants' eye fixations. Our analysis supports the assumption that subjective usage measurements are a reliable approximation for objective usage measurements in case of laboratory experiments with an artifact present. When testing a group with an artifact against a group without an artifact the subjective measurements are no reliable approximation for objective measurements according to our analysis. We conclude that researchers could use subjective usage measurements when comparing different artifact designs. In contrast to this, researchers should rely on objective measurements when testing the effect of an artifact compared to a control group with no artifact.

Our research contributes by providing support for the constraint reliability of subjective usage measurements in experimental settings discussed in the body of knowledge. More specifically, our research results indicate the reliability of participants' usage perceptions of an artifact in an experimental setting in case if the artifact is present and can be (cognitively) used by the participants. Moreover, from a methodological point of view, we exemplary show how to measure objective cognitive artifact usage in experimental settings, based on the immediacy assumption and the eye-mind assumption [12]. Eye-tracking technology enables researchers to utilize the participants' eye fixation as a reliable indicator for their cognitive processing and thus, represents an objective usage measurement. Researchers can apply the presented method to assess the participants' (cognitive) artifact usage in their experiments. Especially experiments in the DSR context can benefit from using eye-tracking technology to enrich the usage measurement [15] as the artifact usage is of high importance in DSR experiments [10]. Researchers following the DSR approach can apply the proposed objective usage measurement in their experiments aiming to gain deeper insights into the participants' usage of the artifact and the artifacts' effects.

Although our research follows established methods, there are potential limitations. We conducted the analysis with only one experimental dataset resulting in limited generalizability. There is an ongoing debate on subjective vs objective usage measurements and our findings add to the body of knowledge. Moreover, our study presents a reliable method on how to assess objective measurements for cognitive artifact usage in experimental settings. The analysis presented in this paper uses the aggregate experimental data as our research is still in progress. As next step, we conduct a detailed analysis of the participants' individual usage behavior during the experiment addressing the following activities. **First**, the screen recordings from the eye-tracking software enables us to track the participants' activities and fixations during the experiment, code the participant's usage behavior accordingly, and derive patterns of varying usage behaviors. **Second**, for the presented analysis, we used the total numbers of fixations as the objective measurement. As the used eye-tracking technology measures every 33ms the participant's eye position on the screen, the gathered fixations might also include fixations that occurred, because the participant is scanning the screen (e.g. investigating the applications in the beginning). Based on reading research in psychology, we plan to code fixation clusters with a duration of at least 200 – 300ms, as this time is required to read and comprehend a sentence [25]. This detailed analysis will enable us, for example, to remove the "non-usage" fixations in the experiment's beginning, when the participants scanned the existing applications, in order to get a clearer picture of their actual usage behavior during the experiment. Both research activities will extent the "richness" of our usage measurement following the suggestions by Burton-Jones and Straub [15]. **Third**, we will incorporate the artifact's usage measurements to explain the participants' actual performance in the experiment and test for moderating variables such as gender, ethnicity, and users' knowledge about the experiments ticketing process. Especially the varying level of participants' process knowledge, which increased during the experiment based on the provided assistance, might have an effect on the participants' usage behavior. The detailed analysis of the eye-tracker recordings will enable us to understand the participants changing usage behavior during the experiment and gain further insights on potential learning effects based on the provided assistance.

In addition to the outlined activities addressing our future research, there are further opportunities. We suggest to conduct more studies on the proposed concept of cognitive artifact usage. There is more work required on the theoretical grounding and conceptualization of cognitive artifact usage. In addition, researchers could apply the eye-tracking technology in their experiments to gather objective usage data and provide more findings on the ongoing subjective vs objective usage debate.

How Does the Crowdsourcing Experience Impact Participants' Engagement? An Empirical Illustration

Julia Troll[1], Ivo Blohm[1]

[1] University of St. Gallen (HSG), Institute of Information Management, St. Gallen, Switzerland
julia.troll,ivo.blohm@unisg.ch

A largely neglected aspect in crowdsourcing research is the "Crowdsourcing Experience" itself, which every crowdsourcee is necessarily exposed to throughout the IT-mediated interaction process, potentially stimulating engagement towards the crowdsourcer. Hence, the crowdsourcees' engagement process is conceptualized and illustrated with empirical findings from a pilot case. It exemplifies that crowdsourcing has the potential to generate high levels of attitudinal and behavioral engagement, depending on prior experiences and perceived cognitions and emotions. Related stimuli characteristics are identified, which serve as a first indication of the foundations of the engagement process. This study offers IS-researchers first insights on the so far under-researched topic of IT-enabled engagement processes between individuals and entities.

Keywords: Crowdsourcing, Crowdsourcing Experience, Customer Engagement, Engagement Process

1 Introduction

Crowdsourcing is an emerging global trend, which 85 percent of the top hundred global brands try to take advantage of [1]. It broadly defines a participative, IT-mediated activity in which a given entity proposes a task to a crowd to create mutual benefit [2, 3]. While there are several functions of crowdsourcing, such as design and innovation, or software development and testing [4], it seems as if crowdsourcers' primary attention is currently paid to managing contributions rather than the crowd, its needs and desires. This is also reflected by research in the field of crowdsourcing, which is dominated by studies assessing crowdsourcing mostly from a crowdsourcer's perspective. However, looking at successful crowdsourcing initiatives, as *My Starbucks Idea* or the *SBB Mobile Preview Community*, in terms of its huge crowds and intense participation, it can be assumed that value is not only created by absorbing knowledge and ideas.

The meaning of value and the process of value creation are rapidly shifting from a product- and firm-centric view to an experience-based view, putting the subject in the center [5]. This can be transferred to co-creation activities itself, in which experiences

Troll, J.; Blohm, I. (2017): How Does the Crowdsourcing Experience Impact Participants' Engagement? An Empirical Illustration, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1036-1050

are created, too. Hence, this paper argues that a largely neglected aspect in crowdsourcing research is the here called "*Crowdsourcing Experience*" itself, which every crowdsourcee is necessarily exposed to throughout the IT-mediated interaction process. This disregard may come with a price. Initiators not only risk to lose valuable contributors during or after the interaction due to perceived negative experiences, but also their reputation. A famous example is given by *Pril's crowdsourcing flop*, in which an undesirable experience by Henkel caused a public PR-disaster [6]. Additionally, initiators miss a promising opportunity to generate crowdsourcees a unique experience, thereby stimulating overall engagement towards the crowdsourcer. This can create additional value, e.g., in form of positive word of mouth and enhanced brand value, increasing in relevance if the crowd consists of (potential) customers and end-users.

First authors recognized the need for an experienced-based perspective on crowdsourcing and called for research [4, 7, 8]. However, no existing study takes a process perspective to systematically assess the end-to-end crowdsourcee's experience. Yet, this is necessary to understand how and why crowdsourcees engage, from a cognitive, emotional and behavioral perspective. To fill this gap, the engagement process is conceptualized, illustrated, and refined with empirical observations from a case, to approach the following question: How does the *Crowdsourcing Experience* impact engagement throughout the IT-enabled interaction process?

First an overview of the research field of crowdsourcing and customer engagement is provided and relevant concepts derived. Then, an empirical illustration is provided and a refined concept discussed. Lastly, relevant research contributions are presented.

2 Conceptual and Theoretical Background

2.1 Crowdsourcing

The fundamental idea of crowdsourcing is that a crowdsourcer (e.g., a company) proposes to an undefined group of contributors (e.g., individuals), henceforth called crowdsourcees, the voluntary undertaking of a task presented in an open call [2]. The ensuing interaction process unfolds over IT-based crowdsourcing platforms [2, 3]. Crowdsourcers can set up their own crowdsourcing platform and processes (e.g., My Starbucks Idea), or they can refer to intermediaries, such as Innocentive or Testbirds that provide a technical infrastructure and access to a crowd. Some offer additional services such as task specification, crowd acquisition, and evaluation of results [9]. Crowdsourcer and crowdsourcees engage in the participative, IT-mediated interaction process to create mutual benefit [3]. For crowdsourcers, this benefit may involve solving problems that cannot be satisfactorily solved in-house, but also enhanced brand visibility [10]. For crowdsourcees, the benefit may be of economic nature (e.g., remuneration) or other needs are satisfied, like social recognition or skill development. Thus, value can be produced by outcomes (i.e., instrumental value) and preceding processes (i.e., experiential value). To better understand the mutual benefits of crowdsourcing, some authors have emphasized the need for researching crowdsourcing from an experience-based perspective [4, 7, 8]. First articles reveal insights on: initial crowdsourcing user engagement, defined as the quality of effort [11]; drivers of sustained participation in micro-task oriented crowdsourcing [12]; an behavioral engagement index for crowdsourcing [13]; crowdsourcee's attitude towards the platform and design choices [14]; and the impact of crowdsourcing on affective commitment in collaborative crowdsourcing projects [15]. It seems that each of those studies either focus on a specific crowdsourcing phase in the interaction process or solely on the experience outcome, from a behavioral or attitudinal perspective. None of those studies take a holistic process perspective to systematically assess the end-to-end crowdsourcees' experience, including pre- and post-participation experiences. Yet, this is necessary to understand how and why crowdsourcees engage for value co-creation. This paper takes a closer look at the concept and process of customer engagement from the relationship marketing literature and applies it to crowdsourcing.

2.2 The Concept and Process of Customer Engagement

Customer engagement (CE) is defined as a psychological state that occurs by virtue of interactive, co-creative customer experiences with a focal agent [16]. Customer experience is the internal and subjective perception of customers' direct and indirect interactions with a firm. The resulting engagement state develops through a dynamic, iterative process that co-creates value between the engagement subject (e.g., customer) and object (e.g., company) [17]. First authors conceptualized the general engagement process of customers [18, 19]. A simplified illustration is given in Figure 1.

According to existing conceptualizations, the psychological state encompasses various combinations of cognitive, emotional, and behavioral dimensions, dependent on perceived stimuli and prior experiences. The cognitive dimension can be interpreted as a more passive state of immersion and absorption or a more active state of cognitive processing to expedite comprehension [20]. The emotional dimension relates to the customer's feelings activated by an experience. Additionally, a behavioral response related to a specific stimulus may be expressed. Addressed dimensions regarding each perceived stimulus are evaluated by the subject and an intermediate state is generated, happening unconsciously. The literature considers satisfaction, delight, involvement and trust as intermediate states that foster the development of engagement, which is defined as a specific type of commitment towards the engagement object [18, 19].

Satisfaction is generally seen as a preliminary state. Alone, it may not result in a desired behavior (i.e., repeat consumption or referral) as expectations are only confirmed according to expectation-disconfirmation theory [21]. If one repeats a satisfying interaction due to perceived attribute-based utility, missing alternatives or switching costs, a so called calculative commitment may develop between the engagement subject and object [19]. Commitment is associated with a specific attitudinal position [19], while calculative relates to rational reasoning. However, those rational bonds may be dissolved easily and are of limited value for a company [18].

Hence, additionally an emotional bond is desired, also called affective commitment. It illustrates a customer's psychological closeness to a focal agent and is positively related to referral and word of mouth (WOM) [18, 19]. It is expressed as a holistic or aggregate judgment, independently from its functional attributes. A feeling of involvement or trust, due to increased familiarity and precise expectations towards the engagement object, is known as a driver [19]. While involvement is described as a feeling of personal relevance and importance, trust is a customer's assumption that a focal agent is able to respond to his needs and has his best interest at heart [22]. Nevertheless, a delightful incident may lead to affective commitment right away, even if the engagement subject is less familiar with the engagement object and relies on a more attribute-based evaluation [18, 19]. Customer delight is defined as a combination of pleasure, joy and elation as well as unexpected levels of arousal or surprise [23].

When both forms of commitment develop throughout the interaction process, customer and company are in an enduring relational exchange with strong emotional bonds [18]. This desired psychological engagement state is related to direct (i.e., repeat consumption) as well as indirect behavioral responses towards the engagement object (e.g., WOM, referral behavior), reflecting the customer engagement value [24].

It can be concluded that familiarity (i.e, prior experiences) with an engagement object is an input factor in the process of engagement, while the experience evaluation constitute the psychological process, leading to a state of calculative and/or affective commitment and behavioral responses as process outcomes. Presuming a feeling of satisfaction, it is supposed that a sense of delight, involvement, and trust operate as drivers of engagement in a customer-company interaction. Active participation in the creation of an offering is widely assumed as a central antecedent [16, 17, 24, 25].

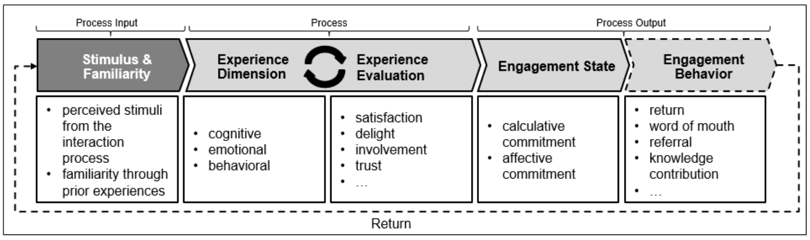

Figure 1. Conceptualized Engagement Process (own illustration)

3 Towards an Engagement Theory of the Crowdsourcing Experience

Independent of the crowdsourcer's original intention, performing a crowdsourcing initiative creates an experience that may foster engagement among crowdsourcees towards the crowdsourcer. The *Crowdsourcing Experience* in this paper is defined as a crowdsourcee's internal and subjective perception of the end-to-end, IT-mediated interaction process, resulting in a psychological state. It is an online experience, driven by several stimuli over one or more virtual channels. Perceived stimuli can be found in the pre-participation (e.g., invitation), participation (e.g., task), and post-participation (e.g., payment) phase. Due to its participative character, the underlying assumption is that crowdsourcing generally has the potential to generate high levels of engagement. Depending on the specific set up of the initiative, crowdsourcees (i.e., the engagement subject) may engage with the crowdsourcer directly or via an intermediary and with other crowdsourcees (i.e., the engagement objects). They can have varying degrees of familiarity concerning the objects (e.g., prior crowdsourcing- or customer experiences), influencing their expectations and experience evaluation. Henceforth, *Crowdsourcee Engagement* is conceptualized as a psychological process that models the underlying mechanisms by which a crowdsourcee develops calculative and affective commitment based on perceived stimuli and prior experiences, resulting in behavioral value-contributions for the crowdsourcer. The unfolding IT-mediated interaction process comprises a set of diverse stimuli, potentially addressing both, the cognitive and emotional experience dimension. The CE literature considers satisfaction, delight, involvement and trust as intermediate states. To explain potential drivers in the context of crowdsourcing, different perspectives can be taken, as crowdsourcees may not only be seen as (potential) customers and influencers, but also take the role of a platform user, worker, and a group or community member (i.e., the crowd).

From an IS-perspective, a system's characteristics, quality and performance may generate user involvement, delight, and trust. For example, characteristics as novelty, variety, aesthetics (affective or sensory appeal), and fun are related to perceived delight [26, 27]. In crowdsourcing, this may refer to an attractive and fun-providing crowdsourcing platform or an appealing virtual object, which is in the center of the task (e.g., a website). According to organizational behavior (OB) research, specific task characteristics, one's identity with it, and rewards may lead to job or task involvement, trust or delight [28]. For example, a good task-person fit and a crowdsourcee's enthusiasm about a task may be related to involvement and delight. Lastly, according to community research, the identification with the crowd may stimulate a sense of involvement throughout the process [29]. Next to these, another driver of engagement is expected to operate in the case of crowdsourcing: empowerment. Ulrich [30] argues that customer empowerment leads to stronger commitment, if additional information about the company can be gained and response is volitional, irreversible, and public. Empowerment positively effects demand and WOM, due to a sense of psychological ownership [31]. In OB-research, it relates to a sense of control, impact, meaning, and self-efficacy [32], which may be stimulated e.g., with a specific task.

Subsequently, out of the intermediate states an overall engagement state arises. If satisfaction is achieved and the crowdsourcee perceives clear utility through participation, a form of calculative commitment towards the crowdsourcer may be gained. If additionally to satisfaction, a sense of delight, involvement, trust, and/or empowerment arises throughout the interaction process, affective commitment may be developed. Resulting direct and indirect behavioral value contributions towards the crowdsourcer may refer to: a) repeat participation; b) virtual or direct WOM; c) referral behavior; d) further voluntary knowledge or feedback contributions, exceeding the scope of the original task; as well as e) consumption activities (buying/ using something from the crowdsourcer). Calculative commitment is related to repeat participation (a) and affective commitment additionally to indirect contributions (b-e).

By assessing the engagement process in the context of an exemplary crowdsourcing case, those relationships will be illustrated and successful patterns of mechanisms and related stimuli characteristics extracted to refine and extend derived knowledge.

4 An Empirical Illustration

Each crowdsourcing initiative can offer crowdsourcees a unique IT-mediated interaction process, consisting of many consecutive and interrelated experience-driving stimuli. This section illustrates how the concept and process of engagement can be useful for interpreting the findings of a qualitative study that investigated the perceived *Crowdsourcing Experience* of participants in a crowdsourcing project, initiated by a leading insurance company from Switzerland. This approach is accepted by recognized outlets and a successful example is provided by Leonardi [33].

4.1 Case Description

In 2015, InsureCorp (name changed) decided to renew its digital communication channels with a “mobile first” strategy. To apply a user-centered approach for developing its new mobile web application, the company decided to use crowdsourcing with potential end-users. Crowdsourcees were offered to test and feedback the web app’s interface and report on functional bugs, usability and provide ideas. They had to go through realistic test scenarios to explore the web app. In return, they were offered a fixed monetary reward. InsureCorp chose to cooperate with a crowdsourcing intermediary, responsible for acquiring the crowd, providing the platform, evaluating contributions, and handling the payment process. They conducted three self-contained crowdsourcing projects (August 2015; January and June 2016), each with a duration of five days, to individually advance parts of the web app with around twenty crowdsourcees per iteration. Each project included the acquisition of a suitable crowd, a definite task, and a closing phase. The last project was assessed in this study.

The case of InsureCorp was chosen because it illustrates a common case in this field and incorporates all characteristics of crowdsourcing, as a concrete task is proposed via an open call through a platform for a specified reward. The goal was to target a diverse crowd, representing potential end-users. As the company developed a certain maturity over iterations, it is expected that in the last one exceptional problems, unusually influencing the *Crowdsourcing Experience*, could be reduced. The crowd was relatively homogenous regarding cultural background, familiarity with the activity, and financial situation, which enabled a comparison of experiences and engagement processes. Lastly, the use of intermediaries is becoming increasingly common [9]. Hence, it could be explored in how far the engagement of crowdsourcees developed differently towards the crowdsourcer, as the central point of interest, and the intermediary.

4.2 Data Collection and Analysis

First, to understand the intended *Crowdsourcing Experience*, three semi-structured interviews and a focus group discussion with the crowdsourcer and intermediary were conducted. Also, to study crowdsourcees’ behavior, data concerning the time spent on the platform and with the web app was tracked. Contributions were analyzed in terms of its length (word count) and level of detail (i.e., under-/ over-fulfillment of task). Demographic information and amount of previous activities were collected from the platform. Finally, seven in-depth, semi-structured interviews (60-90 minutes) with crowdsourcees were conducted to decipher the crowdsourcee's experience along the process. A slightly adapted version of the novel approach from consumer behavior, called "Sequential Incident Laddering Technique" (SILT), was used [34]. Respondents were first asked to recall all stimuli ("critical incidents") from the crowdsourcing interaction process. Subsequently, the interviewer asked simple "what", "why", "how" questions to establish the link between a stimulus and crowdsourcee's (a) cognitive and emotional perceptions; (b) experience evaluation (intermediate state); (c) and behavioral responses ("laddering technique"). In a last interview step, crowdsourcee's final commitment and (planned) engagement behavior towards the crowdsourcer and intermediary was captured. As commitment is also described as an attitudinal judgment, interviewees were asked to describe their attitude to receive insights regarding their emotional and rational disposition. To avoid a recall bias [35] crowdsourcees in this study were interviewed two to seven days after participation. For reasons of better comparability, seven crowdsourcees with some crowdsourcing familiarity were selected, to avoid interviewing overly excited or bored individuals. The interviews were transcribed and assessed, together with the other data sources, by applying qualitative content analysis [36, 37]. A category system based on the theoretical framework of the engagement process was developed and collected data was coded along stimuli: perceived experience dimensions; related engagement object; experience evaluations; resulting attitude; and (planned) behavior. To allow for the identification of new categories and related stimuli characteristics, the system was iteratively adapted. Two researchers independently coded the data by allocating direct and indirect statements to the categories (interpretive approach) and subsequently discussed findings. Insights were used to illustrate how engagement developed for those crowdsourcees throughout the process. The purpose was not to test the framework, but rather to illustrate its use for understanding the potential engagement value of a crowdsourcing initiative.

4.3 The Crowdsourcing Interaction Process of InsureCorp

First, potential experience-driving stimuli along the interaction process were visualized based on the results of the interviews with responsible project managers. The process was then collaboratively discussed and refined in a focus group interview. The result is illustrated in Figure 2.

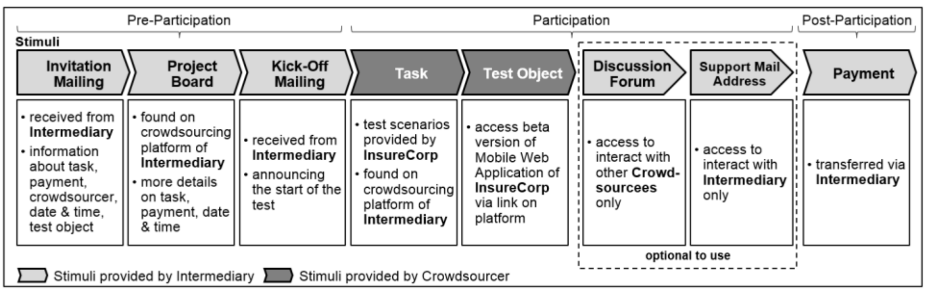

Figure 2. Stimuli along the Crowdsourcing Interaction Process of InsureCorp

It includes two communication channels: email and the crowdsourcing platform of the intermediary. Three potential engagement objects could be identified: crowdsourcer, intermediary, and other crowdsourcees. Five stimuli are solely designed, managed, and communicated by the intermediary to the crowd, while two stimuli (task, test object) are designed and managed by the crowdsourcer. One stimulus (discussion forum) is provided by the intermediary but triggers the interaction among crowdsourcees only.

4.4 Assessment of the Crowdsourcing Experience

By looking at the described attitudes and (planned) behavior, it is observed that different engagement states among crowdsourcees developed, although the overall *Crowdsourcing Experience* was evaluated to be satisfying for all crowdsourcees. A more in-depth analysis of the underlying processes was necessary to identify mechanisms that caused psychological and behavioral engagement outcomes.

The case data shows that the engagement development process throughout the interaction process took several forms among crowdsourcees, depending on prior familiarity with the engagement objects and stimuli perceptions. All previously identified stimuli were generally perceived and mostly experienced by interviewed crowdsourcees, shaping their *Crowdsourcing Experience*, except from the discussion board. That excludes “other crowdsourcees” as a potential engagement object. As expected, crowdsourcees related the stimuli task and test object directly to the crowdsourcer and the rest to the intermediary. Stimuli, related to the intermediary, lead to 80 percent cognitive statements and 54 percent were evaluated to be purely satisfying, while 25 percent were additionally evaluated as trust-enhancing. Stimuli related to the crowdsourcer lead to around 60 percent cognitive statements and only 17 percent were evaluated to be purely satisfying, while even 73 percent were additionally evaluated as delighting, involving, or empowering (see appendix for more details). An integrated framework, incorporating theoretical knowledge from the engagement process (Figure 1) with findings from the assessment of InsureCorp’s crowdsourcing interaction process (Figure 2), is illustrated in Figure 3.

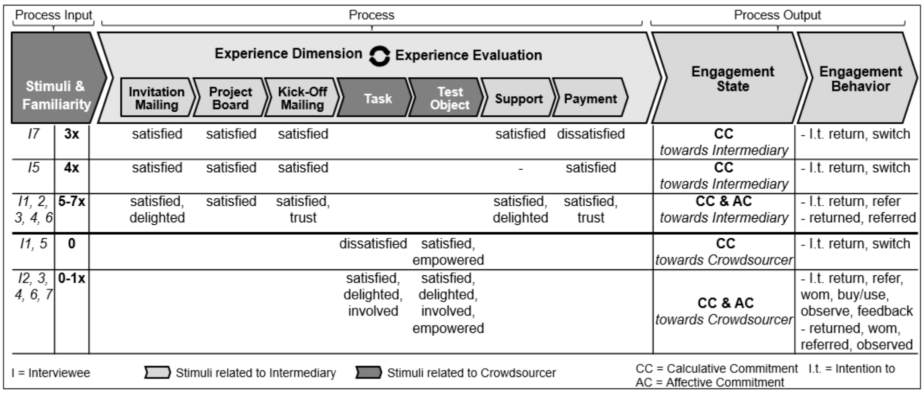

Figure 3. Integrated Framework of the Crowdsourcee’s Engagement Process

Different process patterns were identified that led to affective commitment towards the crowdsourcer and intermediary. First, those five interviewed crowdsourcees (I2, 3, 4, 6, 7), who evaluated the stimuli task and test object as delightful, involving, and/ or empowering, developed a more emotionally based commitment towards the crowdsourcer, leading to more diverse behavioral responses than the other two. Delight arose due to a feeling of surprise, pleasure, fun and enjoyment related to the task and test object (e.g., I2: “it was fun to explore the whole web app and record my feedback in a video”; I7: “those scenarios were new to me, I felt like a real customer”). A feeling of challenge, inspiration, stimulation, and need for solving the task was mentioned when crowdsourcees described themselves as being involved (e.g., I3: “I couldn’t find it but I really wanted to solve that task, so I tested the whole application”; I6: “the app design was very inspiring, it was easy to get caught up by the task”). Those, who felt as being a part of the product-development process and enjoyed having impact on the test object, described the stimulus as empowering (e.g., I2: “it feels good to give feedback for a product that is still in development”). Crowdsourcees, who described those emotional perceptions and experience evaluations, stated that their attitude towards the crowdsourcer changed somewhat, as they perceived InsureCorp as more innovative, modern, open-minded, collaborative, customer-centric, and/or supportive after participation. They also mentioned an improved brand image and a strengthened relationship to the crowdsourcer (e.g., I4: “now, InsureCorp feels more like a partner for me”; I2: “I did not expect that from InsureCorp, seems like a cool company”). This indicates a sign of a stronger form of affective commitment towards the crowdsourcer. While all interviewed crowdsourcees stated to be generally willing to return for repeat participation based on perceived utility, those that mentioned to be delighted, empowered and/ or involved concerning task and test object, were additionally intended to refer the crowdsourcer, conduct of WOM, and buy or use a service of the crowdsourcer due to their positive impression after participation. Some were also interested in observing the development of the test object and providing voluntarily, additional feedback and ideas to the crowdsourcer after the project’s official end. Data showed that involved crowdsourcees spent more time on the platform and with the test object in comparison to others (1.5 to 2 times as long). Contribution-analysis revealed that they did more than was expected in the task (over-fulfillment) and gave more detailed feedback in terms of word count (1.25 to 1.6 time as much). In comparison, those that perceived only satisfaction or even dissatisfaction regarding the task and test object mentioned no intentions for referral, WOM, consumption or observation towards the crowdsourcer and contributed less in terms of feedback.

Second, those five crowdsourcees (I1, 2, 3, 4, 6), who evaluated stimuli related to the intermediary mainly as satisfying but expressed that they developed some trust into the intermediary throughout the process, developed some affective commitment, resulting in more diverse behavioral value contributions for the intermediary. Satisfaction with stimuli as the invitation mailing, project board, and support services, was mainly described through cognitive expressions, relating to the characteristics of the information provided, the platform, or the response time. A feeling of trust towards the intermediary was mentioned in relation to the kick off mailing (e.g., I4: “I felt relieved, when the reminder arrived. I know, I can rely on their processes”), and the compensation (e.g., I2: “I don’t know what others pay, but I assume they are fair”; I1: “the process could be easier, but I’m sure they`ll find a better solution soon”). Negative cognitions of crowdsourcees, who mentioned trust into the intermediary, resulted not in negative emotional perceptions and evaluations. In comparison, other crowdsourcees expressed annoyance in response, resulting in dissatisfaction. Although crowdsourcees described their attitude towards the intermediary mostly rational and used terms as responsive, fair, reliable, effective and well-organized, those that sensed trust throughout the process, used more emotional expressions for the intermediary (e.g., I4: “it was fun to work with them”; I6: “they try their best to make our job easier”) and were willing to refer (or even already referred) the intermediary to friends or colleagues. In comparison, those that mentioned only satisfaction or even some dissatisfaction without showing signs of trust, were only intended to return due to rational reasons of perceived utility (e.g., compensation and skill development), but mentioned to be willing to switch, if another crowdsourcing opportunity arises (e.g., I5: “the intermediary is for me more a means to an end”; I7: “I don’t have any emotional relationship with it”). Thus, only a calculative commitment can be assumed.

The difference between the development of affective commitment towards the crowdsourcer and intermediary may be explained due to two reasons. On the one hand, prior familiarity may play a role. All interviewed crowdsourcees were already familiar with the intermediary (three to seven prior projects) and those that developed trust participated in five to seven other crowdsourcing projects before. Hence, they had quite precise knowledge and expectations regarding the general interaction points, designed and managed by the intermediary. Instead of being easily surprised (i.e., delighted), they rather valued repetitions and dependability, which enhanced their trust. In comparison, familiarity with the crowdsourcer was much lower. Only two crowdsourcees participated in one of the previous iterations. Thus, most were more sensitive for positive surprises. On the other hand, the type of stimuli, related to the intermediary were much less involving or empowering and more of an administrative character, than the ones related to the crowdsourcer. The task and test object allow for intense interaction with the crowdsourcer than a rather transactional stimulus, as an informative mail or payment process. From cognitive and emotional stimuli perceptions and evaluations, relevant characteristics could be identified (see Table 1). Derived characteristics illustrate the foundations of the crowdsourcee’s engagement process.

Table 1. Perceived Stimuli Characteristics

Intermediate State	Related Stimuli Characteristics (as perceived by interviewed Crowdsourcees)
Satisfaction	(a) complete, concrete, understandable information and instructions, (b) clear in/ out-of-scope of task, (c) easy to use crowdsourcing-platform, (d) easy access to test-object (e.g., easy registration, technol. prerequisites), (e) quick response time for support, (f) monetary compensation, (g) quick compensation transaction
Delight	(a) personal style of contact (e.g., personal address, real contact person as sender) (b) personal/direct communication channel for invitation/support (e.g., email/ phone), (c) new/innovative type of task (e.g., video feedback), (d) explorative task (e.g., usability testing), (e) fun-providing test scenarios, (f) new/ innovative design of test object

Involvement	(a) challenging task, (b) stimulating and inspiring design of test-object/ information provided, (c) realistic test scenarios (e.g., put them in the position of a real customer)
Trust	(a) process transparency (e.g., comprehensive information through reminder mails, process details on platform, regular updates), (b) fair compensation (in terms of time and effort), (c) process improvement-attempts/ actions (e.g., news announcing changes)
Empowerment	(a) having impact on whole test object (e.g., explorative task, broad scope of task), (b) changes/ developments in test object at project-end (e.g., feedback report)

5 Discussion

This paper began with the suggestion to take a holistic process perspective for systematically assessing the end-to-end *Crowdsourcing Experience* to understand how and why crowdsourcees actually engage for value co-creation. Therefore, in analogy to the CE-process, a theoretical engagement process for the case of crowdsourcing was derived and its use illustrated with a case.

The underlying assumption was that crowdsourcing generally has the potential to generate high levels of engagement due to its participative character [16, 17, 24, 25]. The attitudinal and behavioral responses by participants in the case illustrated that emotional as well as rational bonds developed towards the crowdsourcer and intermediary, leading to diverse behavioral value-contributions, which exceeded repeat interactions. The case also illustrated that the underlying process of engagement included the emotional response to specific stimuli, which led to delight, involvement, empowerment and/or trust, fostering affective commitment and (planned) indirect value contributions (i.e., WOM, referral, further knowledge contributions, observations, consumption activities). Next to those illustrations of the theoretical concept, the case helped to extend and refine knowledge concerning the underlying mechanisms of the engagement process. First of all, it could be shown that engagement developed differently towards the crowdsourcer and intermediary throughout the process. Hence, participants were able to differentiate stimuli-related experiences and draw separate conclusions. It further showed that stimuli evaluations may depend on prior familiarity with the engagement object and its interactive character. Those rather administrative stimuli, appearing in the pre- and post-participation phase, which were quite familiar for most crowdsourcees, led to mostly satisfaction and trust. In comparison, those rather interactive stimuli in the participation phase, which differed from project to project (i.e., new types of tasks, other test objects), fostered delight, involvement and empowerment, if designed properly (Table 1).

This also relates to the different roles of crowdsourcees, influencing the perception of stimuli and its impact on engagement. It was discussed that from an IS-perspective platform quality and characteristics of the test object may play a role for engagement [26, 27]. The case illustrated that the crowdsourcing platform arose no emotional responses. This might be due to its transactional character and consistency throughout interactions. Here, the goal should be to rather strive for satisfaction and potentially enhance trust into the technology in the long term. The test object however, due to its hedonistic character, led to several emotional responses and arose delight and involvement, leading to longer interaction times and even the desire for further knowledge contributions and observations after participation. It seems to be an important factor that potentially drives affective commitment. Furthermore, from an OB-perspective it was assumed that the task and reward may stimulate emotional responses [28]. In this case, the monetary reward had rather a utilitarian purpose. However, perceived fairness and reliability regarding the transaction process fostered trust over repeat interactions. Moreover, the tasks and test scenarios stimulated delight and involvement due to perceived fun and challenge, which even fostered task over-fulfillment and a more intense interaction on the crowdsourcing platform. Besides, some crowdsourcees mentioned to enjoy having impact on the test object. Thus, perceived relevance of the test object and task may enhance sensed empowerment and eventually affective commitment, as it is predicted by the theory of psychological ownership [32]. From a marketing perspective, the case showed that even (planned) consumption activities could be stimulated due to positive experiences with the task and test object, fostering a positive attitude towards the crowdsourcer and its products. Consequently, from a managerial perspective, it would be effective to design stimuli that foster satisfaction and trust in the pre- and post-participation phase; and delight, involvement and empowerment in the participation phase to enhance engagement.

Nevertheless, those empirical observations are not sufficient to prove relationships, as a single crowdsourcing case was assessed with a limited number of interviews. Yet, the illustrative case can be seen as a pilot study, suggesting a promising methodology and valuable first insights. For future research it is recommended to conduct multiple case studies, including different types of crowdsourcing to identify more engagement-driving mechanisms, patterns, and related stimuli characteristics from a process perspective (e.g., collaborative vs. non-collaborative, paid vs. unpaid, complex vs. micro-tasks, etc.). Additionally, to verify relationships with quantitative research, a survey approach may be applied, which tests for arising drivers and its impact on affective commitment and behavior. Pre- and post-participating engagement states may be compared to verify effects. Besides, experiments with manipulated stimuli may be used to explain concrete effects on engagement outcomes. The provided framework in Figure 4, can serve as a base for future research.

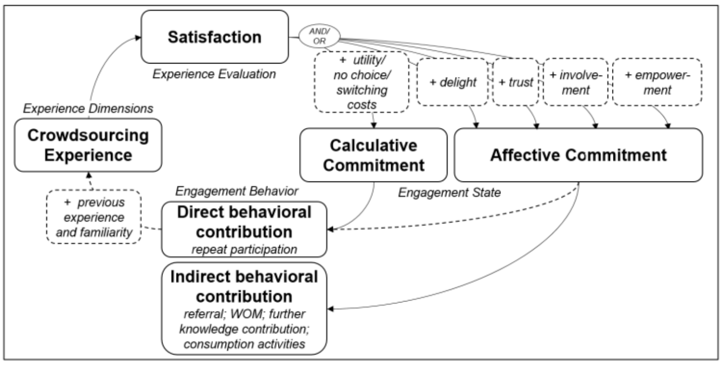

Figure 4. Research Model of the Crowdsourcee's Engagement Process

6 Conclusion

Applying the engagement concept and process to the case of crowdsourcing and deploying an adapted form of SILT as a unique measuring approach is a first step in offering researchers an experience-based perspective on crowdsourcing. The integration of those rather new research fields has the advantage that valuable knowledge for both can be derived. Crowdsourcing facilitates the connectivity of people, organizations and societies via a technological platform. In the center of this research is the IT-mediated *Crowdsourcing Experience*, generated through experience-driving stimuli. Hence, this research contributes to the IS literature, delivering insights on the so far under-researched concept of IT-enabled engagement processes between individuals and entities, from a psychological and behavioral perspective. Additionally, the concept of engagement is considered as a new perspective in relationship marketing research. By illustrating the engagement process with a first case, the aim is to support the progress of the engagement concept from an emergent theme to a more mature construct. Nevertheless, developing a better understanding of the currently realized *Crowdsourcing Experience* and the underlying mechanisms of the engagement process may help practitioners to improve the interaction process and identify engagement opportunities.

Abstract. As information systems (IS) are increasingly able to create highly engaging and interactive experiences, the phenomenon of *flow* is considered a promising vehicle to understand pre-adoptive and post-adoptive IS user behavior. However, despite a strong interest of researchers and practitioners in flow, the reliability, validity, hypothesized relationships, and measurement of flow constructs in current IS literature remain challenging. By reviewing extant literature in top IS outlets, this paper develops an integrative theoretical framework of flow antecedents, flow constructs, and flow consequences within IS research. In doing so, we identify and discuss four major flow streams in IS research and indicate future research directions.

Keywords: Flow theory, flow measurement, flow streams, human-computer interaction, integrative theoretical framework

1 Introduction

In today's digital economy, information systems (IS) are both, a significant investment for companies and an integral part of employees' daily work [1]. Due to technological developments, such as multi-media-rich user interfaces (UIs), IS are able to create highly engaging and interactive experiences [1]. More specifically, the design and implementation of IS plays an important role in whether or not users have holistic experiences such as "flow" when interacting with technology. Moreover, in today's technology landscape, most work-related tasks are at least to some extent IT-mediated. Hence, studying how flow affects pre-adoptive as well as post-adoptive IS use has been acknowledged of theoretical and practical significance [1–3]. Thereby, flow is adopted from the reference discipline of psychology and refers to "the holistic sensation that people feel when they act with total involvement" [4, p. 36].

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Rissler, R.; Nadj, M.; Adam, M.T.P. (2017): Flow in Information Systems Research: Review, Integrative Theoretical Framework, and Future Directions, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1051-1065

However, despite the intense usage of flow-related constructs within IS research, its reliability and validity still remains low [5–9]. Novak and colleagues identified 13 different flow constructs with an average usage rate of only four per study [5]. Conceptually, the inconsistencies also concern the hypothesized relationship between flow and other constructs [8]. Finneran and Zhang [7] concluded that the "diverse flow models demonstrate the different understandings of antecedents, flow experiences, and consequences" [7, p. 98]. Moreover, most flow constructs used by IS researchers only partially overlap with the constructs and measurements suggested by the reference discipline of psychology [4, 10, 11]. In summary, it can be concluded that current IS research summarizes the usage of flow within its discipline as "too broad and ill-defined due to the numerous ways it has been operationalized, tested, and applied." [12, p. 227]

In this paper, we review 43 articles in top IS outlets pursuing the following research question: *What is the state-of-the-art in flow research within top IS outlets?* Our SLR builds upon existing reviews [6, 8, 13] and extends these studies in several ways. We complement the literature-based discussions on flow by Finneran and Zhang [6] and Siekpe [13] with a structured approach including detailed information about the search approach, used databases, search strategy, and study selection criteria. Specifically, we expand the work by Finneran and Zhang [6] by flow dimensions and consequences, as well as incorporate the six flow constructs proposed by Siekpe [13]. Further, building on the nine stream suggestions by Mahnke et al. [8], we consolidate four streams of flow literature by analyzing the operationalization of the identified constructs. In addition, on the basis of our SLR and previous work [6, 8, 13], we synthesize the knowledge of flow in those four streams and develop an integrative theoretical framework, consisting of overarching flow categories, as well as sub-categories (cf. Figure 3). This framework can serve as a 'route map' in understanding the relations between various flow components and their interactions, as well as provide different academic perspectives on flow [14]. Finally, we cluster the identified articles in this framework accordingly to illustrate the most prominent streams and gaps (cf. Table 2).

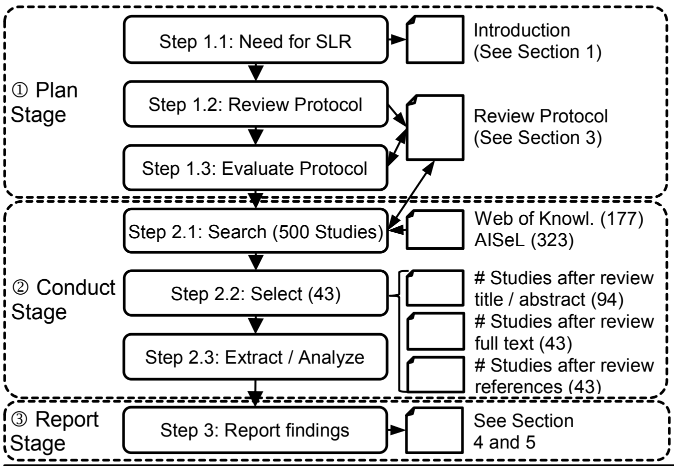
This paper makes five key contributions to IS research and practice. First, we introduce a comprehensive, integrative theoretical framework of flow in IS research [14]. This high-level framework can support both, IS researchers and practitioners to conceptualize the flow phenomenon and guide the design of IS artefacts. Second, we provide a detailed overview of four major flow streams in IS research and position these streams within our integrative theoretical framework. Third, we summarize the results of the literature with respect to the major antecedents and consequences of flow. Fourth, we provide a detailed overview on the commonly used flow constructs within IS research and identify the major challenges in their operationalization. Finally, our review provides suggestions for further research within IS.

2 Fundamentals of Flow

Flow was first investigated by psychologist Mihaly Csikszentmihalyi, who developed a theory of flow in the 1970s based on qualitative interviews with individuals performing (autotelic) activities in a non-professional context without extrinsic rewards

[4]. During the analysis a pattern emerged in which individuals were fully immersed and concentrated on a task at hand – the so called "flow experience" [4]. Further, Csikszentmihalyi differentiated between different degrees of flow ranging from micro-flow (e.g., perceived at taking a coffee break) and deep-flow (e.g., perceived while painting a picture) [4]. Initially, researchers hypothesized that flow experience occurs only in cases, where the performer of an activity does not receive any extrinsic reward (e.g., financial benefits) [4]. However, further studies showed that flow constitutes a general phenomenon occurring in both, extrinsically (e.g., working environment) [2] and intrinsically (e.g., painting, music) motivated activities [4]. Due to this high generalizability and recent enhancements in IS capabilities to foster flow (e.g., via providing multi-media-rich task support), the concept of flow has been widely adopted by researchers to understand user behavior in engaging and interactive technology contexts [1]. For instance, based on an analysis of 43 employees using an e-mail application, researchers established a direct link between flow experience and actual technology use. In the same study, researchers also found a correlation between flow and other constructs, such as perceived communication quality and perceived effectiveness [2]. Generally, the flow phenomenon has been applied in various domains, such as E-Learning [15], E-Commerce [16], Web-Sites [17], Games [18], and Virtual Worlds [19] in order to explain and study user perception and behaviors. Building upon several empirical flow studies in computer-mediated environments, scholars examined the concept through three different angles: (1) *flow antecedents*, (2) *flow experience*, and (3) *flow consequences* [3, 6, 12, 20]. However, the conceptualizations, antecedents, and consequences vary across studies (e.g., [9, 21]).

3 Method



Distribution of Flow Articles in Top IS Outlets

Systems; **ECIS**: European Conference on Inform. Systems

Figure 1. Stages of the SLR and Distribution of Flow Articles

In order to evaluate the current state of flow research within top IS outlets, we conduct a SLR following the guidelines by Kitchenham [22]. The SLR is subdivided into three stages (plan, conduct, and report; cf. Figure 1). During the **plan stage**, we identified the need for a SLR. In a second step, we developed a review protocol and evaluated it. During the **conduct stage**, we executed the search, selected appropriate studies, and analyzed them. Finally, during the **report stage**, we documented our findings.

Research Questions. To keep our systematic review focused, and to answer the overarching research question, we defined several subordinate questions (cf. Table 1).

Table 1. Subordinate Research Questions

RQ #	Research Questions
RQ1	What are the different streams of flow in top IS outlets and how can they be conceptualized into an integrative theoretical framework?
RQ2	What are the antecedents of flow in top IS outlets?
RQ3	How is the flow phenomenon conceptualized and operationalized in top IS outlets?
RQ4	What are the consequences of the flow phenomenon in top IS outlets?

Search Strategy. To support the search process (Step 2.1, Figure 1), we first selected libraries based on our research questions. As our goal was to provide a holistic overview on the state-of-the-art in flow research within the IS domain, our 'field' is the discipline of IS. To get an overview of high quality studies, we decided to include top-tier **IS journals** (cf. Figure 1) from the *IS Senior Scholars' basket of eight*. We also decided to include two major **IS conferences**, namely the *International Conference on Information Systems* (ICIS) and the *European Conference on Information Systems* (ECIS). The outlets were carefully selected on the basis of a ranking list (http://www.core.edu.au/conference-portal), as well as suggestions made by literature to include especially journals and conferences with high quality and reputation [23]. However, it should be mentioned, that we did not include research-in-progress papers. Based on the identified outlets and field of interest, we selected the *ISI Web of Knowledge* as **database to search** for the IS journals. In addition, we selected the *AIS Electronic Library* (AISeL) to retrieve conference proceedings (ICIS, ECIS). The **search string** to conduct our systematic search (Step 2.1, Figure 1) was developed in several steps. First, we extracted "flow" as a starting term from our research questions. Second, we used the term "flow AND information systems" to search for publications within IS using Google Scholar. By reviewing the first 20 hits and by sorting out papers without a focus on the psychological phenomenon of flow, we identified two highly cited papers. Namely, Agarwal and Karahanna [1] and Hsu and Lu [24]. By reviewing the full text, we extracted the term "cognitive absorption" and "cognitive engagement" as highly relevant flow derivations. In a third step, we searched for synonyms but did not find any appropriate synonyms for our study context. Finally, we used Boolean-operators in order to create the final search string: *flow OR cognitive engagement OR cognitive absorption*. Next, we applied the final search string to the **title**, **abstract,** and **keywords section** of publications in the specified digital libraries. We did **not limit** our search to a specific **time period**, as the aim of our SLR was to provide a holistic overview. The overall hits, as well as the final number of selected studies and the percentage distribution are depicted in Figure 1.

Study Selection Criteria. We carefully defined the following inclusion and exclusion criteria: (1) Only empirical studies were included, (2) studies using flow, cognitive engagement, or cognitive absorption in their hypothesis development were included, whereas (3) studies not referencing to the psychological phenomenon of flow were excluded. In the publication selection process (Step 2.2, Figure 1) the criteria were applied to title, abstract, and keyword section excluding 406 inappropriate studies. Second the criteria were applied to full text, again excluding 51 studies. Finally, we reviewed the references but did not find any additional publications, as our SLR is focused on the defined IS outlets and we already found all studies in the selected databases. In summary, we found 43 relevant studies.

4 Flow Streams within IS Research

As depicted in Figure 2, our SLR reveals that starting from 2002, flow received wider attention in IS research and is still very active with an increasing amount of publications. Thereby, on average three papers were published per year in top IS outlets from 2002 to 2016. As 2016 is ongoing, only two studies were found in this year. In the next sections we describe the identified four streams of flow research in IS.

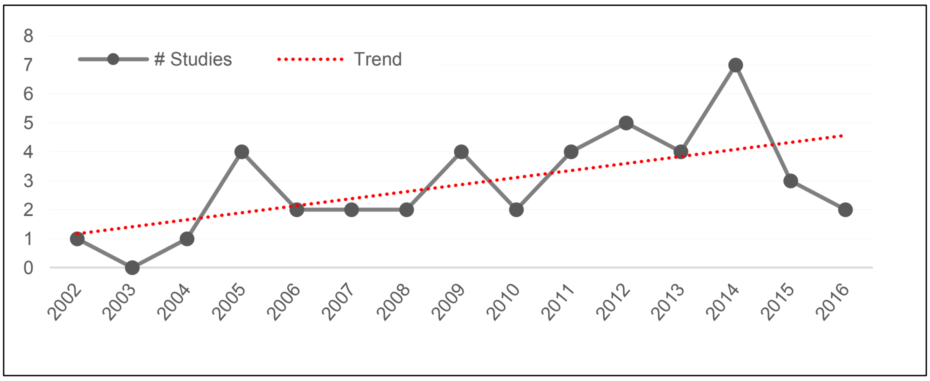

Figure 2. Distribution of Studies over the Years

Stream 1 – Jackson / Marsh / Ghani / Deshpande / Supnick / Rooney. The first stream [3, 20, 25] is based on the work of Jackson and Marsh [25] as well as Ghani et al. [3, 20] entailing nine references. Both research groups use concentration as flow construct consisting of identical items, such as "My attention was focused entirely on what I was doing." [25, p. 34] and "Attention is focused on activity" [20, p. 390]. In addition, the construct of "autotelic experience" used by Jackson and Marsh [25] and the construct of "enjoyment" used by Ghani et al. [3, 20] are highly related as both entail items of positive emotions such as fun or enjoyment [3, 20, 25]. Further, articles in this stream cite and refer particularly to both research groups when conceptualizing flow. For instance, Guo et al. [26] use concentration according to Ghani et al. [20] and combine it with dimensions from Jackson and Marsh [25]. However, it is important to note that some studies in this stream only refer to one research group (primarily Ghani et al. [3]). We assume the reason behind this dominance resides in Ghani et al.'s [3, 20] specific IS focus, whereas Jackson and Marsh [25] are originally allocated in the sports domain. Jackson and Marsh [25] developed the flow state scale in accordance with the proposed characteristics of flow suggested by Csikszentmihalyi [4, 11]. Thereby, the researchers used the following dimensions: (1) challenge-skill balance, (2) clear goals, (3) unambiguous feedback, (4) autotelic experience (5) action-awareness merging, (6) sense of control, (7) loss of self-consciousness, (8) transformation of time, and (9) concentration on the task at hand. Among these dimensions, empirical evidence has shown that **challenge-skill balance**, **clear goals**, and **unambiguous feedback** represent major antecedents of flow [27]. Supported by theory [11] and evidence in literature [28–30], the construct of **autotelic experience** (e.g., operationalized by authors as enjoyment or positive affect [8, 26]) constitutes an important outcome variable of flow. The other characteristics pertain to the phenomenon itself. Particularly, **action-awareness merging** refers to a state, where due to a deep level of involvement, an activity becomes automatic or spontaneous [25]. **Sense of control** refers to the feelings and perceptions of being in charge of the interaction [25]. **Loss of self-consciousness** is described as disappearance of concerns for the self [25]. Further, the **transformation of time** construct proposed by Jackson and Marsh [25] emphasized the altering of time (e.g., slower or faster) [25]. Finally, **concentration on the task at hand** refers to feelings of being focused and concentrated on the task at hand [25]. Ghani et al. [3, 20] conceptualize flow with two main characteristics. Enjoyment resulting from the activity and total concentration [3, 20]. This stream (as depicted in Table 2) predominantly investigates flow in the context of E-Learning and E-Commerce. Thereby flow is investigated multi-dimensionally using constructs such as concentration (66.7 %), and sense of control (55.6 %). With regard to the antecedents, artefact-related antecedents (88.9 %) are highly used. As for flow consequences, this stream predominantly uses behavior-related constructs (77.8 %).

Stream 2 – Agarwal / Karahanna / Skadberg / Kimmel. Within the second stream [1, 31] (17 reference articles), the most common conceptualization of flow is mainly based on Agarwal and Karahanna [1]. The concept of cognitive absorption (CA) includes five dimensions: (1) curiosity, (2) control, (3) focused immersion, (4) temporal dissociation, and (5) heightened enjoyment. Thereby, **control (control of interaction)** is defined as "the user's perception of being in charge of the interaction" [1, p. 673] and **curiosity** refers to "heightened arousal of sensory and cognitive curiosity" [1, p. 668] (cf. third stream). The dimension of **focused immersion** "suggests that all of the attentional resources of an individual are focused on the particular task, thereby reducing the level of cognitive burden associated with task performance." [1, p. 675] **Temporal dissociation** is defined as "the inability to register the passage of time while engaged in interaction" [1, p. 673] and finally, **heightened enjoyment** is "capturing the pleasurable aspects of the interaction" [1, p. 673]. In the same veins like Agarwal and Karahanna [1], Skadberg and Kimmel [31] also conceptualized flow with the dimensions of **enjoyment** and **time distortion** [31]. Thereby, time distortion as well as enjoyment are highly related to the construct of temporal dissociation and enjoyment suggested by Agarwal and Karahanna [1]. This stream (as depicted in Table 2) predominantly investigates flow in the context of the Web, followed by E-Learning and Virtual Worlds. Thereby, most authors in this stream investigate flow as a second-order multidimensional phenomenon through the lens of CA [1]. Constructs of focused immersion (94.1 %) and transformation of time (94.1 %) are used most dominantly. Further, artefact-related antecedents (41.2 %) are dominant, followed by person-related antecedents (23.5 %). As for the flow consequences in this stream, behavior-related constructs (82.4 %) are prior to cognition-related consequences (64.7 %).

Stream 3 – Webster / Trevino / Ryan / Ho. The third stream [2, 32, 33] entails the lowest number of references (seven articles). It originates from the studies of Webster et al. [2] and Trevino and Webster [33] who both suggested four dimensions of flow experience: (1) sense of control over the interaction, (2) curiosity, (3) intrinsic interest, and (4) attention focus [2]. In a later study, Webster and Ho [32] conceptualize the last three dimensions as cognitive engagement. Similar to the definition in the first stream, the dimensions of **sense of control** refers to the feelings of control, as well as the actual control over the interaction [2], whereas **curiosity** illustrates the arousal of sensory or cognitive curiosity [2] (cf. second stream). **Intrinsic interest** is defined as cognitive arousal as well as imagination [2]. The construct of **attention focus** suggests, that the "attention is narrowed to a limited stimulus field, filtering out irrelevant thoughts and perceptions." [2, p. 413] In this stream, authors predominantly investigate the phenomenon of flow through the lens of cognitive engagement [32]. As depicted in Table 2, authors within this stream primarily use the constructs of attention focus and intrinsic interest (both 100 %), followed by curiosity (71.4 %). With regard to the antecedents, artefact-related antecedents (71.42 %) are used most widely. Further, behavior-related constructs (85.7 %) are dominant.

Stream 4 – Novak / Hoffman / Yung / Engeser / Rheinberg. The fourth stream [5, 10, 34] addresses flow from a wider and more general perspective. Hence in Figure 3 this stream is positioned at a higher conceptual level than the other three streams. Novak et al. [5] and Hoffman and Novak [34] contributed to this stream (ten articles) by measuring flow as a one-dimensional construct with a narrative description of flow experience [5, 34]. The operationalization consists of items such as "In general, how frequently would you say you have experienced "flow" when you use the Web?" [5, p. 28]. Similarly, Engeser and Rheinberg [10] also contributed to this stream on a higher conceptual level as they propose a comprehensive flow short scale to measure flow during all activities [10]. Conducting a factor analysis, the researchers found two overreaching and broadly defined factors which they labeled "fluency" and "absorption" consisting of items such as "My thoughts/activities run fluid and smoothly", or "I am completely lost in thoughts" [10, p. 170]. This stream predominantly investigates flow in the context of the Web and Games. With regard to the antecedents, artefact-related antecedents (50 %) are used most. As for flow consequences, all studies include behavior-related constructs in this stream.

Table 2. Flow Streams in Top IS Outlets

5 Integrative Theoretical Framework of Flow in IS Research

In order to address RQ1, we follow the approach of Baumeister and Leary [14] and conceptualize the results of the extant literature in an integrative theoretical framework [14]. By reviewing our final set of primary studies, several interesting patterns appear. First, all of the studies explicitly or implicitly subdivide their research models into *flow antecedents*, *flow experience*, and *flow consequences* [26]. As the separation of flow into this threefold pattern is also generally agreed upon in IS literature [3, 6, 12, 20], we adopt this separation for our theoretical framework.

Flow antecedents. We found that some of the antecedents are related to **tasks-characteristics,** such as clarity of goals [36], and immediate feedback on the task [26]. Other antecedents of flow are related to the **UI**. For instance, in one study, scholars manipulate filler interfaces on travel booking sites to evaluate the effects on flow and perceived waiting time [47]. In a third category of studies, researchers investigate **person-characteristics**, such as gender [54]. Therefore, we follow the approach of Finneran and Zhang [6] and sub-divide antecedents of flow into (1) **P**erson, (2) **A**rtefact, and (3) **T**ask (*PAT-Framework)*. Moreover, in reviewing the results of the extant literature, we do find several constructs rather allocated between the categories of person, artefact, and task. For instance, researchers investigated the influence of skill-demand balance on flow [8, 27, 43]. As such, the balance between demand and skill is neither a pure task-characteristic nor a pure person-characteristic. Similarly, other characteristics, such as user experience (allocated between person and artefact) and the representation of tasks (allocated between artefact and task) are allocated between two characteristics. Thus, we introduce categories between the defined antecedents-sections of person, task, and artefact as depicted in Figure 3.

Flow consequences. We identified three major categories of flow consequences: (1) **cognition**, (2) **affect**, and (3) **behavior**. The proposed categories are well-rooted in recent social psychology research, suggesting that attitude consists of these three distinct dimensions [64]. The affect-related component constitutes the hedonic aspect of the attitude towards an IS, such as moods and emotions. In contrast, the cognition-related component constitutes the utilitarian aspect based on beliefs such as ease of use or usefulness. The behavior-related component depicts the response resulting from affect and cognition (e.g., the intention to use an IS). As we found studies investigating the flow impact on performance, we also add performance to the consequence-section.

Flow experience. With regard to flow, we do not consider autotelic experience as part of flow because Csikszentmihalyi [4, 11] argued that positive affect and flow are two distinct constructs. Thereby, the suggestions made by theorists are also relined by evidence of recent research in this direction [28–30]. In order to integrate the various flow constructs used in IS research (cf. stream section), we first extracted constructs related to the flow dimension of **absorption** [8]. By reviewing six stream research teams [1–3, 20, 25, 32], we extract four constructs. In a second step, we analyze the construct definition and operationalization and identify two distinct constructs, namely, **focused immersion** and **concentration**. Thereby the constructs differ in conceptualization as well as operationalization. **Concentration** consists of items measuring focus, concentration, absorption, and attention [3, 20, 25], whereas **focused**

immersion measures absorption, immersion, the blocking of other attentional demand, and if an individual's attention is distracted easily or not [1]. Focused immersion "suggests that all of the attentional resources of an individual are focused on the particular task, thereby reducing the level of cognitive burden associated with task performance" [1, p. 675]. In a second step, we extract and compare different conceptualizations of time-related constructs used by three authors [1, 25, 31]. As result, we identify two distinct constructs. **Temporal dissociation** emphasize a lost sense of time and a faster time passage [1, 31], whereas **transformation of time** emphasizes the altering of time (slower, faster or stop of time) [25]. As Jackson and Marsh [25] also proposed constructs related to absorption, we add **loss of self-consciousness** and **action-awareness merging** to the integrative theoretical framework. Next, we extract and integrate dimensions used to measure **control**. Thereby, we identify three control-related constructs suggested by literature [1, 2, 25]. By reviewing the conceptualization as well as the operationalization, we identify two distinct constructs. **Control of the interaction** refers to the feelings and perceptions of being in charge of the interaction but also to the actual control over the interaction [1, 2]. In contrast, **sense of control** is solely referring to feelings of being in charge [25]. Finally, by complementing our framework with the dimension of **cognitive engagement** proposed by Webster and Ho [32] and the related dimensions **curiosity**, **intrinsic interest,** and **attention focus** [32], we finalize our integrative theoretical framework as depicted in Figure 3. To provide a comprehensive overview, the framework also lists all research teams in the four streams and maps them to the identified constructs.

Figure 3. Integrative Theoretical Framework of Flow in IS Research

6 Discussion, Future Directions and Conclusion

Despite the growing relevance of the flow construct within IS research for understanding user behaviour and informing the design of IS artefacts, challenges remain in terms of its conceptualization, reliability, and validity [5–9]. We provided a holistic overview on the state-of-the-art in flow research within top IS outlets. In the following we discuss our results along the previously defined four research questions.

Discussion. As for **RQ1**, we identify four major flow streams and comprehensively describe them in Section 4. Reviewing the extant literature, we present an integrative theoretical framework conceptualizing the state-of-the-art in flow research (cf. Figure 3). Further, we map the identified stream research teams to our framework identifying overlaps and differences across the streams. Such understanding supports IS researchers and practitioners to get an overview of the major dimensions to consider when investigating the flow phenomenon. As for **RQ2**, pertaining to the antecedents of flow, we find that most studies use artefact-related antecedents (25 studies) and investigate their effect on flow. The second most used antecedent category is located between person and artefact (15 studies). Furthermore, seven studies investigate antecedents located between person and task (e.g., challenge-skill balance) and another seven studies focus on person-related antecedents, such as skills and personal innovativeness. Finally, six studies use task-related antecedents, such as clarity of goals and investigate. Pertaining to the operationalization of flow in IS research (**RQ3**), our review reveals 11 distinct flow constructs. As depicted in Figure 3, these constructs can be categorized into absorption, control, and cognitive engagement. By mapping the four major streams to the different flow constructs, it becomes apparent that there is a different emphasis on flow dimensions across the literature. While some streams focus on a more general understanding of flow (S4), other streams aim at a more detailed understanding of absorption and control (S1), or focus primarily on cognitive engagement (S3). Finally, with respect to the flow consequences (**RQ4**), our review reveals that almost all of the reviewed studies measure behavior-related consequences (37 studies). The operationalization of this measurement varies though, with 32 studies focusing on behavior-related intentions (e.g., continuance intention, or the intention to buy online), while five studies measured actual user behavior (e.g., actual technology usage or actual continuance in an E-Learning course). Further, there is also a focus on cognition and affect-related consequences of flow. In 20 studies, cognition-related consequences of flow (e.g., ease of use) are measured, whereas 12 studies describe affect-related consequences (e.g., enjoyment). With regard to performance, four studies assessed perceived performance as flow consequence. Finally, another four studies measured performance outcomes objectively (e.g., time for task completion).

Future directions. Our findings suggests several important future directions in IS flow research. First, four major streams were identified in this SLR. However, it became apparent that some streams address flow from a wider and more general perspective, while others apply a more detailed perspective, focusing on different dimensions of flow. In order to contribute to a profound understanding of flow in user experience engineering, future research may reconcile the different views and conceptualizations of flow, thereby establishing a unified theory of flow in IS research.

Second, with regard to flow antecedents, the study of Finneran and Zhang [6] proposes testable propositions that future research could address in a series of (controlled) lab experiments. For instance, understanding whether a clear fit between task and artefact leads to a flow experience could comprise a promising starting point in this direction. In addition, future research should also examine the antecedents located between person and task (e.g., challenge-skill balance), user-related antecedents (e.g., skill, gender etc.), and task-related antecedents (e.g., clarity of goals), which are so far scarcely addressed. With regard to the antecedent category of IS artefacts, which represents the category with the highest number of research studies, many undiscovered artefact characteristics are still not investigated using the lens of flow theory. For instance, future research may uncover if and how IT-mediated interruptions influence the perception of flow and what characteristics of the interruption are affecting flow. Third, additional work is needed on flow consequences. Our SLR revealed that objectively measured performance outcomes are scarce (four studies). Thereby, literature reports contradicting findings in whether flow leads to higher performance or not, hinting at the importance of considering further characteristics of the user environment, which might explain such differences. Thus, using objectively measured performance outcomes may provide valuable new insights for this ongoing discussion, particularly when applied to different contexts. Finally, our SLR reveals that at this stage only one study in top IS outlets employed neurophysiological measurements to investigate flow [43]. However, considering neurophysiological measurements of flow seems to be a promising research avenue, as flow may appear only briefly during activities and such neurophysiological measurements enable the researcher to analyze flow in situations without interrupting the user. Hence, future studies may put further emphasis on complementing self-reported flow measurement scales with neurophysiological measurements, such as electroencephalography, eye tracking, skin conductance, and heart rate.

We are aware that our paper has **limitations**. Due to the focus on top IS outlets (basket of eight, ECIS, and ICIS), promising articles from other reference disciplines (e.g., psychology) were sorted out. However, including top IS outlets in SLR represents a common practice within IS research as "major contributions are likely to be in the leading journals" and conferences [23, p. xvi]. Further, any bias in the selected keywords may also provoke a bias in the conceptualization. To reduce this probability, we carefully subdivided our SLR activities into three stages (plan, conduct, and report; cf. Figure 1) following the structured guidelines by Kitchenham [22].

Conclusion. With the advances in user experience engineering, the phenomenon of flow has become increasingly relevant for IS research and practice. Designing highly interactive and engaging interfaces requires a profound understanding of the flow phenomenon and its role in user experience in pre- and post-adoptive scenarios. By identifying the various streams of flow-related studies in IS research and conceptualizing these streams in an integrative theoretical framework along the dimensions of absorption, control, and cognitive engagement, we hope that this paper contributes to reconcile the numerous ways the flow construct has been operationalized in IS research. We believe that a unified conceptualization of flow in future research will be a cornerstone of user experience engineering and the design of engaging IS artefacts.

Principles in the Design of Mobile Medical Apps: Guidance for Those who Care

Kenny R. Lienhard and Christine Legner

University of Lausanne, Faculty of Business and Economics (HEC), Department of Information Systems, Lausanne, Switzerland
{kenny.lienhard,christine.legner}@unil.ch

Abstract. The promises of mobile technology in healthcare have led to a great many mobile apps in public app stores that target patients with specific illnesses. Medical experts have criticized the status quo of mobile medical apps owing to the low level of professional medical involvement in mobile app design, leading to weak clinical performance and a poor integration of these tools into clinical practice. Grounded in an action design research study, we build and evaluate a mobile app for elderly patients with age-related macular degeneration. We formalize our learnings and provide a set of design principles to guide the effective and feasible construction of mobile medical apps. Our study systematically develops design knowledge that helps to bridge the current gap between the rapid advances in mobile technology and the specific needs of the healthcare sector.

Keywords: mobile health, mobile medical app, mobile patient monitoring, healthcare, design science

1 Introduction

Mobile applications (mobile apps) are seen as a potentially transformative technology that provides individual level support to healthcare consumers and new ways for physicians to partner and interact with their patients. While information used for personal healthcare is traditionally captured via self-reporting surveys and doctor consultations, mobile devices with embedded sensors offer opportunities to establish a continued exchange of information between patients and physicians. Such information exchanges are particularly important concerning patients with chronic illnesses. The promises of mobile health and cutting-edge mobile technologies have led to a great many mobile health apps in public app stores. The two largest mobile platforms, Android and iOS, host more than 165,000 mobile apps on medical topics, of which 9% address topics of screening, diagnosis and monitoring a broad spectrum of illnesses [1]. We focus on this category, and refer to them as *mobile medical apps*.

Innovation in mobile technology has outpaced the critical evaluation of the impact of mobile medical apps [2, 3]. Medical experts have criticized the current state of mobile medical apps, because they are predominantly technology-driven and thus fail to meet the requirements of clinical practice [2]. While existing mobile apps over-

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Lienhard, K.R.; Legner, C. (2017): Principles in the Design of Mobile Medical Apps: Guidance for Those who Care, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1066-1080

emphasize technological aspects, they tend to poorly integrate medical expertise [4]. For instance, only 32% of 63 mobile apps that target patients with colorectal diseases were built based on medical professionals' input on development and content [5]. In another study, a mobile app for melanoma risk assessment available on public app stores was compared with an experienced physician's risk assessment for low-risk and high-risk lesions [6]. The researchers found that the mobile app's sensitivity (i.e. its ability to correctly identify those with a disease) was 20% and its specificity (i.e. its ability to correctly identify those without the disease) 92%. The low involvement rate of medical professionals not only increases the risk that ineffective or even potentially harmful tools will be used by patients, it also leads to a poor acceptance rate of mobile medical apps among physicians and therefore a low integration of these tools into daily clinical practice [7]. Based on these studies, we argue that integrating software developers' and medical professionals' expertise is a prerequisite for designing successful mobile medical apps. However, we still lack knowledge about how to best design mobile medical apps that integrate both aspects. We address this gap in the research with the following research question: *What are suitable principles in mobile medical app design?*

Our research follows a design science research approach "that uses artifact design and construction (learning through building) to generate new knowledge and insights into a class of problems" [8]. In a 30-month action design research (ADR) [9] study, we worked in an interdisciplinary team of researchers and practitioners to develop a mobile medical app for elderly patients with low vision due to cases of age-related macular degeneration. Age-related macular degeneration is a form of sight loss caused by damage to the retina. The result is a shadowlike void in the center of a patient's visual field. We evaluated our artifact in two clinical studies with 124 patients and continuously reflected on learnings, which allowed us to generate design knowledge throughout the process and to refine insights when new inputs became available. We have formulated and transformed our learnings into a generic set of design principles that guide the effective and feasible construction of mobile medical apps. Here, we systematically develop design knowledge that helps to bridge the current gap between the rapid advances in mobile technology and the creation of sustainable mobile app solutions in the healthcare sector.

The paper proceeds as follows. In Section 2, we provide a background on the literature of our study, identify the gap in the research, and formalize the research question. We then describe the research method. Next, we present Alleye – a mobile app that targets patients with age-related macular degeneration. In Section 5, we formalize the learnings from our project and present a set of principles to guide mobile medical app design. Finally, we summarize our paper's contributions, describe the research limitations, and provide an outlook for future research.

2 Background

Mobile medical apps leverage modern mobile devices such as smartphones and tablet computers, built-in sensor technology, and related software development kits (SDKs) to screen, diagnose, and monitor a patient's illness. Screening is the routine examination of individuals for indications of illness or of high risk for illness [10]. Diagnosis is the inferred state that an illness is present in a person [10]. Mobile patient monitoring uses "technology to manage, monitor, and treat a patient's illness from a distance" [11] once an illness has been attributed to an individual.

A number of studies have developed mobile app solutions for particular illnesses, including diabetes [12, 13], asthma [14], and depression [15], and have reported lessons learnt. Goyal et al. [13] take a user-centered design approach, ensuring that the features of a mobile app are informed by the needs of patients with type 2 diabetes. The resulting application allows patients to self-monitor their physical activities, diets, and weights, to identify glycemic control patterns in relation to their lifestyles, and to guide them towards remedial decision-making. Årsand et al. [12] illustrate that their mobile app can motivate type 2 diabetes patients to think about how they can improve their health. The authors conclude that their system has the potential to support the collaboration between patients and clinicians. In another study, Oresko et al. [16] integrate a Holter monitor with mobile technology and develop smartphone-based cardiovascular disease detection. Another study presents a remote monitoring system for elderly patients with multiple chronic conditions [17] that allows users to see current medical reports on their smartphones based on sensor data, to perform new measurements, and to communicate with caregivers via the mobile app. Schnall et al.'s study evaluates existing mobile apps for patients living with HIV and concludes that the design of such mobile apps requires a thoughtful, patient-centered, and evidence-based approach [18].

From a medical perspective, recent healthcare research has revealed that a large number of mobile apps available in public app stores are not based on empirical evidence [19]. These shortcomings can have serious consequences. For instance, Wolf et al. [20] measure the performance of four mobile apps that evaluate photographs of skin lesions. When such a picture is evaluated, the mobile app gives the user feedback about the likelihood of malignancy. The sensitivity of the investigated mobile apps ranged from 6.8% to 98.1%. Hamilton and Brady [4] link the weak performance of some existing mobile apps to low professional medical involvement in the design of mobile apps. Based on the analysis of 111 mobile apps that focus on pain management, one study found that the content of mobile apps contain misleading claims and a lack of academic references [7].

Software technology-oriented communities suggest mobile health frameworks that target developers of mobile apps [21, 22]. One study provides an ontology-based context model and a related application framework that focuses on alarm notification in chronic patient care [22]. Broens et al. [21] suggest a framework to facilitate the use of contextual information (i.e. context acquisition, context provisioning, and context reasoning) for user-tailored mobile apps. While mobile health frameworks are valuable to ensure software component re-usability or functional decomposition, they target the project's implementation phase rather than the design and conceptualization of a mobile medical app. Other studies suggest specific architectural approaches for mobile health app usage [23]. For instance, Kumar et al. [24] performed a comprehensive survey on the use of ubiquitous computing for remote cardiac patient monitoring. They discuss the architecture and quality of service characteristics of the underlying platform for mobile cardiac monitoring systems.

We identified two research opportunities in the scientific literature. First, current studies on mobile medical apps mainly report on the design of illness-specific tools without abstracting higher-level concepts or design principles from their specific solutions. This makes it difficult to apply the learnings from one illness-specific study to the design of a mobile medical app in another context. Second, the rapid advances in mobile technology outpace the rigorous and critical evaluation of the impacts of mobile apps. This leads to a situation in which mobile medical apps continue to proliferate, with little evidence of their effectiveness and little support for understanding how best to design these tools [2]. We build on these gaps in the research and seek to answer the following research question: *What are suitable principles in mobile medical app design?*

3 Research Method

Considering our research goal, we opted for the design science research paradigm, which emphasizes a construction-oriented view of information systems (IS), i.e. research centered around designing and building innovative information technology (IT) artifacts to solve the identified business needs [25]. The research we present here derives rigor from the effective use of the medical and the IS knowledge bases. Our research process followed the ADR approach proposed by Sein et al. [9], a research method for "generating prescriptive design knowledge through building and evaluating ensemble IT artifacts in an organizational setting" (see Figure 1). The ADR project we present here was an engaged research collaboration between academics (two medical and two IS researchers) and practitioners (two senior physicians, a graphic designer, and a software developer). Our ADR study seeks to build and evaluate an innovative IT artifact (i.e. a mobile medical app) and uses heuristic theorizing to synthesize information about artifact solution [26]. The ADR project started in November 2013 with the problem formulation and continued with two building, intervention, and evaluation cycles. The project reached its first complete state in May 2016, when we formalized our learnings from constructing the IT artifact into a set of design principles.

Problem formulation: Our research was driven by the practical need to design a mobile medical app that provides a way for patients to participate in the identification of age-related macular degeneration and the monitoring of this illness. Our case is particularly interesting from both a medical and an IS perspective. From a medical perspective, global projections of any age-related macular degeneration cases are 196 million by 2020, rising to 288 million in 2040 [27]. Current treatment regimens in age-related macular degeneration are suboptimal, owing to 1) the late identification of treatable age-related macular degeneration, 2) non-individualized treatment leading to under-treatment in about 30% of patients, and 3) the challenge to identify the best time for re-treatment after successful treatment and/or treatment suspension. From an IS design perspective, the patients are elderly people who are usually not familiar with touch-based mobile devices; also, owing to their limited vision, it becomes particularly challenging to design an easy-to-use mobile app. Our research effort can be classified as IT-dominant [9], since it emphasizes creating an innovative technological design as its outcome. Our review of extant literature about mobile medical apps revealed that existing studies often report on the design of illness-specific tools, which makes it difficult to transfer their findings when constructing an artifact in another context.

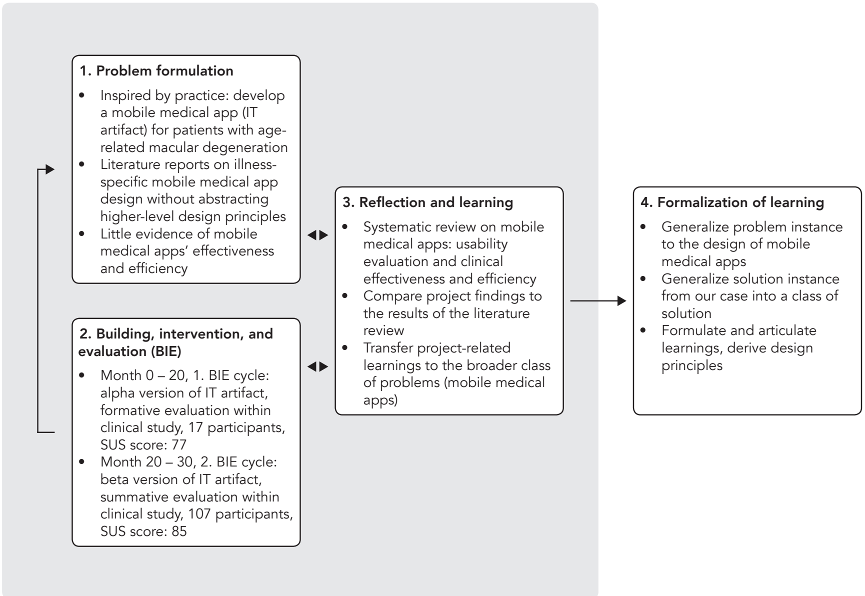

Figure 1. Action Design Research Process (following Sein et al. [9])

Building, intervention, and evaluation (BIE): We built the IT artifact in an agile software development approach with short iterations. During the building phases, we conducted regular meetings (approx. every second week) to evaluate current prototypes in the project team. Each meeting led to new requirements and guided the development of the next prototype version, which we then distributed to members of the ADR team. Overall, we created more than 50 prototypes. Collected data (e.g. field notes from meetings, emails, and visualizations of graphic user interfaces) informed the design of the next prototype version. We also used the prototypes for research purposes, since the data provided us with a history of errors and learnings from the building phases. During the first BIE cycle, we built and evaluated an alpha version of the mobile medical app that included all the functionalities with a strong focus on the measurement task. At that stage, we did not prioritize the presentation and interpretation of the test results in way that is easy to understand by patients. After a project duration of 18 months, we engaged in a naturalistic formative evaluation to determine areas for improvement and refinement of our alpha version. The clinical study took place at the Department of Ophthalmology of the Cantonal Hospital of

Lucerne – Switzerland's largest public eye clinic. This study, in which 17 patients took part, was approved by the Ethics Committee and allowed us to get first-hand feedback from potential end-users. Each patient provided written informed consent. All patients who had had an ophthalmological consultation at the hospital's eye clinic between June and October 2014 were evaluated for inclusion. Patients were excluded if they were unable to use the mobile medical app, i.e. owing to cognitive or visual problems. Patients had a mean age of 78.1 years, and the proportion of women was 53%. Of the participants, 13% used a smartphone daily, while 60% had never used one. During the clinical study, the measurement task had to be executed three times per week, between two routine clinical visits (approx. one month). After data cleaning, we had 240 measurement results.

In the second BIE cycle, we implemented the learnings from the first BIE cycle to build a beta version of the mobile app. The beta version's aim was to be self-explanatory to patients, which required a complete re-design of the user interface and easy-to-understand communication of the measurement results. After several iterations and new prototype versions, we performed a second clinical study as a naturalistic summative evaluation of the IT artifact. We enrolled 107 patients in this study. All patients who had had an ophthalmological consultation at the hospital's eye clinic were evaluated for inclusion. Participants provided written informed consent, and the study was approved by the Ethics Committee. This time, the patients had a mean age of 72.8 years, and the proportion of women was 47%. Of these participants, 40% used a smartphone daily and 53% had never used a smartphone. Compared to the first clinical study, we did not only provide iPod touch devices with the mobile app pre-installed; patients could also use their own smartphone and could download the mobile app via the Apple app store. Of the patients, 29 used their own device. The participants performed repeated self-monitoring measurements between monthly ophthalmological examinations. We collected more than 4,500 measurement results over this clinical study.

In both clinical studies, patients provided oral feedback on the mobile app's user-friendliness, answered pre-defined questions of interest, and filled out the System Usability Scale (SUS). Originally developed by Brooke [28], the SUS is a valid and reliable tool for measuring usability [29]. The SUS has received much attention in the scientific community and, after 30 years from its initial presentation, "has certainly stood the test of time" [29]. In view of the fact that the study participants were elderly patients with substantial visual impairment, and sometimes also impaired cognitive functions, we opted for the short, straightforward SUS as an evaluation instrument. Based on the 500 tools investigated as reference, a SUS score higher than 68 is considered to be above-average [30]. Since the participants in our clinical study were native German speakers, we relied on a German translation of the SUS that was made available via a crowdsourcing project [31].

Reflection and learning: We conducted reflection and learning cycles in parallel to the two BIE cycles. To get an overview of the current state of mobile medical apps, and to learn about their clinical effectiveness and efficiency, we collaborated with medical researchers to perform a comprehensive literature review that integrated the medical and the IS perspectives. We continuously consulted the collected data from the ADR project, i.e. the history of prototypes, presentation material, emails, questionnaire results, opinions from study participants, and measurement results. This allowed us to compare our findings to the literature review results and to apply our situated learning to findings that apply to a broader class of problems. The outcome of the reflection and learning stage was a preliminary set of design principles.

Formalization of learning: Following Sein et al. [9], we distinguish between three levels for this conceptual move. First, we generalized the problem instance to the design of mobile apps that support the monitoring and screening of specific illnesses. Second, we generalized the solutions instance into a class of solution, abstracting highly specific solutions concepts from our own ADR project to make the concepts applicable to the entire class of problems. Third, we captured the knowledge gained in developing an illness-related mobile medical app. Building on the design principles we identified and refined in the previous stage, we fully formulated and articulated our learnings. In the derivation of the design principles, we followed the heuristic theorizing framework suggested by Gregory and Muntermann [26].

4 A Mobile Medical App for Age-related Macular Degeneration

In an engaged academic-practitioner relationship, we built and evaluated Alleye – a mobile app that seeks to provide a way for patients to participate in screening and monitoring age-related macular degeneration. We created this mobile app for Apple's iPhone and the iPod touch, targeting iOS 8.0 and later. It builds on HTML5 technologies and is wrapped inside a web view that provides access to native platform features such as a camera and secure storage. The mobile app has four components: instructions, setup, measurement, and feedback (see Figure 2). For the instructions, Alleye includes a help-center with visual graphics explaining all the functionalities. These graphics were also used by the research assistant to explain the mobile app's use during clinical studies, and patients received a printed booklet with large visual graphics and brief explanations. During initial setup, the patient must insert a unique identification code, so as to match measurement results with his or her electronic health records at the eye clinic. Patients choose to perform the measurement task in training mode or in test mode. The measurement task implemented in Alleye is based on a computerized version of a Vernier hyperacuity alignment task. Hyperacuity is a property of our visual system that allows us to see straight lines as straight. The term derives from the fact that it detects misalignments of borders with a precision that is up to 10 times better than visual acuity. In Alleye, we implemented an alignment task that examines the extent to which the visual system is capable to see straight lines as straight. The performance of an individual completing the measurement task empirically measures the hyperacuity level. Owing to the fact that a drop in hyperacuity precedes a drop in visual acuity, Alleye is capable to detect a decrease of visual acuity before a person sees less. Since this task is monocular (i.e. only the treated eye is open), the patients must select an eye (left or right) before they begin to measure. At the end of each measurement, the patient confirms that the measurement is valid (e.g. that there have been no disturbances). Feedback is provided right after the patient successfully completes a measurement task. The feedback indicates a score and a color scheme inspired by traffic lights, comparing the score to previous test results.

The alpha version of Alleye's user interface followed generic practical guidelines for mobile development. During evaluation in a real-life medical setting, 17 patients reported an average SUS score of 77. From a medical perspective, the first clinical study revealed that the measurement task (i.e. the assessment of the hyperacuity level) is a promising instrument for screening and monitoring patients with age-related macular degeneration. However, we encountered some issues with the mobile app design. For instance, patients could hardly read written text, had difficulties with insufficient color contrast, and the navigation (based on a standard icon-based menu) was unclear to them. To re-design the user interface during the build phase of the second BIE cycle, we simulated the look of the user interface for patients with limited vision and a shadowlike void in the center of their visual field by holding a filter over the mobile device. This provided important insights into the use of colors, minimum font size, or the number of words that should appear on one screen. Further, we implemented a very structured navigation (i.e. minimizing variability via limited navigation options) with buttons occupying the entire screen width in order to guide patients along the mobile app's four components (instruction, setup, measurement, and feedback). The complete redesign of the user interface during the build phase of the second BIE cycle did not impact the measurement task, and captured clinical data could still be compared between the two clinical studies.

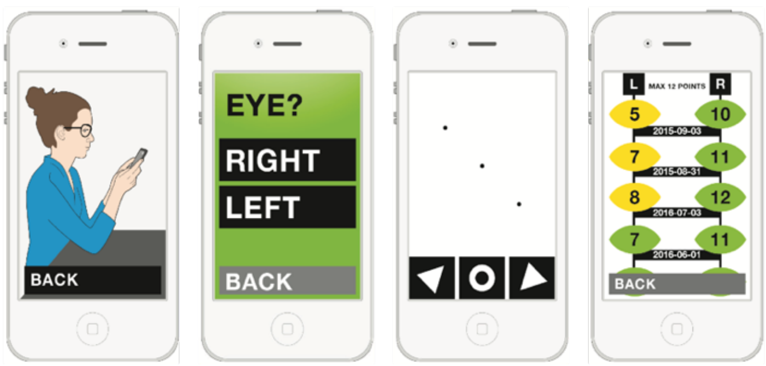

Figure 2. Screenshots of Alleye: Instructions, Setup, Measurement, and Feedback

The second clinical study sought to test the mobile app' use over several months in a real-world medical setting. This would help us to gather data for a longitudinal clinical study and to learn whether or not patients were willing to adopt Alleye and its re-designed user interface. Of 107 patients, 83 provided oral feedback on user-friendliness and filled out the SUS. Compared to the first BIE cycle, the SUS score increased from 77 to 85. We corrected for age and frequent smartphone use in the SUS analysis. In the unadjusted analysis, the estimated mean increase in the SUS score was 8.2 (95% CI: 1.3 to 15.1), while in the adjusted analysis the estimated mean increase in the SUS score only dropped slightly (average SUS score increase 7.5, 95% CI: 0.5 to 14.4, $p = 0.036$). Thus, the user interface optimized for patients with age-related macular degeneration created a higher SUS score. This score was confirmed by oral feedback from patients and a decrease in the help needed by the research assistant to explain the mobile app's usage.

5 Principles in Designing Mobile Medical Apps

Based on the insights gained from the BIE cycles and reviews of other studies on mobile medical apps, we derived four design principles. The design principles' purpose and scope are to provide guidance on how to design mobile medical apps. They capture the knowledge gained about the development of Alleye, and formalize this knowledge to guide the design of other instances of the same class. Justificatory knowledge represents insights from the literature that inform, explain, and validate our design decisions. Table 1 summarizes the design principles, exemplary instantiation based on our research project, and justificatory knowledge.

Table 1. Design Principles and Exemplary Instantiation

Design principles	*Instantiation in Alleye*	*Justificatory knowledge*
DP1: Mobile medical apps should consist of four functional components that guide a patient: instruction, setup, clinical measurement, and analysis and feedback.	• Instruction: help center in mobile app • Setup: identification, select eye for testing • Measurement: alignment task • Analysis and feedback: score and color scheme	[23]
DP2: The user interface should be adapted to cope with patients' physical and cognitive restrictions.	• Limited vision: high color contrast, large font sizes, and buttons that occupy screen width • Cognitive restrictions: limited navigation options, simplify medical information	[32, 33]
DP3: A mobile medical app should build on a robust medical knowledge base, ensuring an evidence-based approach to mobile app design.	• Measurement: hyperacuity level informs diagnosis of age-related macular degeneration • User interface and the use of sensor technology remain independent of the medical knowledge base	[4, 7, 20]
DP4: Mobile medical apps should facilitate both patients' and physicians' routines.	• Instructions trigger conversation between the patient and the physician • Patient feedback should be aligned with actions that the physician can manage and is integrated into his or her routines	[34, 35]

Design principle 1 (DP1): Mobile medical apps should consist of four functional components that guide a patient: instruction, setup, clinical measurement, and analysis and feedback. From our experiences with Alleye, we found that mobile medical apps have four stable functional components that are specific for patient screening and monitoring. Given the logical order of these components, primary navigation elements of mobile medical apps should be structured along these four building blocks in order to provide a patient with guidance. Estrin and Sim [23] present similar components in their seminal paper on an open mobile health architecture, but focus more on technical aspects and leave out the instruction component. The latter is important because it assists the patient through the mobile app's usage and provides explanations on the setup, the clinical measurement task, and the provided feedback. Instructions might be communicated via graphics, audio, and/or videos that support patients who have difficulties reading text. The setup component is crucial to prepare the measurement and to provide context-specific information relevant to perform and analyze the measurement task. For instance, personal data such as weight, age, clinical data, or configuration options might modify the measurement task, are important factors to interpret measurement results, or have diagnostic value (i.e. modify the probability of the presence of the illness). The illness-related measurement is key to the mobile medical app. The analysis and feedback component provides the patient with information about his or her measurement results and might suggest context-specific actions such as the advice to contact a physician. At the same time, feedback should motivate the patient to continue performing clinical measurements. For instance, Marin et al. [36] suggest serious games as a means to keep patients engaged.

Design principle 2 (DP2): The user interface should be adapted to cope with patients' physical and cognitive restrictions. In the development of Alleye, we experienced the limitations of general human interface guidelines provided by mobile platform providers to design mobile apps that target their operating systems. These guidelines provide various user interface patterns, which are helpful to design mobile apps that target a broad audience. However, as we have seen with Alleye, the same human interface guidelines do not consider the very specific limitations of patient groups such as impaired vision, cognitive impairment, or limited motor functions. Designers of mobile medical app should bear in mind end-users' physical and cognitive restrictions [32, 33]. For instance, patients with Parkinson's disease might have difficulties entering data via a smartphone's tiny keyboard. Thus, Parkinson's patients could be provided with structured forms and large buttons to enter data. On the other hand, patients with poor vision can be provided with audio guides and speech recognition instead of written guidance and text fields to enter data. For building the user interface, it is helpful to simulate end-user limitations, so that the designer feels how the mobile app's form and functions works in the hands of future users. In our project, the physicians guided the implementation of this simulation to ensure that designers work with scenarios that are realistic to real-life occurrences. In the case of Alleye, studies on user interface design for elderly people informed the mobile app's development. However, usability studies have certain limitations, since they focus on a user's physical limitations rather than on cognitive restrictions. With

Alleye, we have seen that presenting correct, unbiased information that is hardly understandable by patients not only renders this information useless, but can also cause misunderstandings in patient-physician communication. An evaluation with potential users was required to ensure that patients have the cognitive capabilities to understand the information communicated via the mobile medical app.

Design principle 3 (DP3): A mobile medical app should build on a robust medical knowledge base, ensuring an evidence-based approach to mobile app design. A robust medical knowledge base builds trust among physicians [4, 7], laying the ground for an implementation of mobile medical apps in clinical practice. In Alleye, the assessment of the hyperacuity level informs the diagnosis of age-related macular degeneration. Our mobile app builds on this principle, which is robust. In the course of the use of Alleye, the medical knowledge base might inform us that the changes in hyperacuity are not the same in the various retinal conditions. It might also inform us that, besides hyperacuity, other easily accessible parameters can be measured. While the availability of new sensors embedded in mobile devices might facilitate or even enable the measurement of additional signs and symptoms, they do not necessarily impact the biological model. Advances in mobile technology that impact the mobile app's underlying medical knowledge base would require the mobile app to be clinically reassessed, ensuring that the approach to mobile app design remains evidence-based. While it is very likely that mobile medical apps' forms and functions require adaption and optimization over time owing to technological advances, the underlying biological models and particularly the manifestations (signs and symptoms) of an underlying illness remain fairly stable over time. This is crucial from a medical perspective. Only the stable measurement of clinical parameters allows medical researchers to perform longitudinal clinical studies, and physicians in the hospital can compare a patient's test results over a certain timeframe.

Design principle 4 (DP4): Mobile medical apps should facilitate both patients' and physicians' routines. Patients potentially have a long-term relationship with their physicians. In our project, instructions within Alleye were designed with a specific purpose: They should allow a physician to explain to the patient the mobile app's usage within a few minutes. After basic instructions, the mobile app's use should be self-explanatory. With Alleye, we also learnt that feedback provided after the measurement tasks should be aligned with actions that can be handled by a medical practice. For instance, if the mobile app asks a patient to contact his or her physician because his or her measurement task scores are decreasing, the physician in the medical practice must be aware of the meaning of this call to action. Mobile medical apps offer unique opportunities to improve the quality of the patient-physician relationship [34], since they allow for a continued exchange of clinically useful information that might have remained unrevealed during a routine consultation; such exchanges are of great importance for chronic illnesses in particular. Thus, the design of a mobile medical app for patients is not something that can be done in isolation. Any design of patient routines is linked to the design of the physician's clinical routines. To be fully implemented in routine patient care, it is crucial that a mobile medical app considers requirements from clinical practice. This impacts especially two functional components: instruction (trigger of a patient's routine) and feedback (call to action at the end of a patient's routine). On the one hand, physicians need to explain to the patient the mobile app's use (instructions). This new task should be implemented in existing clinical routines. On the other hand, data collected via a mobile app should become part of the physician's decision-making process. Thus, the mobile app might ask a patient to contact their physician for consultation if their measurement results worsen. The integration of mobile medical apps into clinical routines faces several hurdles, including a lack of knowledge or training on mobile medical apps or incompatibility with current healthcare practices and technology platforms [34]. It is only when physicians adapt their clinical routines to a patient's use of mobile medical apps that the technology's potential can be fully explored.

While DP1 identifies the functional components that guide a patient in using a mobile medical app, DP2 to DP4 provide specific insights on a mobile medical app's architectural design. The identified design principles foster a patient-physician relationship, ensuring that both the patient's and the physician's requirements are addressed when designing a mobile medical app.

6 Conclusion

Mobile medical apps continue to proliferate, with little evidence of their clinical effectiveness and efficiency. From a bottom-up perspective, a number of studies have focused on illness-specific cases of mobile medical apps (e.g. [13–15]). While these studies have revealed important illness-specific insights on building mobile apps in their specific domain, their findings were hardly generalizable to other illnesses. From a top-down perspective, more software technology-oriented approaches provided abstract mobile health frameworks (e.g. [21, 22]) that can be implemented in a broad range of mobile medical apps. This paper links these two research streams by generalizing the solution instance (i.e. a mobile app that targets patients with age-related macular degeneration) into a class of solution. Thus, we abstracted highly specific solution concepts from our project to make the concepts applicable to the entire class of problems (i.e. a mobile medical app that targets patients with a specific illness). Therefore, our study is among the very first to provide principled design knowledge for mobile medical apps. The suggested design principles form a theoretical contribution [26], since they extend the body of knowledge on the creation of mobile app solutions in the healthcare sector. The design principles also assist practitioners in solving current and anticipated problems in the design of mobile medical apps. The abstraction of our learnings allows practitioners to build on the suggested design principles and to apply them in the development of a mobile medical app that targets a different illness than age-related macular degeneration.

Further, our project revealed the importance of involving people from multiple disciplines in a mobile medical app project. In line with our argument, Nilsen et al. [37] criticize current mobile health tools that arise from siloed fields with little reference to previous research. Doing research in an interdisciplinary team involves additional effort, since the team must create and share a vocabulary. However, such an interdisciplinary collaboration enables solutions that could hardly emerge within a single discipline. The application of each of the four suggested design principles in future studies calls for an interdisciplinary collaboration, since they all require inputs from both the medical and the software technology's side.

While our research is grounded in a successful 30-month research project, it has limitations. Although we integrated our insights with findings from the literature to inform, explain, and validate our design decisions, we cannot guarantee that our findings are exhaustive or fully independent of our specific research project. The research we presented here has opened up possibilities for new and exciting future research. Our design principles can serve as a basis to develop a design theory, as suggested by Gregor and Jones [38]. While a design theory provides prescriptions for the design of an artifact, future research should also study de facto implementation and how mobile medical apps change interactions between patients and physicians. What affordances and constraints do mobile medical apps bring to daily clinical practice? And how does the physician's corresponding clinical information system interact with a patient's mobile medical app? These are important issues to address the current gap between mobile technology advances and critical evaluation of the impacts of mobile medical apps in healthcare.

Abstract. Product information and price comparison apps on smartphones play an increasing role in consumers' purchase decision process. Consumers are able to choose from a variety of product information search applications (apps) which mainly differ with respect to the information that is provided to consumers during their search process. The goal of this study is to analyze preferences regarding different information types that such apps provide. We conduct an adaptive choice-based conjoint analysis combined with a between subject experiment for a sample of 330 consumers. We identify differences between high- and low-involvement products. Individual differences are explained using psychometric latent constructs. Our results reveal heterogeneous preferences which also depend on the product category. Consumer attitudes like quality vs. price consciousness and green consumer values influence the valuation of certain information types.

Keywords: Consumer preferences, adaptive choice-based conjoint analysis, mobile commerce, smartphone applications

1 Introduction

The diffusion of smartphones increasingly improves consumers' means to search and access information online using the mobile internet. For instance, in the domain of product information and price comparison consumers are able to choose among many different smartphone applications (apps) for product information search. Such apps are widely used [1, 2]. We consider product information search apps as smartphone applications that provide information on physical products using the mobile internet. Most of these apps provide barcode scanning, location-based services and different types of product information. Today's product information search apps provide a magnitude of different features that go well beyond basic price comparison [2].
There is some research on app success in general. For instance, Lee and Raghu [3] conduct a survival analysis on 300 apps in Apple's App Store and Yang investigates the acceptance of mobile applications among young Americans [4]. However, to the best of our knowledge, there is no literature on consumer preferences regarding app features that is category specific. In particular, so far there is little known about product information search apps and consumers. The goal of this study is to analyze consumer

Fölting, J.; Daurer S.; Spann, M. (2017): Consumer Preferences for Product Information and Price Comparison Apps, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1081-1095

preferences regarding different features of product information search apps with a clear focus on different types of product information that an app might provide. We conduct an adaptive choice-based conjoint analysis combined with a between subject experiment for an online sample of 330 consumers. Here we identify differences between the searches for high- versus low-involvement products. Because consumers' preferences are estimated on an individual level, differences can be explained using psychometric latent constructs in a regression analysis.

Towards this goal we work with three research questions that are related to research gaps that we identify: (1) Which types of product information do consumers prefer in their search process using smartphone apps? (2) How does the distribution of the relative attribute importance differ between information searches for high- versus low-involvement products? and (3) Can information search behavior be explained by a certain set of psychometric constructs? The results are relevant for marketers and smartphone app developers alike. Developers will be able to include consumer preferences in their requirements when designing new apps. Marketers might benefit from our insights in their targeting activities. For instance, retailers could use our findings to provide app suppliers with specific product information for inclusion in their app.

We aim to contribute to the literature in different ways. First, we measure consumers' preferences regarding product information search apps and identify "must-have" and "nice-to-have" features. Here, we focus on features that are related to different types of product information. Second, we provide evidence that these preferences and thus app usage behavior depends on the product category. Third, we explain consumer specific differences based on various consumer attitudes.

The remainder of this paper is organized in the following way: We first review related literature to identify research gaps. Then, we outline our data and method. Next, we present the results of our empirical study with the two subsections adaptive choice-based conjoint analysis and regression analysis. Finally, we discuss implications for practitioners as well as for researchers.

2 Related Literature

In consumer search the identification of sellers and the determination of prices are important, as Stigler [5] points out in his seminal paper. However, the search for information (which is required e.g., for price comparisons) is costly and therefore market inefficiencies may be partly explained by search or transaction costs [5]. The internet facilitates information search and it is widely acknowledged that the internet has a major impact on consumer search behavior [6]. Search on the internet even substitutes search in other channels [7]. The diffusion of smartphones adds a new dimension with the mobile internet. While early stage mobile internet search was mainly browser-based [8], today search is usually driven by apps. Mobile devices (smartphones and tablet computers) are used as both research and purchase devices [9]. Since they are portable and provide location-independent access to the internet they reduce consumers' overall search costs [10].

Smartphones support product information search [1]. While there is some research on optimal product information search [e.g., 14, 15] the term product information is manifold and depends on the context. There are various attributes of products that may be relevant in the decision-making process of consumers. An obvious attribute is price. However, Dickson and Sawyer [11] find that not all consumers engage in price comparisons. Nevertheless, price is an important component of offerings. Product quality, which is reflected by different product characteristics, is also a very important attribute [12]. Furthermore, there are consumers that look also on other aspects, for instance information on environment-friendly production processes [13]. Companies' approach to corporate social responsibility is considered by certain consumers [16]. Furthermore, information on sustainability is relevant for some consumers. Winkler von Mohrenfels and Klapper [17] find that relevant mobile product information may increase brand perception and at least for some product categories (e.g., organic foods) it may increase consumers' willingness-to-pay. Finally, consumers might look for reports of other consumers on their user experience. Such information is easily conveyed via the internet in form of consumer reviews or electronic word-of-mouth [18].

As consumers are subjected to a vast quantity of information their judgment eventually could be blurred. This phenomenon is called information overload. It assumes that consumers exhibit "finite limits to the amount of information they can assimilate and process" [19] and that if these limits are exceeded consumers become confused and make poorer decisions. While it is known what technology (i.e. product information search apps) is able to provide and which different types of product information may be relevant in consumer decision making, it remains open which features of such apps (i.e. which product information) are preferred by their users. This leads us to our first research question: (1) Which types of product information do consumers prefer in their search process using smartphone apps?

Based on previous research the importance of different types of product information seems to vary depending on the situation. There is empirical evidence that information choice behavior of consumers differs by product category [1]. This is consistent with earlier reports that in general consumer behavior varies by product category [20]. During information search, price information is more intensely requested by consumers looking for durables compared to consumables [1]. User reviews are more relevant for consumables. User reviews are also more retrieved in product search concerning utilitarian goods, while the price seems to be more important for hedonic goods. Looking at search goods, information on product characteristics is slightly more demanded as opposed to experience or credence goods [1]. In general, product information needs are correlated with the involvement of consumers [21]. Hence, our second research question is: (2) How does the distribution of the relative attribute importance differ between information searches for high- versus low-involvement products?

Previous literature suggests that consumer preferences are heterogeneous. Based on existing literature a set of consumer attitudes can be identified that potentially plays a role in product information search. The attitude of quality consciousness [22] is an indicator of how thoroughly consumers inform themselves about a product before a purchase. Depending on green consumer values consumers might differently assess information on the sustainability of products or their production processes [23]. Furthermore, price consciousness is an indicator of the effort that consumers take to strike a good deal [24]. With our third research question (3) Can information search behavior be explained by a certain set of psychometric constructs? We will analyze various influencing factors on consumer preferences in this context.

In this study we analyze consumer preferences regarding different features of product information search apps with a clear focus on different types of product information. While there is research on app features like mobile technologies, media integration and social network capabilities (e.g., [2]), or research on category independent app characteristics like price of the app or number of apps by the same developer [3], to the best of our knowledge so far there is no previous research that focuses on features that are related to different types of product information in product information search apps.

3 Data and Method

3.1 Study Design

To answer our three research questions we design a modular study consisting of an online discrete choice experiment with a between subjects design. Regarding the first two research questions we apply a form of conjoint analysis. In this conjoint analysis, we represent a situation in which participants are asked to make choices about product information search apps. We conduct an adaptive choice-based conjoint (ACBC) analysis to estimate consumer preferences.

We gather data through an online survey. For the purpose of a comparative analysis to answer the second research question, we design an online questionnaire with two versions. The two versions differ in regards to the focal product – a high-involvement (HI) product (a laptop computer) and a low-involvement (LI) product (an energy drink). Participants are randomly assigned to one of the questionnaire versions. 330 completed questionnaires could be used for the analysis (156 in the HI- and 174 in the LI-group). The sample consists mainly of students and all the relevant socio-demographic characteristics are approximately equally distributed to ensure for a proper comparison between the two experimental groups (high- and low-involvement product).

In addition to the ACBC analysis, we gather socio-demographic and psychographic data by measuring various latent constructs. These constructs are used to explain the results of the ACBC analysis which relate to the third research question. Here, we apply multiple linear regressions with four relative attribute importance values as dependent variables. The relative attribute importance is estimated through the ACBC using Hierarchical Bayes (HB) on an individual level. As independent variables we employ the constructs mentioned above as they cover individual characteristics regarding consumers' search and purchasing processes. All constructs are measured using a 7-point Likert-type scale. Except for opinion seeking, which contains a reverse-coded item, all constructs are coded in a way that higher scores represent higher levels of the construct.

Consumers' importance of quality and their subsequent effort of gathering information about products before making final purchase decisions are measured by the Quality Consciousness scale [22]. The scale Opinion Leaders and Opinion Seekers [25] is limited to the opinion seeking items in our study because we are only interested in whether consumers are potentially influenced by the attitude of others. In order to measure the degree to which the characteristic trait of considering the environmental impact of one's purchase and consumption behavior influences one's information search, the Green Consumer Values scale [23] is included in the survey. The psychometric measurement of consumers' search effort is based on the search costs scale of Srinivasan and Ratchford [26]. We also include the construct Price Consciousness [24] that evaluates the consumers' willingness to spend an extra effort in order to find low prices for a specified product category.

3.2 Adaptive Choice-Based Conjoint Analysis

Choice of Method and Design. Conjoint analysis (CA) can be characterized as a method for determining consumer preferences for products or services which consist of various distinct attributes [27]. In this paper we apply the adaptive choice-based conjoint (ACBC) analysis which achieves to combine the benefits of adaptive and choice-based conjoint procedures [28]. While classical CA or adaptive conjoint analysis (ACA) ask the respondent to either rank the product concepts or rate them on a scale, choice-based conjoint (CBC) analysis realistically imitates the decision process [29]. ACBC analysis makes use of the benefits of ACA as respondents are able to indicate whether a certain attribute level is completely unacceptable and therefore should be excluded from later questions. In addition, it is possible to indicate "must-have" or "unacceptable" attribute levels which leads to a definite in- or exclusion in the rest of the questionnaire.

To identify suitable products for the two settings (high- and low-involvement product), we transfer generic characteristics of high- and low-involvement purchase decisions – i.e. careful versus superficial information processing, systematic information search versus rather casual information reception, high correlation with personality and lifestyle versus a low correlation, decision for the subjective best product versus decision for an acceptable product and a high influence of reference groups versus a low influence – to particular product categories. Especially computer laptops for the high- and energy drinks for the low-involvement category fulfill the above-mentioned requirements. In course of a pretest we reviewed the selected product categories by applying the Involvement with the Product Category scale by Coulter et al. [30]. The obtained test results suggest a proper choice of product categories. On average energy drinks were rated 2.17 on the involvement scale whereas laptops scored an average rating of 4.5.

Adaptive choice-based conjoint analysis consists of three sections: The build your own (BYO) configuration section, the screening section and the tournament section. In the first section respondents are asked to design their ideal product concept by selecting their preferred attribute levels. As the following concepts will consist of attribute levels

that are relatively concentrated around the respondent's preferred levels, the BYO section is used to reduce the error levels during the rest of the survey.
In the second section of the interview, the screening section, the respondent runs through seven screening tasks, each consisting of four product concepts. Accordingly, each attribute level is depicted at least five times. In the screening section the respondents should indicate the product concepts they would potentially use. The section is intended to realize non-compensatory rules. Therefore, it contains so-called "unacceptable" and "must-have" questions. While the respondents answer the questions in the screening task the software identifies attribute levels, which are systematically being avoided or favored. Correspondingly, after the third screening task the respondent is asked whether one of these recognized attribute levels is completely "unacceptable" or a "must-have". According to the respondents' choices all further product concepts shown will satisfy these specifications.
The tournament section is the last and most important part of the survey. Here, the respondent is asked to make a final decision on a set of product concepts that strictly conform to any cut-off ("unacceptable" / "must-have") rules and that are close to their specified product in the BYO section. Correspondingly, participants can now focus on requirements of secondary importance [28].
All the choice tasks are designed with the software package Sawtooth Software SSI Web, except for the two hold-out tasks that were created manually. These tasks serve as a quality indicator [31] and are constant over all questionnaire versions. According to Johnson and Orme [31] these tasks were created using level overlap. They contain the same concepts in a different order. In contrary to the other choice tasks, hold-out tasks are not utilized for the estimation of the relative importance of the attributes [31].

Choice of Attributes and Levels. In this study, we ask participants to evaluate alternative hypothetical product information search apps based on their attributes. These attributes are the different information features provided by the apps. In order to identify the relevant attributes, a two-stage research process was selected. First, we conduct a market analysis on product information search apps to receive a list of information features that are actually being used in different apps. Second, we execute a literature review to validate the importance and influence of these information features from a theoretical perspective. In course of the market analysis we study six product information search apps, namely Barcoo, Check24, Codecheck, Guenstiger.de, Idealo and Redlaser. The consolidation of the results of the initial market analysis and the literature review yields a total of six attributes, which were chosen for the study at hand. All attributes and their levels are shown in table 1.
The first attribute – price – refers to the fact whether the app provides information on the price of the searched product or not. This attribute relates to the fundamental search literature (e.g., [5]). The second attribute is user reviews and the third is neutral product tests. Both exhibit the same levels as price. Riegner [32] highlights the influence of consumer reviews on purchase decisions in a statistically more descriptive manner, for instance stating that the power of reviews is particularly efficient for pricey electronic products like computers. The fourth attribute is product characteristics. It entails detailed information on product characteristics (e.g., quality information or ingredients

for food). This attribute is divided into three levels. First, product characteristics could be “not available”. Second, it could be available in a raw form or third, it could be available in a condensed or illustrative form. In the latter case the information is presented in a way that helps the consumer to evaluate the information at hand. A typical example for condensed product characteristics is a signal similar to a traffic light. For instance, based on the amount of sugar in a comestible the signal shows red (high amount), amber (average amount) or green (low amount). Since such signals provide an orientation to consumers we assume that they are of higher value in the consumers’ decision process compared to raw product characteristics, especially in times of information overload. The fifth attribute is purchase possibility. We differentiate the following three levels: (1) “no information” on the purchase possibility, (2) “only the name of the retailer” or (3) “exact distance to the retailer” (including the name of that store). It could be shown that consumers might change purchase intentions when they receive information on better offers in the vicinity [33]. The last attribute is information on sustainability. Haws et al. [23] for example conceptualize and demonstrate the influence of an environmentally friendly mind-set on consumer preferences.

4 Empirical Results

4.1 Reliability and Validity

Before presenting and discussing the results of the study, an analysis of the goodness of the available data is required. We assess the reliability of the latent constructs by calculating Cronbach’s Alpha separately for the high-involvement (HI) group and for the low-involvement (LI) group: Quality Consciousness (α_{LI} = 0.77; α_{HI} = 0.79), Opinion Seeking (α_{LI} = 0.95; α_{HI} = 0.97), Price Consciousness (α_{LI} = 0.86; α_{HI} = 0.67), Green Consumer Values (α_{LI} = 0.94; α_{HI} = 0.92) and Cost of Search (α_{LI} = 0.83; α_{HI} = 0.88). The analysis of Cronbach’s Alpha reveals that all latent constructs exhibit a high reliability [34].

Next the reliability, predictive validity and internal validity of the ACBC analysis have to be evaluated. Participant’s choices are potentially influenced by several factors, e.g. negligence and lack of interest. To control for potential biases, two identical hold-out tasks were integrated in the survey. The result of the test-retest statistic shows that 88.4 % of all participants in the HI questionnaire and 82.2 % respectively in LI questionnaire chose the same products in both hold-out tasks. Compared to other studies this test-retest validity is high [35].

To assess the predictive validity of the CBC analysis, we also make use of the hold-out tasks. The predictive validity refers to the ability to predict participants’ choices by using the estimated utility parameters [36]. The corresponding validity measure is the hit-rate. The observed choices were compared to the estimated choices. Here, the hit rate is 76.4 % for the LI and 82.7 % for the HI study. Compared to a random hit rate of 33 % (there are three possible choices) such a hit-rate is considered to be high [37].

The hit-rate which depicts the number of correctly estimated choices can also be used to test the internal validity. Here, we predict subjects' responses to the choice tasks used for estimation. The subsequent hit-rates of 83.4 % for the LI and 85.5 % for the HI study show that a large degree of participants' choices is predicted correctly. The internal validity can thus be considered as high [38]. For the purpose of calculating the predictive and internal validity the none-choice option was not included because in the tournament section of the ACBC the none-alternative was not selectable.

4.2 Estimation and Results

In table 1 we depict the estimated part-worth utilities for the attribute levels in the different groups. Those parameters are normalized (zero-centered) HB estimates. These results indicate face validity. Attribute levels with a higher information content provide higher part-worth utilities. One exception is the attribute purchase possibility in case of HI products. A possible explanation for this finding is consumers' tendency to avoid information overload. As the point of time of searching for information on HI products and the point of time of buying those products might not be identical. Due to the fact that normalized part-worth utilities sum up to zero for each and every attribute, negative part-worth utilities simply denote less desired levels. All signs and therefore the direction of the impact of these utility parameter estimates on the overall utility are plausible.

In contrast to the part-worth utilities of the single attribute levels, a direct interpretation of the superordinate attributes cannot be accomplished [39]. Therefore the measurement of the relative attribute importance is used. The relative attribute importance measures the relevancy of one attribute utility compared to the sum of all attribute utility ranges. To calculate the relative attribute importance, the part-worth utility ranges of each attribute are used. Their part-worth utility ranges are the difference between the highest and the lowest part-worth utility parameter of each attribute. The relative attribute importance of the attribute price is calculated by the utility range of the price divided by the sum of all attribute utility ranges. The same applies to the relative importance of all other attributes. The relative importance for each attribute is depicted in figure 1.

In order to test whether the information search behavior differs significantly for LI and HI products we first compare the variances of each attribute importance. Then we apply a two sample t-test with either equal or unequal variances. While there is no significant deviation of the mean values of the relative attribute importance for the information type price and information on sustainability, all other mean relative attribute importance values differ significantly. Non-parametric Wilcoxon-Mann-Whitney-tests provide congruent results. Thus, these results indeed indicate search behavior to be significantly different for the two product categories.

In both studies price information (34.5 % LI; 33.2 % HI) is of the highest importance for respondents. Likewise product characteristics (24.7 % LI; 27.1 % HI) can be identified to be the second most important feature. The rest of the priority order of the attributes differs in the two groups. In context of information search for LI products participants indicate purchase possibility to be third in the ranking of priority with

15.2 %. This attribute only receives the fifth place in the HI group. This difference might originate from the larger share of the travel costs in the overall price of the product to be purchased.[1] Hence, information on the exact location of a retailer becomes more important the less expensive a product is (ratio of travel costs and price is higher). This interpretation is supported by Kahneman and Tversky's prospect theory. In their behavioral theory they show that consumers perceive decision outcomes as gains and losses, which are defined relative to a certain reference point [40]. As the amount of travel costs increases the overall price (product price plus travel costs) increases, too. In prospect theory travel costs represent losses. In this context a fixed amount of loss x is relatively high for cheaper products.

Table 1. Part-worth utilities (=PWU; HI = High-involvement; LI = Low-involvement product)

Attribute	*Levels*	*PWU HI*	*PWU LI*
Price	Available	99.50	102.90
	Not available	-99.50	-102.90
User reviews	Available	36.06	26.93
	Not available	-36.06	-26.93
Neutral product tests	Available	39.53	28.07
	Not available	-39.53	-28.07
Product characteristics	Condensed information	50.88	49.38
	Raw information	43.22	34.11
	No information	-94.10	-83.50
Purchase possibility	Exact distance to the retailer	9.41	29.14
	Only the name of the retailer	15.43	14.13
	No information	-24.84	-43.27
Information on sustainability	Available	17.61	16.79
	Not available	-17.61	-16.79

A relatively high priority in context of information search is obtained by the attributes user reviews (HI: 12.2 %; LI 9.5 %) and neutral product tests (HI: 13.2 %; LI: 9.5 %). It is quite interesting that the values for the relative importance for these two attributes are that close to each other. This could imply that customers regard user reviews as substitutes for neutral product test reports and vice versa.

In both studies the field of the relative attribute importance is tailed by information on sustainability. Although 59.2 % in the LI study and 69.2 % in the HI study choose to integrate that information feature in the BYO section, the attribute comes up with a relative importance of only 6.2 % in the HI and 6.7 % in the LI group respectively. Correspondingly, consumers value other attributes higher when it comes to a trade-off situation. This finding is confirmed by the results of the screening section. Only 3.6 % of the respondents of the LI and 3.1 % of the respondents of the HI group classify the fact of missing information on sustainability as being unacceptable. Accordingly, for merely 1.6 % (LI group) and 0.7 % (HI group) information on sustainability must be available. Here, it becomes obvious that information on sustainability is rather a "nice-

[1] Please note that here overall price reflects product price plus transaction costs.

to-have" feature. We also identify hygiene factors, e.g., price and product characteristics. Over 96 % of the respondents in both groups choose these two features to be a part of their ideal product information search app. Additionally, the screening section reveals the absence of one of these features to be unacceptable for the majority of the participants.

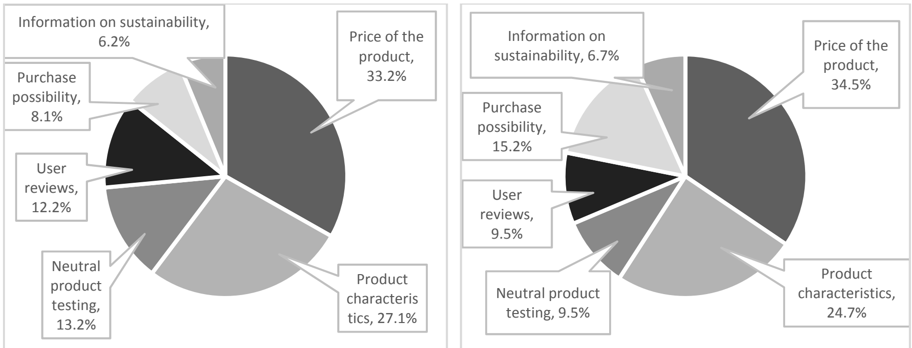

Figure 1. Relative attribute importance (left: HI product; right: LI product)

Subsequently, we analyze the four most important relative attribute importance of the ACBC analysis as a function of the psychometric constructs that we have measured. The relative attribute importance (RAI) provides insights on consumers' attitude towards the different information features while the psychometric constructs measure individual traits concerning consumers' search and purchasing processes. We use multiple linear regressions to explain the relative attribute importance by several psychometric constructs. We estimate the following linear model:

$$\begin{aligned} RAI_{ij} = {} & \beta_{0j} + \beta_{1j} \times quality\ consciousness_i + \beta_{2j} \times \\ & opinion\ seeking_i + \beta_{3j} \times price\ consciousness_i + \beta_{4j} \times \\ & green\ consumer\ values_i + \beta_{5j} \times cost\ of\ search + \beta_{6j} \times \\ & product\ type + \beta_{7j} \times smartphone\ owner_i + \beta_{8j} \times \\ & experience\ with\ product\ information\ search\ app_i + \varepsilon_{ij} \end{aligned} \quad (1)$$

where the dependent variable represents the relative attribute importance of the attributes price, product characteristics, user reviews and neutral product tests. The betas are the estimators of the independent variables of participant *i*. Index *j* reflects the attribute (price, product characteristics, etc.).

First, we test for violations of the assumptions of the linear regression model. To test if our model has a proper functional form, we use the Ramsey test. The results indicate that our models are specified properly. The Breusch-Pagan/Cook-Weisberg test indicates that heteroskedasticity is a problem, however. We therefore use models with robust standard errors [41]. A test for the normality of residuals indicates that the residuals of our models are normally distributed. It is assumed that the residuals are identically and independently distributed. Finally, multicollinearity is not a problem since the maximum variance inflation factor (VIF) is 2.01.

The F-tests depict the overall significance of the particular regression models. All models are highly significant (see table 2). The dummy product type shows that the category of the inspected product (HI vs. LI) plays a significant role for user reviews (+0.023, $p<0.05$) and neutral product tests (+0.031, $p<0.01$). The special importance of user reviews and neutral product tests in case of HI products can be explained by two facts. First, consumers are interested in reducing their perceived risk by gathering as much information as possible and second, they strive for aligning their purchase decisions with the interest of their reference groups. Both information features user reviews and neutral product tests, help to satisfy this need. When looking at price as an information feature of product information search apps quality consciousness (-0.015, $p<0.05$), price consciousness (+0.018, $p<0.01$) and green consumer values (-0.013, $p<0.05$) are significant. Whereas price consciousness has a positive impact on the relative importance of the attribute price, the constructs quality consciousness and green consumer values exhibit a negative influence. This means that people who are willing to spend an additional effort in order to find low prices for a certain product are more inclined to use the price information during their search process. This seems to be plausible as the primary concern and objective of price conscious consumers is to detect and realize relatively low prices in the process of their buying decisions. Contrary to that, opposite signs of quality consciousness (+0.016, $p<0.01$) and green consumer values (+0.01, $p<0.05$) can be observed in the model for the product characteristics. People that consider the environmental impact of their purchase and consumption behavior are less motivated to use the information feature price. Price is not their primary decision criterion. In fact, highly environmentally conscious people even seem to omit the information feature price to not be distracted from their main intention: to make purchase decisions with integrity. This finding also proposes that the price of a product does not primarily effect their purchase decision. Consequently, they exhibit a higher willingness-to-pay if the product satisfies their needs for sustainability. The same relation is observed for quality-conscious consumers. Furthermore, ecologically-thinking consumers refrain from implying user reviews in their search process (-0.009, $p<0.05$). Ecologically thinking consumers might be less influenced by the opinions of others. Whereas, prior experience with product information search apps is not significant in all models, smartphone ownership has a significant positive influence on neutral product tests (+0.024, $p<0.01$). Despite the wide diffusion of smartphones, the smartphone owner group might still include the more solvent consumers. Neutral product test reports are typically not available for free in contrast to user reviews in form of user-generated content.

5 Conclusion

In this paper we analyze consumers' preferences regarding features of product information search apps with a clear focus on different types of information using an adaptive choice-based conjoint analysis. Price information and product characteristics are the most important features across both product categories. The preferences for other features depend on the product category of the focal product. When searching information on high-involvement products neutral-product test information is important. For low-involvement products consumers value information on purchase possibilities more.

As we estimate consumers' preferences on an individual level, we are able to explain differences using psychometric constructs in a linear regression. Consumer attitudes like quality consciousness, price consciousness and green consumer values influence the valuation of app features. For instance, for quality conscious consumers or consumers with high green consumer values price information is less important. Ecologically-thinking consumers prefer quality information and information on sustainability over user-generated content, such as user-reviews.

Our findings provide various implications for practitioners. With product information search apps consumers are not only increasingly better able to conduct mobile price comparisons they are also better informed about product characteristics. Marketers might provide specific types of product information depending on the product category and depending on consumers' characteristics. App users could be targeted with dedicated mobile advertising [42]. They are not only more likely to find a better alternative offer but they are also more likely to react to the advertising [43]. Furthermore, app developers might include these findings on consumer preferences in their requirements when designing new product information search apps or refining existing ones. As this preference information translates well into real app success in major app stores, those findings are highly relevant for developers as well.

As most research, this study also comes with some limitations: For example, we collect our data using a survey. Therefore our analysis is based on stated preferences which are not consequential for consumers and therefore could lead to a hypothetical bias. However, stated preferences can be used to predict consumer behavior to a significant extent [44]. In addition, the attributes of our ACBC analysis are not exhaustive. The multitude of real apps (across different categories) encompasses many more available features (e.g., barcode scanning vs. manual search). Finally, our survey is based on one country. These limitations provide some avenues for future research. It would be interesting to know if the results are different for other product types (e.g., food vs. electronics). Furthermore, aspects such as customer experience or consumer interaction inside a store when using a product information and price comparison app could be analyzed in further research.

How to Gauge the Relevance of Codes in Qualitative Data Analysis? – A Technique Based on Information Retrieval

Alexander Keller[1]

[1] University of Passau, Chair of Information Systems (Information- and IT-Service-Management), Passau, Germany
alexander.keller@uni-passau.de

Abstract. Qualitative research has experienced broad acceptance in the IS discipline. Despite the merits for exploring new phenomena, qualitative methods are criticized for their subjectivity when it comes to interpretation. Therefore, research mostly emphasized the development of criteria and guidelines for good practice. I present an approach to counteract the issue of credibility and traceability in qualitative data analysis and expand the repertoire of approaches used in IS research. I draw on an existing approach from the information science discipline and adapt it to analyze coded qualitative data. The developed approach is designed to answer questions about the specific relevance of codes and aims to support the researcher in detecting hidden information in the coded material. For this reason, the paper contributes to the IS methodology with bringing new insights to current methods by enhancing them with an approach from another discipline.

Keywords: qualitative data analysis; information retrieval; relevance of codes; qualitative methods; information science.

1 Introduction

Qualitative research is an accepted methodology in the information system discipline and since a significant growth in 2005, one can see a stable amount of publications in information system (IS) journals like Management Information Systems Quarterly (MISQ), Journal of Management Information Systems (JMIS) and Journal of the Association for Information Systems (JAIS) [1]. Besides studies which use qualitative research methods to answer specific research questions (e.g. [2–4]), much has been written about recommendations and guidelines regarding how qualitative research is conducted within the IS discipline (e.g. [5–7]). Especially in the IS field qualitative research and the findings it generates often have been seen as a minor discipline accompanied with biases regarding the common quality standards [8]. Therefore qualitative research has a strong need to declare itself and reply critics with its own quality criteria (e.g. [9]).

In their MISQ guest editorial on qualitative research in IS Sarker et al. (2013) introduce the principle of transparency and state that "there is a need for clarity in the logic underlying data analysis" [10]. This paper follows their advice and adds a standardized

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Keller, A. (2017): How to Gauge the Relevance of Codes in Qualitative Data Analysis? - A Technique Based on Information Retrieval, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1096-1110

technique to the repertoire of approaches that are used to analyze data in qualitative IS research. Therefore, I have applied an approach from the information science domain and adopted it for the use in qualitative research. With the technique results are generated that grant additional and hidden insights regarding the relevance of codes derived from textual data. This new technique is called *code appearance and relative frequency index* (CARFI). Besides this methodical contribution the technique especially contributes to the field of IS, where relevance aspects are of special interest when studying technical and behavioral issues regarding the role of information technology (IT) (see actual studies like [11, 12]).

The underlying research process started with the need for an appropriate approach to investigate the relevance of codes and is structured in three phases. In the first orientation phase, the qualitative research discipline as well as the IS discipline have been screened for techniques. Due to no appropriate result the scope has been widened to other disciplines. With finding the information retrieval approach the third phase started that aims to adopt the technique for the usage with qualitative data. The results of this phase are presented in this work.

The paper is structured as follows: First, it is explained which methods, data collection techniques and modes of analysis are used in qualitative research and how they collude in the IS discipline. Besides that, I am looking at the coding process and the different techniques used. This is supplemented with existing quality criteria and shortcomings in regard to the interpretation of qualitative data that motivates the development of new analysis procedures. Based on this, I propose a new technique that helps to identify the relevance of codes in textual data sources. I illustrate the technique with real data from interviews with experts. The paper concludes in a discussion of the presented approach and gives an outlook towards future research.

2 Qualitative Research in IS

In the IS domain qualitative research has a long history and aims to study managerial and organizational issues related to innovations in information and communication technologies [13]. Qualitative research methods have its origin in social science and were developed to understand cultural and sociological phenomena [13]. In contrast to quantitative research the focus of qualitative techniques lies on the observation of complex phenomena and situations which cannot be grasped with quantitative measures. Besides qualitative research being used as the only instrument for studying a research topic, it can be combined with quantitative techniques in the same inquiry in a mixed methods approach. Because of both methodologies having different strengths they can rest upon each other to generate richer results in combination compared to being used alone [14, 15].

2.1 Methods, Data Collection and Modes of Analysis

In qualitative research one distinguishes between various methods which specify the research design and strategy. In Table 1 we shortly present five approaches which are widely used in the IS domain and give references which explain the methods from a theoretical perspective (for the information given in Table 1 also see [13] and [16]).

Table 1. Qualitative Research Methods

Method	Description	References
Action Research	The method is a design-orientated approach and aims to widen the stock of knowledge in the specific domain. The goal is the development of solutions in a collaborative manner. Therefore, several cycles consisting of analysis, action and evaluation steps are needed.	[17–19]
Case Study Research	With case studies, complex phenomena are investigated within their real-life context. The approach focuses on cases which represent instances of a particular phenomenon. Therefore, each regarded case can be seen as a research object, which explicates and illustrates the research subject.	[20–23]
Ethnography	The behavioral method aims to generate findings through participatory observation within the direct environment of the research subject. Therefore, a strong and intensive involvement of the researcher is required to study the phenomena in its social context.	[24–26]
Grounded Theory	Grounded theory is a behavioral method with the goal to systematically develop theory from the interaction between data gathering and analysis. Therefore, the approach consists of a process with several rounds of coding (open, axial, selective) to analyze data in which the theory is grounded.	[27, 28]
Qualitative Content Analysis	Qualitative content analysis is based on an iterative process, which is designed for coding data in relation to a category system. The codes, also called categories, of this system are developed in an inductive (from the information sources) and/or deductive (theory orientated) manner.	[29, 30]

Besides the presented methods of qualitative research, different techniques of data collection are distinguished to gather empirical material for the purpose of data analysis. Qualitative material covers mostly non-numeric information which is collected directly in form of interviews, observations and fieldwork or indirectly from secondary sources like published and unpublished documents [13]. This results in textual information sources like interview transcripts and case descriptions which serve as the foundation for further analysis.

The non-numeric nature of qualitative data results in different modes of analysis compared to quantitative methods. In qualitative research it is essential to understand and interpret the given information in regard to the underlying research questions to ensure that conclusions are drawn in the right context. Therefore, the textual data is processed and text passages are coded with a system of categories to create a foundation for analysis and interpretation [31]. Besides approaches which result from the methodology perspective (e. g. grounded theory), there exist additional modes of analysis that can also be seen as philosophies for interpreting qualitative information. Among others the hermeneutic idea is a way of understanding and interpreting textual information and aims to create an understanding for the "[…] underlying coherence or sense" [32]. Therefore, both understanding the whole text on the one side and interpreting the different parts of it on the other side is relevant for analyzing the given information [33]. The approach targets the understanding of the research subject in general and focusses on the relation between different objects on the basis of textual information.

The semiotic approach aims to investigate the implicit and explicit meaning of texts and is divided into three different categories - the content, conversations and discourse analysis [13]. With content analysis the researcher structures the textual information sources and identifies patterns in regard to the given context [34]. In conversation analysis the background of social interaction and behavior is uncovered with the researcher immersing in the particular situation [25]. Discourse analysis "[…] concerns itself with critically analyzing language […] in the context of social interactions" [35]. With this concept not only the provided content of a person, but also their way of talking is investigated.

Figure 1 shows a summary of methods, data collection techniques and modes of analysis used in IS based on Myers (1997)[13]. As the three different parts are coherent

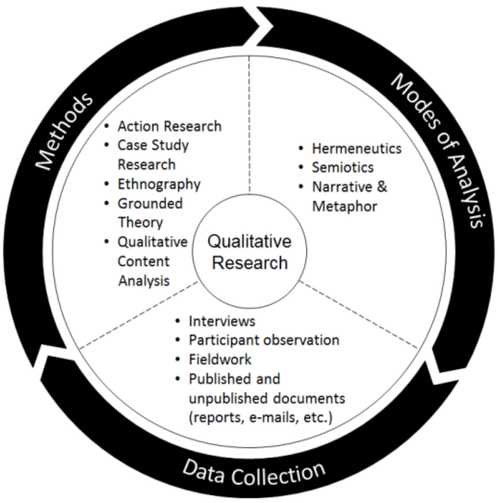

Figure 1. Qualitative Research

and mutually dependent on one another, qualitative research designs evolve from a combination of these aspects.

2.2 Codes and Coding Techniques for Qualitative Data Analysis

With the occurrence of grounded theory methodology the technique of coding emerged in the late 60s and is now said to be one of the most popular techniques of data analysis [36]. Referring to Sarker et al. (2012) about 60% of qualitative studies in the IS discipline use coding techniques to analyze empirical data [1]. Coding is a procedure to structure text and aims to mark segments of textual raw data that contain a specific information in regard to the underlying research question [37]. In the coding process the researcher identifies relevant information in the textual raw data (e.g. interview transcripts, reports, etc.) and attaches an existing or new code to a text segment [38]. A code represents the information given in the data and functions as an empirical generalization of relevant information in regard to the research question.

Looking at code-based qualitative data analysis Gläser and Laudel (2013) distinguishes between two important variations. First the difference in coding themes or coding content and second "[…] the extent to which preexisting theory is used in the coding process […]" [36].
Typically coding results in indexing themes, i.e. a set of codes that "[…] represents the structure of raw data in the text […]" [36]. The intention is to capture the information given in a text segment. In contrast coding content focusses on the content that should be expressed with a particular statement. In this case a code is used as a representation for a typical phenomenon of interest [36]. Besides that, codes can directly be generated from the textual raw data without considering existing theoretical aspects. This approach ensures that the derived codes are not distorted by prior theoretical considerations [39, 40]. In contrast some scholars object to this view by mentioning the importance of ex ante considerations [41, 42]. Miles and Huberman (1984) state that it is not possible to conduct any qualitative analysis without having a conceptual framework that emerges from considerations prior to the data analysis [43]. Therefore, coding techniques either can be used on textual data without any prior theoretical considerations (e. g. grounded theory [40]) or with a theory orientated conceptual framework as a starting point (e. g. deductive qualitative content analysis [30]).

Besides theoretical considerations the researcher has to consider specific guidelines while the data gathering an coding process to ensure a solid data basis for further analysis (see [31, 36, 44]). Negations or intonations are just two sources for biases that occur within the coding processes and can be handled with separate coding iterations.

Although coding can be done manually, software tools (e.g. *NVivo*, *Atlas.Ti, HyperResearch, MaxQDA*) are used to support the researcher in the coding process. Besides the main functionality of attaching codes to text segments the tools provide options for quantification and visualization of results. These different types of illustrations and representations are valuable sources for data interpretation.

2.3 Quality Criteria and Shortcomings in Qualitative Research

The essential and conventional research quality criteria validity and reliability also apply for qualitative research. Notwithstanding the criteria do have other characteristics when used in this domain [45].

Validity describes the quality and information value an approach is able to measure in regard to what it claims to measure. To exclude interfering influences quantitative methods are highly standardized. One can see this standardization in an understated form in qualitative research as well. Especially the approaches for data collection and processing are equipped with rules to ensure a standardized process (e.g. corpus construction [46], coding in grounded theory [27]). But as Flick (2014) mentions the strength of approaches in the qualitative domain often lies in their flexibility [47]. In addition, he indicates that communicational effects are not controllable in a reasonable way. Besides standardization, the credibility and accuracy in qualitative research can be ensured via communicative validation [45, 48]. This can be performed in form of direct member checks that require a validation of the involved people. For example, an interview partner validates the transcript to ensure its correctness. Additionally, the accuracy of the qualitative approach can be confirmed via peer validation with other researchers or experts in the field to ensure that the right methodology is used.
Reliability stands for the robustness of findings and the overall consistency of an approach which is repeated with consistent conditions. In qualitative research identical results not always represent reliable findings [49]. E.g. identical responses in interviews are not a decent indicator for reliability but point to prepared answers which result in falsified findings. For reliable results in qualitative research the context in which the data is collected and the analyses are performed must be described in very detail. This intersubjective tractability helps to understand each part of the study and should lead to other researches drawing consistent conclusions [50, 51].

Besides reliability and validity additional quality criteria are important that are addressed with the proposed approach. Lincoln and Guba introduce credibility as a construct that ensures the internal validity of qualitative research [45]. They emphasize the trustworthiness of findings and recommend approaches like triangulation and negative case analysis. In addition, the intersubjective traceability should be given to ensure that the results and interpretations are objective and confirmable [42]. Although there exist guidelines on how to meet this quality requirement, critics blame the domain for its strong subjectivity when it comes to interpretation of analyzed data [52]. Since the researcher is the one who is collecting, processing, analyzing and interpreting the data some degree of bias is introduced because of his subjectivity [53]. To control this bias, the research progress should be enhanced with techniques that enable a standardized evaluation and interpretation of qualitative data.

3 An Approach to Generate a Deeper Insight into the Relevance of Coded Qualitative Data

Regarding the lack of techniques for objective interpretation and the need to meet the quality criteria credibility and transparency an approach is provided to gather hidden information from coded qualitative data. The presented technique embraces the numerical structure of coded data which results from the assignment of text passages to codes. With the technique the relevance of codes (i.e. an empirical generalization of relevant information in regard to the research question) can be identified. Based on an information retrieval method an index is calculated to compare codes concerning their relevance with regard to the underlying research objective.

3.1 Relevance of Codes Based on Frequency and Appearance

In order to generate conclusions from the coded data it is helpful to compare the identified codes regarding their importance (e.g. [4]). Therefore, a value is necessary to rank each code in respect to its relevance. To calculate this index a standardized procedure is needed that identifies the importance based on the given coding of raw data. In information science the concept of information retrieval describes the process of identifying relevant information resources in collections based on given information needs [54, 55]. As a measure of relevance the two components term frequency and inverse document frequency are used [56, 57]. The first measure covers the frequency of a term by counting its occurrence within the information source. The second measure extends the term frequency by considering not a single information source but all existing sources. Therefore, the inverse document frequency counts the existence of the term in question over all considered information sources. As Robertson (2004) points out, multiplying the two constructs generates "[…] extraordinarily robust and difficult to beat […]" results [56]. Considering this, I adapted the measurement and developed an approach to evaluate the relevance of a code.

3.1.1 Concept

I modified the measurement to make it suitable in the context of qualitative data. This is possible because in the coding process each source of information (e.g. interview transcript) is screened multiple times to identify relevant information (see subsection 2.2). Hence a code can be seen as a term of question in the information retrieval domain. Transferring the mechanism, one can assume, that on the one hand a code is relevant the more often it is mentioned within a single information source. On the other hand, a code is important the more information sources contain the respective code. The following table lists the used mathematical notations and describes their meaning to measure the relevance of codes.

Table 2. Mathematical Notations and Descriptions

Notation	Description
n	Number of information sources
m	Number of codes
i	Index of information sources, $i \in \{1, \dots, n\}$
c	Index of codes, $c \in \{1, \dots, m\}$
f_c	Code-frequency of code *c* within all information sources, $f_c \in \mathbb{N}_0$
f_{ci}	Code-frequency of code *c* within information source *i*, $f_{ci} \in \mathbb{N}_0$
a_{ci}	Binary variable representing the appearance of code *c* in source *i*
$CARFI_c$	Index indicating the relevance of code *c*, $CARFI_c \in \mathbb{Q}^+$
AI_c	Additional information for the relevance of a code *c*, $AI_c \in \mathbb{Q}^+$
w	Wight for additive linkage of AI_c, $w \in [0,1]$
$ECARFI_c$	Extended index indicating the relevance of a code *c* based on $CARFI_c$ and AI_c, $ECARFI_c \in [0,1]$

Regarding the code-frequency (f_{ci}) each information source should have the same weighting (relative code-frequency). Therefore, the number of coded text segments for a particular code *c* in an information source *i* has to be standardized by the total number of codes mentioned in the information source *i*. With regard to Namey et al. (2008) the source-frequency is taken into account as a second measure [58]. It represents the number of information sources which mention the particular code *c* and is calculated with the binary variable a_{ci}:

$$a_{ci} = \begin{cases} 1, if\ code\ c\ is\ mentioned\ in\ source\ i \\ 0, otherwise \end{cases}$$

The following formula represents the relevance of a code *c* containing the two factors relative code-frequency and source-frequency, where c' represents the total number of codes mentioned in information source *i*:

$$CARFI_c = \sum_{i=1}^{n} \frac{f_{ci}}{\sum_{c'=1}^{m} f_{c'i}} \sum_{i=1}^{n} a_{ci} \quad (1)$$

Regarding $CARFI_c$ it is assumed that codes with a high relative code-frequency combined with a high source-frequency matter more and hence have a higher relevance. This is expected because the more often a code appears in an information source relative to the other codes the more important the aspect is within this source. Because of this the relative code-frequency represents an indicator for the relevance of an aspect within an information source. But being coded more often than other codes within a source of information, does not implicate a high relevance. E. g. one must assume that a code which is only existing in one single source has less relevance than a code which is mentioned in all sources. Therefore, the source-frequency is additionally taken into consideration. It counts in how many different sources the code appears. Hence this measure gives an insight into the topic related importance of a code regarding the context of information sources. With the multiplicative connection of the two measures codes are considered as relevant if both the source-frequency and the relative code-frequency result in high scores.

3.1.2 Extended Concept to Include Additional Information

In addition to the absolute and relative frequency other dimensions like intonations can be an indicator for relevance and hence should be considered in the approach. This additional information about the relevance of a code c AI_c can be included with an additive connection of constructs (see equation 2). The additive link is realized with a specific weight w to integrate the additional information in the relevance ranking.

$$ECARFI_c = (1-w)\left(\frac{CARFI_c}{\sum_{c'=1}^{m} CARFI_{c'}}\right) + w\ \left(\frac{AI_c}{\sum_{c'=1}^{m} AI_{c'}}\right) \tag{2}$$

To ensure that the two measures in equation 2 can be combined, both terms of the sum need to be standardized (see denominators of the two terms). Additionally, the sum of weights must equal 1 which leads to the standardized relevance of a code (first term) being weighted with $1-w$ where w stands for the weight with which the additional information is considered. $ECARFI_c$ itself results in a number between 0 and 1 due to the standardization of the related terms.

The same linkage can also be done when information about validation or rankings of codes is available from other information sources (e.g. expert interviews to validate or rank codes). If more than one additional information should be included this can be done with an adaption of weights, where each additional information is linked additive with its own weight where the sum of weights for each term equals one.

If no additional information AI_c is available, $CARFI_c$ as well as $ECARFI_c$ can be used to indicate the relevance of codes. While $CARFI_c$ results in an absolute number $ECARFI_c$ calculates to a relative number, because no additional information AI_c is available ($AI_c = 0, w = 0$). If no term of the sum is emphasized the weights for each term of the sum equal 1 divided by the total number of terms. For example, if the two terms in equation 2 should be considered equally, then $w = 1/2$.

3.1.3 Example with Textual Data from Interviews

The technique has been tested with real data from interviews with entrepreneurship experts to identify success indicators for IT-startups [59]. Eleven interview transcripts were coded on the bases of the methodology proposed from Steigleder (2008). The theory orientated content coding technique results in 22 codes with each of them representing a separate success indicator. The data set in table 3 represents the results of the coding process of textual data from eleven interviews which results in 22 codes. Each code stands for a success indicator for IT-startups.

Table 3. Data Set of Coded Qualitative Data from Interviews

		code c																					
	i	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22
interview i	1	2	0	4	2	2	1	3	2	2	0	2	1	1	0	0	1	0	0	0	0	0	1
	2	3	0	1	1	0	2	0	1	2	0	3	1	0	0	0	5	7	1	4	1	2	0
	3	5	0	0	1	3	0	2	0	0	1	0	1	1	7	0	0	0	0	0	3	1	0
	4	2	1	0	2	3	2	1	1	1	0	0	2	7	0	3	0	1	3	3	1	0	2
	5	0	2	2	2	1	1	0	1	0	1	2	2	0	0	1	5	4	5	3	3	3	7
	6	2	2	2	2	0	1	0	0	2	4	0	0	1	0	4	1	1	0	0	3	0	0
	7	1	1	0	2	1	1	0	0	3	0	0	0	1	0	2	1	4	0	1	0	0	1
	8	2	1	0	2	3	4	0	0	1	1	2	2	6	0	2	2	5	2	2	2	5	1
	9	3	0	0	0	1	2	1	1	3	0	1	2	0	1	0	1	1	3	3	2	3	1
	10	0	0	0	0	0	0	0	0	0	2	1	3	2	2	0	0	0	0	0	2	1	2
	11	1	0	0	2	0	0	2	3	0	0	2	0	0	0	1	1	0	1	0	1	1	1

The values given in the matrix represent the code-frequency of a particular code in an information source (f_{ci}). E. g. code 1 is coded two times in interview 1 which results in f_{11} equals two. The sum of one column results in f_c , e. g. code 1 is coded 21 times in total.

After the interview the experts have been directly asked about their top five factors for startup success. This data has been taken into account as additional information AI_c regarding the relevance for a code. In the example AI_c represents how often a success indicator, i.e. a code c, has been given as answer to this question. E. g. code 20 has six times been mentioned as top five indicator, see table 4.

By calculating the values of $ECARFI_c$ the two aspect ($CARFI_c$ and AI_c) both should be considered equally, i.e. both indicate success in the same manner. This results in $w = 0{,}5$. After applying the technique, the codes can be arranged in an ordered sequence which represents the relevance ranking for the analyzed codes and serves as a foundation for interpretation. The results are represented in table 4 and support the researcher in identifying the relevance and importance of success indicators regarding the underlying research question. Although *handling of market conditions* (rank 11, $ECARFI_{17}$ = 0,042) is the most commonly coded indicator (f_{17} = 23) it is ranked in the middle of the list. This results from a low relative code-frequency and a low value regarding the additional information ($AI_{17} = 1$). Besides that, *perseverance* (rank 8, $ECARFI_2$ = 0,054) with the lowest code-frequency (f_2 = 7) is ranked three spots above *handling of market conditions* because the additional information about the relevance (AI_2 = 5) is considered and indicates an important aspect for startup-success. This shows that experts do not accentuate the importance of being able to handle complex market conditions as much as they emphasize *perseverance* in the interviews.

Table 4. Ranking of Codes Based on *ECARFI*

Rank	Sucess indicator	c	f_c	$\sum_{i=1}^{n} a_{ci}$	$CARFI_c$	AI_c	$ECARFI_c$
1	Customer orientated problem solving	20	18	9	6,07	6	0,095
2	Sales competence and marketing power	1	21	9	6,95	4	0,082
3	Seed-customer and technology partner	16	17	8	4,27	5	0,074
4	Feedback driven product developement	21	16	7	3,56	5	0,070
5	Prototype orientated product developement	22	16	8	4,48	4	0,066
6	Team composition	12	14	8	4,21	4	0,064
7	Industry specific competence	5	14	7	3,26	4	0,058
8	Perseverance	2	7	5	1,14	5	0,054
9	Scalability and market ability	9	14	7	3,74	3	0,052
10	Staff management skills	8	9	6	2,31	3	0,043
11	Handling of market conditions	17	23	7	5,04	1	0,042
12	Industry specific financing	13	19	7	4,49	1	0,039
13	Entrepreneurship and professional experience	4	16	9	5,48	0	0,036
14	Political and regulartory business environment	18	15	6	2,62	2	0,036
15	ICT competence	6	14	8	3,44	1	0,032
16	Conversion capability and speed	7	9	5	1,97	2	0,031
17	Proof of feasability and verification	10	9	5	1,89	2	0,031
18	Industry specifc norms and requirements	19	16	6	2,82	1	0,028
19	Business model felxibility and independence	11	13	7	3,41	0	0,022
20	R&D cooperations	15	13	6	2,88	0	0,019
21	Value orientated thinking	3	9	4	1,28	1	0,018
22	Accelerator or incubator program	14	10	3	1,34	0	0,009

Besides that, one can see that codes with the same source-frequency can be brought to an order. E. g. the *sales competence and marketing power* ($ECARFI_1$ = 0,082) as well as the *entrepreneurship and professional experience* ($ECARFI_4$ = 0,036) were both mentioned from 9 different experts but are ranked on second and 13th place with a difference of 0.036. This results from the fact that experts emphasize the sales skills of the startup team within their interviews and mention it as top 4 success factor. Besides identifying the indicators of IT-startup success, the ranking makes it possible to give recommendations about the relative importance of each aspect which cannot be revealed from a list of simple code frequencies.

4 Limitations and Future Research

Although the approach generates stable results it is subject to some limitations. First, the quality of the results generated can only be as good as the quality of the underlying coding process. Therefore, using the techniques does neither understate the need for a solid data collection nor does it replace a robust coding of the qualitative data. It has to be seen as an additional measure which helps to detect hidden information in coded datasets. Second, although the approach generates neutral and objective results, the researcher still interprets them from a subjective perspective that can result in biases.

Third, it is important to understand that the results only provide an indication for relevance but cannot generate findings that are valid in general. This is due to the structure of qualitative research which aims to understand complex phenomena regarding a specific topic of interest. Fourth, frequency is just one approach to address relevance in an objective manner but does not fit for every qualitative investigation. To grant stable findings it is important to combine the proposed technique with other approaches to judge relevance (e.g. context a code comes from or is related to, verbal traces and actual speech such as laughter). In addition to that supplementary mechanisms can be applied to make the input more robust (e. g. case contrasting proposed by Flick (2014) diminishes the impact of similar sources). Fifth, the approach views each source as equal and includes each code mentioned in a source based on the total amount of codes within this source. Therefore, codes mentioned in sources with a lot of codes are less emphasized then codes mentioned in sources with few codes. This behavior must be considered when using the technique.

Future research should investigate the fit of the presented approaches for qualitative research in more detail. To check the robustness of the ranking, one could use a linear ordering technique which examines the ranking based on additional data sources indicating the ranking. Furthermore, intentionally a small data set was applied to introduce the approach in a simple and understanding manner. Although the approach has been used with large data samples in its original discipline, the next step is the investigation of the behavior with different dimensions of data size in qualitative terms.

5 Conclusion

This paper introduces a new qualitative research approach which expands the existing repertoire of qualitative data analysis methods. Therefore, I draw on an existing approach from the information science discipline to bring new insights to current qualitative methods in IS. The technique is adopted and enhanced to be used on data which results from any kind of qualitative coding process. Hence, the approach can be performed independently of the underlying methodology and does not intend to replace existing procedures but aims to extend them.
By developing the practice, I focused on answering questions about the relevance of codes. The proposed technique results in an index representing the relevance or importance of a code relative to other codes. The generated results can serve as an additional basis for analysis and interpretation of qualitative data sources. Until now analysis was only based on the system of codes and their assigned textual passages. With the additional findings from my approach a deeper insight can be generated that supports the researcher in detecting hidden information in the coded data. Regarding the intersubjective tractability and credibility the standardized measure enables replicable and transparent findings generated from qualitative data. The formalization of the approach makes it obvious how the results revealed. With this, one can counteract the quality issues tractability and credibility on the one hand and fulfill the principle of transparency on the other.

The technique addresses and complements many existing and future qualitative and mixed method studies based on coding techniques in the IS domain. Especially when it comes to large empirical data samples in terms of big data the full potential of the approach can be exploited. As the complexity increases with a growing number of sources the mechanism can support analyzing and interpreting “big qualitative data”.

On the Research Paradigms and Research Methods Employed in the BISE Journal – A Ten-Year Update

Thomas Friedrich, Sebastian Schlauderer, Julian Weidinger, and Maximilian Raab

University of Bamberg, Chair of Industrial Information Systems, Bamberg, Germany
{thomas.friedrich,sebastian.schlauderer,julian.weidinger,maximilian.raab}@uni-bamberg.de

Abstract. In the past decade, there has been an intense discussion in the German-speaking IS research community about the different paradigmatic orientations and the methodological diversity. With the work at hand, we present an overview of the research paradigms and research methods that have been used in the German-speaking IS community, represented by the BISE journal, over the past decade. After analyzing 169 research articles, we contribute an overall picture of research paradigms and research methods, a detailed picture of research methods per research paradigm, and a picture of historical trends in research paradigms and research methods. A comparison with previous studies reveals the unique profile of the German-speaking IS community. However, our results also indicate that there might be a shift in the use of research paradigms and research methods. Hence, this study provides a useful basis for future discussions about the positioning and the challenges of the community.

Keywords: IS Research, Research Paradigms, Research Methods, Meta-Analysis.

1 Introduction

In the past decade, there have been several debates in the German-speaking Information Systems (IS) research community on how the field should develop and position as a scientific discipline [1-3]. Especially the different paradigmatic views between behavior science research and design science research have led to extensive discussions [4-7]. In general, the behavior science research paradigm is concerned with the development and justification of theories that explain human or organizational behavior, while the design science research paradigm intends to create novel IT artifacts to solve organizational problems [8], [9]. Since the establishment of the IS discipline, design-oriented research has been the dominating research paradigm in many European countries, especially in the German-speaking countries where engineering disciplines have a strong position [10], [11]. In the international IS literature, the situation has been quite opposite because most articles published in top IS journals follow the behavior science paradigm [12], [13]. Given the increased pressure to publish in high-ranked international IS journals [14], researchers in the German-speaking IS community have thus been

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Friedrich, T.; Schlauderer S.; Weidinger, J.; Raab, M. (2017): On the Research Paradigms and Research Methods Employed in the BISE Journal - A Ten-Year Update, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1111-1125

concerned that design-oriented research approaches will be gradually displaced by behavior-oriented research approaches [15]. This would not only lead to a loss of identity of the German-speaking IS community but also reduce the methodological diversity which, however, is considered as critical to the relevance of the discipline [15-17].

As an interdisciplinary research field, IS draws upon a wide range of disciplines, such as informatics, economics, engineering, psychology, sociology, or mathematics [18], [19]. Consequently, a variety of research methods has been proposed and used to generate knowledge about the development, implementation, and use of information systems [10], [12], [20]. Meanwhile, several studies exist that examine the research methods and/or research paradigms of the IS discipline [e.g., 12], [13], [20], [21]. However, most of these studies target the international (predominantly the North American) IS community, while the German-speaking IS community has received little attention so far [5]. Well-known and frequently cited in the German-speaking IS community is the study by Wilde and Hess [10], who examined the methodological profile of the IS discipline of the German-speaking countries by examining research articles that had been published between the years 1996 and 2006 in the former German IS journal "WIRTSCHAFTSINFORMATIK". In 2014, the journal has been renamed to Business & Information Systems Engineering (BISE) journal and the publication language has been changed to English [22].

Given the existing debates about the positioning and the challenges of the German-speaking IS community, it becomes important to derive a clear understanding of the paradigms and the research methods that are currently being used in the community [5], [15]. Moreover, when considering the study by Wilde and Hess [10], it is interesting to see if the paradigms and research methods in the community have changed throughout the past decade. In this way, researchers can gain a better understanding of their own discipline and its underlying methodological variety. Such an understanding can moreover serve as basis for a well-informed discussion about the future development of a research community. Therefore, the aim of this paper is to provide a structured and up to date overview of the paradigmatic and methodological profile of the German-speaking IS community. In line with the study by Wilde and Hess [10], the German-speaking IS community in this paper is represented by research articles that have been published in the BISE journal, which describes itself as the "flagship journal of the German-language Information Systems community" [23]. In so doing, we remain able to compare our results with Wilde and Hess [10], which allows us to position this paper as a ten-year update. In particular, we address the following research questions:

1. What research paradigms and research methods have been used in the BISE journal in the past decade?
2. What are the most popular research methods per research paradigm in the BISE journal in the past decade?
3. Have the research paradigms and research methods in the BISE journal changed throughout the past decade?

To answer these research questions, we conducted a systematic meta-analysis on the research articles that have been published in the BISE journal in the last ten years. Research paradigms and research methods were analyzed, categorized, and counted per article. Furthermore, the results were compared with previous studies.

The remainder of the paper is structured as follows. In the next section, we describe the theoretical background. In section 3, we illustrate our research procedure. The results of our analysis are presented in section 4. In section 5, we discuss our results in comparison with other studies, followed by the implications and limitations. In section 6, we conclude by summarizing our results.

2 Theoretical Background

In this section, we provide background information on the research paradigms and the research methods that are used in the IS discipline.

2.1 Research Paradigms in the IS Discipline

According to Hirschheim and Klein [24, p. 1201], a *research paradigm* is "the most fundamental set of assumptions adopted by a professional community that allows its members to share similar perceptions and engage in commonly shared practices". It consists of assumptions about knowledge and how to acquire it, and about the physical and social world. In the IS literature, a variety of research paradigms, as well as classifications of research paradigms, can be found. For instance, Chen and Hirschheim [12], Weber [25], as well as Fitzgerald and Howcroft [26] distinct between a positivist and an interpretive research paradigm, while Iivari [27] as well as Goles and Hirschheim [28] distinct between a functionalist, an interpretivist, a radical humanist, and a radical structuralist paradigm. In these studies, the term research paradigm is used to distinct between different epistemological and ontological positions. However, the term research paradigm has also been established in the IS literature to refer to a problem-oriented process that consists of two phases, problem understanding and problem solving [8], [9]. According to Hevner, et al. [8, p. 76], the *behavior science research paradigm* is understood as a problem understanding paradigm that "seeks to develop and justify theories (i.e., principles and laws) that explain or predict organizational and human phenomena surrounding the analysis, design, implementation, management, and use of information systems. In contrast, the *design science paradigm* is understood as a problem-solving paradigm that "seeks to create innovations that define the ideas, practices, technical capabilities, and products through which the analysis, design, implementation, management, and use of information systems can be effectively and efficiently accomplished" [8, p. 76].

In this paper, we focus on the distinction between behavior science research and design science research because both research paradigms are frequently discussed in the literature when it comes to the positioning and development of the German-speaking IS community [4], [6], [7].

2.2 Research Methods in the IS Discipline

In general, a *research method* can be understood as a set of activities that must be undertaken to conduct research [29]. It is a "well-defined sequence of elementary operations which permits the achievement of certain outcomes if executed correctly" [30, p. 165]. Given the diverse nature of the IS discipline and the different paradigmatic positions, researchers have employed a wide range of research methods to study the design, implementation, and use of information systems. Consequently, various classifications of research methods can be found in the international IS literature [12], [13], [20], [31], [32]. Well-known and frequently-cited in the German-speaking IS literature is the classification of research methods developed by Wilde and Hess [10]. The classification scheme consists of the following research methods: *formal-*, *conceptual-*, and *argumentative-deductive analysis*, *simulation*, *reference modeling*, *action research*, *prototyping*, *ethnography*, *case study*, *grounded theory*, *qualitative/quantitative cross-section analysis*, and *laboratory/field experiment* (detailed descriptions of these methods can be found in Wilde and Hess [10]). We use the classification of research methods developed by Wilde and Hess [10] in this paper because it is well-grounded and adapted to the German-speaking IS literature. Moreover, it covers research methods from the behavior science as well as the design science research paradigm. In contrast, classification schemes proposed in the international IS literature typically do not cover design-oriented research methods (e.g., argumentative-deductive analysis, prototyping, or reference modeling) because these classifications have been developed on studies that follow the behavior science research paradigm [12], [13], [20], [31], [32].

3 Research Procedure

Our research procedure follows the meta-analysis approach of Palvia, et al. [20] and Palvia, et al. [21], who investigated the use of research methods and topical trends in the international IS literature. Note that this approach has also been labeled as descriptive review, which is a particular type of a literature review that introduces some quantification (e.g., through a frequency analysis) in order to verify a particular proposition or to reveal an interpretable pattern [33]. Following Palvia, et al. [20] and Palvia, et al. [21], our research procedure consisted of three stages: (i) data selection, (ii) data classification, and (iii) data analysis.

In the data selection stage, we selected all research articles published in the BISE journal from 2007 (volume 49, issue 1) to 2016 (volume 58, issue 4). The ten year period was chosen with reference to the study by Wilde and Hess [10], who analyzed research articles published in the BISE journal between 1996 and 2006. In line with Wilde and Hess [10], we selected only research articles that have been published in the section "Research Paper" of the BISE journal. Articles published in this section provide complete research results and substantial contributions to the literature. Articles published in other sections, such as "Catchword", "Interview", "Research Note", or "State of the Art", were excluded. Furthermore, the research articles published in volume 51, issue 1, 2009 of the BISE journal were excluded because this issue only includes former best paper articles and some retrospective views on the history of the IS field. After this stage, our final data sample consisted of 169 research articles.

In the data classification stage, we systematically analyzed and categorized the contents of each research article with respect to its research paradigm and its research methods. Each research article was carefully read and categorized by three research assistants independently. The results were then compared in a roundtable session and variations in the results were discussed until a consensus was reached. To assess the inter-coder reliability [34], a 10% random sample of articles was separately categorized by a fourth research assistant, resulting in an agreement of 94% (values of 80% or higher can be considered as acceptable, cf. [34]). According to our research questions, each article was categorized according to the both paradigmatic orientations, behavior science research and design science research (cf. section 2). In case the research paradigm has not been mentioned in an article, we followed the guidelines proposed by [8]. Articles addressing the design and evaluation of IT artifacts were assigned to the design science research paradigm, while articles addressing behavior-related aspects (e.g. use, adoption, or success of IT artifacts) were assigned to the behavior science research paradigm. In addition, we recorded the type of IT artifact that has been designed and/or evaluated in articles following the design science research paradigm. Categories for IT artifacts were constructs, models, methods, instantiations, and design theories [8], [9]. Furthermore, we analyzed the research methods that have been used in each article. For the categorization of research methods, we used the classification of research methods developed by Wilde and Hess [10] (cf. section 2). However, and in contrast to Wilde and Hess [10], we did not only focus on the primary research method of each research article (i.e., the research method that leads to the core contribution of the paper). Instead, we also captured all other research methods that were used and mentioned in an article. In this way, we were able to identify research articles that employed multiple research methods. The use of multiple research methods, for instance, is considered to be important in design science research in which IT artifacts are built and evaluated [8]. Therefore, we assigned research methods used in articles following the design science research paradigm to the build or to the evaluation process of the design science research project. Research methods used in articles following the behavior science paradigm were not assigned to specific stages because these behavior science research typically does not draw upon such a dichotomous research process.

In the data analysis stage, we analyzed the research articles based on the established categorization. The results of this stage are explained in the following section.

4 Data Analysis and Results

We structured the results of our analysis according to our research questions. First, we provide an overall picture of the research paradigms and the research methods that were used in the 169 analyzed research articles. Second, we provide a detailed picture of the use of research methods per research paradigm. Third, we provide a detailed picture of the historical trends in the use of research paradigms and research methods.

4.1 Overall Use of Research Paradigms and Research Methods

Figure 1 depicts the overall use of research paradigms (left side) and research methods (right side). With respect to the research paradigms, 65.1% (110) of the research articles follow the design science research paradigm, while 34.9% (59) of the research articles follow the behavior science research paradigm.

With respect to the use of research methods, the argumentative-deductive analysis (ADA) is used most frequently with 43.8%, followed by the case study (CS) with 30.8%. Other more frequently used research methods are the quantitative cross-section analysis (QNA) with 16.0%, the conceptual-deductive analysis (CDA) with 15.4%, and prototyping (PT) with 14.8%. All other research methods are used less frequently (<11%). Ethnography (ET) has not been used in any of the analyzed articles.

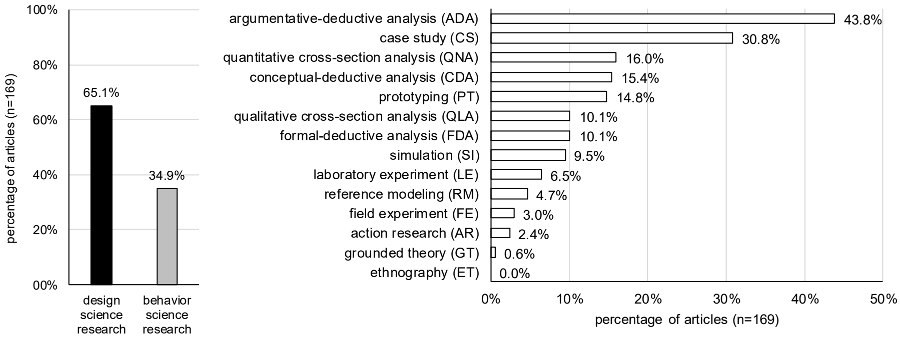

Figure 1. Overall use of research paradigms and research methods

4.2 Use of Research Methods per Research Paradigm

In the following, we first describe the results for the research articles following the design science research paradigm. Then, we describe the results for the research articles following the behavior science research paradigm.

Figure 2 shows the use of research methods of articles following the design science research paradigm according to the design science processes, build (left side) and evaluate (right side). In the building process, the most frequently used research method is the ADA with 47.3%, followed by the CDA with 22.7%. Other more frequently used methods to build IT artifacts are the formal-deductive analysis (FDA) with 14.5%, PT with 11.8%, and reference modeling (RM) with 7.3%. Qualitative cross-section analysis (QLA) with 1.8%, CS with 0.9%, and action research (AR) with 0.9% have rarely been used to build IT artifacts. Research methods that have not been used in the building process are excluded from the diagram. These methods are QNA, simulation (SI), laboratory experiment (LE), field experiment (FE), grounded theory (GT), and ET.

In the evaluation process, the most frequently used research method is the CS (32.7%), followed by the ADA (11.8%) and PT (10.9%). Other research methods that have been more frequently used to evaluate IT artifacts are the QLA (10.0%) and SI (10.0%). LE are used in 6.4%, FE in 3.6% of IT artifact evaluations. Rarely used in the evaluation process are AR (2.7%) and the QNA (1.8%). Research methods that have not been used in the evaluation process and that we excluded from the diagram are the CDA, the FDA, RM, GT, and ET.

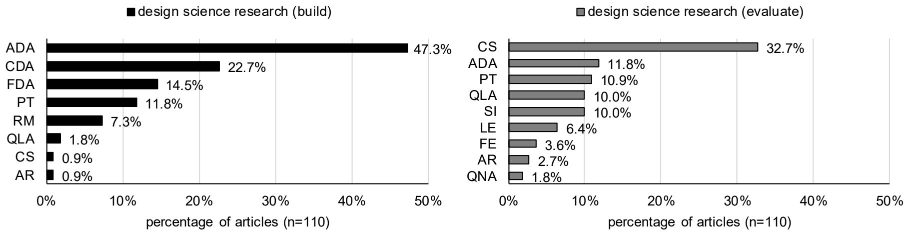

Figure 2. Use of research methods in design-oriented research articles

The separation between the building and the evaluation process enabled us also to investigate frequent combinations of research methods. The diagram on the left side of Figure 3 depicts how often research methods in the building and in the evaluation process have been used in combination. For instance, in 18 research articles, an ADA was used to build an IT artifact together with a CS to evaluate the IT artifact. In nine research articles, an IT artifact was built by using a CDA and the IT artifact was evaluated through a CS. In six research articles, an IT artifact was built by using a FDA and the IT artifact was evaluated through a SI.

The diagram on the right side of Figure 3 illustrates the number of research methods that have been used in design-oriented research articles. 24.5% of the design-oriented research articles only used one research method. In these articles, research methods were only used to build an IT artifact, but not to evaluate it. In 55.5% of the design-oriented research articles, two research methods were used to build and evaluate an IT artifact, while 18.2% of the articles used three research methods. Four research methods have been used in 1.8% of the design-oriented research articles.

method (build) \ method (evaluate)	ADA	SI	AR	PT	CS	QLA	QNA	LE	FE
FDA	0	6	0	0	5	0	0	0	0
CDA	5	2	0	4	9	1	0	2	0
ADA	7	1	1	6	18	6	1	2	3
RM	1	0	2	1	3	4	0	0	0
AR	0	0	0	0	0	1	0	0	0
PT	2	1	0	0	2	1	1	3	2
CS	0	0	0	0	0	1	0	0	0
QLA	1	0	0	0	0	0	0	0	0

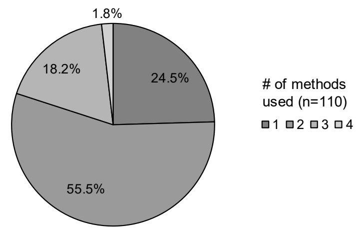

Figure 3. Combinations and number of research methods in design-oriented research articles

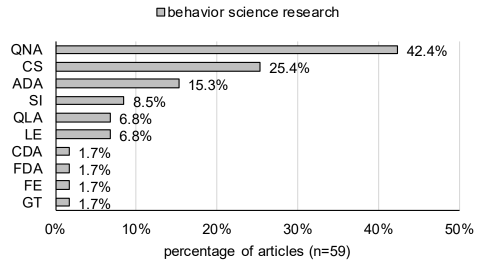
Considering the outcomes of the design-oriented research articles, the most frequent IT artifacts are methods (38.2%) and models (34.5%). Constructs have been build and/or evaluated in 17.3% of the articles. In 9.1% of the articles, the outcome represented instantiations. Design theories have been the outcome of 2.7% of the articles. The latter result reflects recent discussions in the literature that design science research should focus more on the development of design theories [35], [36].

The diagram on the left side of Figure 4 shows the use of research methods of articles following the behavior science research paradigm. In this context, the most frequently used research method is the QNA with 42.4%, followed by the CS with 25.4%. Other more frequently used research methods are the ADA (15.3%), SI (8.5%), the QLA (6.8%), and the LE (6.8%). CDA, FDA, FE, and GT have only been rarely used in these articles. Research methods that have not been used in the behavior-oriented research articles are PT, RM, AR, and ET. We excluded these methods from the diagram.



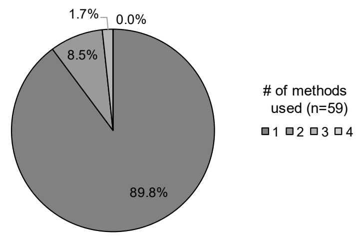


Figure 4. Use and number of research methods in behavior-oriented research articles

The diagram on the right side of Figure 4 depicts the number of research methods used in the behavior-oriented research articles. Most of these articles (89.8%) employ one research method. Two research methods are used in 8.5% of the articles, while three research methods are only used in 1.7% of the articles.

4.3 Historical Trends in Research Paradigms and Research Methods

To identify potential changes in the use of research paradigms and research methods, we analyzed the corresponding historical trends. Figure 5 illustrates the trend of research articles following the design science research paradigm vs. research articles following the behavior science research paradigm.

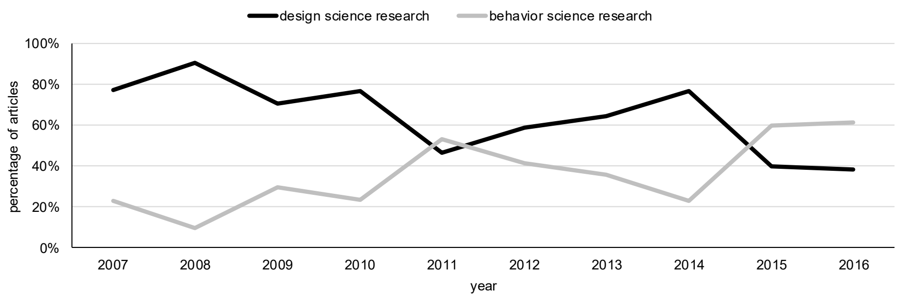

Figure 5. Use of research paradigms over the past decade

From 2007 to 2010, design-oriented research articles were in the majority in the BISE journal (on average, 78.7% design-oriented vs. 21.3% behavior-oriented). In 2011, the percentage of behavior-oriented articles was slightly above design-oriented articles with 53.3% and 46.7% respectively. Between 2012 and 2014, the percentage of design-oriented articles increased from 58.8% to 76.9%, while the percentage of behavior-oriented articles decreased from 41.2% to 23.1%. Since 2015, the trend has changed to, on average, 39.2% design-oriented articles and 60.8% behavior-oriented articles. Furthermore, we analyzed potential changes in the research methods over the past decade. Figure 6 illustrates the trend for the top 5 research methods.

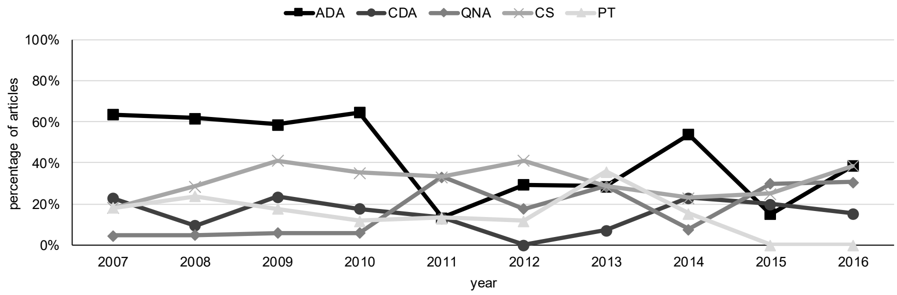

Figure 6. Use of research methods (overall top 5) over the past decade

Between 2007 and 2010, the ADA was the most frequently used research method (on average, 62.3%). In 2011, its use decreased to 13.3%, while between 2012 and 2014, its use increased to 53.9%. In 2015, its use again decreased to 15%, while in 2016, its use increased to 38.5%. Between 2007 and 2009, the use of CS increased from 18.8% to 41.2%. Since 2010, CS have been used, on average, in 33.3% of the articles. Between 2007 and 2010, the QNA has been used, on average, in 5.3% of the articles. Between 2011 and 2013, it was used, on average, in 26.5% of the articles, while in 2014, its use decreased to 7.7%. Between 2015 and 2016, the QNA has been used, on average, in 30.4% of the articles. Throughout 2007 and 2014, PT was used, on average, in 18.5% of the articles. However, since 2015, PT has not been employed in any of the analyzed articles. Between 2007 and 2016, the CDA has been used, on average, in 15.2% of the articles. In 2012, the CDA was not used in any article.

In addition, we analyzed the trend on the average number of research methods used per article over the past decade. Between 2007 and 2012, on average, 1.7 research methods were used per article. In 2013, the average number of methods increased to 2 methods per article. Between 2014 and 2015, the average number of methods decreased to 1.3 methods per article. In 2016, the average number of methods per article was 1.6.

5 Discussion

In the following subsections, we first compare our results with the study by Wilde and Hess [10] and Palvia, et al. [21], who examined the international IS literature. Then we discuss the implications and limitations of our study.

5.1 Comparison of Findings

Our results demonstrate that the majority (65.1%) of the 169 analyzed research articles follow the design science research paradigm, while 34.9% of the articles follow the behavior science research paradigm. When comparing our results with the study by Wilde and Hess [10], who analyzed research articles published in the BISE journal between 1996 and 2006, we notice a slight decrease in the percentage of design-oriented research articles. In the data sample of Wilde and Hess [10], the percentage of design-oriented and behavior-oriented research articles was 70% and 30% respectively. However, our results also reveal that since 2015, about 60% of the articles follow the behavior science research paradigm, while 40% of the articles follow the design science research paradigm. The results are in contrast to Wilde and Hess [10], who concluded that between 1996 and 2006 no indications can be found that lead to a shift in the research paradigms.

Figure 7 compares the overall use of research methods with the study by Wilde and Hess [10]. As suggested by Wilde and Hess [10], research methods are grouped according to their degree of formalization and according to the research paradigm in which these methods are typically applied. Note that the comparison only covers primary research methods (i.e., research methods that lead to the core contribution) since Wilde and Hess [10] only focused on the primary research methods (cf. section 3).

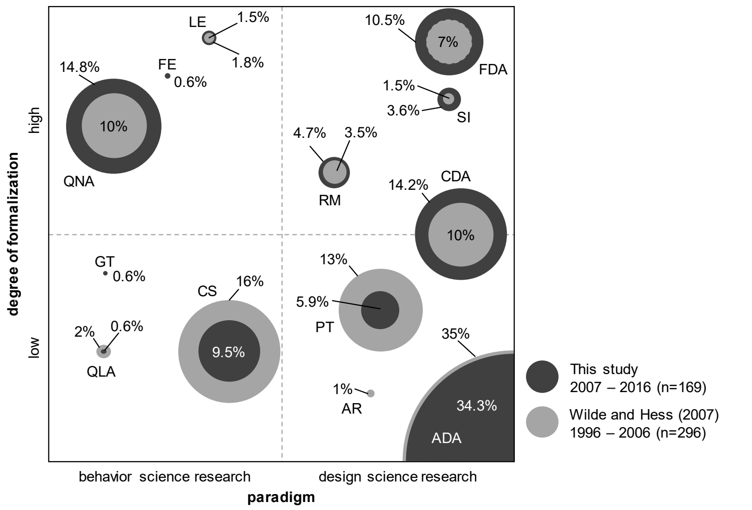

Figure 7. Use of research methods compared to Wilde and Hess [10] (only primary methods)

The results of the comparison illustrate that the ADA hast been the most frequently used method over the last twenty years (from 35% to now 34.3%). Moreover, we can observe an increased use of research methods with a higher degree of formalization, such as the QNA (from 10% to 14.8%), the CDA (from 10% to 14.2%), the FDA (from 7% to 10.5%), or RM (from 3.5% to 4.7%). In turn, the use of research methods with a lower degree of formalization decreased, such as the CS (from 16% to 9.5%), PT (from 13% to 5.9%), or the QLA (from 2% to 0.6%). In the study by Wilde and Hess [10], the six most frequently used research methods in descending order are: ADA, CS, PT, QNA, CDA, and FDA. Wilde and Hess [10] define these methods as the six core methods of the German-speaking IS discipline. Our findings confirm the importance of these core methods because these methods have also been the six most frequently used primary research methods in our data sample but in a different order: ADA, QNA, CDA, FDA, CS, and PT. Note that attention should be given when assigning research methods to research paradigms. For instance, in line with Wilde and Hess [10], we assigned research methods, such as the CS, the QNA/QLA, or the LE, to the behavior science research paradigm. However, as our results in section 4.2 reveal, the CS, for instance, has also been frequently used in design-oriented articles for the evaluation of IT artifacts.

In line with Wilde and Hess [10], we also compare our results with the international IS literature. In this context, Wilde and Hess [10] compared their results with the study by Palvia, et al. [20], who examined the use of research methods in the international IS journals between 1993 and 2003. In 2015, Palvia, et al. [21] presented a ten-year update (2014-2013) of this study, in which they analyzed 2487 research articles published in several top-ranked international IS journals. We compare our results with the study by Palvia, et al. [21] because the suggested classification of research methods is similar to the classification of Wilde and Hess [10] and frequency statistics are provided for each research method. Following the argumentation of Wilde and Hess [10], we merged the research methods suggested by Palvia, et al. [21] with our research methods in the following way: The research methods "literature review" and "literature analysis", as suggested by Palvia, et al. [21], were assigned to the argumentative-deductive analysis, which is conceptually similar to these methods. In a similar way, the methods "survey", "secondary data", and "content analysis" were assigned to the quantitative cross-section analysis. The method "interview" was assigned to the qualitative cross-section analysis and the method "field study" was assigned to the case study. The formal-deductive analysis and the simulation were grouped together since Palvia, et al. [21] do not differentiate between these two methods. Moreover, the research method "speculation/commentary" was excluded since we focused in our analysis on articles that provide complete research results (cf. section 3). Figure 8 illustrates the comparison of our study with the study by Palvia, et al. [21]. Following Wilde and Hess [10], we only compared the use of primary research methods.

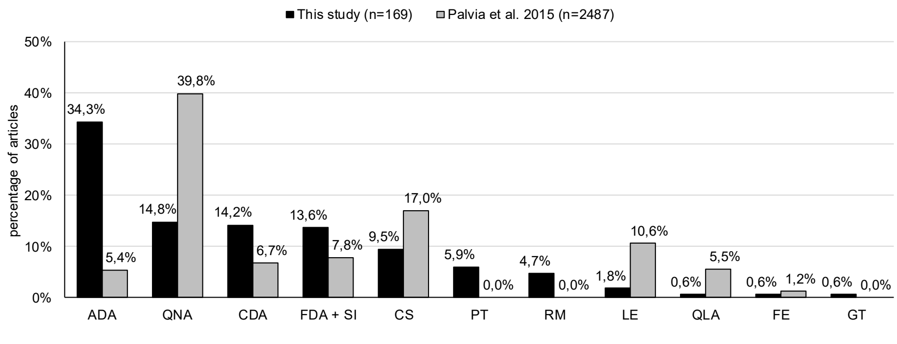

Figure 8. Comparison with Palvia, et al. [21] (only primary methods)

The comparison with the international IS literature reveals that research methods, which are typically associated with design science research paradigm, such as the ADA, the CDA, or the FDA/SI have been quite more often used in our data sample. Interestingly, PT, RM, and GT have not been mentioned in the international IS literature. In contrast, research methods, which are typically associated with the behavior science research paradigm, such as the QDA, the QLA, the CS, or LE, are more often used in the international IS literature than in our data sample. Consequently, our results support the assumption that the design science research paradigm still has a strong position in the German-speaking IS community [10], [11].

5.2 Implications

By illustrating potential shifts in the use of research paradigms and research methods, our results can be used as a basis for future discussion about the positioning and the challenges of the German-speaking IS community. Moreover, our results can also be considered as best practices that support researchers to become more familiar with the profile of the German-speaking IS community. In this way, researchers striving to publish their work in German-speaking IS outlets might better understand how they should position their research and which research methods might best fit to their research projects. For instance, our results show that research articles following the behavior science research paradigm typically employ a quantitative cross-section analysis or a case study. Accordingly, researchers following the behavior science research paradigm can also focus one of these methods or explicitly focus on a less frequently used research method (e.g., grounded theory) in order to generate new insights and further advance the field. Our results also support researchers following the design science research by showing which research methods are typically used in which stage of the design science research process (i.e., build or evaluate) and how these methods can be effectively combined. For instance, our results show researchers following the design science research paradigm that an IT artifact that is built by employing an argumentative-deductive analysis can typically be evaluated through the use of a case study.

5.3 Limitations

Our study has several limitations. First, the German-speaking IS community in this study is only represented by research articles published over the last ten years in the BISE journal. To verify our results, additional journals (e.g., ISeB) and conferences (e.g., WI, MKWI) of the German-speaking IS community have to be examined. Moreover, research articles published in international IS journals (e.g., AIS basket of top journals) and IS conferences (e.g., ICIS, ECIS) should be examined, given the fact that many researchers of the German-speaking IS community publish their work predominantly in the international IS literature.

Second, we focused in our study on the two paradigmatic positions, behavior science research and design science research because these two positions are frequently discussed in the German-speaking IS community [4-7]. However, and as illustrated in section 2, research paradigms can be classified in different ways. Future studies, for instance, can follow the approach of Chen and Hirschheim [12] and examine the use of positivist and interpretative research paradigms in the German-speaking IS literature.

Third, we used the established classification scheme developed by Wilde and Hess [10] to systematically categorize the collected research articles. By doing so, we were able to compare our results directly with the study by Wilde and Hess [10]. While each research method is well described in this classification scheme, it was sometimes not obvious for the research assistants how a particular research article should be categorized. While variations in the results were intensively discussed until a consensus was reached, other researchers might categorize an article in a different way. Nevertheless, we found the classification scheme very robust and we had no reasons for modifications. However, researchers might also apply other classification schemes (e.g., [13]).

Fourth, in our data analysis, we took a more detailed look at the research articles following the design science research paradigm. We made this decision because design science research is considered as the dominant research paradigm in the German-speaking IS community. In a similar way, researchers could also take a more detailed look at research articles following the behavior science paradigm. In this context, research, for instance, could examine average data sample sizes, potential combinations of qualitative and quantitative research methods, or cross-sectional vs. longitudinal studies.

Fifth, we did not consider various environmental factors. For instance, the identified shift in research paradigms (cf. section 4.3) might be a result of the change of the publication language of the BISE journal in 2014 [22]. However, to verify such assumptions, further analyses (e.g., interviews with the journal editors and editorial board members) have to be conducted.

6 Conclusion

In this paper, we summarized which research paradigms and research methods have been employed in the German-speaking IS community, represented by the BISE journal, in the past decade. Doing so enabled us to provide a trend for the last decade on which research methods were most often employed and on how the ongoing positioning discussion of the German-speaking IS community may have led to a change in the diffusion of research paradigms. By examining the use of multiple research methods, we gathered our data in a different way than the study of Wilde and Hess [10]. Accordingly, we were able to depict how many research methods were typically used in one research article and to show in how far the number of methods varied between behavior science and design science articles. Furthermore, we showed which research methods were most often used in combination and which research methods were used to build and to evaluate IT artifacts. With our results, we contribute towards guiding researchers when faced with the decision on how certain IT artifacts could be evaluated or how multiple research methods could be combined in one research approach. Within the light of the IS discipline being an interdisciplinary research field, we, therefore, contribute towards maintaining the paradigmatic and methodological diversity of our community. Moreover, we provide a fruitful and grounded basis for future debates about the positioning of the German-speaking IS community.

Abstract. Self-service Business Intelligence (SSBI) is an emerging topic for many companies. Casual users should be enabled to independently build their own analyses and reports. This accelerates and simplifies the decision-making processes. Although recent studies began to discuss parts of a self-service environment, none of these present a comprehensive architecture. Following a design science research approach, this study proposes a new self-service oriented BI architecture in order to address this gap. Starting from an in-depth literature review, an initial model was developed and improved by qualitative data analysis from interviews with 18 BI and IT specialists form companies across different industries. The proposed architecture model demonstrates the interaction between introduced self-service elements with each other and with traditional BI components. For example, we look at the integration of collaboration rooms and a self-learning knowledge database that aims to be a source for a report recommender.

Keywords: Business Intelligence, Big Data, Architecture, Self-Service, Analytics

1 Introduction

Companies' market capitalization generally consists of enormous amounts of data available to them. However, several companies struggle to use these large amounts of data for analysis or for a decision support as data is often not easily accessible to business users [1]. Business Intelligence (BI) describes the process from collecting data to a fact-based decision support. This decision support is extending from strategic questions into operational environments [2]. This leads to the demand to enable more users to use BI systems. Many companies have to make these decisions in a time-critical environment, which increases the need for a faster technical infrastructure. It is crucial to consider the time a department needs to access the relevant information. Self-service BI (SSBI) provides a solution to these demands. SSBI aims to "empower casual users to perform custom analytics and to derive actionable information from large amounts of multifaceted data without having to involve BI specialists. Power users, on the other hand, can accomplish their tasks with SSBI more easily and quickly than before." [3]

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Passlick, J.; Lebek, B.; Breitner, M. H. (2017): A Self-Service Supporting Business Intelligence and Big Data Analytics Architecture, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1126-1140

Not only the importance of self-service BI rises but also big data analytics is an emerging topic [4]. The increasing volumes of data and the need for advanced analytics means that BI architectures must be adjusted. Many papers discuss parts of a self-service environment but not a whole self-service BI/big data architecture (e.g. [5], [6], [7]). This leads to the following research question:

> *RQ: How is a self-service supporting BI/big data analytics architecture constructed?*

The proposed BI/big data analytics architecture model supports standardized BI reports and new big data analysis, and also enables power users to build their own reports. The research design is described in the next section. After that, the relevant literature is presented. Next, the new architecture and the self-service supporting elements of the collaboration rooms and the knowledge database are explained. Finally, recommendations and implications are given and discussed. Further, the limitations are named and further research is addressed. The paper ends with conclusions.

2 Research Design and Methods

In order to ensure methodological rigor, this study utilizes design science research as the underlying methodology as it is well suited for the development of an architecture. Mainly we were guided by the Design Science Research Model (DSRM) proposed by [8]. Figure 1 shows the phases and the steps that were carried out. Using a literature review based on Webster and Watson, relevant BI and big data architecture models were discussed and a research gap was identified [9]. In the next step ("Objectives definition") SSBI literature was analyzed and demands from practice were included. With these insights a conceptual model was developed. Open semi-structured interviews helped to improve the model in the "design & development" phase. This research method makes a free discussion about the problems and requirements of SSBI possible. Eighteen experts from different industries were interviewed (see table 1). Each expert had at least two years of experience with BI and on average, they had ten years. The interviews lasted on average one hour. The interviews were transcribed and analyzed by categorizing the main statements. Mayring's method makes qualitative statements comparable by analyzing the frequency in which they were mentioned [10]. The improvements were incorporated and the changed model was shown to the experts again. The new improvements were implemented in the next step.

Table 1. Interviewed experts

Job Group	*Expert Number*
Business consultant	1-3
SAP consultant	4-8
BI application developer	9-13
IT manager	14-18

The demonstration and evaluation phase of the original Peffers et al. model was summarized with an applicability check [11]. A focus group consisting of eleven researchers and a group consisting of twelve practitioners discussed the model with regard to whether it adds value for research and practice and whether it can specifically help in the implementation of SSBI.

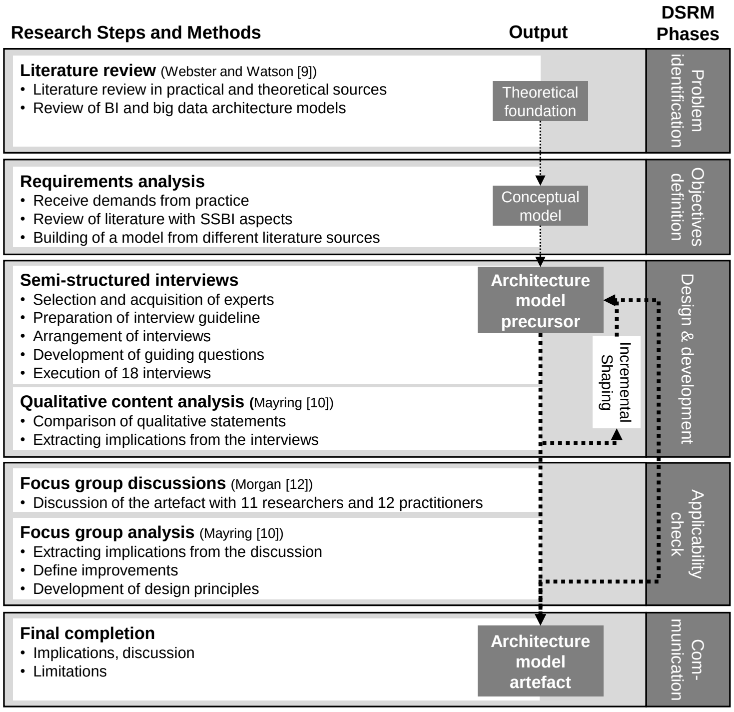

Figure 1. Research design based on [8]

3 Proposed Self-Service Supporting Architecture

3.1 Status Quo and Problem Identification

To identify the status quo of the SSBI research, a literature search was done in the AISeL, ScienceDirect, IEEEXplore, ACM and Emerald database. It was extended to include practitioner resources. Whitepapers by the BeyeNETWORK, The Data Warehousing Institute (TDWI), and Gartner were analyzed. The search keywords we used contained: “Self-Service” in combination with “BI”, “Business Intelligence”, “Big Data”, “Architecture” and “Analytics.” The publication dates ranged from 2005 to the present. The search resulted in 1,258 potentially relevant articles. They were reviewed by title and unsuitable papers were eliminated. If the title did not make a clear decision possible, the abstract, the introduction, and the conclusion were consulted. After that a forward and backward search in the most relevant papers was conducted. This included non-academic literature like whitepapers. Forty articles were deemed highly relevant for the development of the model. The literature review identified eight different BI or big data architecture models. Phillips-Wren et al. propose a big data analytics architecture model based on different other models [4]. The authors analyze existing BI/big data literature and describe a new user group they call data scientists. In the field of data processing infrastructures, Phillips-Wren et al. focus on the use of Hadoop clusters as a solution for big data use cases. Another model proposes a service-orientation character for a BI architecture [13]. They developed a BI architecture model that shows how this service character is implemented and which elements are necessary. Their model does not consider big data analytics use cases in particular. Another model is provided by [46]. In their work they focus on a mapping layer and a semantic layer which should be between the users and a data warehouse. A paper by Imhoff describes the different tracks for data processing in a big data environment [14]. It is a similar idea to the concept of a lambda architecture [15]. None of the previously discussed models make any statements about SSBI. The models by Watson and Eckerson provide some ideas for an implementation of SSBI [16-17]. Watson improved on Eckerson's model. The two models illustrate the difference between top-down and bottom-up BI. Top-down BI describes a BI environment that is very predefined and fixed whereas Bottom-up BI is an open environment that is not predefined [18]. Both models only differentiate between two user groups. [19] developed a model with a focus on SSBI. Their model describes different data processing methods, has a semantic layer, and covers big data analytics use cases. But they do not deal with different user groups. Another concept is to support SSBI with a business level ontology [20]. This is supposed to make the data model more comprehensible for the end user. [21] also propose a semantic layer to realize a unified business view of the data.

3.2 Requirements: Existing SSBI Aspects in Literature

In the second phase of the research design the objectives have to be defined. This is done by reviewing additional literature describing certain aspects of the implementation of SSBI. They can be separated into five groups: Special SSBI governance aspects and guidelines, concepts for an individual BI usage, social media elements in a BI environment, collaboration concepts and concepts for a knowledge database. This is summarized in table 2. Papers with special SSBI governance aspects and guidelines deal with changes in BI/big data analytics governance strategies [22], different ETL ("extract", "transform" and "load") processes [23], the need of special tools [24] or SSBI guidelines [25], [21], [26]. The individual BI usage group includes papers which describe concepts for an individual use of the BI environment. The idea of the integration of social media elements into a BI environment is to support the usage and the collaboration of BI users. Collaborative BI comprises the cooperation in the creation of reports or queries. In this context, it means human cooperation and not the grouping of systems. It is stressed that collaborative BI is not simply an element that has to be implemented into a BI architecture in terms of a technical platform; it also has to begin in the minds of employees [27]. The last group of papers considered deals with a knowledge database. The idea behind it is that the construction of every analysis and report is saved in an additional database. This includes the history of the conducted analyses and the order of their execution. Through that, forecasts of analysis paths should be possible.

Table 2. Overview SSBI literature

SSBI aspects	*Description*	*Sources*
Governance and guidelines	Changes in governance and guidelines for the realization of SSBI	[21-26]
Individual BI usage	Concepts which support an individual BI usage	[5-7], [28-30]
Social media elements	Social media elements in a BI environment	[31-32]
Collaboration	Cooperation in the creation of reports or queries	[5], [25], [27], [33-35]
Knowledge database	Database which saves construction and usage of reports and analyses; also examination of analysis paths	[36-41]

A combination of these elements with a comprehensive BI/big data analytics architecture is still missing. In the following, the focus will be on the architecture itself, the implementation of collaboration rooms, and a self-learning knowledge database. The collaboration rooms can then be connected with existing enterprise social media systems. After developing a first model with the findings from literature the model was improved through expert interviews. The following table 3 shows some of the major changes caused by the expert interviews.

Table 3. Improvements through expert interviews

Model layer	*Description*	*Sources*
Preparation	Multiple data access methods added; added direct access without using a storage system	Experts 1, 5, 7, 11, 13
Storage and analysis infrastructure	Generalization of the storage and analysis infrastructure into three tiers	Experts 1, 3, 6, 15-16
Presentation	Enterprise social networks added, skills added	Experts 4, 11
Knowledge database	Feedback loop added, development of the different use cases of the knowledge database	Experts 2, 4, 12, 15, 16
Governance	Order of the governance aspects according to by the experts mentioned importance	All experts had influence

3.3 Model Overview

In the following, the final model developed with the help of expert interviews is explained. Inspired by existing BI/big data analytics architecture models, the aim is to describe the whole process from the data sources through to the presentation of information. Big data is defined as “a phenomenon characterized by an ongoing increase in volume, variety, velocity, and veracity of data that requires advanced techniques and technologies to capture, store, distribute, manage, and analyze these data.” [42] This is the reason for the need of an advanced technical infrastructure. The changed technical infrastructure leads to a more complex data access for users which effects the possibilities of SSBI and the need to discuss the entire BI process from the source systems to the presentation of the data.

On the left side of the model are the data sources. The data sources are separated into internal and external sources. The data origin shown in Figure 2 are examples of those sources. The next step in data processing is the preparation of the data. Three different ways of accessing data exist. The first one is a direct access tunnel for analysis, where a special integration or caching of the data is not necessary. Second, direct access for real-time analysis is shown. The third method is a classic ETL process. But this process is extended by the possibility of performing an EL(T) process [43]. EL(T) stands for "extract", "load" and an optional "transform" process. This takes into account that in some big data analysis there can be a need for raw data that is not transformed. Different data access methods have to be taken into account for realizing SSBI. This is especially important for data scientists, who need access to raw data. In the proposed model, the storage and analysis infrastructure layer consists of two main and one optional tier. An element for data integration is necessary in every BI or big data environment. The job can be done with a classic data warehouse, but other technologies can take on this job, such as in-memory databases or Hadoop clusters. The other tier is the "big data refinery." This element ensures the necessary infrastructure for big data analysis and includes "experimental platforms." These platforms are essential for the data scientist user group. They need possibilities for experiments where data from different sources can be staged, merged, and analyzed [44]. The last tier consists of optional elements that could be necessary for a real-time BI realization, such as data caches [45]. To simplify access to data across multiple systems, there is the semantic layer which also includes the mapping layer described in [46]. It realizes a unified access to the different storage systems and an easier access to the data for users with low technical skills. A possible embodiment of the semantic layer could be a service oriented architecture. A service oriented BI architecture is described in the work by Pospiech and Felden [13].

The presentation of the data is separated into three portals. This separation is done according to the skill and the need of the BI user. In the dashboards, the users are consumers of predefined reports and they have a low degree of freedom [16-17]. Dashboards are mainly used by casual users. On the other side is the group of data scientists. In their data laboratory they have a high degree of freedom, as well as the access rights and tools to completely build their own analysis and reports. As mentioned above, they need platforms for experiments with new analyses because they are dealing with large and unstructured data sets. Between those two platforms the analytics portal is located. This is the main platform for SSBI applications. Reports are predefined but users can adjust the reports with restrictions. In general, the experts agreed with this representation. Some experts had a slight different user group definition in their own company like Watson also distinguishes between five user groups [44]. These user group definitions can therefore be adapted to the individual needs of the respective company. This is expressed in the following quote: *"Sure, there might be sub-groups, especially within the group of the power users and in the data scientists. But I think with three groups it is quite concise. Those are the right groups in the model. It is also* *meaningful to distinguish the groups by the user skill."* (Consultant, mid-sized consulting firm - interview conducted in German)

In addition to the definition of the different user groups, one expert added that the interaction between the portals plays an important role in supporting SSBI. *"The transition must be very fluent. The dashboard must be easy to use and allow a simple jump into details. So you need to have a drill down functionality. The continuity is important and just the same the usability. One must like to use the tool or the portal, because it is easy to use."* (Head of a quality management department, mid-sized industrial company - interview conducted in German)

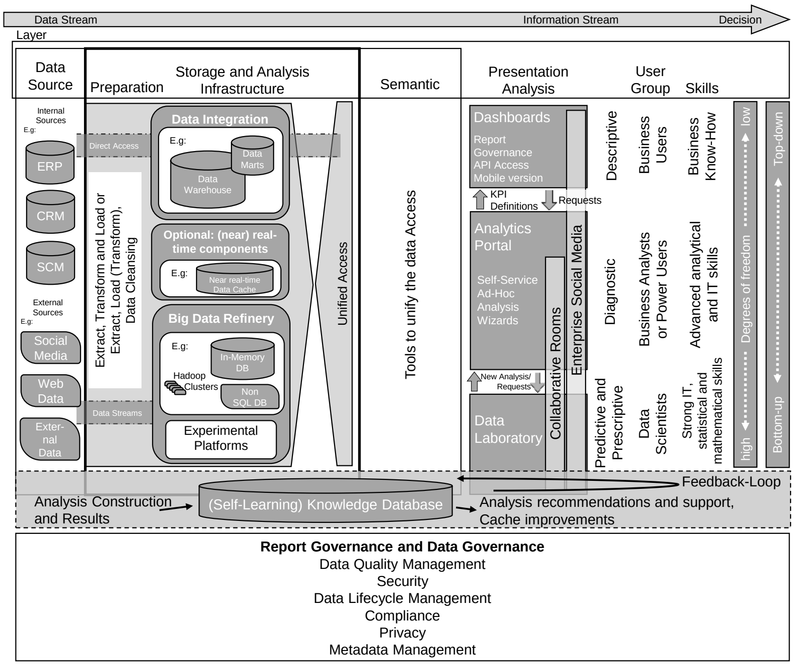

Figure 2. Proposed architecture model

To support the interaction the developed model is connected to an enterprise social network of the respective company. In that way the collaboration rooms can be merged with the enterprise social network and the exchange between the user groups can be encouraged. Below the model different aspects of a report and data governance are mentioned. They are ordered according to a ranking by the experts.

After giving a rough overview of the model the two main elements for the support of SSBI are described.

3.4 Collaboration Rooms

The "collaboration room" architectural component is a platform where a direct cooperation from users of the analytics portal and the data laboratory is possible. Users of the same portal can cooperate while working on the same platform. Also, users of the analytics platform can give feedback for analyses performed by data scientists. Business analysts can also ask for special sub-parts of their analysis to be built by data scientists. It is important for the process that the collaboration history is saved. Today most collaboration communication is done by email. The problem is that only the people involved have access to the origin story of a decision-making process. A collaboration platform can replace email communication. [25]

Figure 3 shows proposed classes of a collaboration room environment. It represents the different user groups and the related platforms. Business users and analysts can create requests for a new report or analysis. Business analysts can also ask for help with the construction of a report. The collaboration can take place inside a user group or business analysts can make requests to data scientists. These requests are connected to one or more reports. Every report belongs to a workspace. This is the main room where the collaboration can take place. Inside a workspace it is possible to create several communication rooms. One-on-one and group discussions are possible. The workspaces in conjunction with the communication rooms provide the opportunity for discussing reports, creating different report versions, and conducting experiments. All these elements support the collaboration between the different user groups of the BI/big data analytics architecture.

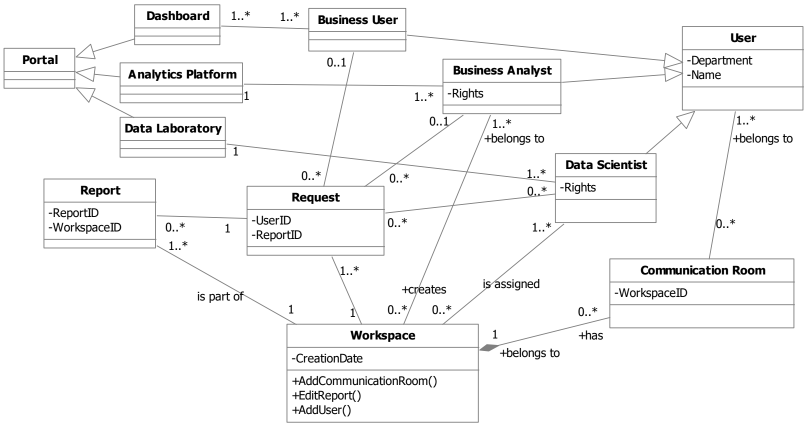

Figure 3. Collaboration environment conceptual class chart

3.5 Self-learning Knowledge Database

The knowledge database saves all performed queries except special experiments in the data laboratory. This includes the results of the queries as well as the queries themselves. It is useful to keep the queries for later use because they can have enormous value for later analyses. An historic analysis database creates the possibility for the replication of an analysis, which makes the building of new complex analysis easier. Here a service orientation shows its advantages because it is possible to easily see which components and services were used by different analyses. There is also added value generated by the possibility of showing related analyses [35]. This helps a business analyst build a new analysis or find further queries that were created in the past or by another user. [36], [39]

After conducting the expert interviews, several reasons for the introduction of a knowledge database were identified. The main reason is to improve SSBI with recommendations for similar analyses or by supporting the developing process of analyses [35], [38]. It can help to improve dashboards because with the database, it is known how often a report was accessed. Another important point is that the knowledge database helps to fill a cache in advance. This is made possible by the self-learning mechanism, which allows predictions. If we know which analyses are accessed frequently, the results can be computed in advance and saved into the cache. Then, fewer calculations have to be computed because the results are already in the cache, which decreases the response time. The prediction of queries can also be done by using Markov models [41].

Figure 4 shows a class chart of the proposed knowledge database. It represents the three potential use cases: Help while building new reports or queries, recommender for further analyses that might be interesting for the user, and intelligent filling of caches. A user builds or calls an analysis. This call is written into the knowledge or meta database just like the analysis path. The analysis path consists of the order and the connected queries a user calls in a session [40]. With the learning engine, all the data from the meta database is analyzed. Intelligent algorithms look for relations inside the queries and between the analysis paths. Different learning engines with different algorithms are possible.

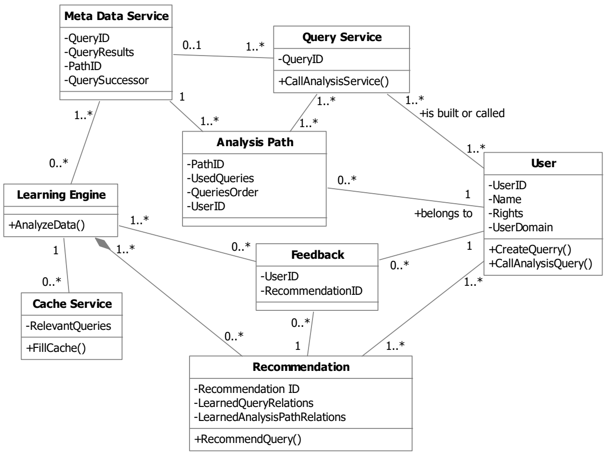

Figure 4. Knowledge database conceptual class chart

A problem could be that big amounts of data are necessary for meaningful results. This was already discussed with the experts: *"What you really need is: First you need a lot of different executions on top of your system. So it won't work in a single enterprise because you won't have enough data for your analytics of the analysis templates or mechanism that work and you need very good feedback functions. So you need to look in the usage data. So what is used and what is successful. […] I think that it will be very hard to build it on premise. It is something that works in pretty large companies because* *otherwise there is not enough usage for this."* (Vice President Platform, cloud BI provider) The results of the learning engine is then used by the recommender engine and the cache service. For the learning process it is essential to have a feedback loop. This means that the user can evaluate the results of recommendation. This feedback is then used by the learning engine for the improvement of the recommendation processes.

4 Implications, Recommendations and Discussion

The aim of academic literature is not only to focus on theory, but also to provide relevance for practitioners in order to prevent research from becoming an end unto itself [11]. For this reason, an applicability check was done after the final model was developed. In two focus groups consisting of practitioners and researchers, it was discussed whether the model can help realizing SSBI. In general, it was stated that the architecture model is helpful because it reduces complexity and gives companies a point of orientation. It was further remarked that for an application in practice, it must be defined further which use cases are relevant for SSBI. The focus groups also discussed potential main user groups in a SSBI environment. The discussion participants thought that it might be a user group that has ad-hoc questions that are not regular. They stated the need of a semantic layer and discussed that a service orientation as described in the model [13] is useful, but it requires a high degree of standardization in processes for the acquisition of information. This is a big problem in companies because these processes are mostly unknown. In the company of the focus group members the aim is to use '*Business Objects Universes'* for the realization of a semantic layer instead of realizing a complete service oriented architecture. In further projects '*SAP Business Objects Design Studio'* will be used for the creation of dashboards and '*Analysis for Office'*, an Add-In for *'Microsoft Excel'*, should be used for the analytics portal of the architecture. A data laboratory is not planned at the moment. The knowledge database can help new users in particular because they can get an idea of what information is available. This is supported by the statement of one expert: *"A typical use case for our big customers is that if you are a user and you create a new report then you have 99% chance that somebody else has already done this report. Exact this report! So that is the simplest thing. You can just search the report, look at the structure, look at the dimensions or whatever components the user is working with and start with what is already there. The second thing is some kind of recommendation. In our case it can be driven by what people will be doing."* (Vice President Platform, cloud BI provider)

Another point is the meaningfulness of the collaboration rooms. A different expert describes the value that is generated through a well-organized collaboration, but notes that there are still good implementations missing. *"I think this is valuable and useful because I think this should be the way into the future. Get out of the habit of each person making his or her own report, but that you can also reuse more of the reports. […] However, in reality it is not so simple to find platforms that make the realization possible. I have not yet seen and experienced properly implemented collaborative rooms in practice."* (Consultant for SAP BI, consulting firm - interview conducted in German) Table 4 summarizes the findings of this research in design principles. Besides these design principles the main output of this research is the architecture model which is presented in Figure 2. It shows the interaction between the elements and their position in the BI/big data analytics process.

Table 4. Design principles

Architecture element	*Design principle*
Data access	The data access via different data sources should be simplified by a unified access. This paper proposes a service orientation for the realization.
Semantic layer	To achieve a unified access to the data there should be a semantic layer which connects the different data sources. This could be in a service oriented but the applicability check showed that other realizations are possible, too.
User groups	To address the individual needs of the BI users, a definition of different user groups is necessary. This paper proposes three different groups but point out that this has to be adjusted according to the structures of the respective company.
Different portals	To address the different needs of the user groups, different portals are suggested.
Collaboration	Collaboration opportunities should be considered in a BI/big data analytics architecture. Enterprise social media can support the collaboration in a BI/big data environment.
Knowledge database	A knowledge database should be used in conjunction with a service oriented architecture to assist new users, for an intelligent cache usage and to help users with building new reports.

In the following section, the results of this research are described and compared with existing work. In terms of a semantic layer, as proposed in the literature [28], [30], the developed model stays universal but sees advantages in a service-oriented approach [13]. This is a concrete solution and it is assumed that this service orientation can be handled well in the knowledge database. Elements like a service repository are seen as being useful in supporting SSBI. Some experts criticized the fact that a service orientation would require a lot of effort in the beginning to standardize all the processes and services. The focus group decided that this might be a general problem of SSBI. The right balance must exist between standardization and flexibility.

In a big data analytics architecture, a new storage and analysis infrastructure is necessary. This paper connects the idea of many big data contributions [4], [17-16], [19] and assigns the new technologies to three tiers, similar to other proposals [14-15]. Especially the big data refinery in conjunction with experimental platforms are important for the independent work of the data scientists. The presented user groups are similar to the definitions of other research [4], [6]. The expert interviews showed that these definitions can be found in practice, but the probability of deviations in practice is high. Therefore, it is important to know the user groups of the BI architecture in order to correctly address the individual needs of each user group in an SSBI context. As mentioned by one of the experts, there is a need of fluent transitions between the portals.

The knowledge database can also support SSBI. It can contribute to an intelligent filling of analysis caches [41] and can recommend further analysis for users, which especially helps new and unexperienced users [36-39]. Analysis knowledge can be preserved with the use of the knowledge database. Nevertheless, the self-learning function is only realizable if enough data is available. This restricts the use of the self-learning function to large companies or to the use in a cloud environment. Research is moving towards presenting a class chart to give a better idea of how a self-learning knowledge database can be built. This enables storing implicit knowledge of BI users which facilitates an increased value for companies. This is supported by the results by Kretzer et al. [39] who find out that the ease of use of a BI platform is higher with a recommendation system. But they do not consider historical data and therefore they not have included learning loop. The developed collaboration rooms are based on the paper by Berthold et al. [25]. A more concrete implementation possibility is presented and the different user roles are shown. [33] describe another approach with the reformulation of queries in a peer-to-peer network. The collaboration rooms can be seen in connection with enterprise social media elements [31-32]. The expert interviews and the focus group discussion confirmed that the value of collaboration in a BI/big data analytics context will increase and collaboration rooms are a solution for that. It is suggested that collaboration rooms are included into companies' BI/big data analytics strategies as presented in Figure 3.

The whole architecture helps companies define their expectations of a BI/big data analytics architecture. When comparing an existing architecture with the proposed model, weak points and improvement potential can be shown.

5 Limitations and Future Work

A rigorous literature review was conducted. Nevertheless, this method has limits. The search was only done with keywords in English. Publications in other languages could not be considered unless they could be found by means of a forward or backward search. Eighteen interviewees were asked for critique and improvements. To obtain more objective opinions, a larger number of interviews would be useful. This could reduce the likelihood that important aspects are forgotten or misrepresented. The background of the experts is rather homogeneous. Most experts are BI consultants or BI developers who are good at discussing the overall architecture. The opinions of business users are still missing. Further research could use these opinions to improve the design of the presentation layer. Especially in relation to SSBI, their view might still be a significant enhancement. Furthermore, different business sectors were not considered. Thus, no statements about the adaption of the architecture to specific branches is possible. Further research can be done by asking how the architecture must be adjusted according to a special domain or how different sizes affect the architecture. It is obvious that the architecture has to be adjusted individually for every company. It was mentioned by the experts, for example, that the realization of a self-learning knowledge database is highly dependent on the amount of potential input data. If a company is not big enough to provide a sufficiently large amount of reports, inquiries, and analyses, there might not be enough input data. The recommendation function is then very limited because the learning algorithm does not get enough data. In such a case, only a simple knowledge database without self-learning algorithm could be realized. Statements about the amount of required data for a good working self-learning BI recommendation algorithm are not possible. Further research is needed with respect to that area. A self-learning knowledge database prototype should be developed. This could enable further discussions on this issue. The alternative would be a cloud-based knowledge database. By analyzing the reporting and analysis paths of several companies, a cloud implementation could deliver meaningful recommendations. But for that to happen, many architecture components would have to be moved to the cloud. Another question is which algorithms can be used to get useful results out of this analysis. The inclusion of the actual decision into the BI process is an outstanding research question. In this context, it could not be explored to what extent the actual decision can be included in the knowledge database.

6 Conclusions

The developed model shows significant progress in relation to other proposals [4], [16]. It is extended especially with regard to SSBI. The ideas result from both practical and academic literature and in particular from interviews with experts. A focus group discussion was used to check the practicability of the model. The new model represents a universal BI / big data analytics reference model. It can be seen as a guideline for companies, who can evaluate their existing architecture with the aim of improving their SSBI or big data analytics capabilities. It takes different user groups and their different demands into account in a BI/big data analytics architecture. Collaboration rooms and a (self-learning) knowledge database are presented as additional supporting elements. Discussions with practitioners have shown that these elements have great potential to support SSBI because they make implicit knowledge of BI users usable. In further research the applicability should be reviewed by various companies.

Abstract. Big data analytics is becoming a veritable source of competitive advantage as it helps companies to better understand their business environment and to create or improve their products and services accordingly. However, big data analytics also poses challenges to organizations with respect to establishing the required capabilities. Building upon a design science research approach and the Work System Theory as a kernel theory, we identify several capabilities necessary to leverage the potential of big data analytics. To achieve this goal, we conducted 16 interviews with experts from an IT-strategy consulting firm. We furthermore organize the identified capabilities into a coherent model. The resulting capability model consists of eight capability groups that contain 34 capabilities. It provides a basis to systematically develop the necessary capabilities for the adoption und strategic usage of big data analytics.

Keywords: big data analytics, capability model, work system theory, design science

1 Introduction

The accumulating evidences of potential benefits provide a legitimation to consider big data analytics (BDA) a sustainable phenomenon rather than a buzzword [1], [2]. BDA opens up new business opportunities, such as using “real-time information from sensors, radio frequency identification and other identifying devices to understand business environments at a more granular level, to create new products and services, and to respond to changes in usage patterns” [2, p. 22]. The implementation of BDA poses challenges especially regarding the development of appropriate organizational competencies [3], [4], because the “expanding sea of data […] is either too voluminous or too unstructured to be managed and analyzed through traditional means” [2, p. 22].

Those challenges originate from the vast amount of data that comes in both structured and unstructured forms and from various sources such as the Web, social media, or the Internet of Things [5], [6]. This leads to specific and novel implications for organizations on a procedural (e.g., new forms of decision-making), organizational (e.g., new employee competencies and new structures) and technological (e.g., new platforms and tools) level. Accordingly, the adoption of BDA requires organizational transformations as well as the development of specific analytical and technological capabilities

(e.g., the effective deployment within the current IT landscape) [1], [7], [8]. For instance, the capability development encompasses the acquisition of sufficient knowledge of how to extract business value from big data and the application and management of the underlying technologies [2], [9]. Companies have a tough time transforming towards a data-driven company and recognizing their data not as a side-product but as a source of competitive advantage. The development and adoption of capabilities represents a first step in following this path. To facilitate this journey, maturity or capability models provide guidance for companies to assess their current situation regarding the capabilities required for a task (i.e., BDA) [10]. However, to the best of our knowledge no capability model exists in IS research, which helps companies to develop and manage big data analytics competencies [11]. In order to address this apparent research gap, we pose the following research question: "*Which capabilities are required to build a big data analytics competence?*" A capability model for BDA will help to assess the current state of a company and to identify necessary initiatives to build required capabilities. To develop such a model in a rigorous scientific process, we follow the design science paradigm. Building upon the Work System Theory as kernel theory and the results of 16 expert interviews, we present 34 capabilities and summarize them in an initial version of our model that will be developed further in future iterations.

Next, we describe the theoretical background and related work. In section 3, we present our research approach. Thereafter, we discuss the interview results and describe the resulting capability model. We conclude by discussing future research avenues.

2 Background and Related Work

To set the background for our research endeavor, we first reflect BDA from a capability perspective, before we discuss related work that is potentially relevant for our research.

2.1 Big Data Analytics as a Set of Capabilities

BDA does not only stand for technological but also for organizational characteristics (e.g., data-driven culture) and their potential to be a source of competitive advantage [4], [12]. From a technological standpoint, BDA as a competence can be characterized by processing requirements with respect to data volume, velocity, variety, and veracity [23]. Big data itself is regarded as the result of all these dimensions [13]. However, conceptualizing BDA purely from a technological perspective does not sufficiently characterize the potential role of BDA in companies [14]. Indeed, BDA requires a data-driven culture, new analytical methods, competencies and capabilities [15]. It "forces us to look beyond the tried-and-true methods that are prevalent" [16, p. 44] today and is characterized by the "belief that large data sets offer a higher form of intelligence and knowledge that can generate insights that were previously impossible, with the aura of truth, objectivity, and accuracy" [17, p. 663]. Data itself is useless if no process of sense-making takes place and the gained insights are not used to make data-based decisions [18], [19]. Successfully translating big data-drawn insights into convincing arguments for managers changes the dynamics of managerial decision-making [5]. In this context, the development of specific BDA capabilities can be seen as a major challenge for companies, especially for those digitizing their business models [8].

BDA has a transformative effect on the organization (e.g., substitution of inefficient business models) or competitive landscapes (e.g., entrance of new players, shift of power), which in turn leads to better organizational performance [1], [3], [8], [13]. BDA uncovers previously unknown patterns, correlations and information and can be seen as a solution for gaining better insights from diverse und previously unexploited data sources (e.g., social media, wearables, RFID) [20]. Organizations nowadays realize that analyzing big data can help to stay competitive in terms of profits, speed, efficiency and customer-orientated service through timely and profound decisions [12]. BDA hence poses a potential competitive advantage [1], [12], [13]. However, before this advantage can be achieved, organizations need to analyze how they can use BDA to improve their business and how they can establish necessary organizational capabilities [19], [20]. Organizational capabilities, in general, comprise skills, abilities and expertise of an organization and they are idiosyncratic and inimitable [21]. Representing a source of organizational value and leading to competitive advantages, they are connected tightly to the history, culture, and experience of the firm [22–24].

In summary, BDA can be understood as a strategic competence to gain analytical insights from big data, which has a specific business value and cannot be analyzed by traditional approaches such as data warehousing. The strategic competence equally results from technological and organizational capabilities.

2.2 Related Work

To identify potentially relevant related work, we conducted a literature review following the guidelines of Webster and Watson [25] and vom Brocke et al. [26]. In accordance with our research question, we examined which capabilities are seen as relevant to build a BDA competence. Furthermore, we were interested in identifying prior BDA management approaches and/or maturity models to verify the research gap. We searched the literature base for articles addressing the maturity of BDA initiatives or the required capabilities. As keywords, we used three search terms (see Table 1) to query the *AIS electronic Library* and the *EBSCO Host Business Source Complete* database. To extend the scope, we also queried *Google Scholar* using a fourth search string [27].

Table 1. Results of the literature review

Database	*Search String*			*Hits*	*Relevant*
EBSCO AIS	“big data”	AND	(“maturity model” OR “capabilities”)	16	9
	“business analytics”			17	1
	“business intelligence”			54	9
Google Scholar	allintitle: capabilities OR "maturity model" "big data"			25	7
Total				**113**	**26**

We screened the titles and abstracts of the articles to sort out irrelevant articles. Additionally, we conducted forward and backward searches based on the identified literature [25]. We then interpreted the remaining articles qualitatively, excluding non-peer-reviewed and redundant articles [25]. We further excluded articles that only use one of the keywords as either the methodological approach or as supplementary information.

In particular, we found several business intelligence maturity models (e.g. [28]–[31]) as well as reviews thereof ([32], [33]). While maturity models targeting the business intelligence or business analytics domains – as antecessors of BDA [1] – are potentially relevant for BDA, BDA differs to a great extent regarding the specific skills, competencies, and, in consequence, the required capabilities [34], [35]. Business intelligence and business analytics rather is focused on storing and analyzing structured historical data that is managed in enterprise systems or data warehouses [34], [36]. The according maturity models aim at supporting this task usually by focusing on capabilities to conduct the extraction, transformation, loading, warehousing, and historic analysis of data [34]. Moreover, some models hardly provide details, making their applicability difficult (e.g., [29], [31]), focus on technological capabilities of companies (e.g., [30]), or do not specifically look at the capabilities needed at all (e.g., [28]). Other models are too specific, focusing solely on topics such as information quality [37]. While these models might also provide guidance for a BDA scenario, BDA differs from business intelligence both in technological and organizational aspects [34]. From a technological perspective, BDA differs regarding the breadth and depth of the processed data as well as regarding the types of questions answered. In particular, BDA builds upon exploration, discovery, and prediction. The experimental nature of BDA in combination with often undefined business questions frequently results in a co-location of BDA units with business units to work closely to the analyzed products and processes [2].

While business intelligence maturity models provide a good starting point for the examination of BDA capabilities, literature only provides sporadic evidence concerning the competencies that are required in such a scenario. Debortoli et al. [34] have identified several capabilities based on an analysis of job descriptions. However, such an analysis can only provide first indications as there might be differences between the capabilities that a big data analyst ideally should bring along and those that are required in practice. An MISQ special issue discusses different analytics techniques and describes, how business intelligence and analytics (BI&A) frameworks can be used to conduct BDA and where they might have to be updated [36]. While several application domains are highlighted, specific capabilities are only mentioned as an aside, though. In particular, the article does not summarize the capabilities needed to succeed in BDA.

We were only able to identify one article focusing on this specific topic [7]. It describes challenges for governmental organizations that aim at using BDA. Proposing a preliminary set of capabilities that organizations ought to have to enhance their service through the use of big data, they address a comparable research question. However, they limit their framework to governmental organizations and only propose domain-specific capability categories. We complement this research stream by investigating, which capabilities are important for private organizations such as enterprises.

3 Research Method

To contribute to the closure of the above-mentioned research gap and to provide guidance regarding the capabilities required to perform BDA, we develop a capability model. The development of the capability model is based upon the design science paradigm, which provides guidelines for the rigorous scientific construction of novel artifacts such as constructs, models, methods, or instantiations [38], [39]. To ensure the traceability of our results, we followed a structured design science process that has been proposed to support the systematic development of capability (maturity) models [40]. This process consists of the problem definition, scoping, model development, and evaluation stage.

During the process, several requirements have to be fulfilled [40]. First, the process should be conducted iteratively. In this paper, we report on the results of the first iteration. Repetitions of the above-mentioned stages will be conducted in future iterations to improve both the structuring of the model and its level of detail. Second, the iterative nature of the process shall be used to apply multiple methodologies such as literature reviews, Delphi studies, or expert interviews [40]. As sources regarding the capabilities required for BDA are still scarce in literature, we decided to begin designing our capability model based on the results of expert interviews, which we conducted to identify relevant capabilities. Third, the developed capability model ought to be compared to existing models to ensure that it indeed provides novel results. To fulfill this requirement, we relate our capability model to existing approaches in section 5. In general, it is furthermore necessary to describe the relevance of the addressed problem to document the problem statement and justify the achieved results [40], [41]. Having documented the first two aspects in the former sections of this paper, we now focus on describing and justifying the results, i.e. the developed capability model.

The design of the capability model is informed by the Work System Theory [42]. We used the holistic enterprise perspective of the Work System Theory as conceptual basis to address all relevant facets of a company that performs BDA to deliver new products/services or to improve existing ones. This includes internal (e.g., internal business units) as well as external customers, which profit from BDA. Generally, a work system is a “view of work as occurring through a purposeful system” [42, p. 91]. It consists of nine components (see Figure 1): *customers* (people receiving products and/or services from a work system); *products* (products and/or services created by a work system); *processes* (work steps to create products and/or services); *participants* (persons doing work during the processes); *information* (either used or created); *technologies* (tools and techniques); *environment* (outside factors affecting the work system); *infrastructure* (resources used by the work system); and *strategies* (goals of the work system). We structure our capability model into different competence fields accordingly.

Moreover, we used the work system components as a structural guideline when interviewing experts about the capabilities necessary to perform BDA. We hence asked for required capabilities in each of the fields. Generally, an expert is someone with privileged knowledge about the topic of interest [43]. As BDA is not a routine task in most companies yet and we nevertheless wanted to obtain knowledge from experts (i.e., people who are intensively involved with BDA), we decided to interview members of a leading consulting firm that is specialized in supporting big data initiatives. In so doing, we gained access to specialists who had significant expertise in BDA and also had worked in different application domains, thus ensuring a broad feedback. Overall, we interviewed two managing partners (MP), three partners (P), eight managing consultants (MC), two consultants (C), and a business analyst (B). We decided to conduct semi-structured face-to-face interviews, since they are considered to be the superior data collection technique for interpretive investigations [44]. The interview guideline was structured according to the recommendations of Myers and Newman [45]. In a first part, we asked for demographic information. With respect to each work system component, we then asked for potential capabilities required to carry out BDA.

To identify relevant capabilities, we performed a cross-interview analysis [46]. First, we analyzed the gathered data using open coding techniques. Doing so allowed us to identify recurrent patterns, which we thematically grouped into segments [47]. From the segments, we could then derive the capabilities that were recurrently emphasized by the experts. Furthermore, we analyzed the segments for consistent and distinctive statements to examine if the experts' perception of the capabilities was homogeneous.

4 Capability Model

Based on the interview results, we identified 34 capabilities (CAP1-CAP34), which were mentioned as important by at least by 25% the experts.

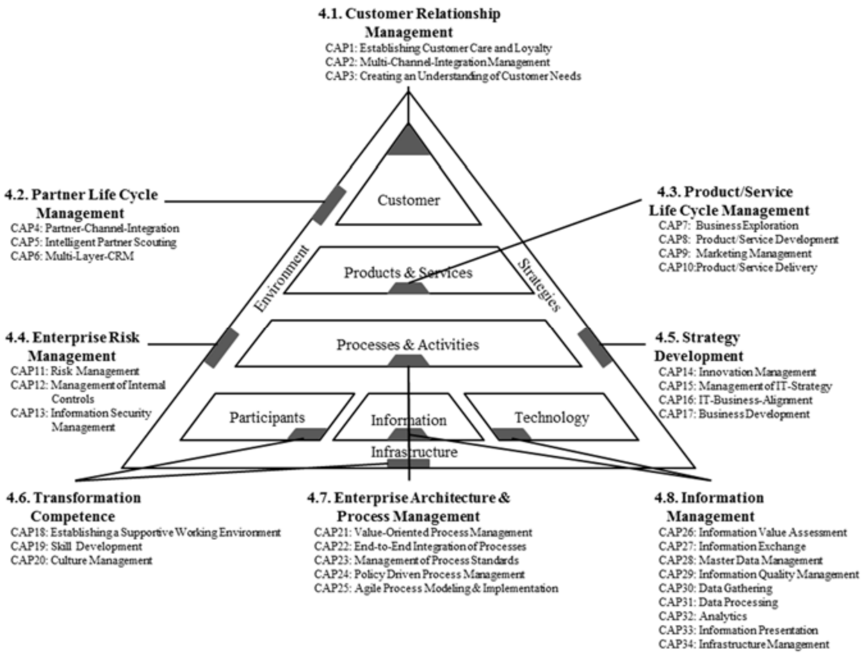

Figure 1. Big data analytics capability model according to the work system elements [42]

Based on their topic, we grouped the identified capabilities into the following eight competence fields, which each contain between two and eight capabilities: Customer Relationship Management, Partner Life Cycle Management, Product/Service Life Cycle Management, Enterprise Risk Management, Strategy Development, Transformation Competence, Enterprise Architecture and Process Management, and Information Management. We arranged the competence fields according to the elements of the Work System Theory in Figure 1. The resulting capability model provides a generic library of capabilities that can be used to assess a company's ability to successfully perform BDA.

Customer Relationship Management (CAP1-3). The capabilities in this competence field describe a company's ability to involve its customers into the value generation. The active involvement of the customers is critical to gather customer data and use it to improve or create products and services. *Establishing Customer Care and Customer Loyalty* (CAP1; mentioned by as important 6 out of 16) facilities helps involving the customer after the buying process and taking care of customer incidents, ensuring customer satisfaction and customer retention and cross-/up-selling: *"I have to make sure that my customer continuously requests my big data enabled services" (P#2). Multi-Channel-Integration Management* (CAP2; mentioned by 7 out of 16 as important) is required to connect traditional channels with new digital channels (like social media, mobile sales etc.) in order to intensify the communication with the customer and generate data: *"You have to make sure that your customers can contact you through any communication channel, which they want to use" (P#1). Creating an Understanding of Customer Needs* (CAP3; mentioned by 6 out of 16 as important) by evaluating appropriate information is a prerequisite to respond to customer requirements and to offer products/services to better suit the customers' needs: "*If I want to offer services or products, improved by big data analyses, I have to be really close to the customer needs in order to appropriately design such services and products" (P#1).*

Partner Life Cycle Management (CAP4-6). Installing BDA as a means to create or improve products/services typically requires the integration of diverse data sources including data from members of the existing value chain or new data suppliers. The capabilities contained in the competence field Partner Life Cycle Management describe a company's ability to flexibly coordinate and integrate such partners in supply chains and to create value by creating partnerships. Providing means for a systematic *Partner-Channel-Integration* (CAP4; mentioned by 6 out of 16 as important) ensures that all partners taking part in the value chain can be integrated. In particular, interfaces and communication protocols have to be established to allow the exchange of data: *"A lot of data is coming from my partners. Thus, it is very important to integrate them with the right channels" (P#1).* A company also has to have an *Intelligent Partner Scouting* (CAP5; mentioned by 4 out of 16 as important) facility to identify suitable network partners with whom to generate a competitive advantage in a specific product/service domain. In particular, this includes an examination of the credibility and reliability of the partner with respect to the dimensions time, budget, and quality to ensure that the partnership does not pose a risk: *"For topics like big data you need the right skills as well as the right partners" (MP#2).* Making use of a *Multi-Layer-CRM* (CAP6; mentioned by 4 out of 16 as important) allows sharing collected customer data with the upstream partners in the value chain, for instance by using the above-mentioned partner channels. In so doing, all members of the value chain can use the collected data of the end-customers to improve their products/services: *"I need to know the customer of my partner and to have the right communication protocols" (MC#8)*

Product/Service Life Cycle Management (CAP7-10). BDA can help to monitor the organizational environment as well as to improve products and services. To benefit from such an approach, a company has to reposition its *Product/Service Life Cycle Management* towards handling big data based products/services. Among others, this repositioning affects the *Business Exploration* (CAP7; mentioned by 4 out of 16 as important) activities of a company. On the one hand, the company needs to develop an ability to introduce new big data based products/services and the ability to withdraw them from the market if they do not add value (release often, sale early). On the other hand the company needs to be able to observe the market to discover potential new entrants: *"This is the whole topic trial and error…develop and see how the service works out and, in the next step, to improve the service" (C#1).*The repositioning also affects the *Product/Service Development* (CAP8; mentioned by 5 out of 16 as important), i.e. the ability of a company to develop big data based products/services according to the customer needs and according to the desired product/service portfolio: *"I have to consider the customers' expectations in order to deliver suitable services and products" (P #2).*By means of an adjusted *Marketing Management* (CAP9; mentioned by 4 out of 16 as important), a company has to ensure the proper marketing of big data enabled products/services. In particular, a company needs to successfully highlight the added value of such products/services, so that potential customers accept the new offerings: *"You have to ensure through specific marketing methods that a customer becomes aware of your service portfolio and says: oh, look, how awesome, they offer services based on big data analyses" (P#2).* Finally, the repositioning also affects the *Product/Service Delivery* (CAP10; mentioned by 5 out of 16 as important), i.e. the ability of a company to continuously deliver big data enabled products/services in time and with the promised quality: *"As service provider I have to be able to package and deliver continuously the insights of the big data analyses" (MC#4).*

Enterprise Risk Management (CAP11-13). The extensive usage of big data in business-critical domains implicates several potential risk factors. The category *Enterprise Risk Management* characterizes the robustness of data-driven business models and ensures an acceptable risk level through appropriate measures. A *Risk Management* (CAP11; mentioned by 5 out of 16 as important) is required to identify and prioritize data-related risks and their probability of occurrence, e.g., data theft. It includes the introduction of measures to reduce the likelihood of data risks and a monitoring system to supervise risks: *„You have to identify and prioritize both the amount of damage and the probability of occurrence of the specific risk" (MC#1).* A corporate *Management of Internal Controls* (CAP12; mentioned by 6 out of 16 as important) helps monitoring compliance guidelines through the development and maintenance of control systems (governance & compliance management system). This includes the definition of compliance guidelines with a focus on the usage of data and the culture of respecting such guidelines: *"I have to do my best in order to stay compliant and create an internal control system" (MC#1).* An *Information Security* (CAP13; mentioned by 8 out of 16 as important) concept is able to address questions of privacy and access management. It ensures the treatment and transferal of data in accordance with compliance guidelines. Access Management focuses on ensuring authentication and authorization when accessing data. Privacy Management guarantees the protection of data, specifies information ownership, and addresses digital identity issues: *"In the context of such services, information security is an essential topic because data is an asset, a production factor. If I cannot handle the data accordingly, I have a huge problem" (MP #2).*

Strategy Development (CAP14-17). BDA as veritable source of competitive advantage must also be part of a company's strategic capabilities. The capability group Strategy Development accordingly addresses the innovative usage of BDA in line with the business strategy and under the consideration of trends. This affects the *Innovation Management* (CAP14; mentioned by 4 out of 16 as important), i.e. the ability to think out of the box to develop new big data based innovations. Trends need to be detected early and monitored: *"In the context of big data I have to be able to react quickly to trends and to use them to my advantage" (MP#2).* A systematic *Management of IT-Strategy* (CAP15; mentioned by 8 out of 16 as important) ought to ensure the derivation of the IT-strategy from company's business strategy. BDA initiatives are part of the IT-strategy in order to manifest its importance and consequently its successful usage: "*In the vein of digitization this capability becomes more relevant as new business models are based on information technology" (MC#8). IT-Business-Alignment* (CAP16; mentioned by 4 out of 16 as important) is the ability to align IT-Strategy and its objectives with the objectives of the business strategy. In the context of BDA, it ensures the proper collaboration and communication between IT department, business department and, possibly, an analytics competence center in order to ensure a successful delivery of services or products: *"It has to be totally in match what IT and business is doing" (C#2). Business Development* (CAP17; mentioned by 5 out of 16 as important) includes the development and identification of new business cases, sales channels, pricing mechanisms and new business models that base on BDA analyses in order to sustain competitiveness: *"Many business models that were successful for decades are marginalized in the era of digitization" (MC#1).*

Transformation Competence (CAP18-20). BDA requires companies to transform current ways of work and their business models because of its disruptive nature. In this context, the capability group addresses a company's competence to transform and adapt to environmental dynamics. *Establishing a Supportive Working Environment* (CAP18; mentioned by 5 out of 16 as important) fosters personal responsibility, a flexible way of work and leadership supported by activity-based working structures and tools that enable employees to work efficiently and effective: *"It is all about leadership, flexible way of work, responsibility, open office and activity-based working environments and the respective supporting tools" (P#2).* For BDA approaches, it ensures a collaborative way of data sharing across departmental boundaries. *Skill Development* (CAP19; mentioned by 14 out of 16 as important) enables employees to address to new topics through trainings and workshops and, in the context of BDA, to develop the skills to handle, to structure, and to exploit heterogeneous (big) data in the business context using tools or technologies: *"Organizations nowadays do not have the people who deal with big data […] This is a big challenge to build up those capabilities […] data alone* *without the right people and the right skill sets to generate insights from this data does not add any value at the end" (C#2). Culture Management* (CAP20; mentioned by 8 out of 16 as important) encompasses introducing and maintaining a culture of open communication through appropriate methods (e.g., continuous improvement or change management). In this context, the belief that data is an essential resource needs to be part of the company's culture: *"You have to get your employees to know that data is a strategic asset on which you can capitalize. The thinking that you can actually monetize your data through services does not yet exist in companies" (C#1).*

Enterprise Architecture Management and Process Management (CAP21-26). To leverage big data to its full potential the respective technologies and tasks need to be effectively integrated into the process and IT landscape. Consequently, the capability group Enterprise Architecture Management and Process Management is about having an understanding for the interplay of applications and for the respective data streams from a process perspective as well as from a technological perspective. It compromises the following capabilities: *Value Oriented Process Management* (CAP21; mentioned by 5 out of 16 as important) is the capability to modularize the own value chain and to integrate the own value chain with the value chain of the partners. Hence, it is a prerequisite for the orchestration of end-to-end value chains across company borders and for an end-to-end data flow between partners: "*You should be able to configure your processes in a variable manner" (C#1). End-to-End Integration of Processes* (CAP22; mentioned by 6 out of 16 as important) ensures the consistency of the process architecture along the process chain over all departments and over organizational and IT boundaries and, consequently, ensures the data flow between partners: *"In the context of big data this capability is a key capability as it ensures continuous flow of data"* (MC#5). *Management of Process Standards* (CAP23; mentioned by 5 out of 16 as important) is about using and managing process standards and predefined processes. In the context of BDA, it has to guarantee the compatibility between various internal and external processes and their data exchange points: *"Against the background of collaboration it gains relevance to use process standards and to orchestrate process chains" (MC#5). Policy Driven Process Management* (CAP24; mentioned by 4 out of 16 as important) ensures that the process design and management is based on the company's legal guidelines in order to stay compliant: *"Especially in the context of big data and privacy issues, the design and the management of processes along the principles and guidelines, which ensure compliance, are a vital point" (P#1). Agile Process Modeling & Implementation* (CAP25; mentioned by 5 out of 16 as important) refers to the application of reference process frameworks, rules of modeling and compositing process chains for the design of functional processes: *"It helps to bring big data enabled products to the market more easily if you have established something like this in the company" (C#1).*

Information Management (CAP26-34). Information is the most valuable resource for BDA. Consequently, Information Management must ensure the rightful management, acquisition, processing, and distribution of information. *Information Value Assessment* (CAP26; mentioned by 9 out of 16 as important) evaluates the significance, relevance and the inherent value of (big) data: *"Data is not a by-product of value creation […] but the source of value for the company and thus for my customers" (P#2).*

To ensure the end-to-end integration of processes and the respective *Information Exchange* (CAP27; mentioned by 7 out of 16 as important) the data flow has to be established via data communication protocols and interfaces. This enables a company to perform the first task of gathering data from different data sources (e.g., partners and customers): *"It is not only about having a huge amount of data but also to have current data as this defines the value of the data" (P#1). Master Data Management* (CAP28; mentioned by 7 out of 16 as important) is about persistently saving critical company data in a structured and retrievable way: *"Is the data we have semantically correct and similar or not?" (MP#1). Information Quality Management* (CAP29; mentioned by 8 out of 16 as important) takes care of data quality and readiness (provisioning at the right time in the right quality). Furthermore, data sources and data streams are monitored and processed in order to avoid blackouts. Especially in the context of BDA the assurance of quality is a prerequisite for reasonable results as the diverse data sources and data structures change rapidly: *"If I deliver big data analytics analyses I have to make sure that my information quality is alright" (MP#1). Data Gathering* (CAP30; mentioned by 8 out of 16 as important) comprehends the identification and gathering of data and (previously unknown) information sources. Data needs to be gathered beforehand from the different sources (e.g., processes, actors, and machines) such that BDA analysis can be performed: *"I have to collect a huge data volume coming from sensors and other sources and know which sources to use" (P#2). Data Processing* (CAP31; mentioned by 8 out of 16 as important) addresses the extraction and integration of structured and unstructured, old and new, external and internal data as well as its structuring, consolidation, transformation and loading: *"If I do not have the right methods to process the data I do not even have to start at all" (C#2). Analytics* (CAP32; mentioned by 10 out of 16 as important) refers to the examination of the data in order to derive new information: *"It's about finding the value and getting information that has been unknown beforehand" (MC#4).* In this vein, new algorithms, which are capable to analyze big data, have to be developed/used that allow a company to derive insights from connected data pools. *Information Presentation* (CAP33; mentioned by 8 out of 16 as important) is essential for the digital delivery of BDA analyses. The results of those analyses needs to be visualized in a digestible manner such that the customer understands the value at a glance: *"I have to display the information I generated in a reasonable manner such that the customer can actually use the data" (MP#2). Infrastructure Management* (CAP34; mentioned by 7 out of 16 as important) ensures the provisioning and maintenance of the technological infrastructure e.g., scalable big data database systems like Hadoop: *"Which infrastructure do I need to enable big data in the first place? Do I need in-memory data bases or Hadoop clusters?" (C#2).*

5 Conclusions and Future Research

Although "big data" belongs to the most intensively discussed topics today, little research has investigated the capabilities required to effectively perform BDA. Building upon the holistic enterprise perspective of the Work System Theory and the results of 16 expert interviews, we have developed a model that provides information about several capabilities, which are potentially required to conduct BDA. In sum, we identified 34 generic capabilities that we assigned to eight capability fields: Customer Relationship Management, Partner Life Cycle Management, Product/Service Life Cycle Management, Enterprise Risk Management, Strategy Development, Transformation Competence, Enterprise Architecture and Process Management, and Information Management. The capability model gives an initial, yet unique and empirically grounded overview of the competencies that are generally required for BDA.

The results of our research have implications for academia and practice alike. From an academic perspective, the created model embodies a theory of the organizational capabilities necessary to fully leverage the potential of BDA. Although this topic appears to be of critical importance to ensure the success of big data initiatives, it hardly has been examined until now. While we have only carried out a first iteration of our design science endeavor so far, the results show that the derived capability model significantly differs from those that have been proposed for the business intelligence domain. Even though some aspects appear to be relevant in both domains, leveraging the potential of BDA appears to require additional organizational and technological capabilities. In this respect, the results of our research endeavor corroborate recent findings in literature [34]. At the same time, the developed model is both more comprehensive and more structured than other capability models that have been developed for the electronic government domain in parallel [7] or related approaches that focus on gathering concrete competencies (such as NoSQL databases, JAVA programming etc.) from job descriptions [34]. Accordingly, it advances the current body of knowledge with novel findings. For practice, the presented capability model delivers a benchmark against which companies can assess their organizational capability to leverage big data initiatives. In particular, the capability model provides the semantics for company-internal assessments of its ability to benefit from BDA. The capability model furthermore is a step towards providing an instrument, which supports the development and transformation of organizational capabilities in order to perform BDA more effectively.

Note that the relevance of the presented capabilities might vary depending on the big data scenario. This means that capabilities, which are highly important in one scenario (e.g., CAP4: Partner-Channel-Integration during supply chain improvement through BDA), might be of less importance in another scenario (e.g., in the context of a BDA service which improves customer interaction based on customer data). Moreover, some capabilities rather point to foundations for the successful usage of BDA (e.g., Infrastructure Management). In future research iterations, we will therefore also focus on separating different types of capabilities and on providing guidelines for systematically using (parts of) the model in different application scenarios. To develop a preliminary rating scheme, the analytical hierarchy process (AHP) as a proven, reproducible, and comprehensible management instrument will be used [48]. In doing so, the question, which capabilities are important in a particular usage scenario, can be solved based on pairwise comparisons of the capabilities and the input of decision makers [48]. We plan to address and illustrate the use of AHP in the context of our model in future work.

There exist several limitations in the light of which our research results have to be interpreted. Most notably, we have only conducted one iteration of the design process so far. The results might hence not be stable yet. In particular, not all capabilities are on the same level of detail and they might also not be disjunctive or exhaustive yet. Additional limitations arise because we so far have only interviewed big data consultants as experts. While this strategy originated from the impression that BDA is not a daily routine in companies yet and consultants might hence be among the persons with the most and diversified experience, our results might suffer from sample bias, because the experts worked for a single consulting company and shared certain practices. To increase the reliability of our findings, we plan to carry out additional iterations of the design process in which we will also involve experts with backgrounds from different companies. Moreover, we will apply additional research methodologies to verify our results. Finally, we have to emphasize that we have only evaluated our capability model by comparing it to related approaches so far. Although we used qualitative data for the design of the model, thus equipping it with empirical evidence, we will need to conduct empirical evaluations to further strengthen the quality of the results. To mitigate this limitation, we plan to evaluate our initial artifact, in particular its utility [49], using the four-step method of Venable et al. [50]. We intend to perform an ex-post naturalistic evaluation drawing on either a case study or a survey as evaluation method [50]. We plan to perform our evaluation at an original equipment manufacturer for the automotive industry that is on the edge of leveraging BDA to a great extent.

To fully leverage the potential of BDA, various organizational capabilities have to be developed [1], [9]. Despite the presented limitations, we hope to provide a basis to clarify and further investigate these capabilities with the presented capability model.

Abstract. The popularity of design thinking as an innovation paradigm grows continuously. More and more schools and firms implement innovation processes inspired by design thinking, but they lack easy and nonintrusive methods for monitoring the progress of teams following those processes. Consequently, interventions from coaches, teachers, or supervisors tend to rely on intuition or require intensive and intrusive examination of team dynamics. This study uses by-products from the design process and proposes automated assessment of lexical diversity as a monitoring method in process-driven design thinking projects. Thereby, it contributes to the research on the relation between text production and creativity in design projects. To the practical end, it suggests how digitalized by-products of design activities such as notes and documentation, can be leveraged to support the teams as well as coaches, teachers, and supervisors.

Keywords: design thinking, lexical diversity, documentation, creativity in teams, progress monitoring

1 Introduction

Establishing innovation culture in education and industry comes along with propagation of specific problem-solving strategies including particular tools and processes showing when and how to apply those tools. This holds also for a continuously booming innovation paradigm: design thinking (DT) – firms and schools around the world borrow from each other and propagate "successful" DT process models and implement them in their own innovation departments and classes [1–3]. They struggle, however, with an ongoing monitoring of the design teams' progress along the process [4]: Do the teams go the right path? Do they make enough improvement from one phase to another? When to intervene and when not? This paper shows the power of the words used in the documents produced by the teams: using metrics based on the vocabulary diversity bears great potential for identifying design team's progress without expensive external assessment or self-reflection episodes.

A constantly growing community of teachers, practitioners, and researchers applies DT and similar, process-dependent methods when solving wicked problems. They benefit from the agility and flexibility of the methods, as well as from the fragmentation of

13th International Conference on Wirtschaftsinformatik,

Dolata, M.; Uebernickel, F.; Schwabe, G. (2017): The power of words: Towards a methodology for progress monitoring in design thinking projects, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1156-1170

the problem and solution space enforced by the particular tools and processes. Consequently, the problems and possible solutions become more tangible, comprehensible, and user-specific. Despite large number of handbooks and guides for DT [1, 5, 6], the practitioner-oriented community still lacks deep understanding of what actually happens during a DT project. This knowledge would support the coaches and supervisors at monitoring the progress of design teams as they follow the process and at proposing meaningful interventions. As for now, they mostly rely on intuition and experience – based on the findings, we claim that their tasks could be even partially automated. Additionally, generalized set of observations regarding DT would also help the researchers with creating abstract toolset-independent models of design and creativity, which could be then transferred to novel contexts. Since the community around DT is growing continuously, we expect that the discussion on the related topics will intensify [7].

As a paradigm, DT relies on the design, production, and analysis of artifacts [1, 2]. During workshops, temporary notes capture ideas in form of easy drawings and simple descriptions for prototyping. Prototypes capture ideas in a tangible, plastic form for testing. Observations and intermediate results collected in tests are recorded as voice or text for later analysis. And, finally, results of the analysis are made persistent as text or diagrams for use in design workshops. Thanks to the recent technological progress, most of the data is shared virtually across team members, gets regularly archived in common repositories, and has textual character or format which can be automatically turned into text (e.g., voice recordings via auto-transcription or photos via character recognition). Consequently, we find ourselves in a situation where, on the one hand, organizations struggle with monitoring design teams, and on the other hand, those teams produce and file more and more potentially relevant and easy-to-process textual data. As explained below, previous research found a link between lexical diversity and the creativity of a narrative – in an educational context not related to any project group work or design documentation [8]. It also provides some evidence, that textual analysis of final documentation produced by design teams helps assessing their overall performance [9, 10]. However, as the literature leaves open whether and how those insights can be used for monitoring purposes in long-term projects, we hypothesize that *vocabulary diversity of documents produced within a DT project exhibits patterns which reflect the DT process* and, consequently, can be used to monitor the progress of design teams with regard to this process.

This study handles the above hypothesis, while analyzing a set of data produced by 15 design teams in an educational context in 6 continuous years. First, the paper discusses the process-based view on DT and ways proposed to monitor progress in similar projects; it also motivates usage of language metrics as a monitoring instrument. Second, it discusses the methodology used including the metrics used for the current analysis. Next, it provides an overview of results followed by the discussion thereof in light of what we know about DT and progress measurements. Finally, it summarizes the insights and explicates limitations of the study along with directions for future work.

2 Related Work

2.1 Design Thinking as a process

Design thinking (DT) is an innovation paradigm that gains increasing popularity and reputation. It originates from the academic world, where it was conceptualized as a teaching methodology in the area of mechanical engineering [2, 7, 11]. Later on it found its way to industry and is applied to solve practical problems in a variety of industries [5, 7, 12]. Successes of consulting firms like IDEO popularized DT as a mindset – institutions who wanted to replicate its success required, however, also a more hands-on guidance [13]. Consequently, DT was formalized as a toolset including a family of process models to be applied in previously unknown contexts [1–3, 11, 14].

Available literature proposes various formulations of the DT process. Large part of the models focus on the iteration through divergent and convergent phases when developing multiple prototypes [2, 5, 13]. More advanced models introduce blocks to differentiate between user-centered (e.g., empathize, define) and prototype-centered (e.g., ideate, prototype, test) [6]. Yet other models propose a chronological process built around phases that formulate specific requirements at the prototypes developed therein [1, 3, 11, 15]. The availability of phase-specific requirements and goals suggests that it is possible to monitor teams' progress through comparing prototypes produced in each phase with the phase goals. However, this kind of assessment requires extensive human power, especially in cases where large numbers of prototypes are produced. Also, this method is prone to subjectivity. This leads to the question whether a more objective and less extensive way of monitoring is possible.

This study focuses on the DT process model established in mechanical engineering education at Stanford [11] and adapted in a multi-national community of universities [1, 3, 16]. The macro process consists of seven milestones divided in two large phases: the divergent phase and the convergent phase. The milestones in the divergent phase include [1]: (1) *design space exploration* (DSE) – understanding the problem space and topics related to the creative challenge, (2) *critical function prototype* (CFP) – defining the principal needs of the stakeholders and addressing them through prototypes, (3) *dark horse prototype* (DHP) – reframing the challenge and questioning previously obtained insights through further "crazy" prototypes. The divergent phase closes with (4) *funky prototype* (FKY), where most promising results are compiled into complex and open prototypes. The funky milestone forms a bridge to the convergent phase consisting of the following milestones: (5) *functional prototype* (FNL) – providing a preview for the final prototype and its key aspects, (6) *X-is finished prototype* (XFP) – designing and developing a single function of the final prototype to the last extent, (7) *final prototype* (FIN) – integrating successful elements from previous milestones into single, coherent, and high-resolution prototype. Throughout the divergent phase, teams develop large numbers of low-resolution prototypes, while in the convergent phase they invest time into specifying the scope and functionality of a single prototype. Along this macro process, teams engage in multiple design iterations (micro-process) consisting of such steps as [1]: (1) need-finding and instant expertise, (2) brainstorming, (3) prototyping, (4) testing, and (5) re-defining the problem. Steps (1) and (2) have clearly a divergent character, steps (3), (4), and (5) prompt the teams to reflect and converge.

Adherence to the process is one of the essential success factors in DT projects [17]. Consequently, monitoring the progress of teams in the macro process seems to be essential for the team itself, as well as their facilitators, managers, partners, and sponsors. Even though the process provides specific prototype requirements that could be used for a kind of assessment-based progress monitoring, it would require additional human power and could lead to subjective assessment. Publications which propose particular process models leave the question open, how to monitor their implementation in an efficient and effective way [1, 5, 6].

2.2 Monitoring design process

In most general sense, monitoring involves being aware of the state of a system. With regard to DT, by monitoring we mean whether the DT-typical mindset and toolset [14] is understood and properly followed by the team. This monitoring may address interpersonal, relational, performance, or process level. The role of monitoring in DT is essential: First, it shall enable ongoing feedback regarding the facilitation success [18]. Second, it shall help with assessment of the team's performance [19]. Consequently, being aware of the team's state and its performance with regard to the process model has an essential character for a process-dependent DT implementation.

A simple measurement of creative performance may involve characterization and statistics regarding the generated ideas [20–23]. This monitoring method uses such concepts as complexity of ideas, their amount, originality, etc. While well applicable to controlled group assignments in a test setting, the adaptability of such measurements to DT seems questionable. Complex prototypes often involve several ideas, which may be new or a specification of previous ones [24]. Consequently, monitoring using statistics about ideas did not find much attention in the DT community.

Another thread of research focuses on the assessment of the social dynamics in design teams and social characteristics thereof. Two approaches dominate in this thread: psychometrics and affect-oriented measurements. Psychometric approaches rely on such tools as the Myers-Briggs Type Indicator (MBTI) [25] or similar self-reflection tools. They have been successfully employed for team composition and prediction of its outcome [26–31]. Observations of team dynamics without a self-reflection loop rely on the availability of a trained, external observer. Their potential has been confirmed

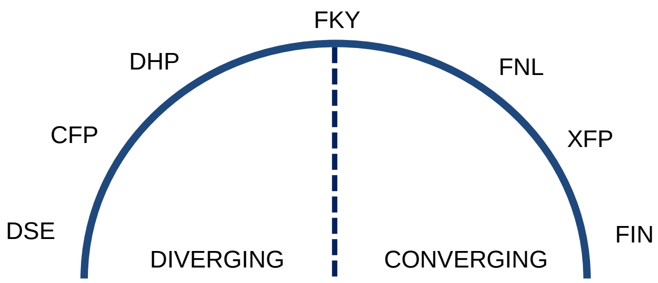

Figure 1. Phases and milestones in a DT project – chronologically from left to right [15].

with a set of studies especially from the DT community [32–35]. While team dynamics and psychometric compatibility has impact on the teams outcome, it does not help with monitoring team's progress in a process. In fact, its results may be misleading: a team that established excellent team dynamics for an early phase in the process (e.g., CFP) and does not make any progress beyond this phase, will be identified as successful by the above methods. Additionally, self-reflection and independent observation are expensive – they require dedicated time from the team or the observer. They may also be perceived as intrusive by the team. While being a well-promising idea in a laboratory, psychometric and team dynamics monitoring leaves open multiple questions on its applicability in real-world projects.

Yet another way to go involves analysis and understanding of all kinds of artifacts used or produced within creative teamwork [36–38]. This fits into the paradigm of multimodal analysis of human-generated content and actions [39]. While this approach catches the complexity of processes in artifact-oriented creative activities such as design, it has not yet turn into practical applications, thus remaining at the abstract level of frameworks and models.

To conclude, the growing popularity of DT leads to increasing attention in research. The various process models and their role for the success of DT have been extensively addressed. In parallel, several options for monitoring the team's progress with regard to the process have been proposed. However, a non-intrusive monitoring technique is still missing. Nevertheless, some preliminary studies relate language use of design teams and their overall performance [9, 10, 40, 41] – we take them as an inspiration and discuss their potential for process *monitoring*.

2.3 Language in creative processes

Language does not only describe the reality, but also "makes" it (e.g. in form of performative utterances [42]). Three primary roles of language in design can be defined: representational (explaining design process and design rationale), instrumental (communicating and recording design intent and rationale), and constructive (contributing to the design process) one [40]. Spoken language is used to describe things (ideas, concepts, information chunks) that enter the design process, while written language is used to describe things that should stay in the process or that could be useful at a later stage [10, 40]. This opens the possibility to analyze written language as a way to assess and monitor the outcome teams produce.

Language, beyond supporting and constituting design activities, is an essential element of creative processes, i.e., inventions. Vivas [43] writes that what creative persons do is "not to invent something new, but to extricate out of the subject matter at hand its own proper structure or order" – this structure is given by language in communication [8]. Several studies empirically confirm the structural nature of creativeness [44, 45]: the structure such as language drive and inform creative performance. Consequently, we argue that *language* and *creative performance* mutually influence each other – patterns discovered in one shall be reflected by specific patterns in the other one: if the creative performance is driven by the process, the language-features will be likely to reflect this process too. However, the studies that inform our argument leave it open, which characteristics of language shall be considered.

The link between creative performance and narrative performance is supported by the discourse in the area of language acquisition psychology. Narrative performance and creativity both share a number of qualities, particularly if it comes to divergent thinking [46]. Creativity, and, particularly, divergent thinking require, among others, ability to produce wide variety of ideas (flexibility) and ability to produce unusual ideas (originality). These two qualities are, also, proposed as sources for wide range of vocabulary in narrative tasks [46–48]. Lynch and Kaufman [8] identify three main factors (out of 7 main and 24 sub-factors) that have moderate factor loadings on creativity assessment: verbal diversity, readability, and consistency, whereas the first one has the highest factor loading. In other words, human judges as generally more creative perceive texts that exhibit higher diversity. Importantly, in the above studies text composition / text judgment was the main task given to the test persons. However, DT is not about writing texts, but about thriving innovative ideas. Documentation is mostly considered only a side-product of teams' activities and communication is not a goal by itself, but should support ideation and creation of the intermediate and final prototypes. Therefore, it remains open whether regularities regarding lexical diversity will hold for text others than narratives intended to be creative.

Accordingly, language of collaboration and its relation to team's creative performance has been approached within the DT community. Already in 1996, Mabogunje and Leifer [9] show that design teams in the area of mechanical engineering who introduce novel noun phrases in the mid-term and final documentation tend to produce better and more creative results than teams less innovative in their language use. Dong [10, 40] who, also, focuses on design teams in the area of mechanical engineering shows that other qualities of written language, such as coherence and presence of sentimental statements also correlate with teams' performance. However, studies leave it open how to monitor the progress of teams along a predefined process and how to use the metrics for continuous assessment rather than post-mortem analysis of projects and teams.

Overall, the role of language and evolution of language is highly relevant for creative performance and collaboration; however, it remains underspecified how language evolves over time in design teams and how it thus can be used to guide facilitation efforts. Moreover, longitudinal studies of creative performance in teams are rare, but very valuable and needed [49]. Already in 1984, McGrath [50] appealed for closer consideration and deeper research on longitudinal team collaboration. His call still remains up-to-date, in particular if it comes to teams working on creative tasks in organizational or nearly-organizational context [51–53].

3 Methodology

The context of our study is a graduate course at a Swiss University. In this class, students are taught to apply design thinking on a real-life innovation challenges, offered by industry partners. Challenges originate from different market sectors and reflect the real needs of the involved industry partners – each team works on a different challenge.

The design teams consist of graduate students with multidisciplinary backgrounds, as well as prior working experience. Each team receives coaching from DT experts. Additionally, industry partners nominate an employee as a company-internal contact partner for the team. During the course of 10 months, the teams pass the milestones described above in order to finish their projects and provide a final prototype.

The teams experience co-located and distributed collaboration. Except for the sessions with the coaches and facilitators twice a week for ca. 2 hours, the teams are free to organize their collaboration process. Sometimes, the routines get adjusted throughout the process – teams tend to intensify synchronous and co-located collaboration towards the end of the process and shortly before the particular milestones. Teams are free to choose media and technologies to support their collaboration effort. A common and non-interchangeable element for all teams forms a media wiki used as knowledge base. It was introduced into the course to enable for cross-inspiration and cross-pollution between teams within a year's class and, also, between different years' classes.

Each team regularly updates their wiki section. It includes basic information on the team, the industry partner, and the challenge. Furthermore, teams document their progress in wiki while describing (1) insights obtained through ethnographic user studies, (2) ideas implemented as prototypes along with evaluation results, and (3) experiences collected through collaboration with other teams or in research trips. They upload photos, videos, and other material into their shared space. Established in 2008, the wiki has become a large repository of design knowledge from several generations of students in this course. As of 2016 the wiki includes information for 38 challenges in German or English. For this study, we consider a subset of 15 challenges from years 2008-2015 documented in German. The overall number of documents considered equals to 630.

We decide to use the German part of the wiki because large majority of the course participants have been German or Swiss German native speakers (more than 95%). Consequently, those students who decide to run their wiki section in English, actually, choose to use a foreign language. Aware of the differences regarding lexical diversity and other related characteristics between the mother tongue and second or third language, we deliberately exclude documents written in English from this study.

To assess the lexical diversity, we employ MTLD (Measure of Textual Lexical Diversity) [54]. While, in general lexical diversity refers to ratio of total number of words to the number of different unique word stems, we decide to use the specific metric of MTLD for a particular reason – according to the empirical tests run by McCarthy and Jarvis [54] it is resistant to length-induced variance in texts of 100 to 2000 words. 98% of documents considered in this study are of this length. As most measurements for lexical diversity, MTLD takes Types-Token Ratio (TTR) into consideration, however it expresses the mean length of sequential word strings with a given TTR value (the optimal value of this factor was empirically estimated to equal to 0.7 [54]). In other words, it provides information on the average text length (measured by number of words) with a TTR above the used treshold – if the results is 100, it means that on average after each 100th word the TTS value dropped below the threshold of 0.7. To assure the measurement to be robust, the MTLD algorithm applied in this study does a forward and backward run through the text to compute the final outcome [55].

4 Results

Comparison of lexical diversity of documents from the divergent phase (milestones: DSE, CFP, DHP) and the convergent phase (FNL, XFP, FIN) shows a clear picture: while mean lexical diversity in the divergent phase equals to 242 (Standard Deviation SD = 67, Standard Error Mean SE = 3), in the convergent phase MTLD yields on average an outcome of 192 (SD = 78, SE = 10). The difference is significant and accounts for $p < 0.001$ ($t = 4.73$, $df = 73$; in a two-tailed unpaired Student's t-test without assuming equal variances – this test was chosen due to unequal samples – see below).

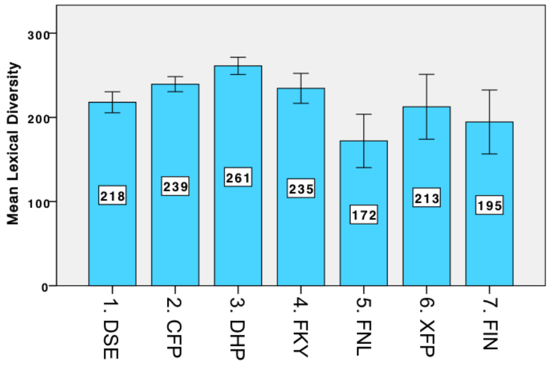

Figure 2. Mean lexical diversity (measured with MTLD) of documents for each milestone in the DT process. Data considered for 15 projects (630 documents). Error bars: 95% CI

Comparison of lexical diversity for subsequent milestones allows for analysis of process-typical tendencies. For easier comprehension, Figure 2 includes the chart representing the mean values along with error bars. In the divergent phase, we can identify a growing tendency – lexical diversity increases significantly from milestone to milestone. MTLD algorithm yields the following values: for documents in DSE it yields 218 (SD = 66, SE = 6), in CFP – 239 (SD = 63, SE = 5), and in DHP – 261 (SD = 69, SE = 5). For each step, we compute a Student's t-test and provide its results in Table 1.

FKY is the first milestone with a drop in the lexical diversity: mean lexical diversity of documents equals to 235 (SD = 81, SE = 9). However, the largest drop occurs afterwards, i.e., when the mode changes to converging. MLTD computation for the milestones in the convergent phase average to the following values: FNL – 172 (SD = 71, SE = 15), XFP – 213 (SD = 84, SE = 18), FIN – 195 (SD = 19, SE = 18). As presented in Table 1, no significant difference between those milestones could be identified – while this may be an effect of smaller number of documents considered for the statistical analysis (cf. Table 1; teams produce fewer documents as they converge and exhibit tendency to collect information in few central documents), we can definitely see that none of the phases in the convergent phase exhibit higher lexical diversity than any of the phases in divergent mode. Additionally, no clear tendency – neither growing nor lessening – can be identified for the convergent phase. We attribute the difference regarding the standard error (reflected by the length of error bars) to the number of documents teams produce in particular phases: in the divergent phase, the number of distinct documents is higher, while in the convergent phase the number of distinct documents is lower; consequently, the average figures on document lengths for each phase in each team lie further away from each other in the divergent phase.

Milestones and their short forms
Design Space Exploration DSE (111)
Critical Function Prototype CFP (193)
Dark Horse Prototype DHP (174)
Funky Prototype FKY (83)
Functional Prototype FNL (22)
X-is Finished Prototype XFP (21)
Final Prototype FIN (19)

Considered milestones	Results of a T-test regarding comparison of mean lexical diversity for the two considered milestones		
	t	df	p
DSE → CFP	2.744	220	.006 *
CFP → DHP	3.154	353	.002 *
DHP → FKY	2.579	139	.011 *
FKY → FNL	- 3.53	36	.001 *
FNL → XFP	1.691	39	.100
XFP → FIN	- 0.69	38	.491

Table 1. Results of the t-test for lexical diversity in subsequent milestones. On the left: list of all milestones with their respective short forms and number of documents considered.

To confirm the significance of the results that can be clearly seen in Figure 2 (by comparing the error bars), we decided to run a Student's t-test. Due to different number of documents in each phase in each team and because we did not want to exclude any documents from the analysis, we decided to employ a two-tailed unpaired t-test without assuming equal variances – the results for each subsequent pair of milestones can be seen in Table 1. We also run a two-tailed paired t-test where we used samples of 19 random documents from each milestone to assure that measured effects do not occur simply due to the large number of documents or difference between milestones in this regard. The results of those t-tests confirmed the significance of the results while yielding p-values $p<0.05$ in large majority of cases for milestone pairs marked with an asterisk in Table 1, i.e., those where difference regarding lexical diversity is significant.

5 Discussion

The results presented above confirm the hypothesis expressed in the introduction: lexical diversity of texts produced in a DT project can deal as a metric to monitor the progress of a team with regard to the DT process. The following reiterates this finding while pointing to the consequences it has for the monitoring of DT activities.

5.1 Particularities of the DT process

We observe, that the lexical diversity of the documents grows significantly between the milestones in the divergent phase – and reaches its peak in the dark horse phase, where teams are encouraged to leave behind previous ideas and consider totally new ideas and approaches [1, 2]. Dark horse prototypes enjoy a special status in the design thinking community – they are often presented as the source of final ideas and solutions [17]. With the above results we confirm that this milestone is, in fact, special – also with regard to the lexical diversity: it is clearly the milestone that exhibits the significantly highest lexical diversity out of all milestones. Interestingly, as soon as first consolidation efforts are made – in the funky milestone, where teams combine knowledge from previous milestones without the necessity to focus on a single coherent prototype – a slight drop in the lexical diversity occurs. We claim, that this reflects the fact, that they drop some ideas and concepts and tend to combine the most promising ones.

However, the most dramatic drop in lexical diversity occurs, where teams are pushed to converge while focusing on a single prototype built around coherent concepts. When considering the role of written language in DT process as a medium to retain things for later reference (representational and instrumental-recording role [40]), the changes in lexical diversity reflect the evolution of solution space. While in the divergent phase, the scope of potential solutions is rather large and should grow even further, in the convergent phase it is clearly limited. It is the time, where teams change their work modus from creativity to execution [1, 11] and they assess their own performance rather in terms of completing predefined tasks than in providing unexpected solutions [11]. The lack of significant differences during the convergent phase has possibly two reasons: (1) during that time, teams generate fewer documents as they concentrate on building their prototypes and do not produce new knowledge that needs saving; (2) the milestones are not as distinct as in the divergent phase – they merge into one another. Nevertheless, also in the convergent phase some variance occurs. While not being significant, the difference between FNL and XFP phases points to an interesting aspect of the DT process: the functional prototype focuses on a set of key concepts and is mostly built around a story which allows for preview of the final functionality – a successful story tends to be coherent and concise, however in XFP teams have small divergent elements, e.g., when they look for and decide between possible technical solutions to implement the single, "X" feature. Consequently, the changes of lexical diversity between particular phases reflect how goals and tasks evolve throughout a DT project.

Importantly, the projects we consider for the current study, follow a very popular DT process. Through its rigidity and the available hands-on guidance [1], it enables for a relatively easy transfer from one context to another. Consequently, it attracts attention from educational sector as well as from the industry [11]. We claim, that the presented results contribute even further to the better understanding of this particular process and its building blocks or phases. Though, it remains open, whether similar patterns can be identified in projects following another DT process model [2, 5, 6, 15].

5.2 Lexical diversity in creativity

Our findings confirm the interrelation between language production and creativity. In such complex processes as group creativity it is almost impossible to make conclusive hypothesis regarding causal relation between variety of words and divergent thinking.

Does divergent thinking cause the lexicon growth, or does lexicon growth cause divergent thinking? In accordance with previous studies [8, 42–45], we argue that language has a structural nature and, along with the predefined process, it gives a specific structure to the creative efforts of a design team [42, 43]. With this in mind, providing means to enrich the vocabulary of design teams may positively influence their creative performance in divergent phase, while reducing stimulation may positively influence team's performance in convergent phase. This opens possibilities for design of stimulation systems with specific focus on the vocabulary.

The currents study provides insights that go beyond the previous literature in twofold direction. First, it provides evidence for the link between the creative effort and textual production, even if production of the text does not constitute the central task during this effort. Consequently, it extends the findings presented by Lynch and Kaufman [8]. While our study points to the link between lexical diversity and creativity in a longitudinal project context, it leads to the question whether similar effects can be observed in local context: Do descriptions of "more creative" prototypes tend to use more diverse vocabulary? Answering this question suggest a direction for further research.

Second contribution this study makes to previous research on relation between lexicon and creativity relates more to the DT context. Mabogunje and Leifer [9] as well as Dong [10, 40] provide evidence for the relation between the overall assessment of the project (done after the project) and specific linguistics qualities of documentation (sentimentality, coherence, appearance of neologisms). We extend the list of relevant characteristics by pointing to lexical diversity as a possible and easy-to-apply metric. As opposite to previous research [9], which focused on arbitrary division of time (limited to three academic quarters) and related the results primarily with academic grades, our solutions provides higher-granularity observations on the teams' progress across the DT process. Additionally, the method proposed in here does not require extensive preprocessing [9] and can be applied to documents with a short length, which, normally, include only few noun phrases. Application of the proposed metric for performance monitoring would require further research, as discussed above.

5.3 Lexical diversity and monitoring of creative processes

Resilient methods for monitoring design processes are now necessary more than even before, as the popularity of agile design and innovation methods grows particularly fast. Using texts for assessing design teams progress provides a way to monitor DT teams without steady human control and without use of such intrusive tools as surveys and other psychometrics. In line with this, teams tend to produce and digitalize more and more data, especially side products from their design activities. This opens options going beyond the ones suggested in previous literature.

Monitoring and interventions relying on observing social dynamics of teams is extensively propagated within the DT community and is considered one of the central tasks of teams coaches [11, 17, 32–35]. Similarly, much attention is put on the controlled, conscious team composition and its effects [26–31]. Those efforts require very intensive observations, good intuition, and readiness to intervene from the coaches, thus compromising teams' autonomy and distracting them from the actual task. Even though we accept arguments for intensive coaching of innovation projects, especially with unexperienced designers, with lexical diversity we point to a source of additional, independent data useful for coaching. Since such measurement can be done independent of the team and does not require extensive human power from the coach, nor his or her intuition, it offers an objective and nonintrusive way of monitoring.

Monitoring based on statistics regarding number of singular ideas [20–23] or various qualities of prototypes [36–38] provides another way for nonintrusive process monitoring. While well applicable to particular brainstorming or prototype-design sessions, those methods are hardly applicable for DT, because prototypes and artifacts used therein are often complex and unusual. Comparing them directly with each other, even within a single project, may feel like comparing the incomparable. Under those circumstances, focusing on and monitoring side products of the design process seems reasonable. While this study provides evidence for a relevant role of vocabulary and its diversity, we claim that more metrics can be applied in similar way, just to mention argument structure in documents, cohesiveness, sentimentality, or comprehensibility.

Automatizing the method described in this study are possible directions for future design efforts to establish, e.g., a DT coach cockpit. Such a cockpit could provide on-the-go analyzes of documentation generated by the team, as well as their communication data (most teams use, e.g., WhatsApp to discuss or document ideas). The central insight from the study to be applied in such a system are the lexical diversity differences between phases. For instance, if the system detects a drop of lexical diversity in the textual material produced by a particular team between the CFP and DHP, i.e., a signal of converging tendencies in a divergent phase, the coach may intervene by providing more diverse stimulation material, introducing additional assignments, or organizing brainstorming workshops. The system may support the coach by monitoring other relevant information, such as the structure of documents or the relation between them [43, 45, 46]. Another point to observe would be the number of meetings between team members to assess whether possibilities for ideas transfer occurred at al. As for now, coaches intervene based on their subjective observation intuition, and are limited to the face-to-face meetings with the team. An independent metric, lexical diversity, makes it possible to change this punctual monitoring routine to a continuous monitoring, which in turn allows for more precise and swift interventions as well as more dedicated coaching.

6 Conclusion and Limitations

To conclude, this paper confirms the intuition inspired by earlier research in design engineering [9, 40] and in text creativity [8, 46, 47] that evolution of vocabulary in design documentation reflects the process models applied in such collaboration. Following this finding, one can speculate about the usage of documents produced by the team as a source of knowledge on team's progress. It also confirms the strong connection between the language we use and our state-of-mind. If a mutual relation between the two is assumed [43], then stimulating language will enhance creative performance, and experiencing creativity will result in observable changes in language. Consequently, both dimensions should be considered in collaborative systems designed to support creative and divergent thinking. Our findings as well as the discussion shall inspire the scientific community to reconsider the topic of creativity support, in particular, with regard to long-term innovation projects. The DT community benefits from better understanding of the process model it promotes and how it influences the communication in design teams. Finally, facilitators of design projects may use the findings to control the progress made by teams, both in organizational and educational context.

While we postulate that language can be used for monitoring and stimulation of creativity in design teams, we acknowledge the fact, that language, and particularly, lexicon is not the only important factor in this regard. We would see it as ethically doubtful, if, e.g., university grades were depending on the lexical diversity or similar measurements. In fact, linguistic performance of an individual may vary and depends on daily mood, psychophysical state, and other independent factors, such as team composition.

Additionally, this study concentrates on the differences between phases in a "normal" case, simulated by the average measurements of all teams – comparison of lexical patterns between very successful and less successful project would provide further support for monitoring. Beyond that, it would allow for performance assessment of teams and not only their adherence to the process. To conduct such study, we would, however, require extended material – dividing 15 teams in two or more groups depending on their grades results in small "n" and yields results with only limited statistical significance. We therefore call for further research in this area with a more extended data set. Also, establishing the relation between the lexical diversity and the actual creativity of the ideas described in the considered documents would provide additional evidence.

Another related question addresses the influence of mother tongue and second/third language on the linguistic performance in design process documentation. We concentrated on the German texts in this study and disclosed wiki sections written in English, i.e., in a foreign language for the authors and presumed audience. However, it would be definitely an important extension of the current study to run the same analysis on data generated by native speakers of other languages.

{marcel.rhyn,ivo.blohm}@unisg.ch

Abstract. Crowdsourcing represents an innovative approach that allows companies to engage a diverse network of people over the internet and use their collective creativity, expertise, or workforce for completing tasks that have previously been performed by dedicated employees or contractors. However, the process of reviewing and filtering the large amount of solutions, ideas, or feedback submitted by a crowd is a latent challenge. Identifying valuable inputs and separating them from low quality contributions that cannot be used by the companies is time-consuming and cost-intensive. In this study, we build upon the principles of text mining and machine learning to partially automatize this process. Our results show that it is possible to explain and predict the quality of crowdsourced contributions based on a set of textual features. We use these textual features to train and evaluate a classification algorithm capable of automatically filtering textual contributions in crowdsourcing.

Keywords: Crowdsourcing, Machine Learning, Text Mining, Automatization

1 Introduction

In recent years, crowdsourcing has increasingly gained attention as an innovative approach to harness the collective resources of a broad and diverse network of people over the internet. The fundamental idea of crowdsourcing is that an organization proposes the voluntary undertaking of a task to an independent group of contributors in an open call [1, 2]. It seeks to mobilize the creativity, knowledge, or distributed workforce of a large panel of people who perform value creation activities that have previously been carried out by designated agents, such as employees or third-party contractors. The approach grants scalable access to remote resources and allows tasks to be completed in a parallelized fashion regardless of time and location. In this vein, crowdsourcing has been found to greatly improve the efficiency and effectiveness of problem-solving in organizations [3, 4].

However, the potential that arises from the decentralized contributions provided by a crowd comes with a critical challenge. The quantity and complexity of information that needs to be processed and evaluated in crowdsourcing is high – especially when the contributions are submitted in a raw, textual format. In 2006, for example, more than 140’000 international participants joined the IBM Innovation Jam and submitted

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Rhyn, M.; Blohm, I. (2017): A Machine Learning Approach for Classifying Textual Data in Crowdsourcing, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1171-1185

over 46’000 ideas in a single crowdsourcing contest [5]. Similarly, the devastating earthquake in Haiti during January 2010 generated over 13’500 crowdsourced messages on online maps that were used to locate emergencies and distribute relief supplies [6]. As these contributions are submitted by a diverse network of people with different backgrounds and degrees of expertise, textual data in crowdsourcing usually entail a high amount of noise and ambiguity. Thus, the process of manually evaluating the data and filtering out low quality contributions is arduous and lengthy [2]. It generally accounts for one of the most time-consuming and cost-intensive steps in crowdsourcing [7]. For example, it took Google almost three years and 3’000 employees to condense the 150’000 proposals submitted to its *Project 10 to the 100* [2].

Text mining and machine learning algorithms represent promising solutions to cope with the vast amount of contributions in crowdsourcing [8]. They provide the means to discover patterns and extract useful information from textual data in a fast, scalable, and repeatable way [9]. In this vein, they offer the potential to automatically evaluate and filter contributions in crowdsourcing. Although multiple studies have asked for such automated approaches, research on crowdsourcing is still lacking feasible models for this task [7, 10]. Our study aims to close this gap by addressing the following research question: “What textual characteristics can be used to assess and automatically predict the quality of contributions in crowdsourcing?” To answer this question, we choose a two-pronged approach that has already been used similarly in related studies [11]. First, we apply an explanatory regression analysis to examine textual characteristics that are associated with contribution quality in crowdsourcing. Then, we use these textual characteristics for predictive modeling with machine learning algorithms. That is, we build a classifier capable of predicting the quality of the contributions based on their textual characteristics.

Hence, the contribution of our study is twofold. For researchers, we provide a set of variables and models to explain and predict contribution quality in crowdsourcing. These models and variables can be used to assess textual contributions with machine learning algorithms and, thus, contribute to a partial automatization of the evaluation process. For practitioners, we build a classifier based on the Random Forest algorithm that incorporates these variables. It is capable of automatically filtering high quality and low quality contributions submitted by a crowd and makes the process of reviewing large volumes of textual feedback more efficient.

The remainder of this paper is structured as follows. In Section 2, we discuss the characteristics of textual contributions in crowdsourcing and review existing evaluation methods for this type of data. In Section 3, we derive hypotheses regarding the relationship between textual characteristics and contribution quality in crowdsourcing. In Section 4, we describe the methodology for testing these hypotheses with a regression analysis and outline our approach for predictive modeling with machine learning algorithms. Finally, in Section 5 and 6, we analyze the results and illustrate their implications for both researchers and practitioners.

2 Related Work

2.1 Textual Data in Crowdsourcing

The fundamental principle of crowdsourcing is the use of an open call to engage a wide network of potential contributors who submit their solutions to a set of tasks broadcasted by a company [1]. In this vein, crowdsourcing facilitates the collection of information and the distribution of problem-solving to a mass of users that are coerced into productive labor [6]. On the flipside, opening up the participation to a decentralized crowd of individuals makes it more difficult to control the content and format of the data [12]. This is especially challenging for the broad range of crowdsourcing settings that are based on contributions submitted in an free text format, such as ideas on open innovation platforms [5] or user feedback in crowdsourced software testing [7]. These textual contributions represent an unstructured data format and come with several problematic characteristics regarding both their contextual and their representational quality [13]. First, there is no ground truth to contributions such as ideas, feedback, or reviews. Hence, for these types of textual contributions, it is inherently complex to assess and compare contextual characteristics such as the relevancy or the completeness of the information [14]. Members of a crowd may have different perceptions of what is relevant or interesting for such a task and will typically cover a broad range of topics in their contributions [12]. Some contributions may lack focus and specificity; others may even include contradictory or false information [2]. Second, the representation of information in textual contributions is generally of high variance and diversity [6]. Depending on their background and their degree of expertise, members of a crowd may express themselves in very distinct ways, using different expressions for similar issues or similar expressions for different issues [2]. Hence, not only is there a wide range of potential topics but also a wide range of potential descriptions for these topics. This is aggravated by the fact that textual data generated by a crowd typically entail a high amount of noise due to spelling mistakes, grammatical errors, excessive punctuation, or informal writing styles [6].

2.2 Evaluation Methods for Textual Data

Given the previously described characteristics of textual data in crowdsourcing, it is difficult to use traditional approaches to quality control [15]. For example, it is not possible to employ gold standard data as there is typically no ground truth to which the contributions can be compared. Hence, companies rely on a manual assessment of the contributions. That is, someone has to read the contributions, evaluate the quality of the content, compare it to the requirements of the task, and either accept or dismiss the input for further consideration by the company [7]. Expert panels that review and select relevant inputs represent one of the most reliable yet impractical means for this step [14]. The volume of textual data and the rate at which they are created in crowdsourcing often exceed their information processing capacities [2]. Other approaches rely on the crowd itself for the evaluation of the contributions. However, multiple studies have shown that the design of ratings scales is highly challenging and often fails to produce reliable results [16]. For example, rating scales have been found to frequently face the problems of bimodal distributions or self-selection bias [17].

In consequence, a number of studies have experimented with text mining and machine learning algorithms to support the evaluation of textual data in crowdsourcing. Walter and Back [18] use text mining algorithms to cluster ideas submitted to innovation jams in an attempt to provide decision support for expert panels reviewing the contributions. Similarly in the domain of crowdsourced software testing, existing research has used text mining approaches to automatically cluster bug reports and prioritize them for the developers [19]. In the humanitarian aid sector, Rogstadius et al. [20] and Barbier et al. [6] outline the use of text mining algorithms for clustering crowdsourced incident reports and extracting named entities (e.g., locations or family names) in order to make the coordination of appropriate responses more efficient.

Hence, existing studies have already examined how the large number of textual contributions can be clustered and organized for companies trying to analyze the multitude of diverse topics and content submitted by the crowd. We extend this body of literature by analyzing textual characteristics that can be used to explain and predict the quality of the contributions. This allows companies not only to organize the variety of contributions, but also to automatically identify relevant inputs with machine learning algorithms and filter out those that are likely not to bear any value.

3 Hypotheses Development

For developing our model, we draw upon well-established textual features discussed in related literature [21–25] to operationalize the previously described contextual and representational characteristics of crowdsourced data and examine how these features are associated with contribution quality in crowdsourcing. Contextual characteristics account for the amount and the relevancy of the information provided in textual data. Representational characteristics account for the extent to which the text is presented in a clear and intelligible manner [21].

First, the amount of information in a textual contribution has frequently been discussed as one of its most important features by related literature [22, 24, 25]. Longer contributions contain more information that could potentially be relevant for the company than shorter ones [21]. It is also easier for companies to act on feedback that is well elaborated [2], as it allows them to build a more comprehensive and coherent representation of the information in the text [14]. For example, Riedl et al. [16] note that "more accurate, understandable, and comprehensive information enables decision makers to perform better" (p. 12). On the other hand, they emphasize that contributions that are short and less elaborated tend to deliver less information that could be required for an accurate understanding of the contributions and appropriate decision making [16]. Second, related literature also emphasizes the need to consider the relevancy of the information in a contribution [21, 25]. Otterbacher [21] quantifies the extent to which a product review contains terms that are statistically important across other reviews. Similarly, Weimer and Gurevych [25] use similarity features to measure the relatedness of a post to a forum topic. For crowdsourcing in particular, relevant contributions are typically characterized as containing clear and specific information for the companies to act on [2], while vague and blurry descriptions have been found to be detrimental to contribution quality [16]. Hence, we hypothesize as follows:

Hypothesis 1. The length of a textual contribution is positively associated with the quality of the contribution.

Hypothesis 2. The specificity of the terms used in a textual contribution is positively associated with the quality of the contribution.

Besides contextual characteristics accounting for the amount and the relevancy of the information, a second layer of analysis is concerned with the representational characteristics of a contribution [21, 26]. On the one hand, representational characteristics can be used as means to measure the sophistication of a contribution [21]. For example, the readability [27] is frequently used to analyze the syntactic and semantic complexity of a text [26]. In crowdsourcing, a higher readability of a contribution should enable companies to better understand the submitted content and extract relevant cues or information more easily [14]. On the other hand, representational characteristics can be broken down to purely superficial aspects, such as the extent to which a contribution respects common writing standards or reveals irregularities [11, 25]. Poorly written contributions containing spelling errors and grammatical mistakes increase the noise and ambiguity in the data [26]. Such irregularities impose a higher cognitive load on the recipient in the company and make the contributions prone to misinterpretation [14]. Hence, they are likely to be detrimental to the interpretability or clarity of crowdsourced contributions and may render the acquisition of the embedded information more difficult for companies. Thus, we define the second set of our hypotheses as follows:

Hypothesis 3. The readability of a textual contribution is positively associated with the quality of the contribution.

Hypothesis 4. The number of spelling mistakes in a textual contribution is negatively associated with the quality of the contribution.

4 Methods and Data

In order to answer our research question, we combine two independent data sources: textual contributions from a crowdsourcing project for which we apply text mining algorithms to make them eligible for statistical analysis and an expert-based baseline measure of contribution quality. This allows detailed insights into the automated classification of the contributions with machine learning algorithms.

4.1 Data Collection

For our study, we retrieved textual data from a crowdsourcing project in the field of software testing. We conducted a crowdsourced software test in cooperation with a

German-based intermediary that ranks amongst Europe's leading platforms in this domain and manages a crowd of more than 100'000 international software testers. The test was designed as a user acceptance test for a website and has been carried out in August 2015 over the course of 5 days. It consisted of open tasks that asked the testers about their opinion on positive and negative aspects of the website as well as suggestions for further improvement. This setting was chosen for several reasons. First, user acceptance tests for websites represent one of the most frequently performed types of software tests by crowdtesting platforms, as they allow companies to gather feedback from real end users of the software [7]. Second, user acceptance tests typically lead to a large amount of textual data which are especially time-consuming to evaluate by experts or developers. Third, the feedback retrieved during user acceptance tests resemble contributions in other domains, such as ideas in innovation management or reviews in product development. This allows the results of our study to be transferred to other crowdsourcing contexts and ensures their generalizability.

We received 309 contributions in a raw textual format from 104 testers who represent the target demographic of the website and who were randomly assigned to the software test by the intermediary. On average, the contributions contained 41 words with a standard deviation of 38 words. All contributions were written in English.

4.2 Expert Evaluation of Contribution Quality

As discussed previously, there is no ground truth to contributions such as ideas, feedback, or reviews. In the absence of objective measures, it is necessary to employ an expert-based baseline measure for contribution quality [14]. Therefore, we adapted the Consensual Assessment Technique for our study [28]. We asked two software experts to manually review the feedback. Both experts are involved in the development of the website for which the user acceptance test has been conducted. Thus, they are qualified to evaluate the contributions of the crowd. They independently reviewed all test reports by using the same evaluation scheme. The evaluation scheme is based on the framework proposed by Blohm et al. [14] for crowdsourcing and includes four criteria: relevance, elaboration, feasibility, and novelty. To cover these criteria, we used questions developed by Nørgaard and Hornbæk [29] who applied them analogously for assessing usability feedback in software testing. Hence, they are suitable for our study which is concerned with similar feedback to user acceptance tests. Each criterion was rated on a 5-point Likert scale. To validate the ratings of the experts, we calculated the weighted Cohen's Kappa for each criterion [30].

Table 1. Cohen's Kappa Statistics

Relevance	**Elaboration**	**Feasibility**	**Novelty**
0.78**	0.76**	0.77**	0.73**

Note: **substantial agreement, see Landis and Koch [31]

The strength of agreement as listed in **Table 1** is substantial [31] for all criteria, indicating that we have reliable quality measures. We used the mean to aggregate the expert ratings. Since we analyze contribution quality as a multidimensional construct [14], we followed past research [32–34] and calculated a composite score for contribution quality by averaging the ratings.

4.3 Variables and Measurements

We draw upon related literature [21–25] and use the textual features derived in Section 3 as variables to explain and predict the quality of the crowdsourced contributions. We use two variables (i.e., length and specificity) to account for their contextual characteristics and two variables (i.e., readability and spelling) to account for their representational characteristics.

Length. We measure the length of a contribution by counting the total number of words per contribution.

Specificity. We measure the specificity by building the sum of all TF.IDF-indices for a contribution. The TF.IDF-index represents a term weighting scheme that accounts for the importance of a particular term in the data set based on the term frequency and the inverse document frequency [35]. Generally speaking, broad and frequently used terms by the crowd (e.g., "bad" or "design") will receive lower values than more specific terms (e.g., "unintuitive" or "navigation"). For calculating these TF.IDF-indices, we follow the commonly used bag-of-words approach with a vector space model and apply standard preprocessing steps [36]. More specifically, we tokenize the contributions by breaking them up into individual terms. We apply standard transformations to the single terms, including normalization (i.e., transforming all characters to lower-case), stop word filtering (i.e., removing terms such as articles or prepositions that bear no value for the analysis) and stemming (i.e., reducing terms to their root form to avoid duplications) with the Porter stemmer [37].

Readability. We follow Ghose and Ipeirotis [11] as well as Blohm et al. [14] and measure the readability of the text by calculating the Coleman-Liau index [27] for each contribution. This index captures the complexity of the contributions by analyzing part-of-speech tags and measuring the average length of their terms and sentences. A higher index indicates a better readability for the text.

Spelling. Finally, we measure irregularities and non-conformance to writing standards by counting the number of spelling errors per contribution. In order to ensure that the spelling errors were accurately captured, we manually reviewed all 309 contributions.

5 Models and Results

5.1 Explanatory Regression Analysis

In this section, we use regression modeling to analyze whether the textual features of the contributions are associated with their quality. The length of a contribution, the specificity of the terms, the readability of the text, and the number of spelling errors represent the independent variables. The contribution quality as rated by the experts represents the dependent variable. The results are depicted in **Table 2**.

Table 2. Regression Analysis

Coefficient	Estimate	Std. Err.	t-value	p-value	
(Intercept)	2.890	0.039	74.395	< 2.2e-16	***
Length	12.091	0.783	15.451	< 2.2e-16	***
Length (poly 2)	-4.730	0.694	-6.813	5.18e-11	***
Length (poly 3)	2.930	0.710	4.124	4.82e-05	***
Specificity	1.752	0.721	2.429	0.016	*
Readability	2.333	0.708	3.297	0.001	**
Spelling	-1.847	0.814	-2.269	0.024	*

Note: ***p < 0.001; **p < 0.01; *p < 0.05

Residual Standard Error: 0.683; R-Sq. (adj.): 0.554; F(6,302): 64.8; p-value: < 2.2e-16

It shows that the length (t = 15.451; SD = 0.783; p = < 2.2e-16) and the readability (t = 3.297; SD = 0.708; p = 0.001) of a contribution are highly significant indicators for its quality. Both features are positively correlated to the quality of the contribution. Interestingly, as indicated by the polynomials, we observe a diminishing marginal utility effect associated with number of words in a contribution, which seems conceptually reasonable. Writing 55 instead of 5 words benefits the contribution more than extending it from 150 to 200 words. Regardless of this effect, our results still support H_1 which states that the length of a textual contribution is positively associated with the quality of the contribution. The model also supports H_3 and shows that the readability of a textual contribution is positively associated with the quality of the contribution. Similarly, the specificity of the terms (t = 2.429; SD = 0.721; p = 0.016) and the number of spelling mistakes (t = -2.269; SD = .814; p = 0.024) in a contribution are significant indicators for its quality. The former is positively correlated to the quality of the contribution. The latter is negatively correlated to the quality of the contribution. These results support H_2 and H_4. The model reveals a high value for R^2 and explains the quality of the contributions significantly well. We found no evidence that potential effects between the individual contributors and their contributions affect our results. We also examined the residuals and found our model to be sound. There are no signs of heteroscedasticity nor autocorrelation. The residual show to be normally distributed. We can conclude that the proposed variables explain the quality of crowdsourced contributions at statistically significant levels. We find support for our four hypotheses and will use these findings as the foundation for predictive modeling.

5.2 Predictive Modeling

Based on the previously analyzed variables, we train and evaluate a classifier that is capable of predicting the quality of the contributions and automatically filter them. A binary classification allows for a clear selection rule [2] that decides on whether the contributions fulfill the quality requirements and are thus eligible to be forwarded to the organization for further consideration or whether they are of poor quality and should be filtered out to not induce unnecessary workload. Hence, we represent the evaluation of the contributions as a classification problem. We set the threshold for separating high quality from low quality feedback to 3.5, which is comparable to previous studies conducted for product reviews [11], and labeled the contributions. As a result, 83 contributions were classified as high-quality contributions, whereas 226 contributions were classified as low-quality contributions. This distribution is consistent with findings documented in previous studies on the quality of crowdsourced contributions [11, 2]. We tested different classification algorithms and compared the performance of Logistic Regression, Naïve Bayes, k-Nearest Neighbor, Decision Trees, and Random Forest for this study. We found the Random Forest algorithm to perform substantially better in classifying the contributions compared to the other approaches – both regarding the accuracy and the receiver operating characteristic. Our findings are consistent with comparative experiments conducted for similar classification tasks [11]. Thus, we focus on the results of the Random Forest algorithm.

The Random Forest algorithm [38] builds a large number of decision trees with different combinations of the given variables. These decision trees are internally trained and evaluated using random subsets of the same data. The Random Forest model then averages the decision trees. In this vein, it reduces the variance that comes with individual decision trees, provides information about the importance of the variables for the classification, and overcomes the risk of overfitting [39].

We use 100 decision trees for our Random Forest model and set the cutoff for the model's probability estimates at the standard value of 0.5. To build and evaluate the classifier, we followed the widely used k-fold cross-validation approach with 5 folds. That is, we randomly split our data set in a stratified manner into 5 subsets. 4 subsets are used to train the classifier with the given labels. The remaining subset does not include the quality labels and is used evaluate the performance of the classifier by comparing the labels predicted by the Random Forest algorithm to the actual labels provided by the experts. We measure the accuracy, the sensitivity, the specificity[1], and the receiver operating characteristic [40]. This procedure is repeated until each split of the data set has been used to train and evaluate the classifier.

The results of the cross-validation reveal an accuracy of 80.03% on average for our Random Forest model. Thus, by only using the four variables based on our proposed textual features, the algorithm is able to automatically predict the quality of the crowdsourced contributions and correctly classify them in over 80% of the cases. The classifier shows a very high specificity of 87.73%, indicating that it performs exceptionally well at recognizing and filtering low quality contributions. As suggested by the slightly lower sensitivity measure (60.27%), it is more difficult for the algorithm to achieve a high true positive rate. The sensitivity of the classifier can be increased by adjusting the cutoff for the probability estimates. Lowering the cutoff by 20% increases the classifier's sensitivity to 75.30%. Naturally, however, this comes at the expense of reducing its specificity to 76.56%.

---

[1] It is important to note that, in this context, specificity refers to a statistical measure that describes the true negative rate.

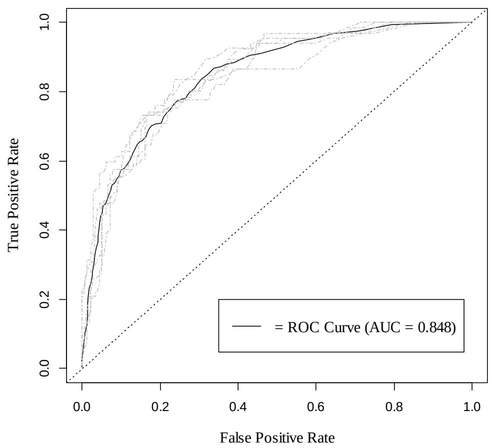

Figure 1. Receiver Operating Characteristic

The curve of the classifier’s receiver operating characteristic (ROC) is depicted in **Figure 1**. It plots the true positive rate against the false positive rate [40]. The diagonally plotted line represents the strategy of randomly guessing the quality of the contributions. A classifiers that reaches the upper triangular region of this line exploits information in the data and performs better than the random classification strategy [40]. The area under curve (AUC) is equivalent to “the probability that the classifier will rank a randomly chosen positive instance higher than a randomly chosen negative instance” [40], making it also equivalent to the Wilcoxon test of ranks. Here, the AUC reveals a high value of 0.848. Hour classification algorithm performs very well.

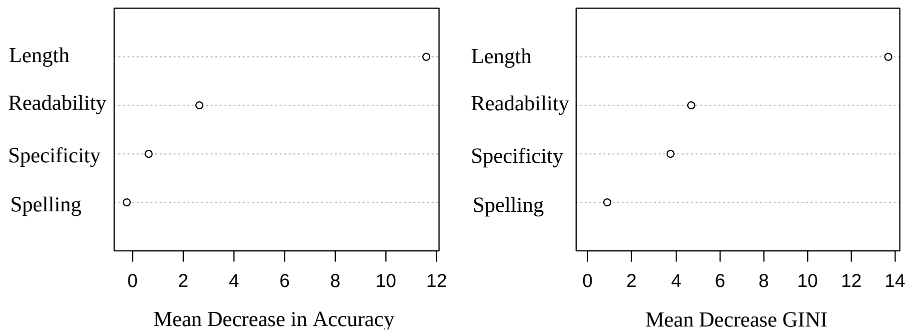

Figure 2. Variable Importance Plots

Finally, **Figure 2** displays the importance of the four proposed variables, measured by the mean decrease in accuracy and the mean decrease in node impurity (i.e., Gini index) for each variable [41]. All variables were used by the Random Forest algorithm and have predictive power. The length of the contribution is by far the most important variable for the classification. When aiming for a sparse prediction model, the variable “Spelling” may be omitted without risking much worse results.

6 Discussion and Implications

The models and results presented in the previous section yield two important findings. First, we find support for our hypotheses and show that the length of a contribution, the specificity of the terms, the readability of the text, and the number of spelling errors are all associated with contribution quality in crowdsourcing at statistically significant levels. Therefore, in a second step, we used the textual characteristics in combination with an expert-based baseline measure for contribution quality to train and evaluate an algorithm capable of predicting the contribution quality and classifying the data. Even for a small data set of 309 contributions, our Random Forest classifier achieves an accuracy of 80.03%. The algorithm has shown to perform especially well at recognizing and filtering low quality contributions. It outperforms random classification substantially and also achieves a much higher accuracy compared to a naïve classifier that would always predict the category with the majority of the ratings (i.e., 73.14%). Thus, our Random Forest algorithm proves to be very reliable. These findings have valuable implications for both researchers and practitioners alike.

6.1 Theoretical Implications

To the best of our knowledge, we are the first to show that it is possible to reliably explain and predict the quality of contributions in crowdsourcing based on textual features of the data alone. We provide empirical evidence for the relationship between both contextual and representational characteristics of contributions and their quality in crowdsourcing. This indicates that well elaborated and precise solutions, ideas, or suggestions are vital for companies trying to leverage the information submitted by a crowd. Furthermore, our results suggest that companies require textual contributions to be presented in a clear and easily interpretable manner to fully benefit from them.

Moreover, we contribute a set of models and variables to operationalize these contextual and representational characteristics. The models and variables proposed in our study have been shown to work well with algorithms capable of automatically assessing and classifying textual contributions. In this vein, we provide the foundation for partially automating the evaluation of textual data in crowdsourcing, which has frequently been requested by related literature. Kittur et al. [10] emphasized that, while "quality control is improving for tasks with a closed set of possible answers, we still have few techniques for open-ended work and highly skilled tasks" (p. 7-8). The authors specifically asked for studies to analyze potential metrics and propose feasible approaches to predict output quality. In crowdsourced software testing in particular, related work has expressed the need for efficient mechanisms to assess the quality of crowdsourced contributions and automate the evaluation of the data [7]. With our study, we close this gap and extend existing research that already uses machine learning and text mining algorithms to cluster the variety of topics covered in crowdsourcing projects [6, 18–20] by providing both the appropriate variables and models for an automated evaluation of high quality and low quality contributions in the potentially large sets of textual data. Regarding the importance of different variables, we found the length of a contribution to be the most effective indicator for explaining and predicting its quality. Both the readability of the contributions and the specificity of the terms are positively associated with the quality of the contributions at highly significant levels but reveal only moderate predictive power for classification algorithms. Interestingly, spelling errors have shown to be the least important feature for the classification and may even be omitted for sparse models. Therefore, our findings may help researchers in selecting variables for predictive modeling in crowdsourcing.

6.2 Practical Implications

Our proposed Random Forest classifier allows companies to substantially reduce the amount of information that needs to be reviewed manually. It shows that the classification algorithm is capable of automatically identifying high quality contributions in large data sets and removing those that do not fulfill the quality requirements defined by the companies or platforms. In this study, we set the threshold to only include the top 30% of the contributions. Hence, the algorithm can make the evaluation of the results submitted to crowdsourcing projects much more efficient and offers both time and cost savings. It is possible to incorporate the algorithm directly as a filter mechanism on the platforms or in tools for companies retrieving data from these platforms.

We also show that the sensitivity and specificity of the Random Forest algorithm can be adjusted to fit the preferences of practitioners. As both measures are inherently linked to each other, the decision to increase one measure will always come with the trade-off of decreasing the other. If the costs of wrongfully rejecting a high quality contribution is higher than the cost of wrongfully including a low quality contribution in the evaluation process, this is a trade-off that should potentially be considered.

Finally, our automated machine learning and text mining approach also contributes to practitioners in the domain of software testing. Related work already proposes algorithms that can be used to evaluate technical bug reports more efficiently. For example, it is possible to automatically assess the severity of the bug reports [42] and detect duplicates in the data sets [43]. As our data stem from crowdsourced software testing, we extend these findings and provide developers with an approach to facilitate the evaluation of test reports obtained in user acceptance testing, user experience testing, or usability testing. These contributions are typically submitted in a free text format and entail a high workload for the developers [7]. Our proposed classifier may help developers in evaluating these types of test reports more efficiently.

6.3 Limitations and Future Research

As with any research, our work does have its limitations. First, the manually assigned quality labels used for our data set are inherently dependent upon the rating scales and the subjective judgements of the experts. We attempted to address this issue by using scales that have been developed specifically for crowdsourced contributions as analyzed in this study [14]. Furthermore, we let two experts independently review the contributions. The Cohen’s Kappas indicate an intersubjective agreement between the experts. Second, the data set stems from a crowdsourcing project in the field of software testing. We aimed to provide as much generalizability as possible by choosing a user acceptance test setting that yields contributions similar to other crowdsourcing contexts that are based on textual data, such as ideas, feedback, or reviews.

The findings presented in this study may encourage future efforts to analyze the performance of the proposed features or models in different crowdsourcing settings and expand on our initial results. There is still great potential in making the algorithms cost-sensitive and studying the optimal trade-off between sensitivity and specificity in crowdsourcing. Furthermore, as we focused on the textual characteristics of a contribution, future work may also examine the role of non-textual characteristics and analyze features such as the experience or the expertise of the individuals who submitted the contributions. Finally, text mining and machine learning methods benefit from large data sets. Hence, we need scalable concepts for labeling crowdsourced contributions and training algorithms with more data. Addressing these issues would pave the way for leveraging the full potential of machine learning in crowdsourcing.

7 Conclusion

The process of manually reviewing and filtering large volumes of textual contributions has been a longstanding challenge in crowdsourcing. Given the unstructured format of textual data and the diversity of inputs submitted by a crowd, identifying valuable inputs and separating them from low quality contributions that cannot be used by the companies is very time-consuming and cost-intensive. In this study, we propose an approach based on the principles of text mining and machine learning to partially automatize this process. Our results indicate that it is possible to explain the quality of crowdsourced contributions purely based on textual features, such as the length of a contribution, the specificity of the words, the readability of the text, and the number of spelling errors. We use these textual features in combination with an expert-based baseline measure to train and evaluate a classification algorithm that is capable of reliably predicting the quality of the contributions and automatically filtering them for companies.

Abstract. Bei Konsumentscheidungen greifen Verbraucher auf ihr vorhandenes Wissen über Marken zurück, welches sie im Gedächtnis in Form von Markenassoziationsnetzwerken organisieren und deren Kenntnis es erlaubt Verbraucherentscheidungen besser zu verstehen. Traditionell werden Markenassoziationsnetzwerke mittels reaktiver, befragungsorientierter Instrumente direkt von Verbrauchern erhoben. Gleichzeitig hinterlassen unzählige Verbraucher online in nutzergenerierten Inhalten (UGC) ihre verbal explizierten Wahrnehmungen freiwillig und unangeleitet und erzeugen damit eine neue Datengrundlage zur nichtreaktiven, passiven Erhebung von Markenassoziationsnetzwerken. Traditionelle inhaltanalytische Verfahren, wie die qualitative Inhaltsanalyse, ermöglichen aufgrund der Quantität, Heterogenität und Erstellungsgeschwindigkeit von UGC entweder nur Stichprobenbetrachtungen, oder sind mit prohibitiv hohen Aufwänden verbunden. Somit erfordert die nichtreaktive Erhebung von Markenassoziationsnetzwerken aus UGC neue, computergestützte Verfahren, zu denen der vorliegende Artikel einen methodischen Beitrag leistet. Auf Grundlage von sprachlichen Mustern traditionell befragungsorientiert erhobener Markenassoziationen wird ein Text Mining Verfahren zur Extraktion von Markenassoziationsnetzwerken aus UGC vorgeschlagen, anhand einer Vergleichsstudie diskutiert und der Einsatz für die Markenführung demonstriert.

1 Einleitung

In Zeiten der Informationsüberlastung und sich zunehmend angleichenden Produkten und Services können Verbraucher diese oft nur schwer unterscheiden [1, 2]. Bei Unsicherheit, sowie in Konsumentscheidungssituationen greifen sie daher auf ihr bereits vorhandenes Wissen über Marken als Entscheidungshilfe zurück [1, 3-5]. Dieser als Markenwissen bezeichnete Beeinflussungsfaktor wirkt auf den kundenorientierten Markenwert [3, 6, 7], wenn Verbraucher mehr oder weniger positiv auf die Elemente des Marketing-Mixes eines markierten- gegenüber eines unmarkierten Produktes oder Services reagieren [1]. Der kundenorientierte Markenwert liefert somit diagnostische Informationen für das Entstehen des monetär messbaren, finanzorientierten Markenwertes, welcher die vom Verbraucher akzeptierte Wertdifferenz zwischen einem unmarkierten und einem markierten aber gleichwertigen Produkt oder Service bezeichnet. Um sich Wettbewerbsvorteile zu verschaffen und den finanzorientierten Markenwert zu erhöhen, müssen Unternehmen daher Strategien zur Steuerung des kundenorientierten Markenwerts entwickeln [1, 2]. Die Ableitung von Strategien setzt allerdings zunächst eine entsprechende Konzeptualisierung sowie die Operationalisierung entsprechender Messgrößen voraus. Gemäß der Konzeptualisierung nach Keller [1] wird der kundenorientierte Markenwert durch das Markenwissen im Gedächtnis des Verbrauchers bestimmt. Dieses setzt sich aus der Markenbekanntheit (Brand Awareness) und dem Markenimage (Brand Image) zusammen [1]. Während die Markenbekanntheit die (Wieder-)erkennungs- und Erinnerungsleistung an die Marke beeinflusst, manifestiert sich das Markenimage in Netzwerken von Markenassoziationen im Gedächtnis der Verbraucher [1]. Diese netzwerkorientiere Sichtweise des Markenimages anhand Markenassoziationsnetzwerken gründet auf der Theorie des Human Associative Memory Models [8] und der Spreading Activation Theorie [4] aus der Kognitionspsychologie. Demnach wird das semantische Gedächtnis des Menschen als Netzwerk aus informationstragenden Knoten (Assoziationen) sowie Kanten unterschiedlicher Stärke verstanden und Aktivierungen einzelner Knoten pflanzen sich entlang der Kanten fort, um weitere Knoten zu aktivieren. Markenassoziationen repräsentieren solche informationstragenden Knoten und entstehen aufgrund direkter (z.B. Verwendung) wie auch indirekter Erfahrungen (z.B. Word-of-Mouth (WoM) der Konsumenten mit dem Leitungsangebot eines Unternehmens [1, 2, 9]. Ein netzwerkorientierter Ansatz Markenassoziationen zu repräsentieren, soll letztlich dazu beitragen, ein besseres Verständnis davon zu erhalten, wie Verbraucher die Marke- sowie das sich aus Menschen, Orten und Nutzungsszenarien zusammensetzende Umfeld der Marke wahrnehmen [10]. Dies schafft eine Grundlage, Präferenzen und Auswahlentscheidungen, und damit die Determinanten des kundenorientierten Markenwertes zu verstehen [1, 10, 11]. Henderson et al. [10, 11] zeigen diese diagnostische Stärke, indem sie aus der Struktur von Markenassoziationsnetzwerken Markenmechanismen wie Markengleichheit, -Verwechselbarkeit oder Verwässerungseffekten erklären können. Keller [1] argumentiert zudem, dass kundenorientierter Markenwert entsteht, wenn Verbraucher starke, vorteilhafte, sowie einzigartige Markenassoziationen besitzen. Letztlich setzen strategische Maßnahmenplanungen zur Schaffung von kundenorientiertem Markenwert jedoch zunächst die Erhebung von Markenassoziationsnetzwerken als diagnostische Kenngröße voraus. Klassischerweise erfolgt die Erhebung von Markenassoziationen zur Markenimagemessung anhand befragungsorientierter Erhebungsinstrumente zu denen Farsky [12] einen umfassenden Überblick gewährt. Den Erhebungsmethoden ist gemein, dass sie auf reaktiven Befragungen basieren. Aufgrund von Aufwand und Kosten sind Unternehmen jedoch zunehmend an neuen kosteneffizienten Methoden interessiert [13]. Gleichzeitig nutzen heutzutage unzählige Verbraucher das Internet und Social Media Kanäle um freiwillig und unangeleitet, öffentlich zugänglich ihre Einstellungen, Gefühle und Meinungen zu verschiedensten Themen zu verbreiten [14-16]. Diese öffentlichen und häufig in Textform vorliegenden nutzergenerierten Inhalte (User-generated Content : UGC) bieten als qualitative Datengrundlage das Potenzial, Explizierungen von individuellem Markenwissen zu enthalten was eine neue Datenquelle zur nichtreaktiven, passiven Erhebung von Markenassoziationsnetzwerken eröffnen würde. UGC stellt damit eine potentiell kostengünstige und zudem jederzeit verfügbare Alternative zu mittels traditioneller Verfahren erhobener Stichproben dar [13]. Da Markenassoziationen in textbasiertem UGC allerdings durch Worte und Phrasen ausgedrückt werden, müssen diese zunächst identifiziert und extrahiert werden. Als traditionelle Methode kann hier die qualitative Inhaltsanalyse in Betracht gezogen werden, bei welcher ein Analyst Markenassoziationen und Relationen zwischen diesen Assoziationen manuell identifiziert und codiert. Die Menge und Erstellungsfrequenz, sowie das dezentrale Vorkommen von UGC führt jedoch dazu, dass entweder nur eine Stichprobe des insgesamt vorhandenen UGC betrachtet werden kann, oder dass große (manuelle) Aufwände notwendig werden, die zu prohibitiv hohen Kosten der Erhebung führen können. Dies führt zur Notwendigkeit neuer computergestützter Verfahren um den öffentlich vorliegenden UGC zur Ableitung von Markenassoziationsnetzwerken zugänglich zu machen. Der vorliegende Artikel widmet sich dieser Forschungslücke und schlägt ein Verfahren vor, um computergestützt Markenassoziationsnetzwerke aus UGC zu extrahieren. In Abschnitt 2 wird hierzu zunächst ein Überblick über verwandte Arbeiten gewährt und von der vorliegenden Arbeit abgegrenzt. Darauf aufbauend schlägt Abschnitt 3 dann ein neues, automatisiertes Textanalyseverfahren zur Extraktion von Markenassoziationsnetzwerken aus UGC vor. Dieses Verfahren wird dabei induktiv anhand von Sprachmustern aus traditionell erhobenen Markenassoziationen entwickelt. Abschnitt 4 wendet die vorgeschlagene Methodik auf das Beispiel der Marke Google im Kontext des autonomen Fahrens an, und diskutiert den Einsatz der vorgeschlagenen Methodik als diagnostisches Tool für Markenführungsmaßnahmen. Abschnitt 5 schließt mit der Diskussion der Limitierungen und gibt einen Ausblick auf künftige Forschung.

2 Verwandte Arbeiten

Die Extraktion von marketingrelevanten Informationen aus UGC hat in den vergangenen Jahren an Bedeutung gewonnen. Der vorliegende Artikel der eine Methode zur Extraktion von Markenassoziationen aus UGC vorschlägt, grenzt sich wie folgt von anderen Beiträgen ab. Zum einen finden sich Beiträge bei denen Markenassoziationsnetzwerke entweder nicht aus UGC, sondern traditionell über

Befragung erhoben [17-19] werden. In anderen Beiträgen stellt UGC zwar den Untersuchungsgegenstand dar, jedoch werden anstatt Markenassoziationsnetzwerken beispielsweise Marktstrukturinformationen [16] in Netzwerken abgebildet. Weiterhin wurden zu Markenassoziationen ähnliche Konstrukte mittels Text Mining aus UGC extrahiert, jedoch keine Netzwerkstrukturen erhoben, sondern beispielsweise Ranglisten aus Markenassoziationen [20], Produkteigenschaften [21] oder allgemeinen Features [22]. Eine erste Arbeit welche die Extraktion von Markenassoziationsnetzwerken aus UGC und den Nutzen für die Markenführung zeigt [23], ist die Arbeit von Gensler et al. [23] . Im Gegensatz zum hier vorliegenden Beitrag fokussieren Gensler et al. [23] dabei jedoch auf eine spezifische Produktbewertungsplattform als eine bestimmte Ausprägung von UGC und nutzten hier besondere Eigenschaften der dort vorliegenden Produktbewertungen um Markenassoziationen zu extrahieren anstatt den Textinhalt [23]. Dies erlaubt es zwar, das diagnostische Potenzial der Erhebung von Markenassoziationsnetzwerken aus Produktbewertungen zu zeigen, wird jedoch dadurch eingeschränkt, dass die vorgestellte Methodik nicht ohne weiteres auf andere UGC Quellen erweitert werden kann. Damit kann die vorgestellte Methodik nur eine spezifische Stichprobe des verfügbaren UGC auswerten. Der vorliegende Artikel ordnet sich in die bestehende Forschung dahingehend ein, den Fokus von Gensler et al. [23] unter Anwendung zu [22] oder [21] ähnlicher Textanalyseverfahren zu erweitern und damit erstmalig einen Vorschlag zur ganzheitlichen Extraktion von Markenassoziationsnetzwerken aus UGC zu unterbreiten.

3 Vorgeschlagenes Verfahren zur Extraktion von Markenassoziationsnetzwerken aus UGC

Im Folgenden wird das Verfahren zur Erhebung und Konstruktion von Markenassoziationsnetzwerken aus UGC vorgestellt und anhand des Beispiels der Marke Google im Kontext des autonomen Fahrens illustriert. Das vorgeschlagene Verfahren folgt einem 8-stufigen Erhebungsprozess, der sich an das Vorgehen von Gensler et al. [23] anlehnt. Dies sind (1) Festlegung des Untersuchungsobjektes, (2) Datensammlung, (3) Datenbereinigung, (4) Extraktion von Markenassoziationen, (5) Sentimentanalyse, (6) Bestimmung der Assoziationsstärke, (7) Bestimmung der Verbindungen zwischen Assoziationen, sowie (8) die Konstruktion des Markenassoziationsnetzwerks.

3.1 Festlegung des Untersuchungsobjektes

Im ersten Schritt ist zunächst die Entscheidung für ein Untersuchungsobjekt zu treffen. Hierbei kann es sich um eine Marke, Dachmarke, Produktmarke oder ein Themenumfeld handeln. Im Rahmen dieses Beitrags wird als illustrierende Studie, das Untersuchungsobjekt als die Marke „Google“ innerhalb des Themenfeldes „autonomes fahren“ definiert. Beim autonomen Fahren handelt es sich um eine Innovation im Automobilbereich, bei dem sich Fahrzeuge in naher Zukunft selbstständig fortbewegen ohne das Eingreifen des Fahrers. Im Rahmen dieser Technologie haben

Fahrzeughersteller wie Audi, BMW und Mercedes oder Tesla, jedoch auch vermeintlich branchenfremde Unternehmen wie Google oder Apple Milliarden von Dollar in die Entwicklung investiert. Schlussendlich ist jedoch die Akzeptanz von Verbrauchern maßgeblich für den Erfolg der Markteinführung und Verbraucher treffen ihre Entscheidung auf Grundlage ihres vorhandenen Wissens in Form von Assoziationsnetzwerken. Daher ist die Kenntnis der Assoziationsnetzwerke, insbesondere im Umfeld des autonomen Fahrens, ein wichtiger Schritt für Marken potenzielle Wirkmechanismen im Hinblick auf ihren Markteintritt zu verstehen oder um ihre Marken so zu positionieren dass ein erfolgreicher Markteintritt möglich wird.

3.2 Datensammlung

Innerhalb der Datensammlung müssen im Internet solche Texte gesammelt werden, welche von Verbrauchern veröffentlicht wurden und sich thematisch mit dem Untersuchungsobjekt befassen. Im Rahmen des hier beschriebenen Verfahrens wird hierzu die Nutzung von allgemeinen Web-Suchmaschinen wie Google.com oder Bing.com vorgeschlagen. Hierzu muss eine entsprechende boolesche Suchabfrage formuliert und an die Web-Suchmaschine geschickt werden. Die von dieser zurückgelieferten Verweise auf Webseiten (uniform ressource locator – URL), sowie die Webseiten selbst werden mittels eines sog. Web-Crawlers abgerufen und gespeichert. Im Rahmen der illustrierenden Studie wurde für diesen Prozess ein Web-Crawler entwickelt, welcher die boolesche Suchabfrage aus Abbildung 1 an die Google Suchmaschine übermittelt, und auf Grundlage der zurückgelieferten URLs die korrespondierenden HTML Webseiteninhalte in einer zentralen Datenbank abspeichert. Insgesamt wurden hierbei 1.1 Millionen englischsprachige HTML Webseiteninhalte von unterschiedlichen URLs gesammelt, welche sich über einen Zeitraum von zehn Jahren zwischen April 2005 sowie April 2015 erstrecken.

Google AND (“autonomous driving” OR “self driving car” OR “self driving cars” OR
“driverless car” OR “driverless cars” OR “autonomous vehicle” OR “automated driving”
OR “piloted driving” OR “driverless car”)

Abbildung 1: Search Query

3.3 Datenbereinigung

Um möglichst relevante UGC Textbeiträge für die Extraktion von Markenassoziationen zu verwenden, wird ein dreistufiger Bereinigungsprozess vorgeschlagen. In der ersten Stufe müssen zunächst Textbestandteile aus den jeweils gesammelten, einzelnen Webseiten erkannt und isoliert werden, da diese üblicherweise nicht nur aus den eigentlichen Textbeiträgen, sondern auch aus anderen Elementen wie z.B. Navigations-, Werbungs-, Kopf- und Fußbereichen bestehen. Diese Elemente werden zusammenfassend als Boilerplate bezeichnet und können möglicherweise Teile der booleschen Suchanfrage beinhalten, obwohl sie inhaltlich keine Informationen tragen (z.B. „autonome Autos“ als Menüpunkt in Navigationselementen). Jede einzelne Webseite kann dabei mehrere irrelevante Boilerplate-Elemente wie auch mehrere relevante Inhaltselemente beinhalten. Zur Erkennung und Entfernung von Boilerplate-Elementen wird der Ansatz von Kohlschütter [24] empfohlen und verwendet. Dieser basiert auf generischen Eigenschaften von Web-Dokumenten (z.B. link-zu-text Verhältnis) und kann daher als robust gegenüber heterogenen Inputdokumenten angesehen werden, was eine Charakteristik der hier beschriebenen Datensammlung ist. Die zweite Bereinigungsstufe dient der Erkennung und Bereinigung von Duplikaten, welche sonst möglicherweise zu Verzerrungen aufgrund von Mehrfachzählungen - beispielsweise bei der Bestimmung von Markenassoziations- und Vernetzungsstärken - führen können. Duplikate treten beispielweise dann auf, wenn der selbe Inhalt unter unterschiedlichen URLs abrufbar ist (z.B. Druckansichten oder Produktbeschreibungen). Absolute Duplikate können hierbei einfach mittels zeichenweiser Vergleiche erkannt und bereinigt werden. Im letzten Schritt der Datenbereinigung werden nun nicht nutzergenerierte Inhalte (non-UGC) von der Datengrundlage entfernt, da die im Ziel zu erhebenden Markenassoziationsnetzwerke die Verbraucherperspektive abbilden sollen und somit ausschließlich von Verbrauchern erzeugte Inhalte (UGC) von Interesse sind. UGC findet sich im Internet verstreut auf sozialen Netzwerken, Foren, Blogs, Produktbewertungsplattformen, E-Commerce Webseiten und letztlich potenziell auf jeder Webseite, die eine Kommentarfunktionalität anbietet. UGC liegt also dezentral vor, und vermischt sich auch mit non-UGC wie z.B. redaktionelle Artikel, Produktbeschreibungen oder Werbung) [25]. Somit ist es zweckmäßig in den gesammelten Dokumenten, non-UGC Dokumente zu bereinigen. Egger et al. [25] haben gezeigt, das textbasierter UGC inhärente Eigenschaften aufweist, die es erlauben ein binäres Textklassifikationsproblem zu formulieren und mittels Maschinenlernverfahren zu adressieren. Im Rahmen der illustrierenden Studie wird dem Vorgehen von Egger et al. [25] gefolgt und manuell eine Stichprobe von 422 Dokumenten als UGC (214) und non-UGC (208) annotiert um ein sog. Gold Set zu erzeugen. Dieses Gold Set stellt die Grundlage an Dokumenten, welche für das Anlernen eines Klassifizierers verwendet werden und beinhaltet für jedes dort enthaltene Dokument die korrekte Klassifizierung in UGC oder non-UGC. Auf Grundlage dieses Gold Sets wird dann ein auf Support-Vector-Machines (SVM) [26] basierender Klassifizierer unter Verwendung von 10-fold Cross-Validation angelernt. Die 10-fold Cross Validation ist dabei eine Vorgehensweise den Klassifizierer anzulernen und zu validieren. Hierbei wird das Gold-Set in 10 gleichgroße Segmente unterteilt. Von diesen Segmenten werden in 10 Iterationen, jeweils 9 Segmente zum Anlernen des Klassifizierers und eines zur Validierung des Klassifizierers verwendet. Die Validierung erfolgt anhand der Metriken Precision, Recall und Accurracy (Abbildung 2). „true positive“ entspricht hierbei einer gemäß des Gold Sets korrekten Klassifizierung als UGC, „true negative“ einer korrekten Klassifizierung als non-UGC, „false positive“ einer Fehlklassifizierung als UGC und „false negative“ einer Fehlklassifizierung als non-UGC.

$$precision = \frac{true\ positive}{true\ positive + false\ positive}$$

$$recall = \frac{true\ positive}{true\ positive + false\ negative}$$

$$accurracy = \frac{true\ positive + true\ negative}{true\ positive + true\ negative + false\ positive + false\ negative}$$

Abbildung 2: Kennzahlen zur Validierung der UGC Klassifikation [25]

Als Ergebnis der Validierung des illustrierenden Beispiels wurde eine Accuracy von 92.29%, eine Precision von 97.18% und Recall von 89.61% bei der UGC Klassifizierung erreicht. Die Anwendung des angelernten Klassifizierers auf die gesammelte Dokumentenkollektion und Bereinigung von non-UGC führt letztlich zu einem Korpus von 33.866 UGC Dokumenten.

3.4 Extraktion von Markenassoziationen aus Freitexten

Zur Konstruktion des Markenassoziationsnetzwerkes sind zunächst die Netzwerkknoten, also die Markenassoziationen zu bestimmen. Bei der vorliegenden Datengrundlage aus textbasierten UGC Dokumenten, manifestieren sich verbal explizierte Markenassoziationen als Textbestandteile in Form von Worten und Phrasen. Um solche Worte und Phrasen in textbasiertem UGC zu finden, die potenziell Markenassoziationen repräsentieren, ist jedoch die Kenntnis darüber notwendig, wie Verbraucher Markenassoziationen verbal explizieren. Nach Lawson [27] werden Markenassoziationen üblicherweise durch Konzepte repräsentiert, die grundsätzliche Eigenschaften, ähnliche Produkte und Themen, Produktverwendungen oder zusammenfassende Bewertungen beschreiben. Nach unserer Kenntnis finden sich jedoch weder in der Opinion Mining noch der Markenführungsliteratur derzeit Beiträge, welche sich der linguistischen Beschreibung von verbalsprachlich explizierten Markenassoziationen widmen. Dies wäre jedoch für die Konstruktion von Text Mining Verfahren zur Aufdeckung von Markenassoziationen von entscheidendem Wert. Als erste Annäherung wird daher im Rahmen dieses Beitrags folgendes induktives Vorgehen vorgeschlagen, um Merkmale von Markenassoziationen zu beschreiben und diese Beschreibungen für die Konstruktion von Text Mining Verfahren nutzbar zu machen. Auf Grundlage einer Studie, die mit einem traditionell zur Erhebung von Markenassoziationen eingesetzten Verfahren durchgeführt wurde, werden sprachliche Regelmäßigkeiten exploriert, die dann Grundlage des zu konstruierenden Text Mining Verfahrens bilden. Dieses induktive Vorgehen erlaubt es zum einen, aus Bekanntem auf Unbekanntes zu schließen und zum anderen, erste Indikationen der Übereinstimmungsvalidität zu messen, indem die Ergebnisse eines etablierten Erhebungsinstrumentes mit dem hier vorgeschlagenen Erhebungsinstrument verglichen werden [28]. Als traditionelles Erhebungsinstrument wird hierzu die Methode der freien Antwort [29] verwendet, welche zur Verfahrensklasse der assoziativen Verfahren [12] zählt. Bei der freien Antwort werden Probanden nach ihren initialen Gedanken bezüglich eines verbalen Stimulus befragt. Im Rahmen der hier durchgeführten Studie wurden dazu 50 Probanden über die Amazon Mechanical Turk Plattform rekrutiert. Die Probanden stammten aus Nordamerika waren zu 64,7% männlich, im Alter zwischen 25 und 40 Jahren, besaßen zur einen Hälfte einen High School oder Collage Abschluss, zur anderen Hälfte einen Bachelor oder Masterabschluss. In der über ein Online-Formular zugänglichen Befragung wurden die Probanden gebeten, 10 Dinge verbal zu explizieren, die ihnen spontan einfallen wenn sie an „autonomes Fahren“ und „Google“ denken.

Das Ergebnis der quantitativen Vermessung der erhobenen Assoziationen zeigt, dass 65% (329) der insgesamt 500 erhobenen Assoziationen aus einem bis drei Worten bestehen. 42,6% (213) der Assoziationen bestehen gar aus nur einem-, bzw. 15,4% (77)

aus zwei Worten. Daraus lässt sich schließen, dass Verbraucher ihre Assoziationen offenbar vorwiegend als kurze Informationseinheiten wiedergeben. Um nun verbalsprachliche Muster zum Einsatz für das hier vorgeschlagene Text Mining Verfahren feststellen zu können, werden die erhobenen Assoziationen jeweils in eine Sequenz von Wortarten abgebildet. Hierzu wird ein sogenannter Part-of-Speech Tagger (PoS-Tagger) eingesetzt, der jedem Wort innerhalb der Assoziation ein Part-of-Speech Tag (PoS-Tag) -also eine Wortart zuordnet. Im Rahmen dieser Untersuchung wurde der PoS-Tagger von Schmidt [30] auf die einzelnen Assoziationen angewendet und somit für jede Assoziation eine Repräsentation in Form einer PoS-Tag Sequenz erzeugt. Diese Pos-Tag Sequenzen erlauben es nun, die für Assoziationen üblicherweise verwendeten Wortarten, sowie Gemeinsamkeiten in Wortartenabfolgen zu beschreiben. Im Ergebnis zeigt sich, dass nur 15 PoS-Tag Sequenzen mehr als einmal vorkommen, allerdings in der Lage sind, 61,8% der Assoziationen zu konstruieren. Die durchschnittliche Länge dieser Sequenzen beträgt 2,3 Worte. Die verbleibenden 38,2% der Assoziationen werden hingegen von 189 PoS-Tag Sequenzen konstruiert, die jeweils in dieser Form nur einmal vorkommen. Bei Betrachtung der häufigsten Sequenzen zeigt sich, das Assoziationen am meisten durch einzelne und zusammengesetzte Nomen (z.B. <technology>, <safety concerns>) konstruiert werden (~30%), gefolgt von einzelnen Adjektiven (~16%, z.B. <efficient>), sowie der Abfolge von <Adjektiv, Nomen> (6%, z.B. <innovative technology>) oder <Nomen, Adposition, Nomen> (2%, z.B. <safety of driver>. Zusammenfassend kann damit geschlossen werden, dass Nomen und Adjektive die wichtigsten Wortarten zur Bildung von Assoziationen darzustellen scheinen. Die Kombination von Adjektiv und Nomen als beschreibende Attribute wie z.B. „innovative technology“ stellt das am häufigsten vorkommende Muster bei Assoziationen dar. Diese Erkenntnisse werden nun genutzt um ein Text Mining Verfahren zu konstruieren. Hierzu wird ähnlich zur oben durchgeführten Charakterisierung von Markenassoziationen ein Vorgehen aus Tokenisierung, Part-of-Speech-Tag (PoS-tag) Sequenzuntersuchung, sowie Sentimentanalyse vorgeschlagen. Zunächst werden dazu die UGC Dokumente in kleinere Bestandteile mittels Tokenisierung [31] segmentiert um für jedes Dokument eine Menge von Sätzen, sowie für jeden Satz eine Menge von Worten erhalten. Da nicht sichergestellt werden kann, dass in den gesammelten UGC Dokumenten Verbraucher ausschließlich über Google und autonomes Fahren sprechen und alle extrahierten Assoziationen sich auf diesen Untersuchungsgegenstand beziehen, wird die Menge der mittels Tokenisierung ermittelten Sätze auf jene reduziert, in denen sich Hinweise auf den Untersuchungsgegenstand finden (z.B. die Nennung von Google). Auf Grundlage dieser selektierten Sätze, wird dann eine PoS-tag-Sequenzuntersuchung zur Erhebung der Markenassoziationskandidaten durchgeführt. Es wird dazu jedem einzelnen Wort eines Satzes ein PoS-Tag mittels des Ansatzes von Schmidt [30] zugewiesen. Dies erlaubt es, für jeden aus Worten bestehenden Satz eine Sekundärrepräsentation zu erstellen, welche allein aus einer Sequenz von PoS-tags besteht. Diese PoS-tag Sequenzen erlauben es nun, Muster zur Extraktion von Markenassoziationen anzuwenden. Auf Grundlage der oben beschriebenen sprachlichen Charakteristika von Markenassoziationen wird hierbei beispielsweise das PoS-tag Muster <Adjektiv, Nomen> verwendet um Wortsequenzen wie <technological innovation> als Markenassoziationskandidaten zu extrahieren und in einer Datenbank zu speichern.

3.5 Sentimentanalyse

Bei Markenassoziationen ist die emotionale Orientierung (z.B. positiv, negativ, neutral) von besonderem Interesse. Keller [1] beispielsweise beschreibt das kundenorientierter Markenwert nicht nur durch die im Gedächtnis der Konsumenten vorhandenen starken und einzigartigen, sondern auch vorteilhaften – also positiven - Markenassoziationen entsteht. Daher sollte für die extrahierten Markenassoziationskandidaten die Valenz, also das sog. Sentiment bestimmt werden. Liu [32] liefert hierzu einen umfassenden Überblick über verschiedene Techniken. Da das Forschungsfeld der aspektorientierten Sentimentanalyse hinsichtlich der Erkennungsgenauigkeit schnell voranschreitet, sieht die hier vorgeschlagene Methodik das Einsetzen jeweils aktueller Verfahrensweisen der aspektorientierten Sentimentanalyse vor. Im Rahmen der illustrierenden Studie wird ein einfacher lexikonbasierter Ansatz vorgeschlagen und genutzt, welcher für jede extrahierte Adjektiv-Nomen Kombination ein referenzierendes Lexikon wie z.B. SenticNet [33] zur Bestimmung der emotionalen Orientierung anhand des Adjektivs verwendet. Als Ergebnis der vorangegangenen Schritte wird nun für jedes Dokument eine Menge von Markenassoziationskandidaten (z.B. „leading technology“, „innovative brand“ oder „threatened privacy“) erhalten. Das jeweilige Bezugswort (z.B. das Nomen: „technology“, „brand“, „privacy“) repräsentiert dabei die Markenassoziation, die referenzierenden Worte (z.B. Adjektiv: „leading“, „innovative“, „threatened“) werden als tonalitätstreibende Aspekte verwendet.

3.6 Bestimmung der Assoziationsstärke

Die Assoziationsstärke beeinflusst wie schnell und einfach Assoziationen aus dem semantischen Gedächtnis eines Kunden abgerufen werden können [1]. Starke Markenassoziationen, sogenannte „Branded Features“ [10], sind also jene, welche die meisten Kunden mit der Marke in Verbindung bringen und an die sie als erstes im Markenzusammenhang denken. Sie definieren die Marke aus Kundensicht und werden daher auch als „Essenz“ der Marke bezeichnet [34]. Aus diesem Grunde stellt die Stärke von Assoziationen ein wichtiges Attribut zur Beurteilung von Markenassoziationsnetzwerken dar [1]. Angelehnt an traditionelle, qualitative Erhebungsmethoden [34], bei denen die Stärke einer Assoziation anhand der Häufigkeit der Nennung einer Assoziation durch Studienteilnehmer ermittelt wird, soll im Rahmen der hier vorgeschlagenen Methodik die Stärke einer Assoziation anhand ihrer Vorkommenshäufigkeit charakterisiert werden. Hierzu wird ein 2-Mode Netzwerk konstruiert, welches zur Bestimmung der Assoziationsstärke mittels der Gradzentralität [35] dienen soll. Zur Konstruktion des Netzwerkes werden zwei Typen von Knoten unterschieden. Dokumentknoten existieren für jedes UGC Dokument. Als zweiter Typ existiert für jede Markenassoziation die aus einem Dokument extrahiert wurde ein Assoziationsknoten. Jeder Assoziationsknoten eines Dokumentes wird mit jeweils dem korrespondierenden Dokumentknoten über eine Dokument-zu-Assoziation Kante verbunden. Wird eine Assoziation (welche über ihren Namen sowie die emotionale Orientierung zu identifizieren ist) in mehreren unterschiedlichen Dokumenten genannt, so existiert der Assoziationsknoten dennoch nur einmal, wird jedoch mit jedem Dokumentknoten (und somit dem korrespondierenden Dokument) mit einer Dokument-zu-Assoziationskante verbunden. Abbildung 3 illustriert die Erstellung dieses 2-mode Netzwerk. Hierbei entspricht die Gradzentralität des Assoziationsknoten [35, 36] der Anzahl der Dokumente in denen die jeweilige Assoziation existiert. Um Vergleichbarkeit herzustellen, wird die Gradzentralität mit der Gesamtanzahl von Dokumenten normalisiert.

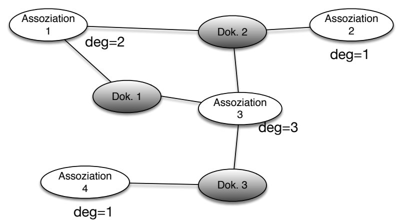

Abbildung 3: 2-mode Netzwerk zur Bestimmung der Assoziationsstärke

3.7 Bestimmung der Verbindung zwischen Assoziationen

Während im vorangegangenen Abschnitt das vorgeschlagene Verfahren zur Ermittlung der Stärke von Assoziationen dargestellt wurde, wird nun das Vorgehen erläutert, um Verbindungen zwischen Assoziationen sowie deren Stärke darzustellen. Aus kognitionspsychologischer Sicht wird die Verbindungsstärke zwischen Assoziationen charakterisiert durch die Stärke mit der diese miteinander im Gedächtnis verknüpft werden. Sie beeinflusst damit Aktivierungsausbreitung („spreading activation") [1], also die Wahrscheinlichkeit das weitere Assoziationen im Gedächtnis des Verbrauchers aktiviert werden, wenn eine einzelne Assoziation z.B. durch Marketing-Mix Aktivitäten aktiviert wird [4, 37]. Im Gegensatz zu traditionellen Consumer-mapping Verfahren [17] können die Verbindungen zwischen Assoziationen im hier vorgeschlagenen Verfahren nicht direkt durch Befragung von Probanden ermittelt werden. Daher wird angelehnt an das von Teichert und Schöntag [38] vorgestellte Verfahren, die Annahme getroffen, dass aus der implizit gemeinsamen Nennung von Assoziationen auf vorhandene Assoziationsnetzwerke geschlossen werden kann. Pro Dokument wird dazu jeweils ein vollständiger Graph aus den dort extrahierten Assoziationen konstruiert (Abbildung 4). Dem unterliegt die Annahme, dass die vom Verbraucher innerhalb eines UGC Dokumentes verbal explizierten Assoziationen im Gedächtnis in einem gemeinsamen Bezug stehen. Über die gesamte Dokumentenkollektion wird dann gezählt, wie oft jeweils ein Paar von gleichen Assoziationen in unterschiedlichen Dokumenten gemeinsam auftritt. Jeweils zwischen diesen Assoziationspaaren wird dann eine gewichtete Kante erzeugt, deren Gewicht dieser Kookkurrenz entspricht – also der Anzahl der Dokumente in denen die beiden Assoziationen gemeinsam auftreten. Da häufig vorkommende Assoziationen in dieser Betrachtung eine höhere Wahrscheinlichkeit haben mit anderen weniger häufig vorkommenden Assoziationen aufzutreten, kann ein Korrekturfaktor einbezogen werden, um solche Verbindungen hervorzuheben die häufiger als zu erwarten wären auftreten.

Statistische Unabhängigkeit vorausgesetzt, entspricht die Wahrscheinlichkeit, dass zwei Assoziationen zufällig gemeinsam auftreten, dem Produkt der relativen Häufigkeit (bzw. normalisierten Gradzentralität) der beteiligten Assoziationen. Diese zu erwartende Wahrscheinlichkeit kann von der relativen Häufigkeit des gemeinsamen Auftretens (Quotient aus absoluter Kookkurrenz zweier Assoziationen und der Vorkommenshäufigkeit der schwächeren Assoziation) abgezogen werden. Abbildung 4 zeigt das resultierende Assoziationsnetzwerk auf Grundlage von zwei einzelner vollständiger Dokumentnetzwerke.

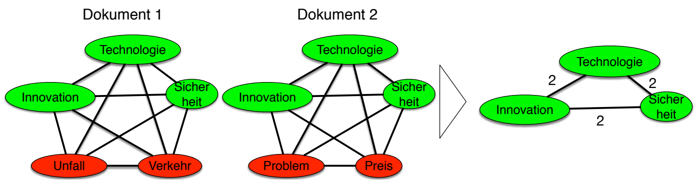

Abbildung 4: Per Dokument und Kookkurenznetzwerke

3.8 Konstruktion des Markenassoziationsnetzwerkes

Zur Konstruktion des Markenassoziationsnetzwerkes werden die Netzwerke aus den Abschnitten 3.6 und 3.7 kombiniert. Hierbei wird das Netzwerk aus Abschnitt 3.6 zum einen dazu verwendet, mittels der normalisierten Gradzentralität die Stärke der Assoziationsknoten zu beschreiben und zum anderen um einen Schwellwert zur späteren Berücksichtigung der Assoziationen im Markenassoziationsnetzwerk festzulegen. Das Netzwerk aus Abschnitt 3.7, welches die Verbindungen zwischen Assoziationen beschreibt, wird dazu um die Information der Assoziationsstärke ergänzt.

Im Bezug zur illustrierenden Studie zeigt Abbildung 5 das Netzwerk der Top-50 Assoziationen für Google im Kontext des autonomen Fahrens. Als Schwellenwert für das gemeinsame Auftreten zweier Assoziationen wurde 18 gewählt. Die Assoziationsknoten wurden gemäß des Anteils positiver (grün), negativer (rot) sowie neutraler (orange) Tonalität eingefärbt. Die Gradzentralität der Assoziationen ist im Zentrum der Assoziationsknoten dargestellt. Insgesamt kann festgestellt werden, dass die im Markenassoziationsnetzwerk in Abbildung 5 vorhandenen Assoziationen inhaltlich ebenfalls bei der befragungsbasierten Studie aus Abschnitt 3.4 wiedergefunden werden können, was eine erste schwache Indikation der Vergleichsvalidität sein könnte. Allgemein sind im Netzwerk in Abbildung 5 zwei schwach miteinander vernetzte Subnetzwerke zu beobachten. Das erste Subnetzwerk beinhaltet Assoziationen die dem Themenfeld des „autonomen Fahrens" zugeordnet werden können. Diese Assoziationen sind entweder direkt oder in zweiter Ordnung mit der Assoziation „car" verknüpft. Direkt verknüpfte Assoziationen lassen dabei auf die von Google durchgeführten Prototypentests schließen wie z.B. „testing", „prototype", „area" und „state". Andere Assoziationen betonen gesellschaftliche, soziale oder persönliche Aspekte. Hierzu zählt beispielsweise die Assoziation „safe", die stark mit der Assoziation „car", sowie „driver" verknüpft ist. Das zweite Subnetzwerk hingegen zeigt Assoziationen, die nicht unbedingt auf das autonome Fahren schließen lassen, jedoch scheinbar starke Markenattribute darstellen, die von Verbrauchern in kontextunabhängig wiedergegeben werden. Hierzu zählen „computer“, „company“, „services“, „search“, „computer“, „project“, „technology“, „wearables“, „Google Glass“, „devices“ oder „android“. Auffällig ist, dass das erste, dem autonomen Fahren nahe Subnetzwerk, schwach über die Verbindung der zentralen Assoziation „car“ mit der Assoziation „project“ des zweiten Subnetzwerkes verbunden ist, autonomes Fahren also möglicherweise als eines von mehreren Projekten Googles wahrgenommen wird.

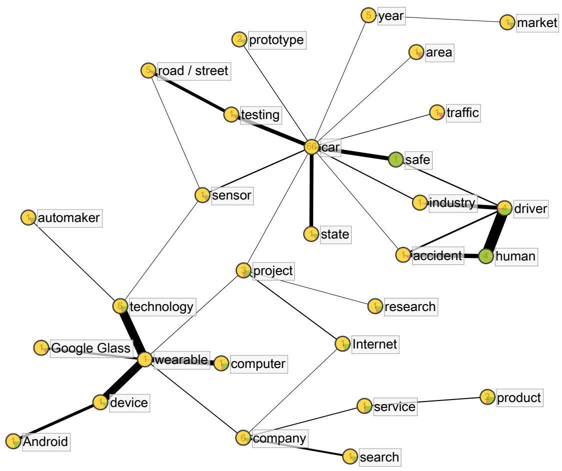

Abbildung 5: Assoziationsnetzwerk Google im Kontext autonomes Fahren

4 Einsatz zur Imagediagnostik

Die Verwendung netzwerkanalytischer Verfahren auf Markenassoziationsnetzwerken und die Interpretation in Bezug auf Markenführungsmaßnahmen wurde insbesondere von Henderson auf Grundlage von durch Befragung erhobenen Markenassoziationsnetzwerken untersucht [10, 11]. Die im Rahmen dieses Beitrags vorgestellte Methodik zur Erhebung von Markenassoziationsnetzwerken aus nutzergenerierten Inhalten können ebenfalls als Grundlage solcher Untersuchungen dienen. Henderson et al. [10] unterscheiden grundsätzlich zwischen Intra-Netzwerkanalysen und Inter-Netzwerkanalysen [10]. In der Intra-Netzwerkanalyse wird auf einzelne Assoziationsknoten fokussiert. Die Gradzentralität wurde hier beispielsweise verwendet um besonders starke Assoziationen sog. „Branded Features“ zu untersuchen. Da diese Branded Features von Verbrauchern als besonders wichtige Markenattribute wahrgenommen werden, sollten diese bei Markenführungsmaßnahmen besonders herausgestellt werden. Henderson et al. [10] verwenden hier beispielsweise die Maße der Gradzentralität (Anzahl der Kanten zu anderen Assoziationsknoten) sowie der Betweenness-Zentralität (Anzahl der kürzesten Wege, die über den Assoziationsknoten zu anderen Assoziationen führen) um die wichtigsten Branded Features zu beschreiben. Im Bezug auf die hier angeführte illustrierende Studie könnte die Gradzentralität Hinweise darauf geben, welche Assoziationen von Verbrauchern mit

Google im Bezug auf das autonome Fahren thematisiert werden und somit wichtige Markenattribute darstellen. Die Verwendung der Betweenness Zentralität könnte verwendet werden, um zu untersuchen wie gem. der Idee des Spreading Activation Networks [4] die Wahrscheinlichkeit besteht, dass eine gewisse Assoziation aktiviert wird, wenn eine andere Assoziation im Markenassoziationsnetzwerk aktiv ist. Marketingmaßnahmen können diese Assoziation dann ansprechen (oder nicht ansprechen) um dafür zu sorgen (oder zu verhindern), dass andere Assoziationen aktiv werden. Neben der Intra-Netzwerkanalyse bietet sich ferner die Möglichkeit unterschiedliche Netzwerke, oder Segmente von Netzwerken zu vergleichen um unterschiedliche Marktsegmente gegenüberzustellen oder Gemeinsamkeiten und Unterschiede in der Verbraucherwahrnehmung herauszuarbeiten. Mit einem geeigneten Informationssystem, welches das hier vorgestellte Verfahren implementiert, könnten beispielsweise Netzwerke anhand der Beiträge einer bestimmten Webseite oder eines Zeitraums segmentiert werden, da für nahezu jedes Dokument die Webseite sowie der Zeitpunkt der Veröffentlichung bekannt ist. [10] führen als Beispiel für Inter-Netzwerkanalysen auch das Maß der Netzwerkdichte als Vergleichskriterium an. Ein sehr dichtes Netzwerk für eine einzelne Marke könnte hierbei eine Indikation auf eine unklare Positionierung geben und somit auf eine mögliche Verwässerung des Markenwertes hinweisen [39]. Gleiches kann angenommen werden, wenn ein Markenassoziationsnetzwerk im Zeitverlauf an Dichte gewinnt [11].

5 Diskussion und Ausblick

Im Rahmen dieses Beitrages wurde ein Verfahren vorgeschlagen, welches potenzielle Markenassoziationen aus UGC extrahiert und somit zur Methodenentwicklung im Bereich der automatisierten Verbraucherforschung beiträgt. Das Verfahren wird hierbei aus der Literatur zur Markenführung und Kognitionspsychologie abgeleitet, ist im Vergleich zu befragender Forschung aufgrund Automatisierung ggf. schneller und potenziell kostengünstiger [13]. Sofern den UGC Beiträgen Metadaten wie Zeitstempel angefügt sind, ist eine Analyse mit dem Verfahren auch rückblickend durchführbar. Den Hauptnutzen besitzt das Verfahren jedoch darin, dass es UGC als eine bisher nicht oder nur schwer holistisch zugreifbare Datenquelle für die Markt- und Verbraucherforschung zugänglich macht. Es lässt sich festhalten, dass mittels unterschiedlicher Intra- sowie Inter-Netzwerkanalysen potenziell Marketing-relevante Informationen abgeleitet werden könnten. Dem vorgelagert stellt sich jedoch zunächst die wichtige Frage welche Gegenstand der folgenden Forschung sein sollte, ob die hier vorgestellten Netzwerke validiert werden können. Ein Ansatz wäre es, die Übereinstimmungsvalidität zu überprüfen: Hierbei wären mit einem „etabliert und als valide geltenden" Verfahren Assoziationsnetzwerke zu erheben und diese mit den Ergebnissen des hier vorgestellten Verfahrens zu vergleichen. Erste Indikationen wurden hier im Vergleich der erhobenen Assoziationen zu einer befragungsorientierten Studie geliefert. Weiterhin besteht die Frage, wie geeignete Schwellwerte für das Berücksichtigen von erhobenen Assoziationen (z.B. anhand der Gradzentralität) zu setzten sind, da im Vergleich zu befragenden Instrumenten hier nicht 10 oder 20 Assoziationen sowie Relationen zwischen Assoziationen erhoben werden, sondern Hundertausende bis zu mehreren Millionen. Letztlich stellt das hier vorgestellte Verfahren einen ersten Ansatz dar, Markenassoziationsnetzwerke aus der digitalen Flut von nutzergenerierten Inhalten als diagnostisches Instrument für die Markenführung verfügbar zu machen. Konkrete Instanziierungen dieses Verfahrens in Form von Informationssystemen (z.B. zum Marketing-Controlling) würden dem unternehmensinternen Methodenkanon zur Marktforschung und Markenführung eine neue Datenquelle erschließen und somit neue, substantielle Erkenntnismöglichkeiten über die Markenwahrnehmung der Verbraucher im Internet eröffnen. Wir hoffen daher, dass andere diesen Ansatz aufgreifen und weitere Forschung im Bereich der textanalysebasierten Erforschung von Markenassoziationsnetzwerken stattfindet.

Abstract. Traditional checkout systems are labor-intensive and can be a source of great frustration for customers having to wait in line. In contrast, automated checkout systems seamlessly scan, total and charge a customer's purchase to a registered payment account while they are simply leaving the store. We focus on the main challenge of automatically detecting customer purchases. To this end, we develop a checkout system that leverages data mining techniques to (i) reliably and timely detect items leaving the shopping floor area and (ii) assign them to individual customers. We demonstrate the system's feasibility using a large data set collected in the laboratory under real-world conditions.

Keywords: Data Analytics, RFID, Internet of Things, Automated Checkout

1 Introduction

While RFID solutions are commonly used in retail supply chains for automatic detection of logistical units in upstream and backroom processes, front store customer-facing applications have not progressed beyond pilot trials. RFID solutions for this "last mile" of the supply chain are especially challenging because of the sheer number and variety of simultaneously moving objects. Complexity is further increased by the manner in which objects are transported (stacked, in bags, etc.), unpredictable customer behavior, and suboptimal store layouts. Against this backdrop, we consider RFID-based automated checkout systems, which promise great value potential for the retail industry [1]. Our research objective is to decompose the challenge of such systems into tractable sub problems and demonstrate the feasibility of a pilot implementation.

2 Automated Checkout System Requirements

Traditional checkout systems are labor-intensive and can be a great source of frustration for customers when having to wait in line. To reduce costs retailers have started adopting self-service systems which enable shoppers to scan, bag and pay for their purchases with little or no help from store personnel [2, 3]. These systems, however, offer hardly any improvements over traditional checkout with respect to the customer

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Hauser, M.; Günther, S.; Flath, C.; Thiesse, F. (2017): Leveraging RFID Data Analytics for the Design of an Automated Checkout System, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1201-1204

experience, potentially offering an even worse experience. In contrast, automated checkout systems scan, total and charge a customer’s purchases to a registered payments account while they are simply leaving the store.

In our research, we focus on the main challenge of automatically detecting customer purchases. Here, we must cope with two problems: The system (i) has to reliably detect all purchased products and (ii) assign these to individual customers. Undetected products cause direct losses to the retailer and inventory inaccuracy resulting in out-of-stock situations [4]. Incorrectly assigning items to a customer, on the other hand, may lead to customer dissatisfaction and interruptions of in-store operations [5].

Academic literature on automated checkout systems is sparse. To the best of our knowledge, only one group of researchers have developed a system (“MyGrocer”) that addresses the previously mentioned challenges [6, 7]. This solution relies on shopping carts equipped with RFID readers that detect objects placed in the carts. Similar to this approach, we also rely on RFID for the detection of products. In contrast to optical barcodes, RFID allows identification of products at the item level. In addition, identification does not require a direct line of sight between the tag and the reader device, which allows for simultaneous bulk detection of multiple objects. In contrast to the previous studies, we decided against RFID-equipped carts for several reasons: First, shopping carts are not used in all types of retail stores (e.g., fashion retail stores) which limits the generalizability. Second, the costs for equipping shopping cart with RFID readers are very high [7]. In addition, there are high operating costs for regular service of the carts. Instead, we propose an automated checkout system that is implemented at the exits of retail stores and does not require customers to use specific devices. This system facilitates the detection of items in carts and items carried by customers.

The MyGrocer carts only need to detect items within them. In this case, sufficient data quality can be achieved by selecting RFID antennas with read ranges of only 20cm. In our case, the antennas need to detect items that leave a store through an exit gate, which requires antennas with large read range and high power. Unfortunately, this in turn leads to the detection of RFID tags carried nearby by the gate instead of through the gate. Secondly, assigning items to customers can hardly be realized with hardware-based approaches. Customers would have to wait in line and pass the gate one after the other to avoid purchases of different customers being read at the same time.

3 Description of the Automated Checkout Artifact

We pursue a design-oriented research approach to create an automated checkout artifact that (i) reliably and timely detects items leaving a store and (ii) correctly assigns them to individual customer. The architecture combines hardware components and software components. The hardware component consists of two RFID reader installations, a ceiling-mounted system which tracks items in the store and a gate-mounted system that helps to detect items that are leaving the store (see Figure 1). This infrastructure collects low-level RFID data that is then processed by the software components.

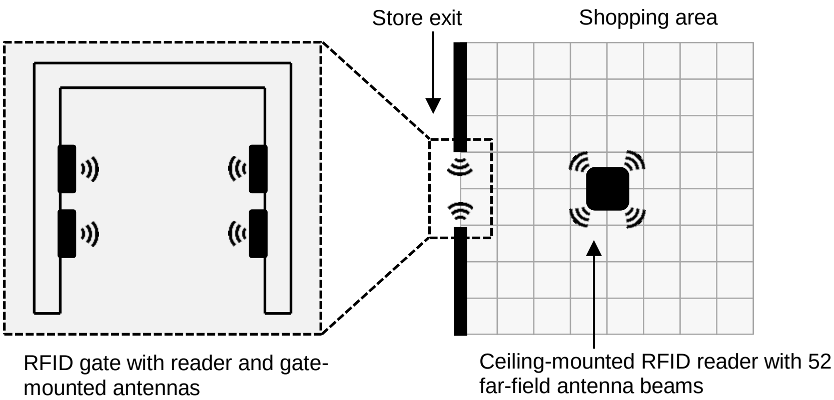

Figure 1. Hardware infrastructure with two distinct RFID reader installations

There are two distinct software functionalities. The *first* software component uses data mining techniques to reliably and timely detect items that are leaving the store. To this end, we extract features from the low-level RFID data, which contain information regarding observed real world events. One simple example is the maximum received signal strength value measured in a series of detections of a particular tag within a certain time interval. With these features we train classification models that are able to distinguish between items that leave the store through the exit gate and others. We follow the conceptual approach described in Hauser et al. [8]. However, we go beyond the state-of-the-art by considering run fragments in real-time instead of evaluating completed paths ex-post. The *second* software component assigns items leaving the store (identified by the first component) to individual customers. To this end, we infer item paths in the shopping area and then apply cluster analysis to group them. The procedure rests on the assumption that the paths of items purchased by one customer are more similar to each other than to paths of other items.

4 Expected Contribution and Future Work

We use a large data set collected in a laboratory environment for instantiation and evaluation of the artifact. Our experimental setup takes into account the limited process control in retail stores by considering multiple walking paths, varying numbers of persons and items as well as different movement speeds. Our experimental design includes 18 different tests. We repeated each of the tests 50 times. We then perform 5-fold validation to ensure representative results. We found that the artifact reliably and timely detects all shopping baskets carried out of the shopping floor area. On average, the baskets were detected 0.41 seconds before customers stepped out of the sales floor area. In addition, 94% of the shopping baskets assigned by the artifact contained the correct items.

These misclassifications arise in two particularly challenging test scenarios where multiple customers approach the exit gate simultaneously on very similar (almost identical) movement paths. In practice such a situation could easily arise when friends are shopping together which highlights the limitations of the pilot implementation. Nonetheless, our initial study demonstrates the fundamental feasibility of RFID-based automated checkout. Going forward, we want to evaluate our artifact in different test environments to evaluate its generalizability. In addition, we want to include additional, richer test settings (e.g., scenarios in which customers take objects from shelves that are placed near the exits). Our ultimate objective is to ensure feasibility under real-world conditions.

Decision Support for the Automotive Industry: Forecasting Residual Values using Artificial Neural Networks

Christoph Gleue[1], Dennis Eilers[1], Hans-Jörg von Mettenheim[1], Michael H. Breitner[1]

Abstract. The leasing business is one of the most important distribution channels for the automotive industry. This implies that forecasting accurate residual values for the vehicles is a major factor for determining monthly leasing rates: Either a systematic overestimation or underestimation of future residual values can incur large potential losses in resale value or, respectively, competitive disadvantages. In this paper, an operative DSS with the purpose of facilitating residual value related management decisions is introduced, with a focus on its forecasting capabilities. Practical implications are discussed, a multi-variate linear model and an artificial neural network approach are benchmarked and further, the effects of price trends and seasonal influences are investigated. The analysis is based on more than 150,000 data sets from a major German car manufacturer. We show that artificial neural network ensembles with only a few input variables are capable of achieving a significant improvement in forecasting accuracy.

Keywords: Decision Support Systems, Business Intelligence, Artificial Neural Networks, Residual Value Forecasts, Car Leasing

1 Introduction and Motivation

The leasing market is an important business segment for car manufacturers. Automotive assets, which include passenger cars and commercial vehicles, accounted for a volume of 65% (178.2 billion Euros) of total new leasing contracts granted in 2014, which makes it the largest individual asset segment of the European leasing market [1]. Almost a third of all new cars sold by German premium brands in 2015 was financed with leasing [2]. Hence, this business model provides tremendous market opportunities, particularly for car manufacturers and leasing companies. Nevertheless, there are also risks which are difficult to quantify. The focus of our research is the so-called residual value risk [3]. While the customer pays a contractually-fixed leasing rate over the entire period of use, the residual value of the vehicle is uncertain until the end of the leasing period. In order to compensate the loss in value of the vehicles with adequate leasing payments, forecasts of residual values must be as exact as possible. Hence, accurate forecasts of future residual values constitute a critical success factor for competitiveness in the leasing market. Either a systematic over-estimation or under-

Gleue, C.; Eilers, D.; von Mettenheim, H.-J.; Breitner, M. H. (2017): Decision Support for the Automotive Industry: Forecasting Residual Values using Artificial Neural Networks, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1205-1219

estimation of future residual values would have negative consequences. If an overestimate is determined, the leasing payments may be lower, but not sufficient to compensate the loss in value of the vehicle. If predicted residual values are systematically too low, higher leasing rates must be set. This means that either avoidable competitive disadvantages occur or leasing rates must be substantially subsidized by car manufacturers. Car manufacturers nowadays often already have a sufficiently good data history of completed transactions in the leasing sector. They also record resale prices in the used car market for the corresponding vehicles. This potential, however, is often not sufficiently utilized to improve predictions of residual values.

In our research, we introduce an operational Decision Support System (DSS) which was developed and successfully implemented in cooperation with a large German car manufacturer. Although the incorporated higher-level analyses, management reports and visualizations are equally important parts of the aforementioned DSS, they all rely on proper data handling and a reliable forecasting methodology. Thus, in this paper we focus on the forecasting module of the system. The residual value forecast is a typical regression problem in which certain characteristics such as the age and mileage of a particular vehicle determine its residual value. The study is based on more than 150,000 records of completed leasing transactions and resale values over a period of four years (2011-2015). Linear models and Artificial Neural Networks (ANN) are implemented in this study. For this purpose, the development of vehicle values depending on the model age and time factor is of particular interest. The model age measures the time between the market launch of a new model class and the resale date of a specific vehicle belonging to this class. The continuously increasing model age means that the expected residual value of two identical vehicles of exactly the same age and with the same mileage is not constant over time. In addition, prices are influenced by general market conditions, accounted for by a time component in our analysis. Furthermore, the residual values on the used car market are subject to seasonal fluctuations within a year (a critical factor for ANN forecasts [4]). In order to allow for an unbiased forecast of estimated residual values over several years, these influences are examined more closely.

The remainder of this paper is structured as follows. The next section 2 provides an overview of the existing literature in the field of residual value forecasts. The structure of the DSS and the available input data are presented and explained in section 3. Section 4 specifies an exploratory analysis about trends and seasons in the used car market and subsequently introduces the forecasting model based on ANNs. The results of the analysis are presented in section 5. Section 6 provides a discussion and addresses limitations, implications for practical use and further research opportunities. Section 7 concludes with a short summary.

2 Related Work

This section presents the existing literature in the field of residual value forecasts. Due to the exclusivity of the data, only few studies on this subject exist. This fact, however, also highlights the enormous research potential. One of these studies is provided by Lessmann et al. [5]. On the basis of 124,386 transaction data of the same vehicle model (upper class) of a major car manufacturer, the authors develop a decision support system by means of a support vector regression (SVR). This method extends the classical linear regression such as to permit a non-linear transformation of the independent variable. Each vehicle is described by 176 attributes. The large number of attributes results from the use of dummy variables that represent features such as different optional equipment. Transaction-specific characteristics such as typical features of the customer constitute a crucial point in this method. The authors demonstrate the benefits of using this information in a forecasting model. As such, they recommend the expansion of residual value forecasts within the company to achieve improved predictive power on the basis of exclusive datasets which are not available to external service providers or residual value institutes.

Wu et al. [6] forecast used car prices on the Taiwanese market. Their input parameters comprise the cars brand name, the year of manufacture, the engine type and an equipment index. A new combination of ANNs and ANFIS (adaptive neuro-fuzzy inference system) models are proposed to improve forecasting accuracy. An earlier study carried out by Lian et al. in 2003 describes the problem of the residual value forecast from a time series perspective [7]. Evolutionary Artificial Neural Networks (EANNs) are used in this study to model the residual value of vehicles (all 24 months old) over time (from 1993 to 1997). The authors find cyclical fluctuations, according to which the residual value is at a high level at the beginning of the year and falls to a lower level towards the end of the year (see section 4.1 of our paper for a similar seasonality analysis). Other studies often use mostly macroeconomic indicators in addition to internally available data sources in order to explain the residual value distribution. Prado implements the price of diesel fuel and the industrial production index as explanatory variables in addition to vehicle-specific variables such as age and mileage [8]. At the present time, it is evident that no scientific standard methods are reported in the respective literature. Fan et al. provide a comparison between data mining model approaches such as AutoRegressive Trees (CART), ANNs and linear regression [9]. Their investigations focus on heavy construction machines. According to their analyses, the CART model provides the best results compared to the ANN and the linear regression model.

Besides the purely data-driven forecast techniques, other theoretical model approaches exist to explain price developments and the implications for risk management. This aspect is not a focal point of our work. For a deeper insight, we refer to [10], [11] and [12].

3 System Structure and Input Data

In the following sections, the data and methodology presented in this paper are put in the larger context of a DSS for residual value- and leasing-related issues. In section 3.1, an overview of the complete system structure (see figure 1) is presented, followed by a more in-depth description of the input data used for this study in section 3.2.

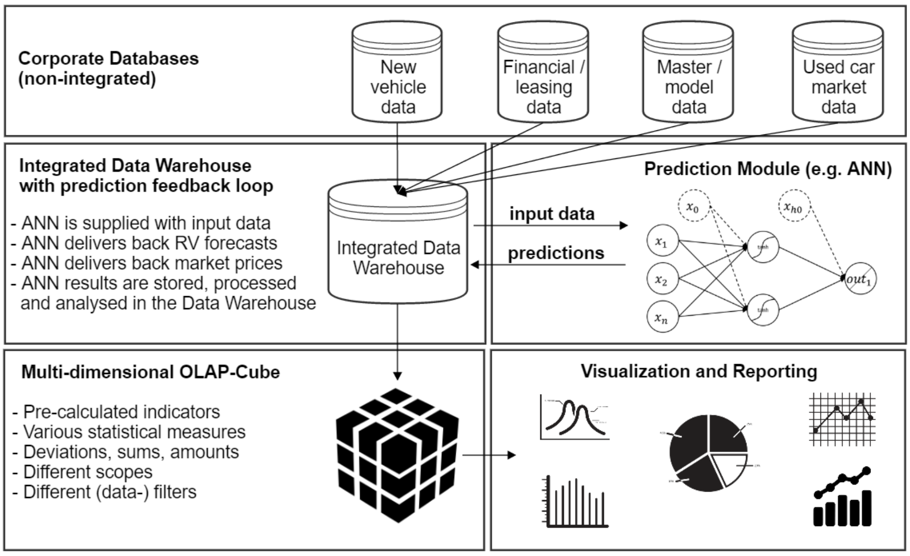

Figure 1. Decision Support System for RV forecasts

3.1 Structure of a DSS for Residual Value Forecasts

In this section, the larger context of the DSS in which the prediction module we focus on is implemented, is explained (see figure 1). The forecasting models need to be trained with historical data. Thus, the first step of the development was to collect and integrate data from different sources within the corporation. The most important of all sources is the used car market database, which stores all used car data collected from the dealerships. It contains every single transacted resale in Germany since 2011, including the Vehicle Identification Number (VIN) as a unique identifier for the vehicle, its mileage, the age of the vehicle, additional model information (e.g. model type, engine, fuel type etc.), resale date and the desired output of the forecasting model, the net resale price. As all data from this source is entered manually in the dealerships and then transferred via a common interface for all dealer management systems in the market, it has to be joined and validated with data from other, internal sources to serve as training data set for the forecasting model (see section 4.2).

One of those sources is the new vehicle database, which collects data from the factory invoicing system directly after production. Besides the corresponding VIN numbers, it contains the original list price of the vehicles, divided into base price, color surcharge and the extra charge for optional equipment, the complete list of optional equipment packages and also an indicator if the vehicle was produced for a promotional offer (with a discount on the original list price).

The information delivered by these systems is decoded using additional data from a Master Data Management system which contains general information about model types, promotional campaigns (such as list price discounts on special edition models), engine power and capacity, gearbox type (manual, automatic, double clutch), number of gears and the model age (number of months since the market launch). Ultimately, there is a connection to the leasing database which provides the initial forecasts and market prices assumed by the captive leasing company. For every single resold vehicle, all of the aforementioned information is gathered, cleansed and stored automatically in a central, integrated data warehouse. This data warehouse, in turn, has a direct connection to the prediction module. The (trained) forecasting model is being fed with input data directly from the data warehouse, predicts market values (actuals) and expected residual values for all vehicles in the database and delivers them back to the data warehouse, where they are stored for further processing and analyses. The next and penultimate layer of the DSS is a multi-dimensional cube for Online Analytical Processing (OLAP). It serves as the basis for visualizations and reports for different purposes, e.g. benchmarking of the forecasting models, market analyses and, most importantly, leasing- and pricing-related decision support. It provides numerous pre-calculated indicators, deviations, sums, amounts, arithmetic means and other statistical measures as well as pre-configured scopes and data filters, e.g. to differentiate between the list price of special edition and standard models or young used cars and cars representing the traditional leasing segment with a leasing term of at least 12 months.

Hence, the OLAP cube can be seen as an extensive toolbox for management reports and visualizations. Used correctly, it can be utilized to find answers for many different used-car- or leasing-related questions, as e.g. individual dealership sales performance rankings, analyses of the used car market price levels after external shocks, monitoring of the car manufacturers' own residual value setting or influences of particular parts of optional equipment on the resale price. These reports need to be configured once on the OLAP level and can then be standardized and visualized with additional software.

The modules previously described, from data collection and integration to reporting and visualization, all play an important role in the operational DSS outlined in this section. Nevertheless, all the results and reports in our particular area of application rely on accurate predictions of actual market values and, even more importantly, most accurate residual value forecasts. Subsequently, the prediction module and its mode of operation represent the core of our DSS and thus, the main focus of the research presented in this paper. The next section 3.2 provides a description of the input data used for the forecasting model.

3.2 Input Data

The data covers a period of four years from 2011 to 2015. Vehicles are included in the database as soon as they have been successfully resold on the used car market after the end of the leasing period. By this means, the residual values realized on the market are included in the database. We distinguish between individual vehicle-specific and model-specific variables. The vehicle-specific variables refer to the leasing contract agreements, which include the mileage, the leasing term (age of the vehicle) and extra charges for special colors and optional equipment. The model-specific variables describe the general characteristics of the vehicle and are the same within each model group. 928 different models are represented in the data. Table 1 shows the available vehicles' features.

Table 1. Input data variables

Variable	*Type*	*Description*
pricecolor	continuous	Extra charge for the color as a percentage of the list price
priceequipment	continuous	Extra charge for optional equipment as a percentage of the list price
mileage	continuous	Vehicle mileage in km/100,000
agevehicle	continuous	Vehicle age (registration date to resale date in days)
pricecolor	continuous	Extra charge for the color as a percentage of the list price
agemodel	continuous	Age of the model since its market launch in months
enginecapacity	continuous	Engine capacity in cubic centimeters
enginepower	continuous	Engine power in horsepower
fourwheel	binary	Four-wheel drive indicator
fuelcode	binary	Gasoline (B), Diesel (D), CNG (EG), LPG (AG)
geartype	binary	Transmission types: automatic (A), double-clutch (D), manual (S)
residualvalue	continuous	Residual value in percent ($\frac{resale\ price}{list\ price}$)

These variables are directly related to the vehicles under investigation. Using the available data, a linear regression analysis is first carried out to explain the residual values. The linear model is specified with all the variables listed in table 1. As expected, the age of the vehicle as well as the mileage have a significant negative impact on the residual value. For a forecasting application, the model age is also a crucial factor. Here we face the problem that the age of a specific vehicle model constantly increases over time. Compared to the age of a specific vehicle where we have a wide range of training examples, the age of the vehicle model is not available beyond the present point in time. The results of this regression analysis indicate that in-sample, the effect of the model age is significantly negative. Using this factor in a forecasting application therefore requires extrapolation techniques. Another interesting finding is that the extra charge for optional equipment has a negative effect on the residual value, which shows that the more optional equipment a vehicle is fitted with, the more value it loses over time in percentage terms.

4 Forecasting Model Specification

4.1 Trend and Seasons in the Used Car Market

In this section we use the residuals of the previously mentioned regression analysis to investigate the phenomenon of seasonality and trend in the used car market, which provides valuable insights to perform a subsequent unbiased forecast. Using the regression approach, all effects of the aforementioned independent variables are eliminated. The following approach is applied: firstly, residuals are sorted with respect to time. Secondly, the residuals for each month during the observation period are averaged. This results in a monthly time series of averaged residuals. Figure 2 shows the resulting time series.

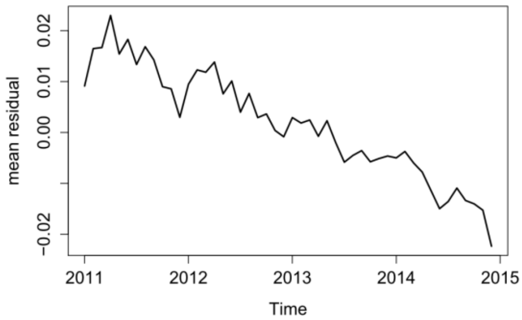

Figure 2. The influence of the time factor on the residual value

The results show a clear downward trend during the four years of observation. After controlling for all contract-specific variables, the results indicate a price decline based on general market conditions (the regression already controls for the constantly increasing model age) for used commercial vehicles. Since we are also interested in seasonal patterns, a decomposition of this time series is performed by the Seasonal and Trend decomposition using Loess (STL) method [13]. A seasonal period of 12 (for each month) is assumed. Figure 3 shows the time series decomposition to determine seasonal and trend effects. The ordinate shows the mean residuals in total (data) and their three different components. It can be observed that the residuals are subject to a trend and a season. The detrended seasonal component shows that towards the end of the year, lower residual values are achieved than during the rest of the year. Accordingly, the residual values tend to be higher during spring, even though these effects are rather small (in the range of 0.8 percentage points of the list price during a year). In order to control for the effects analyzed above, a new regression model is specified according to equation 1, which incorporates a vehicle model independent time factor and also controls for the seasonal components using monthly dummy variables.

$$rv_k = c + \sum_{j=1}^{13}(\beta_j \cdot feature_{j,k}) + \gamma \cdot Time_k + \sum_{m=1}^{11}\left(\delta_m \cdot Month_{m,k}\right) + \varepsilon_k \qquad (1)$$

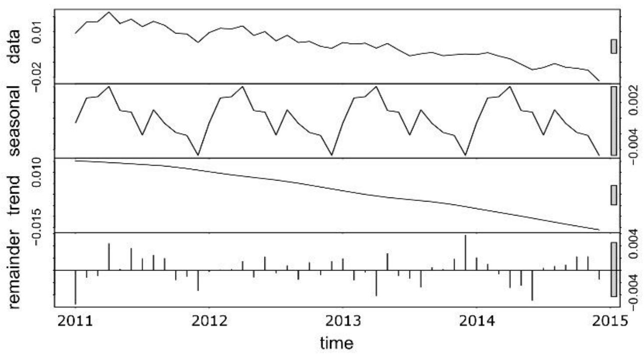

Figure 3. Time series decomposition: seasonal and trend effects

We use the resulting residuals to test for misspecification due to non-linearity with the BDS (Broock, Dechert and Scheinkman) test [14]. The null hypothesis (ε_k is iid) is rejected by the test at the 1% level ($\Delta\varepsilon = \sigma\varepsilon$ and embedding dimension m = 2). Therefore, the linear specification is still rejected by the BDS test. In a forecasting application which can be used in practice, there are tools available to incorporate non-linear relationships in a very effective way. These require careful data handling in comparison to linear models to avoid misleading results. This especially applies to noisy real world data. ANNs are introduced in the following section, which also provides a description of how to preprocess and prepare the data on hand.

4.2 Forecasting with Artificial Neural Networks

ANNs [15] are particularly suitable for the use with non-linear relationships. Their applications range from forecasts in the finance [16], [17] and risk management [18] area to Decision Support Systems [19], [20]. They are robust to very noisy, unstructured, or missing data [21], have powerful pattern recognition capabilities [22] and are therefore well suited to the present real-life problem. Even though many previous studies have shown the potential of this method in forecasting and prediction applications, a proper implementation and validation as well as an accurate data pre-processing is necessary to achieve reliable results [23]. ANNs may be viewed as a method for non-linear function approximation. In this paper, feed forward networks are used. These are composed of several layers of neurons. A first layer (input layer) describes the independent variables which are used to explain the phenomenon. These neurons are connected by weights θ_1 to a further layer (hidden layer), which in turn is connected to the output $h_\theta(X)$ (or a further hidden layer) by the weights θ_2. The hidden layer is thus in turn the input for the following layer. This pattern can be repeated any number of times (any number of hidden layers), each with any number of neurons within the layers. A three-layer feed forward ANN is defined by:

$$h_\theta(X) = \theta_2 \tanh(\theta_1 X) \tag{2}$$

The hidden neurons and, optionally, the output neurons transform their weighted sum of inputs by means of an activation function (usually the hyperbolic tangent).

$$f(X) = \tanh(X) = 1 - \frac{2}{e^{2X}+1} \tag{3}$$

The structure of an ANN is shown in figure 4. To be able to perform a function approximation, the ANNs are trained with training patterns (input x_k, output y_k represent the training pattern k). The randomly initialized parameters (weights) are determined using an iterative process. To avoid the problem of overfitting, a cross-validation is performed. Therefore, the training patterns are split into a set on which the ANNs are actually trained, I_t, and a set of validation patterns, I_v, to estimate the out-of-sample performance. The approximation quality of the ANN is evaluated by calculating the training and validation error functions

$$\varepsilon_t \equiv \frac{1}{2}\sum_{k\in I_t}(h_\theta(x_k) - y_k)^2 \text{ and } \varepsilon_v \equiv \frac{1}{2}\sum_{k\in I_v}(h_\theta(x_k) - y_k)^2. \tag{4}$$

We use an early stopping approach (error on the validation set increases) to obtain ANNs with good generalization capabilities. The best performing ANNs (based on validation error) are then combined in an ANN ensemble, so that the arithmetic mean is used as the actual result of the forecasting model. In this study, the “Fast Approximation performed with Universal Neural Networks” (FAUN) neurosimulator [24] is used for this purpose.

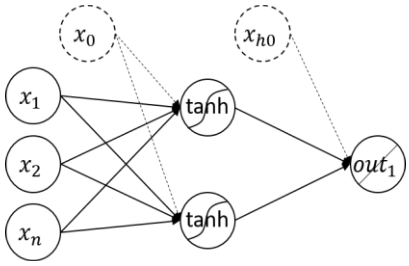

Figure 4. ANN (three-layer feedforward network)

As mentioned above, a usable forecasting application involves constantly increasing, time-dependent parameters: the model age and the time factor in general, which includes all external economic influences and market conditions. Both factors and their influence are not measurable (represented in the data) beyond the present point in time. Including data from the whole time period in the training process (e.g. separating training and testing data randomly from the database) leads to a look-ahead bias in the forecasting result. The training and forecasting periods are presented in figure 5. The forecasting model is trained with data from 2011 and 2012. The out-of-sample performance is documented with data of completed leasing contracts in the following two years (half-year intervals).

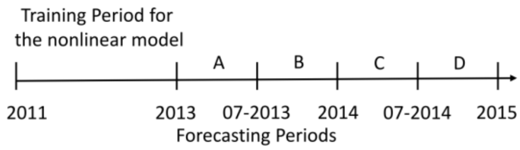

Figure 5. Forecast time line

Since ANNs are sensitive to outliers, we perform a data cleansing before the actual training process is started. For this purpose, 2000 three layer perceptrons including all variables shown in table 1 are trained to a local minimum on the training data. The best ANN (in-sample) is selected and tested for errors. Subsequently, every data set for which $|h_\theta(x_k) - y_k|$ is greater than a threshold value c is removed. As the threshold value c is defined as the 95% quantile of the errors, this means that 5% of the data are removed. This process is repeated a second time. We choose this approach as a result of an extensive cross validation process in which we evaluate the out-of-sample errors of the resulting ANN models with different data cleansing methods (e.g. removing more/less data; performing the procedure only once or three times; manual outlier removal). A manual analysis of the identified outliers reveals that in the case of outliers with higher residual values than expected, additional equipment (like e.g. additional cooling or tool storage equipment) had been installed after specifying the leasing contract, which led to a higher initial value and thus, also to a higher residual value. In the case of outliers with lower residual values than expected, the cars' overall condition (e.g. accidents) had not been properly reported in the data filtered by this approach. As we aim for accurate residual value predictions for accident-free vehicles without additional installations, these outliers had to be excluded from our analyses. For the actual training of the forecasting model, three-layer perceptrons with 4, 6 or 8 hidden neurons were tested. For each of the different topologies, 2000 networks were randomly initialized and trained to a local minimum. On the basis of validation data which is not represented in the training data set, the best 30 networks were selected and the arithmetic means of these approximations were used as a result. The ANN models with 6 hidden neurons yielded the smallest error regarding the validation data. In the next section, the results of the analyses are presented.

5 Results

This section presents the results of the linear and non-linear function approximations. ANNs generally provide good results for interpolation tasks. This means that the function approximation works well if the presented values lie within the input/output ranges of the training data. An extrapolation far beyond these ranges is difficult to realize. The forecasting application with ANNs for the third and fourth year (hence not represented in the training data regarding the time variables) uses the characteristics of new vehicles as inputs but sets the model age and time factor to the maximum value represented in the available data for these periods. The result is a so-called current market value, which reflects actual prices on the used car market. Table 2 (a) shows the resulting bias (mean error defined in equation 5) when using these forecasting models for predictions in the following two years.

$$mean\ error = \frac{1}{n}\sum_{i=1}^{n}(real\ value_i - forecast_i) \tag{5}$$

Table 2. Adjusted and non-adjusted forecasts of the ANN

(a) Non-adjusted forecast

Period	*Mean error*	*P-value*
A	0.00836	0.0524
B	-0.01028	0.0074**
C	-0.01551	<0.001***
D	-0.04640	<0.001***

(b) Adjusted forecast

Period	*Mean error*	*P-value*
A	0.00836	0.0524
B	0.00220	0.5637
C	0.00533	0.1817
D	-0.01787	<0.001***

***, **, * indicate statistical significance at the 0.1%, 1% or 5% level, respectively.

A t-test with the null hypothesis that the mean error is zero (unbiased) already rejects the hypothesis in the second forecasting period at the one percent significance level.

The actual residual value (forecast), in contrast to the market value, is now adjusted by a linear factor resulting from a time series regression of the first two years of data. The adjustment of the ANN forecast is performed according to equation 6.

$$rv_{t+n} = Market\ Value_t + \left(\beta_{agemodel} + \beta_{Time}\right) \cdot n \tag{6}$$

Table 2 (b) shows the results after the linear adjustment. The adjusted results show that the bias is now also insignificant for the forecasting periods B and C. For period D, the forecasting model is still biased. An investigation of possible non-linear dependencies in the time dimension is a topic for future research. This implies that a database of more than one complete business cycle must be investigated. The linear adjustment currently undertaken is a correct assumption for at least one and a half year forecasts, as indicated by the time series decomposition shown in figure 3 and the results listed in table 2 (b). The proposed linear model specified by equation 1 is now tested against the ANN forecast with a linear adjustment for the model age and time factor. To evaluate the linear model in a forecasting benchmark, a regularization term is incorporated for the training process. We choose a ridge regression approach (L2 norm) to prevent potential overfitting of the linear model. The lambda parameter is selected by cross validation. Due to the small number of parameters compared to the large number of training patterns in the years 2011 and 2012, the lambda parameter with the best performance is close to zero (0.04), so the linear model barely suffers from a high variance problem. Table 3 shows the results, the root-mean square error (RMSE) and the mean-absolute error (MAE), of the two forecasting methods for each of the four time periods. As evident from the increasing trend in the error measures, the forecast becomes more inaccurate the longer the forecasting period is. The non-linear relationships between the vehicle characteristics are represented significantly better by an adjusted ANN method than by a pure linear model. The Diebold-Mariano test [25] rejects the hypothesis that both methods have the same accuracy at any confidence level.

Table 3. Benchmark results

Period	*Measure*	*Adjusted ANN*	*Linear*	*DM-Test*
A	RMSE	0,07834	0.08554	<0.001***
	MAE	0.05638	0.06287	
B	RMSE	0.08026	0.08824	<0.001***
	MAE	0.05821	0.06515	
C	RMSE	0.07995	0.08965	<0.001***
	MAE	0.05891	0.06788	
D	RMSE	0.08218	0.09113	<0.001***
	MAE	0.06051	0.06857	

***, **, * indicate statistical significance at the 0.1%, 1% or 5% level, respectively.

Besides the significant performance improvements, these results are indeed economically relevant in our practical application compared to former, simplistic predictions based on data from external service providers for residual value estimations. In the next section, we discuss the results and provide an outlook for further research.

6 Discussion

The challenge of forecasting residual values for commercial vehicles was examined in this paper. An accurate forecast as a substantial part of a larger DSS is crucial for managing the exposure risk of car manufacturers and dealers in the leasing business. A systematic bias in both directions (too high or too low predictions) leads to negative consequences, either for competitiveness or the resale margin. The aim was to establish a purely data-driven approach for forecasting residual values based on information about past transactions. The results indicate that ANNs are well-suited for such noisy and unstructured data. Nevertheless, thorough data preparation and outlier detection is important in order to achieve good results. We show how ANNs can be used to preprocess and filter the database and how a forecasting model can be designed based on an ANN approach. ANNs are often criticized owing to their black-box nature. By means of a transparent description of the topology selection and data cleansing process, it is possible to mitigate the problem and make the results reproducible. ANNs are often only used at present as an alternative tool to benchmark different methods. However, an optimization within the whole ANN framework can help to improve the forecasting capability of this method.

Accordingly, the influence of the model age on the residual value over time and a general time factor have been investigated in more detail. This is necessary due to the fact that the model age (the period of time a specific vehicle model has been on the market since its market launch) is a factor which is not measurable beyond the present point in time, as it is a continuously increasing value. This also applies to the time factor, which takes account of all external market conditions. Although both factors remain uncertain, they play a crucial role in an actual, usable forecasting application. All other explanatory variables such as the age of a specific vehicle or its mileage are represented in the data for a sufficiently wide range of values. In the present study, the time-dependent factors were investigated in detail in order to linearly adjust the non-linear model to mitigate this problem. A clear downward trend in the residual values was identified with increasing model age and time. A reason for this may be the declining attractiveness of a particular vehicle model, which means that customers tend to buy a newer generation of products. As a result, older vehicle models must be offered at a lower price.

Moreover, the seasonal component of the used car market shows systematically lower residual values in December and higher residual values during the first quarter of a year. This empirical observation may be explained, e.g. by dealers trying to meet their sales targets towards the end of the year. Although these observations might be a special phenomenon for the type of vehicles examined in our study (commercial vehicles), it is a topic for further research investigating these patterns for a broader range of vehicle classes in order to formulate a more general statement. The entire analysis carried out in this paper is based on data between 2011 and 2015. From an economic point of view and in relation to the automotive market, this period does not include any major crises or boom phases. As the DSS and all necessary interfaces presented in section 3 are already successfully implemented, market data, as well as the corresponding internal data from corporate systems and databases, is being automatically recorded and stored in the central data warehouse for further processing. It is of interest to investigate how the results and the forecasting model quality change by analyzing data covering a longer period of time, including information about the behavior of residual values during crisis and/or boom phases in the database.

As previously mentioned, it is possible that external factors such as consumer demand, competitors' decisions, fuel prices or macroeconomic developments, e.g. measured by an industrial production index, also have a significant impact on the achievable resale price. Such factors were not included in this study for two reasons. Firstly, a complete theory which explains all factors that influence the used car market does not exist. This could take the form of a "fishing license" (alluding to the factor models of asset pricing). Up to now, however, not enough data is available to test the out-of-sample influences with a sufficiently long time horizon. Secondly, the problem of a look-ahead bias is the major concern in this application. The factors which drive prices on the used car market must be measurable at the time of the contract conclusion. This is a necessary precondition for performing a usable forecast in practice. In order to avoid biased predictions, however, economic indicators must also be forecasted to provide additional forecast model input data. To achieve a broader understanding of residual value data in general, an extensive study about different kinds of internal and external factors must be conducted in addition to benchmarks of proposed forecasting methods in the literature. Since each of the aforementioned, related studies have their own protected data with different characteristics, a benchmark of their methods is hardly interpretable if it is performed solely on one specific data set, because one method may not suit all kinds of data. Addressing this issue is an important topic for further research.

The above paragraph of the discussion is directly focused on the forecasting methodology implemented in our system. In the greater context of an entire DSS, the particular use case presented in this paper serves as a general example that by using methods and tools from the field of business intelligence, predictive analytics and data science, corporations can obtain valuable, business-critical information from data that is often already internally available. It also shows that this information, properly prepared and visualized, can support or even induce management decisions and help to monitor the consequences. In the particular case of the DSS presented in section 3, many use cases beyond residual value forecasts have already been realized, from the assessment of individual dealership performance to the measurement of the impact of internal decisions or external effects. Another practical example from our project is the simulation of different market scenarios, e.g. the assessment of the car manufacturers' risk exposure if residual values suddenly drop due to an unexpected external shock such as financial crises, new legislations or competitors' decisions. The results of such "stress tests" support the financial/controlling department in the establishment of appropriate provisions to cover these risks.

One of the major disadvantages of such systems is that they are usually quite complex. Understanding the whole process of how results are determined requires a deep technical and mathematical understanding and, most importantly, the necessary time. At this point, complexity may become a problem, as time usually is a scarce factor in management. Decision makers need to be able to trust the results, especially if important decisions are to be based on them. In an operative, real-life DSS, it is our experience that technology acceptance can be strengthened e.g. by a clearly arranged data quality assurance dashboard and, in general, reports whose visual appearance is not completely new to the receivers' eye. Subsequently, professional communication of project results, analyses and ultimately, between managers, analysts and developers is inevitable and plays an important role in earning the necessary confidence.

7 Conclusion

In the course of this paper, we investigated means to reduce the residual value risk car manufacturers and leasing companies face in their daily business. For this purpose, a DSS with forecasting capabilities was developed, implemented and tested. As accurate residual value forecasts are a critical success factor in this business, the focus has been put on suitable forecasting methodologies. ANNs have proven to be a reliable method for this purpose and thus, were implemented in the forecasting module of the DSS presented in this paper. It is necessary to mention that this system is in operative use and under constant improvement, as data is being automatically collected, cleansed, stored and used to improve the accuracy of future residual value forecasts. Furthermore, the flexibility of the integrated data warehouse and OLAP cube allow the investigation of a wide range of further, business-critical issues. From the performance measurement of dealerships to the impact of pricing strategies, promotions and discounts on residual values as well as interdependencies of the new and used car market, many future research opportunities are conceivable.

From a more general perspective, it can be concluded that corporations usually have access to large amounts of exclusive, unstructured, unintegrated data, which, properly processed, prepared and interpreted, have the potential to make a difference in daily business or even in important strategic decisions. This potential should not remain unexploited. Nevertheless, the information obtained still relies on humans with expert knowledge to interpret and communicate the results correctly. In a practical environment, close coordination between these experts and decision makers is crucial for the success of such projects. Since easy to understand reports can reduce complexity, build up trust and thus, facilitate communication, further research should also concentrate on proper visualization of data and analyses.

Abstract. In this paper, we address the question if there is a disruption of individual mobility by self-driving cars ahead. In order to answer this question, we take the user perspective and conduct a longitudinal study of social media data about self-driving cars from Twitter. The study analyzes 601,778 tweets from March 2015 to July 2016. We use supervised machine learning classification to extract relevant information from this huge amount of unstructured text. Based on the classification, we analyze how risk and benefit perceptions of self-driving cars develop over time, and how they are influenced by certain events. Based on the perceived risks and benefits, we draw conclusions for the acceptance of self-driving cars. Our study shows that a disruptive innovation of self-driving cars is not likely as risk and benefit perception issues indicate a lack of acceptance. We provide suggestions for improving the acceptance of self-driving cars.

Keywords: Machine learning, Risk Perception, Self-Driving Cars, Technology Acceptance, Text Classification

1 Introduction

In this paper, we address the question if there is a disruption of individual mobility by self-driving cars ahead of us. The impressive recent technical developments, for example of the Google Car and the Tesla Autopilot, draw a performance trajectory characteristic for disruptive innovations [1]. They already demonstrate the technical feasibility of self-driving cars. However, other previously new technologies in the individual mobility sector such as electric cars [2] or ridesharing [3] have been available since decades but still have a low market share. So will there be a disruption of individual mobility from human-driven cars to driverless cars as it occurred from horse-drawn carriages to horseless carriages as some articles predict [4]?

The evolution of transportation has faced numerous trials as it grew over time. We have gone through many diverse phases, including walking, biking, horses, coaches, trains, and cars. It is safe to assume that this steady chain of development of faster vehicles with improved features continues. Over the past decade, a countless amount of research has been invested into self-driving cars [5]. Companies such as Google,

Kohl, C.; Mostafa, D.; Böhm, M.; Krcmar, H. (2017): Disruption of Individual Mobility Ahead? A Longitudinal Study of Risk and Benefit Perceptions of Self-Driving Cars on Twitter, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1220-1234

Tesla, and BMW are investing in the development of self-driving cars. Especially because of these high investments, we must remember a significant key factor for the success of emerging technologies: technology acceptance [6].

In recent times, self-driving cars have become a controversial topic (e.g., because of ethical concerns [7]). Despite the efforts of researchers in pushing the technical boundaries of science and technology, there are key factors that need to be considered. One of the most meaningful factor is people's concerns regarding this emerging technology [8]. People's perceived risks and benefits towards self-driving cars will be central determinants of their public acceptance [9]. Public acceptance is what will eventually determine, when and how self-driving cars will actually be put to use, making it a crucial factor to take into consideration. As Michael Toscano, CEO of the Association for Unmanned Vehicle Systems International once said "The technology maturation is there, but the public acceptance is not there" [10].

Opinions regarding self-driving cars such as risk and benefit perceptions are affected, and perhaps even shaped, by the news [11]. If we succeed in explaining the logic behind people's various opinions concerning self-driving cars, we will be one step closer towards tackling the issue of technology acceptance. Therefore, we use supervised machine learning classification to extract this information from a set of 601,778 tweets obtained from the microblogging service Twitter.

Twitter has often proven to be a valuable source of data for prediction and monitoring of diverse phenomena ranging from disease outbreaks [12] to political elections [13]. Users of Twitter face a limit of 140 characters per message, referred to as "tweet", to include all relevant information. Despite their brevity, tweets contain valuable information encoded in natural language [14]. It is an ongoing challenge to extract this information from the vast amount of noise present on Twitter. We build on previous findings from sentiment analysis [14] and machine learning classification to extract information from a rich dataset of tweets.

The remainder of this paper is structured as follows. First we give an overview about technology acceptance literature and self-driving cars in general in section 2. Second, we describe the data extraction from Twitter, preprocessing the data, and model generation including its evaluation in section 3. Third, we describe the results in section 4. Fourth, we discuss our results in section 5. In section 6, we conclude with a summary of the results, limitations, possibilities for further research, and contributions to research and practice.

2 Theoretical Background

In this section, we give an overview about current literature disclosing the significance of acceptance towards self-driving cars from an Information Systems (IS) and public acceptance perspective. We give an introduction to self-driving cars and present the current scientific knowledge and surveys relevant to the acceptance of self-driving cars. We conclude this section by summarizing the theoretical background, thereby motivating the research from a theoretical perspective.

2.1 Technology Acceptance

Technology acceptance is one of the main research streams of IS research and the technology acceptance model (TAM) being a crucial source of many research endeavors [15]. The aim of TAM is to explain and predict if and why information systems will be used by individuals [6]. TAM predicts user acceptance by using three basic constructs: Perceived usefulness, perceived ease of use, and behavioral intention to use the system under consideration.

Several models were derived from the TAM with the Unified Theory of Acceptance and Use of Technology (UTAUT) being one of the most established ones that integrates eight models of technology adoption including TAM [16]. It includes the constructs of TAM and adds social influence (i.e., the degree to which influential people think the user should use the particular system) and facilitating conditions (i.e., the perceived level of organizational and technical support for the system, which is also considered a direct predictor of technology use). Individual factors such as age and gender moderate the relationships between these constructs and technology acceptance and use. Several researchers have extended the UTAUT model [17].

Many extensions of TAM and UTAUT have recognized the importance of risk perception for user acceptance. For example, Martins et al. [18] study Internet banking adoption and conclude that risk perception is an important factor. Lancelot Miltigen et al. [19] study end-user acceptance of biometrics and find that the greater the perceived risks, the lesser people will accept this technology. Despite several promising approaches, risk perception has not been included in one of the central IS acceptance models [17].

Public acceptance research recognizes that many technologies have been rejected by people because of societal controversies, causing negative consequences for the commercialization of technologies [8]. Considering the vast investments in research and development of self-driving cars and the potential benefits of this technology for society, rejection of this technology could have severe consequences. In particular, unpredicted events and accidents that recently occurred with self-driving cars such as the first human casualty [20] could lead to fear and reluctance to adopt.

A very influential model of technology acceptance in the public acceptance field specifically focuses on the relationship between perceptions of risks and benefits, trust, and technology acceptance [9]. The study found that perceptions of risks and benefits directly influence technology acceptance.

2.2 Self-Driving Cars

The National Highway Traffic Safety Administration (NHTSA) [21] defines five degrees of car autonomy which have different extents of connection between cars and the Advanced Driver Assistance Systems (ADAS) and the level of control the car carries. These systems can have full control of the car or can just be an assistance system for the driver. The levels vary from non-autonomous at all to fully-autonomous and are defined as follows [21]:

- Level 0: (Non-autonomous): The driver is in complete control of the vehicle.

- Level 1: (Function Specific Automation): Automation involves only specific control functions. (i.e. pre-charged breaks, electronic stability control)
- Level 2: (Combined Function Automation): Automation of two primary control functions in unison to relieve driver of control of these functions.
- Level 3: (Limited Self-Driving Automation): The driver has the choice to give up control of all safety-critical functions under certain conditions, yet the driver is expected to be available for occasional control.
- Level 4: (Full Self-Driving Automation): The vehicle has full control of all safety-critical driving functions under all conditions. The driver's availability is completely unnecessary.

The current automation level of self-driving cars is level 2. The drivers are still required to monitor the car and need to be ready to take over control at any time. There could be severe consequences if a driver fails to comply (e.g., [20]). However, many drivers are misusing the system, for example by even leaving the driver's seat entirely while driving on a public road using the Autopilot feature of a Tesla Model S [22]. Considering how difficult it is for the driver to get back in the loop and react properly to certain traffic situations [23], such reports are even more troubling and show that also exaggerated benefit perceptions could have negative implications for technology acceptance.

Recent surveys have indicated that 56% of people have positive opinions towards self-driving cars, while 13.8% carry negative concerns, and 29.4% are neutral towards the topic [24]. Supporters argue that since 93% of car accidents are due to driver error [25], the use of self-driving cars would reduce car accidents by that exact amount [5]. However, opponents of this view state that these vehicles would introduce new risks that do not exist now, such as system failures or offsetting behaviors. Schoettle and Sivak's analysis [24] concluded that self-driving cars may be no safer than an average driver and that they may result in the increase of total crashes if self- and human-driven vehicles are used simultaneously.

Many recent surveys have shown that people are generally accepting self-driving cars (e.g., [26]) even if only little is known about the technology. If self-driving cars become available people may just begin to recognize potential issues as it was the case with active cruise control where people began to recognize the loss of control at the first time deployment [27].

2.3 Summary

Risk and benefit perceptions are likely to play a central role for the acceptance of self-driving cars. Even before public availability, risk and benefit perceptions should be closely monitored to identify the issues of people with the technology. Issues can be accurate risk perceptions that need to be addressed or benefits that can be exploited in an early stage of development. Extensions of the TAM, UTAUT, and models from other fields of research have shown that risk perceptions are direct antecedents of technology acceptance.

Another kind of issues are distorted perceptions of both benefits and risks [28], which we already see with the first available self-driving car technologies. An overestimation of benefits might lead to misuse of self-driving cars, disappointment of initial users, and can have fatal consequences. Underestimation or not even recognizing benefits on the developer side could lead to self-driving cars that do not exploit their full potential. An overestimation of risks by the public could lead to resistance against self-driving cars before they even become publicly available [29].

Taking this into account, we identify the need to study risk and benefit perception of self-driving cars. Instead of distributing questionnaires, we use a novel approach to identify risks and benefits by analyzing the vast amount of existing data about self-driving cars on social media. We use supervised machine learning classification to classify tweets, which allows us to analyze them qualitatively and quantitatively. Classification of documents written in natural language is a common approach from opinion mining [30]. Thereby, we avoid certain issues with questionnaires and studying technology acceptance, for example common method variance [31].

3 Method

In this section we describe our approach from data extraction to model application. We follow the process suggested by [32]. First, we obtain tweets using the Twitter Search API. Second, we preprocess the tweets to improve data quality, reduce dimensionality, and avoid misclassification. Third, we evaluate the machine learning classification algorithm.

3.1 Data Extraction

The dataset consists of tweets concerning self-driving cars that were obtained using the Twitter Search API [33]. Furthermore, we developed a Java application as the Twitter Search API only allows to retrieve tweets not older than one week [34]. In order to conduct a meaningful longitudinal analysis, it was essential to allow for longer date intervals by fetching the tweets daily and storing them in a database. A MongoDB NoSQL database was used to store the complete tweets as they were returned by the Twitter API including their date of creation, the username of the tweet creator, the message that was tweeted, and a unique identifier of the tweet. We started the data collection for this analysis on March 03, 2015 with the last tweets being posted on July 15, 2016. We used the following set of search queries (SQ) in our Twitter API requests:

- SQ1: self driving OR driverless OR autonomous OR automated
- SQ2: tesla OR google OR apple OR icar OR ford OR opel OR gm OR general motors
- SQ3: volkswagen OR vw OR daimler OR mercedes OR benz OR bmw OR audi OR porsche

The search queries have been fixed before the data collection and consist of a combination of topic-related keywords (SQ1), names of U.S.-based companies working on self-driving cars (SQ2), and German car manufacturers (SQ2 and SQ3). Especially

SQ2 and SQ3 resulted in many tweets that were not concerned with self-driving cars. However, at the beginning of our research in March 2015, we wanted to make sure that the search queries still find the relevant tweets without having to change the search queries. In total, we collected 1,859,619 tweets. For the data analysis, the tweets were filtered using a regular expression[1], which ensures that only tweets containing one of the following terms are included in the data analysis: driverless, self-driving, autonomous driving, automated driving, autonomous car, and automated car. In addition to traditional filtering using strings, the regular expression also allows slight variations of the terms, such as "driver less" or "driver-less". This selection method reduced the number of tweets to 601,778.

For training the machine learning classifier we used a dataset of 7,482 tweets, which were manually classified by one person using the three labels "Risk", "Benefit", and "Neutral". "Risk tweets" describe perceived risks of self-driving cars while "Benefit tweets" describe benefit perceptions of self-driving cars. "Neutral tweets" do not contain risk nor benefit perceptions, for example: "Google starts testing driverless car in Austin […]" or "New self-driving Google car heads to streets […]." The distribution of the tweets is shown in Table 1.

Table 1. Descriptive statistics of the training dataset

		Class	
	Risk	*Benefit*	*Neutral*
N	751	701	6,030
%	10.0	9.37	80.6

The tweets were created in the time range from beginning of January 2010 to June 2014 and collected by crawling the "top tweets" about self-driving cars from the Twitter website prior to this study. These are "popular Tweets that many other Twitter users have engaged with and thought were useful" [35]. Both, the training dataset and the collected tweets were created by potential consumers and from users with commercial interests, for example, self-driving car manufacturers or news providers. For this analysis, we will not differentiate between the authors of the tweets. With the "top tweets", we could get an overview of the discussion about this topic on Twitter, which helped to design this study. However, we refrain from analyzing these tweets since they only represent a small fraction of the actual tweets published from January 2010 to June 2014 and are probably highly biased through the proprietary selection algorithms of Twitter. We only use them as "training data" for machine learning classification.

3.2 Data Preprocessing

We performed changes to the content of the tweets to reduce dimensionality and avoid misclassification, which is a common step in text classification [32]. We use the text

[1] We used the following regular expression: (driver.?less | self.?driving | autonomous.?driving | automated.?driving | autonomous.?car | automated.?car)

mining package “tm” for preprocessing, which provides a text mining framework for the statics software R [36]. The preprocessing steps are described in more detail in [36].

First, we transformed all characters in the text of the tweets to lower case. Like most of the preprocessing steps, this decreases readability for humans. However, machine learning classifiers for text classification mainly rely on statistical features of the provided textual data and, thus, profit from such transformations. Second, we removed punctuation, numbers, and hyperlinks. Since we will not perform a grammatical analysis, punctuation is not required to determine the classification of the tweets. Third, we remove English stopwords as provided by the tm package. Additionally, we removed the Twitter-specific stopwords “via” and “rt”. Fourth, we use stemming to further reduce dimensionality of the tweets. Stemming reduces words with the same stem to the same word by stripping derivational and inflectional suffixes, for example: “driving” is stemmed to “drive”.

Having performed the described transformations, the text of the tweets now should mainly contain words that are useful for the machine learning classification. In the last step, we transform the textual representation of the tweets into a document term matrix. Only words containing at least two characters and occur at least ten times in the tweets are included as terms. The terms are weighted by the term frequency (i.e., the number of occurrences of a certain term). Terms are, in our analysis, single words (i.e., unigrams) We apply all of the described preprocessing steps to both the training data and the tweets we want to classify.

3.3 Model Generation and Evaluation

The basic idea of supervised machine learning text classification is to automatically assign classes to documents using a much smaller set of training data. The training data usually contains manually classified documents from which the machine learning algorithms create a model that determines how to classify new documents. There are many different machine learning algorithms available for this task such as Naïve Bayes, maximum entropy classification, or Support Vector Machines (SVM) [37].

We decided to use the SVM algorithm for text classification, which has been shown to be highly effective for this task [37, 38]. It does not require extensive parameter tuning and is able to cope well with large feature vectors as it is usually the case with text classification [38]. The basic idea of SVM is to find a hyperplane that separates the documents (i.e., tweets) according to their classification with a margin that is as large as possible, which is basically an optimization problem [37]. We use the LIBSVM implementation of SVM that allows classification, regression, and other learning tasks [39]. For our analysis, we use C-support vector classification for classification.

For this analysis, we set the regularization parameter C to of the SVM to one and select a linear kernel function since text classification problems are often linearly separable [38]. We compute several metrics to evaluate the SVM. First, we conduct a 10-fold cross validation to determine the accuracy of the classifier. Accuracy is defined as the overall number of correct classifications divided by the number of instances in the dataset and a k-fold cross-validation randomly splits the training data into k mutually exclusive, approximately equal sized subsets (i.e., folds) [40]. The algorithm uses one of the *k* folds to evaluate the classifier by computing the accuracy and the other *k – 1* folds to train it. The cross-validation showed an average accuracy of 87.7%, which is a very good value considering similar studies (e.g., [41]) and is much better than classification based on hand-picked keywords [30].

For the second evaluation, we split the training data using a random selection of 80% (N = 5,957) of the tweets for training the SVM and 20% (N = 1,525) for evaluating the classification performance. We then compute several metrics based on the confusion matrix shown in Table 2.

Table 2. Confusion matrix of the SVM algorithm

		True class		
		Risk	*Benefit*	*Neutral*

	Benefit	4	76	22
	Neutral	61	62	1191

The accuracy with the fixed training set is 88.33%. We computed the "no-information rate", the largest proportion of the observed classes, since there is a large imbalance between the classes [42]. The no-information rate has a value of 80.85%. Additional metrics were computed according to [42] and are listed in Table 3.

Table 3. Metrics by class

Metric	*Risk*	*Benefit*	*Neutral*	*Average*
Sensitivity	0.5517	0.5170	0.9659	0.6782
Specificity	0.9790	0.9811	0.5788	0.8463
Pos. Pred. Value	0.7339	0.7451	0.9064	0.7951
Neg. Pred. Value	0.9541	0.9501	0.8009	0.9017
Prevalence	0.0951	0.0964	0.8085	0.3333
Detection Rate	0.0525	0.0498	0.7810	0.2944
Detection Prevalence	0.0715	0.0669	0.8616	0.3333
Balanced Accuracy	0.7654	0.7491	0.7724	0.7623

While accuracy showed very good values, we could identify issues of the SVM classifier resulting from the imbalanced training set. For example, the difference in sensitivity between Risk and Benefit tweets suggests, that the SVM recognizes benefit-related tweets better than risk-related tweets.

4 Results

With an overall total of 601,778 tweets, we obtained 459.751 (76.4%) neutral tweets, 63,599 (10.6%) stated benefits (*BT*), and 78,428 (13.0%) stated risks about self-driving cars (*RT*). The risk ratio (RR) and benefit ratio (BR) were calculated as follows:

$$RR = \frac{RT}{RT+BT} = \frac{78{,}428}{78{,}428+63{,}599} = 1 - BR = 0.5522 \quad (1)$$

$$BR = \frac{BT}{RT+BT} = \frac{63{,}599}{78{,}428+63{,}599} = 1 - RR = 0.4478 \quad (2)$$

In 2015, we collected 490,284 tweets of which 376,923 (76.9%) of the tweets were neutral, 50,098 (10.2%) stated benefits, and 63,263 (12.9%) stated risks about self-driving cars. The *RR* in 2015 is 0.5581 and *BR* is 0.4419. The ratio of neutral tweets did not change much over the years: Of 111,494 tweets in 2016, 82,828 (74.3%) of the tweets were neutral, 13,501 (12.1%) stated benefits, and 15,165 (13.6%) stated risks about self-driving cars. *RR* in 2016 is 0.5290 and BR is 0.4710. The results are summarized in Table 4.

Table 4. Number of tweets per year by class

Year	*Total*	*Neutral*	*Benefit*	*Risk*	*RR*	*BR*
2015	490,284	376,923 76.9%	50,098 10.2%	63,263 12.9%	0.5581	0.4419
2016	111,494	82,828 74.3%	13,501 12.1%	15,165 13.6%	0.5290	0.4710
Overall	601,778	459,751 76.4%	63,599 10.6%	78,428 13.0%	0.5522	0.4478

The ratio of neutral tweets, *RR* and *BR* did not change much over the years. This could indicate that the SVM classifier and the underlying training data is well-suited for classifying tweets about the risk and benefit perceptions of self-driving cars. It might also show that *RR* and *BR* is a good measure to analyze risk and benefit perception in further research. Closer inspection of *RR* and *BR* showed that it did change between the months (Figure 1) and might be an important indicator for issues in risk and benefit perception. However, as the SVM classifier detects benefit-related tweets better than risk-related tweets, the *RR* (*BR*) metric is suspected to be lower (higher) than the reported one.

We identified a spike in *BR* in August 2015 in Figure 1. By inspecting the tweets from August 2015, we found that many tweets mentioned the announcement of autonomous crash trucks that help to improve safety at road construction sites [43]. Drivers of crash trucks are usually in a very dangerous situation. Removing the driver could save many lives and was obviously very well received by the public.

Plotting the tweets over time, we could observe several changes in the number of risk and benefit tweets. For example, the graph of risk tweets (Figure 2) shows a peak in the number of Risk tweets in November in 2015.

The chart in Figure 2 also displays an increase of benefit-related tweets during the month of November in 2015. A close inspection of the tweets leads us to believe that the general increase of tweets was perhaps due to the International Driverless Cars Conference that occurs annually in November.

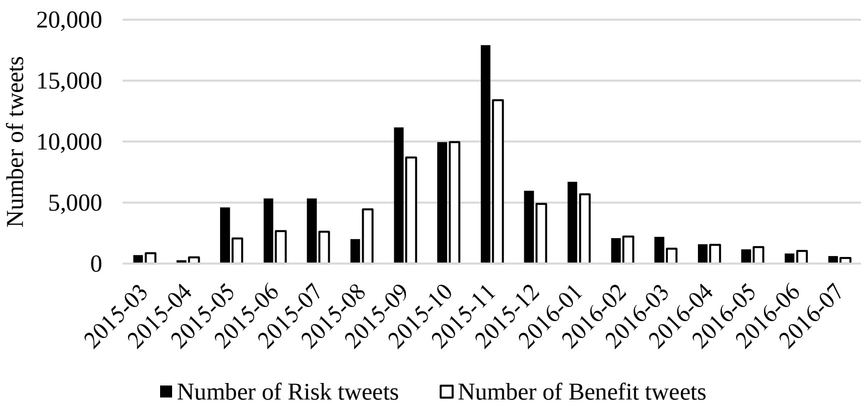

Figure 2. Number of Risk and Benefit tweets per month

5 Discussion

Before discussing the results in more detail, we discuss the limitations of this research. The tweets returned by the Twitter Search API are determined by proprietary algorithms and are not a representative sample of the overall tweets [44]. Furthermore, Twitter users are not a representative sample of the population [44]. As our analysis is based on English tweets, the main population analyzed might be located in the U.S. and should not be considered a representative global or U.S. sample [45]. In addition, only a small fraction of tweets in our dataset contain a geolocation so that we could not differentiate between different regions, which remains an ongoing issue in Twitter research [46]. As the training dataset plays an important role for training and evaluating the SVM, results depend on its quality. As described in the previous section, we found indications that the training data is of high quality but further robustness checks could provide additional evidence for the quality of the training data. Considering these limitations, however, we found interesting results that we carefully discuss in this section. This allows us the get valuable insights about people's perceptions as previous Twitter research has [14].

The RR and BR values calculated in this study indicate that people have reservations regarding self-driving cars. People tweet about risks of self-driving cars almost three times as much than about the benefits. Even if the difference might not be as big as this number suggests due to the limitations of our analysis, technology acceptance would not be guaranteed in the current state, making a disruption of individual mobility seem unlikely in the near future. This presents a problem that needs to be tackled before self-driving are sold to the public. We calculated the BR and RR values of separate years, to analyze the tweets over time and could find a small increase in RR from 0.5581 to 0.5290 (+5.2%). This might indicate that the impressive recent technical developments do not affect risk and benefit perceptions much and communication strategies should be reconsidered.

Suggestions for improvement can be derived by going over the tweet contents of the classified tweets, and trying to understand the reasons behind both risk and benefit perceptions towards self-driving cars. Among the different risk-related tweets, most of the tweets displayed concern towards the vehicles' accident, for example: "[…] Google's driverless cars have been involved in four car accidents" or "CAR CRASH Google Self Driving Cars to Decide if You Live or Die […]". This might be a case of a distorted perception of a risk as it contradicts current research. Experts argue that 93% of car accidents are due to driver error [23] and the use of self-driving cars could reduce car accidents by that exact amount [6].

People also display distrust towards the manufacturing companies and conveyed their love for driving, for example: "Sorry @google not going to buy a self driving car I like driving and don't trust your technology". In this case, benefit perception might be distorted. While driving can be enjoyable in certain situations, we find ourselves often confronted with less enjoyable aspects of driving such as traffic congestions, long monotonous highways with speed limitations, or on the search for a parking space in increasingly crowded cities. The author of this tweet might not be aware of this perspective, which could be used in communication strategies to improve benefit perceptions.

Furthermore, people also displayed fear for their own safety and privacy (e.g., "[…] Can #driverless #cars be made safe from hackers?"), where hacking someone's car could allow others to take control of your vehicle. Hackers might even go as far as writing viruses that could be transmitted from car to car. This is a risk that could proof to be real. We already see hacker attacks on current cars. These hacking attacks could cause physical harm to the passengers, which might be perceived more severe than having a personal computer hacked even if the consequences can be severe, too (e.g., huge financial losses, loss of private documents, publication of sensitive data). Manufacturers of self-driving cars need to be aware of that and provide strategies of how to avoid hacking of their vehicles.

Regarding the tweets that were classified as benefits of self-driving cars, many users were especially attracted to the fact that they could save time through self-driving vehicles, for example: “Sleepy time in the car for a in back seat. Wish I had a self driving car & I coulda joined em……”. This is also might be a case of distorted benefit perception since only full self-driving automation or level 4 automation [21] allows sleeping while driving. The current level of automation is 2 and it is likely to take some years until we arrive at level 3 or even level 4 automation. Meanwhile, many drivers are misusing current self-driving, for example by even leaving the driver’s seat entirely while driving on a public road using the Autopilot feature of a Tesla Model S [20]. People expecting to soon be able to sleep while driving might become disappointed if such systems will not be released soon as suggested by some developers of self-driving cars.

In general, people are impressed by the innovation put into the self-driving concept, for example: “[…] That hyper-futuristic driverless Mercedes has been spotted in San Fran – again […]”. Most benefit tweets reflected that people were simply excited to try something new, for example: “[…] A perk of living near Google… We saw the self-driving car today on the highway!” Developers of self-driving have recognized that people are excited about this new technology and the benefits it could provide. Consequently, they are investing in the development of self-driving cars and already promise features that will first be implemented in several years. If communication strategies are not adjusted, this excitement could cause exaggerated risk perceptions and a misunderstanding of the benefits self-driving cars are going to provide. Focusing only on the benefits and even generating exaggerated benefit perceptions could have adverse effects on public acceptance of self-driving cars.

6 Conclusion

The results indicate the need for developers and manufacturers to listen to the voice of customers of self-driving cars and probably rethink their communication strategy. By analyzing 601,778 tweets using supervised machine learning classification, we identified the need to clearly reassure the public of their risk perceptions. People tweet more about risks of self-driving cars than about the benefits. Many of the supportive tweets indicated that the benefit perceptions neglect the actual state of the technology and, thus, could be dangerous or lead to disappointment when trying the new technology for the first time. Getting potential customers to perceive the objective benefits of self-driving cars such as increased safety and increased comfort might increase benefit perception sustainably. This would lead to less disappointment with self-driving cars when they become available to the broad public and, thus, lead to higher acceptance. It is not likely that self-driving cars will disrupt individual mobility in the near future due to the lack of acceptance.

This analysis focused only on Twitter. Further research could replicate this approach using different machine learning algorithms, datasets, and other new technologies. It was not in the scope of this paper to optimize the machine learning text classification to reach the best possible classification accuracy of the SVM. By tuning the parameters of the SVM or generating additional training data, analyses could be improved. Further research of self-driving cars could be based on other keywords and use other approaches such as topic modeling [47] instead of supervised machine learning to remove the effortful manual classification of Tweets.

With the applied optimizations for text classification we could achieve sufficient accuracy of the text classification. Combined with manual inspection of the classified tweets to identify the cause for certain developments of risk and benefit perceptions, we could make well-founded suggestions for improving the public acceptance of self-driving cars. We identified a promising metric, risk rate *RR*, which can be used to study risk and benefit perceptions in social media. Furthermore, we identified issues in the communication strategies of self-driving car developers.

Abstract. Achievement of the ambitious environmental sustainability targets requires improvement of energy efficiency practices in private households. We demonstrate how utility companies, having access to smart electricity meter data, can automatically extract household characteristics related to energy efficiency and adoption of renewable energy technologies (e.g., water/space heating type, age of house, number and age of electric appliances, interest in installation of photovoltaic systems etc.) by using supervised-machine-learning-based green IT artifacts. The gained information enables design of custom-tailored interventions (such as promotion of personalized energy audits, ecologic services and products, or load shifting mechanisms) that trigger residents' behavioral change toward environmental sustainability as well as improvement of utilities' key performance indicators. Moreover, realizing privacy preservation concerns, we investigate the influence of smart meter data granularity and the amount of survey responses required for the artifact development on the household classification quality.

1 Introduction

In order to promote energy efficiency and the integration of renewable energy sources, policy makers have placed high hopes on networked electricity meters that measure and communicate consumption information at a high resolution in time [1]. These so-called smart meters offer, besides improvements to the utilities' billing processes, timely consumption feedback for residential customers, render dynamic tariff schemas possible, and provide input to home automation systems. Ultimately, smart meters should help citizens to reduce their electricity consumption and motivate shifting loads to support the integration of renewable, fluctuating electricity sources. Early studies have reported promising effects including energy savings as high as 15% [2], and many countries mandated utility companies to roll out the technology among their residential customers. To date, more than 50 million smart meters have been deployed in the EU, and industry expects 154 million devices by 2017 [3].

The initial enthusiasm for the technology, however, has faded recently. More carefully designed studies that were not affected by sampling bias (e.g., from primarily observing volunteering, motivated users) showed savings of only around 3% and little response to incentives for load shifting [4]. Moreover, the mostly poor design of feedback campaigns together with deficient data protection practices raised substantial privacy concerns among consumers [5]. It has become evident that relying on the mere effects of consumption information and dynamic tariffs is not sufficient to advance energy literacy, motivate the hoped-for behavioral change, nor to trigger investments in saving technologies [6].

We argue that the current, disappointing performance of smart metering is not a problem of the technology as such, but resides in an insufficient information extraction from the available metering data. Feedback interventions, for example, that are tailored to individual recipients have been shown to achieve substantially higher saving effects and to reach a better user acceptance [7]. Such measures (e.g., providing concrete advice or comparisons to similar households, offering services that reflect the household's characteristics, etc.) typically yield considerably lower cost per kWh saved (or shifted) than tax credits and rebates and meet higher public acceptance than prohibitive regulations [8]. Load shifting measures, control of heating systems or combined micro heat and power plants can also considerably benefit from information beyond pure metering data if, for example, up-to-date knowledge on the presence of the inhabitants is available. While strong evidence supports the benefits of using such specific information on households to conduct consumer-specific energy efficiency campaigns [8], a major problem is, that the required data to conduct such campaigns is not available for large scale deployments. This reduces the benefits of smart metering infrastructures dramatically.

The research outlined herein lies within the scope of energy informatics - an emerging discipline concerned with analysis, design and implementation of information systems to reduce energy consumption [9, 10]. ***We strive for providing the missing link between smart meter data and powerful energy efficiency measures***. We show how data collected at 15-minute granularity from out-of-the-shelf smart electricity meters can be used to infer energy-efficiency related characteristics of residential dwellings (e.g., water/space heating type, age of house, number and age of electric appliances, interest on installation of photovoltaic systems etc.), ***using supervised machine learning*** techniques. Automatically mining this information – with the consent of inhabitants – enables large-scale, targeted saving advice and better input to home automation systems that can significantly contribute to reduction of energy consumption and advancement of environmental sustainability.

2 Research Objective and Theoretical Context

A number of researchers have developed methods to predict household characteristics data from energy consumption data. The approaches differ with respect to the type of data available (e.g., load records, household survey reports), their resolution in time, and the output variables of interest. The potential to recognize characteristics from load curves depends on the data granularity – the finer the granularity is the better recognition performance can be achieved. Vast research has been done on the recognition of devices from the data of extreme granularity (Hertz and Megahertz frequency) – in the field of Non Intrusive Load Monitoring (NILM) [11, 12]. While sampling rates far beyond one megahertz are quite common in industrial or lab settings, the smart metering infrastructure that is currently being deployed and is expected to be in the field for the next 20 years does not provide such fine grained data. Therefore, the NILM methods will not be compatible with the standard meters deployed in most households [13].

Several authors have investigated coarser consumption data. Chicco [14] provides an overview of the clustering methods for electrical load pattern grouping. In the field of recognition of energy efficiency characteristics which we focus on, Fei et al.[15], proposed a method to detect heat pumps from the daily energy consumption data. Beckel et al. [16] used 30-minute data reduced to 26 features to infer 18 household properties, most of which relate to the inhabitants' life situation (age, family, employment, social class, etc.), and three directly relate to energy efficiency (number of appliances, cooking type and lightbulbs). Hopf et al. [17] and Sodenkamp et al. [18] improved Beckel's algorithm by extracting 88 features, applying filtering methods and by refining the properties. Sodenkmp et al. [19] included weather data to Beckel's algorithm using a multi-dimensional classification method called DID-class.

Further works employ conventional yearly consumption readings for dwelling classification. Kozlovskiy et al. [20] detected old gas heating systems for a targeted cross-selling campaign in Belgium. Sodenkamp et al. [21] predicted household probability to register on an energy efficiency portal for customer engagement campaigns in Germany and Switzerland. Hopf et al. [22] used yearly consumption and geographic data from OpenStreetMap and GeoNames to detect living area, household type and number of residents.

Our overarching goal is to **examine the usage of machine-learning-based smart meter data analytics methods in the practice of energy utility companies and their contribution to the environmental and economic sustainability.** In this work, we go beyond the state-of-the art by identifying eleven energy-efficiency related household characteristics (space heating type and age, water heating type, heat pump usage in a household, house age, number and age of appliances, presence and interest in photovoltaic and thermal installations, number of recently completed energy efficiency measures, and type of cooking facility) from smart meter data at 15-minute granularity, which we collected from a Swiss utility company. We extract 93 features from the consumption data and include weather data represented by 40 features. Finally, we investigate the effects of data granularity. This information can be used for the development of targeted energy-efficiency measures (e.g., saving tips, promotions of installations of renewable energy systems, load shifting campaigns). To enable algorithm training and testing we designed and conducted an online survey. Thus, our first research question is as follows:

RQ 1. *To what extent is it possible to recognize energy efficiency related household characteristics from smart meter data using machine learning methods?*

The availability of detailed electricity consumption data-traces to the utilities is associated with consumers' privacy concerns [5]. Depending on the company policy and local legislation, utilities make use of different data granularities. The typical aggregations vary between 15-min, 30-min, hourly and daily levels. For daily data, some utilities differentiate between the HT (high tariff, during the day) and NT (low tariff, during the night) consumption. Data with lower frequency contains less information about customers' behavior and we expect the performance of our classification algorithms to degrade when applied to such data. Therefore, we test how different data granularities influence the resulting classification performance and formulate our second research question as follows:

RQ 2*. To what extent do different granularities of smart meter data influence the recognition quality of energy efficiency related household characteristics?*

3 Data Description

For our data science study, we cooperated with a utility company in Switzerland with about 9`000 customers that provided us with household electricity meter readings at 15-minute granularity in the timespan between June 1st 2014 and May 31st 2015. For the same time period, we acquired hourly weather-data from the U.S. National Climate Data Center [23]. Together with the utility, we conducted a web-based customer survey about energy efficiency related household characteristics between June and September 2015. All customers received an invitation to the survey attached to their bimonthly bill. In this survey, we collected data on 527 households, which corresponds to a response rate of 6%. We matched the survey results with smart meter data using respondents' names and addresses.

Based on the survey responses, we defined and extracted 11 energy efficiency relevant household characteristics (*properties*) that include at least two *classes* (see Table 1). The class definition was either naturally given (e.g., heat pump exists / does not exist) or we empirically set class borders by using quantiles. When we used quantiles for defining the class border, we either aimed to separate the households in equally sized classes, or wanted to identify a specially interesting class (e.g., high purchasing intention for solar installation). The total number of households per property does not necessarily respond to the total number of households participating in the survey, since the survey participants left some questions unanswered. The amount of excluded instances due to the missing data is different per property and lies mostly at 23.48 %, except for "Age of residency" with 23.91%, "Age of appliances" with 34.35%, and "Age of heating" with 40% of all survey participants excluded.

Table 1: Energy efficiency related household properties with classes defined from survey responses; q_x denotes statistical x percentile of the survey responses (relative class sizes are not necessarily identical to the percentiles by definition for numerical values, due to categorical survey variables).

Property	**Classes**	**Definition**	**Class size**	
			Abs.	**Rel.**
Age of appliances	New	Avg. appliance age < $q_{0,25}$	153	33,41%
	Average	Avg. appliance age between $q_{0,25}$ and $q_{0,75}$	152	33,19%
	Old	Avg. appliance age > $q_{0,75}$	153	33,41%
Num. of appliances	Few	Number appliances < $q_{0,25}$	149	28,27%
	Average	Number appliances between $q_{0,25}$ and $q_{0,75}$	280	53,13%
	Many	Number appliances > $q_{0,75}$	98	18,60%
Cooking type	Electric	Number electric stoves > 0	484	91,84%
	Not electric	Number electric stoves = 0	43	8,16%
Efficiency measure	No	Number completed energy efficiency measures during the last 15 years (insulation of basement / roof / building envelop, or window replacement)	304	57,69%
	Few		109	20,68%
	Multiple		114	21,63%
Heat pump	No	Existing heat pump	453	85,96%
	Yes		74	14,04%
Age of residency	< 10	Age (in years) of the building the household is living in	71	13,65%
	10-29		147	28,27%
	30-74		219	42,12%
	≥ 75		83	15,96%
Interest in solar	Low	Purchase intention coefficient < $q_{0,50}$	387	73,43%
	Average	Purchase intention coefficient between $q_{0,50}$ and $q_{0,75}$	49	9,30%
	High	Purchase intention coefficient > $q_{0,75}$	91	17,27%
Solar installation	Yes	Photovoltaics or solar heating existent	29	5,50%
	No	Neither photovoltaics nor solar heating existent	498	94,50%
Age of heating	New	Space heating age < $q_{1/3}$	128	33,51%
	Average	Space heating age between $q_{1/3}$ and $q_{2/3}$	135	35,34%
	Old	Space heating age > $q_{2/3}$	119	31,15%
Space heating type	Electric	Space heating = „*Electric heating*"	21	3,98%
	Heat pump	Space heating = „*Heat pump*"	66	12,52%
	Other	Other space heating	440	83,49%
Water heating type	Electric	Water heating = „*Electric heating*"	81	15,37%
	Heat pump	Water heating = „*Heat pump*"	63	11,95%
	Other	Other water heating	383	72,68%

4 Analysis

In this section, we describe our data analysis methodology and results. We first seek to answer the first research question:

RQ 1. *To what extent is it possible to recognize energy efficiency related household characteristics from smart meter data using machine learning methods?*

To answer this question, we follow the four-step procedure described below.

Step 1: Feature Extraction. At the beginning, it is important to reduce the raw data dimensionality and transform the data to a more usable form. Consumption time series are divided into single weeks, since from previous work we know that a weekly energy consumption is sufficient to perform household classification [16]. We extracted *93 features from 15-min smart meter data* for each week, that are adopted from previous works dealing with 30-min smart meter data [16, 17]. The details can be found in the project report [24]. The extracted features cover four categories: consumption (e.g., in the morning, noon, evening); ratios of consumption figures (e.g., consumption in the morning vs. noon, daytime vs. night); statistics (e.g., variance, quantiles); others (e.g., number and average heights of consumption peaks).

Besides the smart meter features, we defined and used *40 features describing the correlation between electricity consumption and weather data*, since a positive effect of weather data on the classification performance was shown in the previous study [19]. For each weather variable (temperature, wind speed, sky cover, and precipitation), we calculate eight features: overall correlation over the week, correlation during the day and during times of the day (night, daytime, evening), correlation of minima in both time series, correlation of weather minima and consumption maxima, and ratio of the weekday and weekend correlations.

Finally, we use 133 features for our analysis. Due to the space constraints we cannot present all the features (interested reader is referred to [24]), but we list 10 most frequently selected features in the final prediction models for all household properties with a short description in Table 2.

Step 2: Feature selection. After having prepared the feature vectors, we select relevant features for each property separately. This is done to reduce overfitting and speed up the calculations by removing the irrelevant features. We tested the following feature selection methods: Correlation based (cfs), consistency based (consistency), Based on the importance from random forest (importance), statistical test for the difference in distributions (chi.squared), entropy based (gain.ratio), forward feature selection search (forward-selection), backward feature selection search (backward-selection), no feature selection (none). For the methods description see [25].

Table 2: The top 10 selected features and their description

Rank	Feature	Description
1	t15_above_2kw	Time with consumption above 2 kW
2	t15_value_min_guess	Time with consumption above minimal consumption
3	r15_wd_evening_noon	Relation between evening and noon consumption on weekdays
4	r15_mean_max_no_min	Relation between mean and max consumption with subtracted

		minimum
5	t15_time_above_base2	Time with consumption above estimated baseline
6	r15_evening_noon	Relation between evening and noon consumption
7	t15_const_time	Time with nearly constant consumption
8	t15_daily_min	Average daily minimum
9	r15_min_wd_we	Relation between minimum of consumption on weekdays and weekends
10	r15_var_wd_we	Relation between the variance of consumption on weekdays and weekends

Step 3: Classification. As the next step we train the model based on the selected features and evaluate the following six well-known classifiers that have implementations in the statistical programming environment GNU R: AdaBoost [26], k Nearest Neighbors (kNN) [27], Naïve Bayes [27], Random Forest [28], Support Vector Machine (SVM) [29].

Step 4: Evaluation. To measure the classification performance, we are interested in testing how many households are correctly classified in each available class. These numbers are typically presented in the form of a confusion matrix. To compare the different confusion matrixes between each other we calculate two measures from the confusion matrices:

- Accuracy**:** It is defined as the portion of correctly classified instances from the number of total classification instances and can take values between 0 and 1, where 1 corresponds to perfect prediction and 0 to total misclassification. Accuracy is easy to interpret, but in the situation where the classes are unbalanced (i.e., one class occurs much more often than the others) a classifier that always predicts a majority class can achieve high accuracy. Therefore, this measure can be slightly misleading if applied to such unbalanced properties.
- Matthews Correlation Coefficient (MCC): It is an alternative measure that is more suitable for the unbalanced problems. It is a correlation coefficient between the observed and predicted classifications. In the case of binary classification problem, it is equal with the phi statistic [30]. We use MCC definition for multiclass problems [31, 32]. MCC can take values between -1 and 1, where 1 corresponds to the perfect classification, -1 to the total disagreement between the predictions and real observations and 0 for the classification that is not better than random prediction. MCC lacks the easy interpretability of the accuracy measure, but it is a good compromise among discriminancy, consistency and coherent behaviors with varying number of classes, unbalanced datasets and randomization [31].

To calculate the performance measures, we first split the data into the *test set* (10%) from the *main data* by using a stratified split (the distribution of classes in the test set deviates at most with one household from the distribution in the main data). For the main data, we use 4-fold cross-validation to select the best classification algorithm and feature selection method.

Then, we take the features describing a single week (week number 34, from 12.01 to 18.01.2015). The features of the main dataset are centered and scaled to have mean

0 and standard deviation 1. The features in the test set are then scaled with the same proportions. All households with missing or not available values for the chosen week are removed, as well as the feature vectors that are constant for all households. This problem occurs mainly with weather features that are constant during the week (e.g., precipitation and sky cover).

Performance of the individual classifiers for week 34 is presented in Figure 1, together with two benchmark measures: random guess ($RG = 1/K$, where K is the number of classes in one property) and biased random guess ($BRG = \sum h^2$, where h is the relative class size of each class for one property, as displayed in Table 1). The figure illustrates, that no single classifier provides the best classification performance for all properties. Similarly, no best feature selection technique for all properties can be found. Therefore, we choose the classification configuration (feature selection and classifier) that produced the best result for MCC and list it in Table 3.

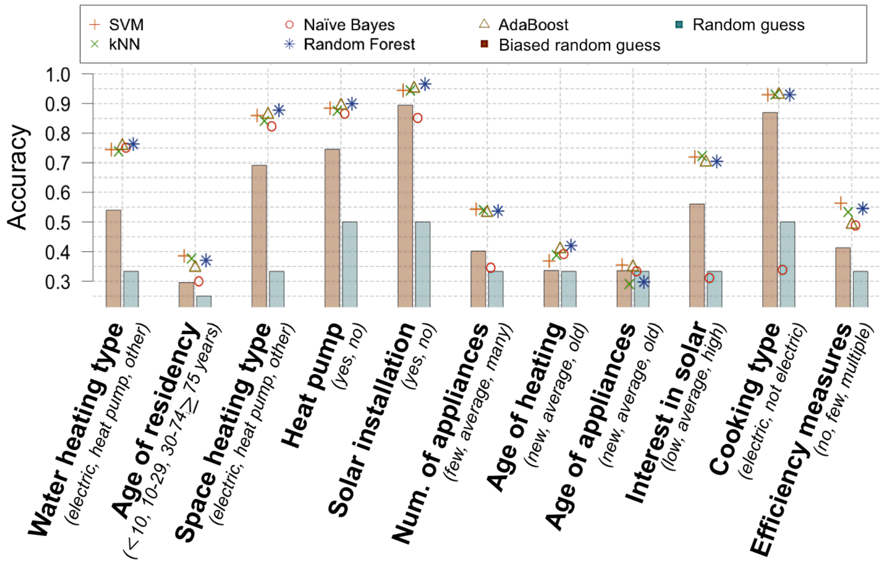

Figure 1: Comparison of classification performance of individual classifiers without feature selection (week number 34)

With these best performing classifier configurations, the final model is trained on all households that are not in the test set. Predictions are then made for the test set and are then evaluated in terms of both the accuracy and MCC. We repeated the training and prediction process for all 29 week of data that were not excluded due to public or school holidays or missing values. The results for every week are then aggregated with a simple ensemble classifier [33], that averages the prediction probabilities for each class and thus forms one single multi-week-classifier. The final predictions for the test data are then evaluated with respect to both the accuracy and MCC. The results are presented in the Figures 2 and 3.

As the result, we can answer our first research question positively: It is possible to predict most (9 from 11) energy efficiency relevant household properties better than by using random guess. We especially achieved good results for the prediction of properties related to the room and water heating (*Space heating type*, *Water heating type*, and *Heat pump*). The properties *Cooking type* and *Efficiency measures* could not be predicted adequately with our approach. But even with the negative MCC, the results can still be valuable for utility companies that usually do not know what household belong to which class: the application of the classifier can perform better than random guessing.

Table 3: The best performing configurations

Property	Feature selection method	Classifier
Space heating type	cfs	Random Forest
Water heating type	none	Random Forest
Heating age	gain.ratio	Support Vector Machine
Age of residency	cfs	AdaBoost
Age of appliances	chi.squared	Naïve Bayes
Cooking type	none	Random Forest
Heat pump	chi.squared	Random Forest
Solar installation	none	Random Forest
Efficiency measures	cfs	AdaBoost
Num. of appliances	none	Random Forest
Interest in solar	chi.squared	Random Forest

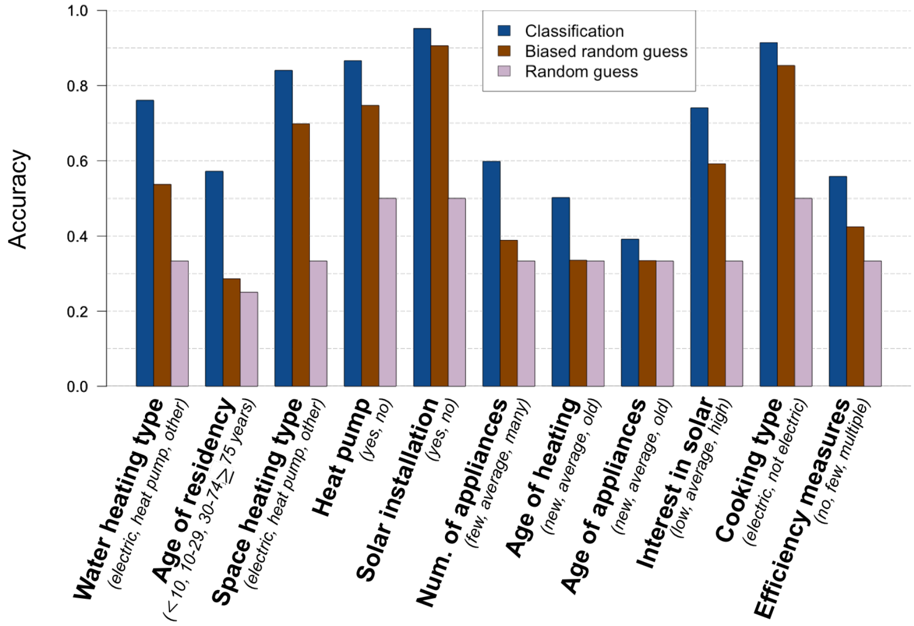

Figure 3: Classification results for all properties measured with accuracy, compared to random guess and biased random guess

RQ 2. *To what extent do different granularities of smart meter data influence the recognition quality of energy efficiency related household characteristics?*

To answer this question, we have to repeat the classification process as described in RQ1 for different data granularities. We simulate the different granularities by aggregating the existing 15-minute smart meter data up to the following typical aggregation levels: 15-minute, 30-minute, 60-minute, daily NT/HT (low-tariff during the night / high-tariff during the day), and daily. The NT consumption is measured during different times by different utility companies. For this case we will assume that NT consumption is measured between 23:00 and 07:00.

For each data granularity, we adapted the defined features that are reasonable for the data granularity: For 30-minute and 60-minute data we use features analogously to the 15-minute ones. For the NT/HT and daily aggregation levels we define 14 and 7 different features respectively that describe the consumption during the weekdays and weekends, the relations between different consumptions and the variance. Naturally, a large set of the 15-min smart meter features cannot be calculated for HT/NT or daily measurements (e.g., features on consumption during times of the day, or peaks of the load curve). Additionally, we compare the results to the worst case of only having a single weekly value (1 feature).

The classification is repeated for a single week only. We exclude the weather variables from this analysis, because we want only to show the value of the data at different granularities. The consideration of weather will have more value for the finer granularities, since it is also available on the 15-minute level. For calculations at each granularity levels, the features from coarser granularities are also included. This is done to ensure that important features are not missed on any granularity level. E.g., if there is a good feature that we calculate based on the daily data, but do not for hourly data, then we will get better results for daily granularity than for the hourly data, even though we could get the same or better result by including this feature with hourly data. In this way, we get a large number of features, especially for the 15-minute data, and therefore we perform feature selection with the three best performing methods on the 15-min data (cfs, chi.squared, gain.ratio), and without feature selection.

In Figures 4 and 5, we show the best classification performance that was achieved for different granularities with one of three feature selection methods or without feature selection using Random Forest classifier. Since our goal in this analysis is to compare the best possible performances of different data granularities, we do not create overfitted models that are not necessarily designed to predict household classes for new households, and use the same data for training and test. Therefore, the results cannot be compared with those presented in Fig. 2 and 3, but they give an impression on the impact of data granularity on the classification performance. We can conclude from the results, that ***there is not much difference between using the 15-, 30- and 60-minute data*** for the prediction of the energy efficiency relevant household characteristics. There is a large drop in performance by using the daily (HT/NT and 24-hour) data for some properties. Using the weekly values shows the worst performance, demonstrating the value of finer granularity data.

5 Discussion and Conclusions

The objective of our study was the identification of energy-efficiency and renewable energy related household characteristics based on smart electricity meter data. For the development of our methodology and the training of our machine-learning based green IT artifact, we used smart meter data collected at 15-minute granularity from a Swiss utility company and conducted a customer survey in 2015. In this paper, we have shown that it is possible to identify 9 from 11 proposed energy efficiency relevant household properties (including space heating type and age, water heating type, existence of heat pumps, number and age of appliances, existence and interest in solar installations, and house age) with average accuracy over all properties of 70%. The artifact could not identify the properties "number of completed energy efficiency measures" and "type of cooking facility". Furthermore, we have shown that the smart meter data aggregated at hourly values is sufficient to detect 8 from 11 properties with only a small loss of prediction quality, compared to 15-minute data. Importantly, tools for the recognition of household characteristics must be used under clearly documented privacy preservation conditions and with user consent. Development of law-based guidelines for energy consumption data treatment in the analytics tasks is an important task that should be solved in the next future.

We have identified the following limitations of our work. First, this study is based on the online survey implying the selection bias, which means that we cannot be sure that our sample used for the algorithms training and test is representative and that the results hold for all utility customers. Further, we worked together with a utility company that serves customers from one city and the surrounding area - this introduces a regional bias into the analysis. In addition, we only considered 11 household properties in this work - the results may differ when new properties are included.

In the future work, we plan to conduct field studies to investigate the effects of personalized interventions toward the households selected using the presented algorithms. The interventions can include offers of energy-efficiency products and services, customized consultancy on energy efficiency measures, or normative feedback. We could show the economic, ecologic and social potential of such interventions in a recent study [20] where households with inefficient heating systems were identified based on annual gas consumption data. We expect much better results with the use of smart meter consumption data as shown in this paper. In this setting, we also plan to recognize combined properties (e.g., old house without conducted energy-efficiency measures, or homeowners that are interested in solar installations) from the electricity consumption and weather data. We also plan to reproduce and expand the presented results by cooperating with utility companies serving customers from other geographic locations. A more detailed approach would investigate how the combined changes in granularity and data volume affect the classification performance. Additionally, we used only a simple ensemble learner, that computes the mean value from individual predictions, to aggregate classification results from multiple weeks. Using a more advanced approach that takes the varying performance during different seasons into account could further improve the results.

Being an example for a data science research, our work still allows for empirical validation of the effects from applying the developed artifact in field. Moreover, we demonstrate how to integrate the end-users (utility customers) in the IS research. Ultimately, the proposed artifact is applicable to virtually every smart meter deployment worldwide without changes in the hardware, and thus can ***considerably contribute to the society's energy targets***.

Dead or Alive? A Formal Decision Model for Deciding on Customer Recovery Investments

Dominikus Kleindienst[1] and Daniela Waldmann[1,2]

[1] University of Augsburg, FIM Research Center, Augsburg, Germany

Abstract. As digitization makes customer migration easier and more attractive, managing customer recovery becomes increasingly important for organizations. In this context, the challenge is to avoid two error types that can occur with customer relation recovery. First, mistakenly investing in customer relations that are active ("alive"), and, second, mistakenly not investing in migrated customer relations ("dead"). Consequently, considering the probability that a customer relation is "alive" or "dead" is necessary. Based on this probability, an economically reasonable decision has to be made whether to invest in individual customer relation recovery or not. However, existing literature often neglects the above mentioned probability. Accordingly, based on a comprehensive discussion of related work, we propose a formal decision model on whether to invest in customer relation recovery, considering the probability that the customer relation is still "alive" or "dead." To demonstrate the decision model's applicability, an illustrative case with a sample calculation is presented.

Keywords: customer data, customer recovery, digitization, decision model

1 Introduction

In all types of organizations, customers come and go or, following Schmittlein et al. [1], there are customers who are “alive” (i.e., maintain an active customer relation) and customers who are “dead” (i.e., left the organization for whatever reason). With digitization as a main driver of the global economy, making this distinction is becoming more and more challenging: customer migration becomes easier and more attractive as digitization is breaking down barriers of entry, enables more transparent markets, and is comparatively impersonal [2]. Therefore, the importance of managing customer recovery is increasing. This challenge intensifies in settings where customers are not bound by contracts and have the possibility to change between different vendors [3, 4]. On the other side, digitization does not only amplify customer migration, but can also be an advantage for organizations because of the significant increase in available customer data [5]. Consequently, with the increasing amount of available data, opportunities to identify customer insights from data continue to expand. Organizations have the possibility to collect, store, and analyze available customer data [6] and use it, among others, for custom-designed investment decisions in the recovery of individual customer relations.

The related literature already provides models for deciding between different marketing investment alternatives [7, 8] and develops guidelines for acquisition and retention decisions [9, 10]. However, although economic aspects such as cost-benefit-trade-offs are investigated in the literature, it is not always clear for which customer relation a recovery is actually required. To illustrate this, it would, for example, not be reasonable to invest in recovering a customer relation, which is active and would likely realize further transactions anyway. However, as the point at which a customer relation becomes inactive cannot always be known for sure, it has to be estimated using indicators such as a low number of transactions or an unexpectedly long time since the last transaction [1]. Therefore, if a customer relation is still “alive” can be estimated as a conditional probability, given certain purchase information [1].

In summary, customer recovery faces two challenges. First, organizations need to identify the probability that a customer relation is to be considered “dead” or “alive.” Second, once such probability can be estimated, the question is at which probability an investment in the recovery of an individual customer relation is economically reasonable. Thus, we aim at an analytical solution to the following research question: how can a decision maker decide on investing in a customer relation on the basis of the probability that the customer relation is still “alive“?

To answer this question, we develop a formal decision model based on the following ideas. On one hand, investing in the recovery of a customer relation is only reasonable if the present value of future cash flows when investing is higher than the present value of future cash flows when not investing in the recovery of a customer relation. On the other hand, deciding on investing in customer recovery should consider the probability that a customer relation is “dead” or “alive.” Consequently, we compute a threshold from which on investment in an individual customer relation is economically reasonable.

We structure the paper starting with a discussion of the problem context and related work. Further, we propose the decision model and demonstrate its application by a sample calculation. Lastly, we discuss the resulting decision model.

2 Problem Context

Digitization makes customer focus more valuable for organizations and a bigger challenge, as customer migration becomes easier and more attractive than before [11]. In this environment, organizations do not only need to acquire new customers and build loyalty among existing customers, but also target migrated customers. Typically, customer migration arises as soon as there is a gap between the priorities of the customer and the activities of the organization [12]. From an organization's perspective, the reasons for such a gap can be manifold: the lack of success in identifying and using interesting market opportunities, limited information about competitors, no effective communication with the market, no comprehensive customer service, or missing knowledge about customer needs, their perceptions, preferences, and behavior [13]. In summary, in order to avoid customer migration, organizations need to increase customer satisfaction as it affects customers' repurchase likelihood [14]. Customer satisfaction can, for example, be defined as a cumulative evaluation of a customer's purchase and consumption experience to date [14–17]. Generally, customers are considered "alive" as long as they are still cultivating an active relation to the organization, and "dead" if they terminated their relation to the organization for whatever reason [1]. To recover "dead" customer relations, an organization needs to first identify the respective customers. On the one hand, identifying if a customer relation is "alive" or not can be obvious. For instance, if customers cancel their cell-phone contract and change their provider, the customer relation would clearly be considered "dead." On the other hand, there are contexts in which a customer relation transition from "alive" to "dead" is not always that easy to detect for companies, as customers "may not notify the firm when they leave" [1]. This holds true for hotel stays, air travel, or large online retailers such as Amazon, where customers are not bound by contracts and have the possibility to switch between different vendors [3, 4]. Hence, particularly in non-contractual customer relations, it is a challenge for organizations to know whether a customer relation is "alive" or "dead" [1]. One indicator for companies whether a customer relation is "alive" or "dead" is a customer's purchasing information (e.g. an unexpectedly long time period since the last transaction). However, a long transaction break does not necessarily mean that a customer relation is definitively "dead" [18].

Generally, related literature approaches this topic by modeling customer migration. Several researchers use recency in models that predict customer behavior. For example, Bult and Wansbeek [19], Bitran and Mondschein [20], Fader et al. [18], and Rhee and McIntyre [21] find a negative association between recency and purchase likelihood. Dwyer [22] identifies "always-a-share" customers' purchase probability by developing a purchase decision-making tree based on historical buying data. The Dwyer model is used in most customer lifetime value (CLV) research [23]. Comprehensive explanations on the CLV can be found in Kumar and Reinartz [24] for instance. Blattberg et al. [10] extend the Dwyer model and use the “recency, frequency, monetary index” to develop the purchase decision-making tree [23]. In brief, literature has long contributed to the understanding of customer migration and the factors affecting it. However, at this point, no concrete implications for customer recovery investments have been derived.

Customer recovery campaigns are a specific kind of customer campaigns. According to the campaign management process of Englbrecht [25], campaigns are mainly characterized by target group, channel, and content. Hence, investment decisions are to be made between different campaign alternatives comprising possible target groups, channels, or content. Here, the target group comprises migrated customers, or in other words “dead” customer relations. Channels, for instance, are categorized into offline channels, such as stores or catalogues, and online channels, such as mobile apps, email, or websites. They can also be differentiated by direct and indirect channels, distinguished by whether there is an intermediary responsible for managing the relationship between the customer and the organization [26]. Typically, the content of customer recovery campaigns can entail special offers, discounts, vouchers, coupons or other incentives for recovering customer relations.

For deciding on competing marketing investments, the literature provides numerous approaches. For example, Rust et al. [7] provide a framework to trade off competing marketing investments on the basis of financial return. Neslin et al. [8] demonstrate how to target the right marketing to the right customers at the right time to maximize CLV. Venkatesan and Kumar [27] recommend CLV as a metric for selecting customers and designing marketing programs, as they provide empirical evidence for the existence of a relationship between marketing actions and CLV. As such, Glady et al. [28] show that the dependence between the number of transactions and their profitability can be used to increase the accuracy of the CLV. Venkatesan and Kumar [27] point out that literature provides guidelines for acquisition and retention decisions [9, 10]. There are also studies on the basis of which customers should be “eliminated”: Reinartz and Kumar [29], for instance, demonstrate how to decide on terminating a customer relation or not. In summary, literature provides various discussions and models concerning investments in customer relations. However, to the best of our knowledge, there is no formal decision model on the economic feasibility of customer recovery investments while considering the probability that a customer relation is actually “dead.”

In order to fill this gap, we introduce a calculation to identify the most economically reasonable investment alternative out of multiple customer recovery investments, and propose a decision model that advises whether to invest in customer recovery or not. Based on an existing decision model designed to manage data currency [30], we premise our model on the probability that a customer relation is still “alive.“ The detailed decision model is described in the subsequent chapter.

3 Decision Model

The basic idea of the model is to decide on investing in customer recovery or not by comparing a threshold from which an investment is economically useful to the current probability that a customer relation is "alive." This threshold depends on investment specific variables, such as the costs of the investment and an effectiveness factor, and customer specific ones, such as the present value of future cash inflows of a customer relation. Beside, we make some assumptions in our decision model. First, the decision model is designed to cover a single period. Second, we assume that the organization's risk attitude is neutral when deciding on customer recovery investments. Third, for reasons of simplicity, we only distinguish between "dead" and "alive" customers and do not consider possible attributes in between.

The decision model has four steps: (1) selection of the most economically reasonable investment alternative; (2) determination of the current probability that a customer relation is "alive;" (3) derivation of the threshold; and (4) making the investment decision.

Step 1: Selection of the most economically reasonable investment alternative

Organizations have to decide between several investment alternatives for customer recovery. As such, the decision underlies the expected cash flow $E(CF_{ij}) \in \mathbb{R}_0^+$ of a customer relation i $(i = 1, \dots, n \; with \; n \in \mathbb{N})$ when successfully recovering it with a specific investment alternative j $(j = 1, \dots, m \; with \; m \in \mathbb{N})$. To calculate $E(CF_{ij})$, the present value of future cash inflows of a customer relation $\pi_i \in \mathbb{R}^+$, the investment costs $I_j \in \mathbb{R}^+$, and the effectiveness factor $\eta_{ij} \in (0; 1]$, which determine the success probability of a recovery investment, are necessary as they all influence the economic assessment of the investment alternatives. The domain of π_i is defined as $\mathbb{R}^+$, as only customers with positive cash flows are of interest. The domain of η_{ij} excludes the value 0, as we exclude investment alternatives for which customer recovery is impossible. Additionally, investments in customer relations with negative expected cash flows $E(CF_{ij})$ are not economically reasonable. Therefore, $E(CF_{ij})$ is only defined for $\pi_i \cdot \eta_{ij} - I_j \geq 0$. Hence, the calculations represented by equation 1 lead to the economically optimal investment alternatives J^*.

$$J_i^* = \{j \in (1, \dots, m); \forall k \in (1, \dots, m) \setminus \{j\} : \; E(CF_{ik}) \leq E(CF_{ij})\},$$
$$\text{with } E(CF_{ij}) = \pi_i \cdot \eta_{ij} - I_j, \tag{1}$$

where J_i^* represents the set of all indices j for which the expected cash flow $E(CF_{ij})$ of a customer relation i for a specific investment alternative j is maximal. In case of multiple resulting indices j, that is, indices j with the same expected cash flows, $E(CF_{ij})$, the decider should take the investment alternative j that is cheaper after normalization to effectiveness (e.g., if $J_i^* = \{1,2\}$ and $I_1 < I_2 \cdot \frac{\eta_{i1}}{\eta_{i2}}$, then decide for $j = 1$).

Step 2: Measuring the probability that a customer relation is "alive"

In the following, we use the model for assessing conditional probability of Schmittlein et al. [1] as a basis for estimating the probability that a customer relation i is "alive." According to Fader et al. [31], the model of Schmittlein et al. [1] shows an impressive predictive performance, its empirical validation is often presented, and there are several applications in different contexts, such as customer profitability, churn prediction, and customer base analysis [4, 18, 29, 32–35]. The conditional probability $P_i("alive"|Information) \in [0;1]$ depends on a customer's individual purchasing information [1]. This can be $Information = x, t_x, T$, where x is the number of transactions observed in the time interval $(0, T]$ and $t_x (0 < t_x \leq T)$ is the time of the last transaction [1]. That means that recency and frequency are sufficient statistics for an individual customer's purchasing behavior [18]. $P_i("alive"|Information)$ represents the actual probability that a customer relation i with an observed behavior is still "alive," which should be compared to the threshold in order to make an economically reasonable investment decision.

Step 3: Threshold derivation

As it is highly improbable to know for sure if a customer relation is "alive" or "dead," there is always the possibility that the organization comes to a "correct" or "wrong" investment decision for a customer relation i. Regarding "wrong" investment decisions, it is possible that organizations either unnecessarily invest in "alive" customer relations (see Table 1, case Ia) or do not invest in "dead" customer relations with positive expected cash flows in case of customer relation recovery (see Table 1, case Ib). By taking such "wrong" decisions, the organization either unnecessarily loses investment costs or cash inflows which might result from investment j. Accordingly, cases IIa and IIb represent "correct" decisions as long as $\pi_i \cdot \eta_{ij} \geq I_j$. Table 1 represents all possibilities of total expected cash flows depending on $P_i("alive"|Information)$ and the decisions to invest in customer relations or not.

Table 1. Matrix of the total expected cash flow

Decision	*"Dead"* $1 - P_i("alive"\|Information)$		*"Alive"* $P_i("alive"\|Information)$	
Investment	IIa	$\pi_i \cdot \eta_{ij} - I_j$	Ia	$\pi_i - I_j$
No investment	Ib	$-\pi_i \cdot \eta_{ij}$	IIb	π_i

The total expected cash flow of case Ia represents the present value of future cash inflows π_i resulting from a customer relation i minus the investment costs I_j of investment alternative j for investing in a customer relation (see equation 2). Here, the investment costs I_j arise unnecessarily.

$$E(CF_{ij})(investment \wedge "alive") = \pi_i - I_j. \tag{2}$$

In contrast, case Ib leads to a lost present value of future cash inflows $-\pi_i$ caused by not recovering a customer relation i. This lost present value of future cash inflows, which corresponds to opportunity costs, only comes into force to the extent to which the customer recovery investment would have been successful, which is represented by the effectiveness factor η_{ij}:

$$E(CF_{ij})(no\ investment \wedge "dead") = -\pi_i \cdot \eta_{ij}. \tag{3}$$

Given $\pi_i \cdot \eta_j \geq I_j$, investing in a “dead” customer relation and not investing in an “alive” one are correct decisions. Hence, case IIa entails the present value of future cash inflows of a customer relation π_i multiplied with the effectiveness factor η_{ij}, reduced by the costs of investment I_j:

$$E(CF_{ij})(investment \wedge "dead") = \pi_{\boldsymbol{i}} \cdot \eta_{ij} - I_j. \tag{4}$$

Case IIb represents not investing in an “alive” customer relation, which results in the present value of future cash inflows $\pi_{\boldsymbol{i}}$:

$$E(CF_{ij})(no\ investment \wedge "alive") = \pi_i. \tag{5}$$

Based on these mathematical terms, the threshold for an economic decision on whether to invest in a customer relation or not can be deduced. From an economic point of view, investing in a customer relation is only reasonable if the total expected cash flow in case of an investment for recovering a customer relation is higher than the total expected cash flow for not investing (see equation 6). The cases Ia, Ib, IIa, and IIb arise with the probabilities that a customer relation i is “alive,”$P_i("alive"|Information)$, or already “dead,” $1 - P_i("alive"|Information)$, as presented in Table 1. Equation 6 covers decisions under risk neutral preferences:

$$\begin{gathered} E(CF_{ij})(investment \wedge "alive") \cdot P_i("alive"|Information)\ + \\ E(CF_{ij})(investment \wedge "dead") \cdot (1 - P_i("alive"|Information))\ > \\ E(CF_{ij})(no\ investment \wedge "alive") \cdot P_i("alive"|Information) + \\ E(CF_{ij})(no\ investment \wedge "dead") \cdot (1 - P_i("alive"|Information)). \end{gathered} \tag{6}$$

After computing terms 2–5, we solve the inequality for $P_i("alive"|Information)$ (see equation 7), which results in the threshold $T_{ij} \in [0;1)$:

$$T_{ij} > P_i(\text{"}alive\text{"}|Information),$$

$$with\ T_{ij} = \frac{2\pi_i\eta_{ij} - I_j}{2\pi_i\eta_{ij}}. \tag{7}$$

The threshold enables making investment decisions in which the total expected cash flow in case of an investment is higher than the total expected cash flow for not investing in recovering a customer relation.

Step 4: Making the investment decision

To make the investment decision D_i for a customer relation i, the organization should now compare the probability that the customer relation is still "alive," $P_i(\text{"}alive\text{"}|Information)$, with the threshold T_{ij}:

$$D_i = \begin{cases} invest & for\ T_{ij} > P_i(\text{"}alive\text{"}|Information) \\ not\ invest & for\ T_{ij} \leq P_i(\text{"}alive\text{"}|Information) \end{cases}. \tag{8}$$

In summary, the four proposed steps lead to an economically reasonable decision on whether to invest in an individual customer relation's recovery or not by comparing the threshold to the current probability that a customer relation is "alive," as per equation 8.

4 Application and evaluation

We illustrate the applicability, completeness, understandability, feasibility, and operationality of the decision model by an example in which an online retailer aims at recovering possibly "dead" customer relations. At the same time, the online retailer wants to avoid unnecessarily investing in "alive" customer relations. By using our decision model, the online retailer addresses only those customer relations for which an investment is reasonable on the basis of the probability that they are "alive" compared to the calculated threshold. As such, we show the economic benefit of the decision model.

Step 1: Selection of the most economically reasonable investment alternative

At first, the online retailer has to identity different investment alternatives for customer recovery and select the most economically reasonable investment alternative for every customer relation i. In our example, the online retailer selects four possible investment alternatives j, that is, two different channels, letter and mail, and two different contents, voucher and special offer. According to the experience of the online retailer, customer recovery via letter is more effective than email, and a voucher is more effective than a special offer. Moreover, in this example, customer recovery with vouchers incurs more investment costs than special offers. Table 2 shows the effectiveness factor η_{ij} and the costs of the four investment alternatives I_j.

Table 2. η_{ij} and I_j for the investment alternatives

		Special offer via letter ($j = 1$)	*Voucher via letter* ($j = 2$)	*Special offer via email* ($j = 3$)	*Voucher via email* ($j = 4$)
η_{ij}	$i = 1$	0,09	0,05	0,17	0,08
	$i = 2$	0,08	0,06	0,08	0,17
	$i = 3$	0,06	0,19	0,08	0,15
I_j		USD 20	USD 30	USD 12	USD 22

To select the most economically reasonable investment alternatives for different customers according to Formula 1, we take the present values of future cash inflows π_i of three customers as example: $\pi_1 = USD\ 640$, $\pi_2 = USD\ 857$, and $\pi_3 = USD\ 428$. Table 3 shows the expected cash flows for each customer relation i and the four different investment alternatives j.

Table 3. $E(CF_{ij})$ for the customer relations and investment (USD)

		Investment alternatives			
		$j = 1$	$j = 2$	$j = 3$	$j = 4$
Customer Relations	$i = 1$	35.89	3.52	**97.07**	32.33
	$i = 2$	45.75	20.96	55.46	**126.67**
	$i = 3$	7.33	**52.06**	21.98	40.09

The results of Table 3 show that the most economically reasonable investment alternative for the customer relation $i = 1$ is $j = 3$, for $i = 2$ is $j = 4$, and for $i = 3$ is $j = 2$ (see bold marked values in Table 3), as these investment alternatives have the greatest expected cash flow for the different customers as per equation 1.

Step 2: Measuring the probability that a customer relation is "alive"

Next, the online retailer has to quantify the probability that a customer relation is still "alive," $P_i(\text{"}alive\text{"}|Information)$. For instance, the organization can follow Schmittlein and Peterson [32] and Reinartz and Kumar [4], who determine the probability depending on recency and transaction frequency. For example, we assume the following values for the three customers: $P_1(\text{"}alive\text{"}|Information) = 0.30$, $P_2(\text{"}alive\text{"}|Information) = 0.96$, and $P_3(\text{"}alive\text{"}|Information) = 0.23$.

Step 3: Calculation of the threshold

Further, the online retailer has to calculate the threshold for the customers and the selected investment alternative by using equation 7.

Table 4. Results of the threshold T_{ij}

	$J_1^* = 3$	$J_2^* = 4$	$J_3^* = 2$
T_{ij}	94.40%	92.60%	81.72%

Step 4: Making the investment decision

The application of equation 8 shows whether the online retailer should invest in the customer relations or not by comparing the threshold T_{ij} with the probability that the customer relation i is still "alive," $P_i("alive"|Information)$.

Table 5. Investment decision for the customer relations i

			D_i
$i = 1$	T_{13}	94.40%	invest
	$P_1("alive"\|Information)$	30.00%	
$i = 2$	T_{24}	92.60%	not invest
	$P_2("alive"\|Information)$	96.00%	
$i = 3$	T_{32}	81.72%	invest
	$P_3("alive"\|Information)$	23.00%	

Table 5 shows that the online retailer should invest in customer relation $i = 1$ and $i = 3$ because the results of the threshold T_{13} and T_{32} are greater than $P_1("alive"|Information)$ and $P_3("alive"|Information)$, respectively. For customer relation $i = 2$ the investment decision is not to invest, as T_{24} is less than $P_2("alive"|Information)$.

Next, we explain why the evaluation criteria is fulfilled. First, applicability is shown by conducting this example calculation. Further, this evaluation type demonstrates the decision model's completeness as all input variables are comprehensive and quantitative measures. The evaluation criterion understandability is shown as the actual measure is easy to interpret and applicable for users. Feasibility and operationality is given as the parameters are determinable, well defined, and the decision model is based on a quantitative measurement. Additionally, the data necessary for the model calculation are accessible and affordable, as the number of transactions or the time of the last transaction usually exist in organizations. In order to evaluate the decision model from an economic perspective, we extend the sample calculation and instantiate the decision model with 10,000 customer relations that have equally distributed probabilities of being "alive" in an interval of 0–100% and equally distributed expected cash flows in an interval of USD 0–1,000. The effectiveness factors of the investment alternatives are equally distributed in an interval of 0–20%. In this sample calculation, we use the parameter setting of the four investment alternatives listed in Table 2. In case of a perfect estimation of the probabilities that customer relations are still “alive,” $P_i("alive"|Information)$, the sample calculation reveals that about 25% of individual recovery investments can be saved, which leads to significant cost savings by applying the decision model. As shown in Table 6, a sensitivity analysis suggests that – on the one hand – estimation errors of expected cash flows and effectiveness factors only lead to disproportionately low changes in cost savings. That is, the model can said to be robust in terms of these parameters.

Table 6. *Impacts of estimation errors on cost savings*

Parameter estimation error	***-20%***	***-15%***	***-10%***	***-5%***	***0%***	***+5%***	***+10%***	***+15%***	***+20%***
$\boldsymbol{\eta_{ij}}$	+1%	0%	0%	0%	0%	-1%	-1%	-2%	-2%
$\boldsymbol{E(CF_{ij})}$	+6%	+5%	+3%	+1%	0%	-2%	-4%	-6%	-7%
$\boldsymbol{P_i("alive"|Inf.)}$	-82%	-71%	-56%	-29%	0%	+25%	+48%	+72%	+92%

On the other hand, the sensitivity analysis exposes that $P_i("alive"|Information)$ has to be estimated carefully, as estimation errors lead to disproportionately high changes in cost savings. However, even for poorer estimations, savings on a low percentage basis can be generated, that easily be significant in monetary terms for large customer recovery investments.

5 Summary and Discussion

In this paper, we point out that, for customer recovery, distinguishing between “alive” and “dead” customer relations becomes a challenge with the increase in market transparency and impersonality. Therefore, organizations risk wrong investment decisions when managing customer recovery. Addressing this challenge, literature offers solutions to determine the economic value of a customer relation as a basis for this decision. However, to the best of our knowledge, no approach considers the probability that a customer relation is “alive” for such investment decisions. Therefore, we combine these ideas in a formal decision model for deciding on customer recovery in an economically reasonable manner by considering the probability that a customer relation is “dead.” In doing so, we strive for practical applicability and demonstrate the decision model’s operationalization in an illustrative example.

Nevertheless, our decision model has limitations that stimulate further research. First, further research should examine the decision model in a real world context in order to evaluate its usefulness [36]. However, we can evaluate the decision model in terms of its applicability, completeness, understandability, feasibility, and operationality by using an example. In doing so, we follow Sonnenberg and Vom Brocke [36], and argue that it is reasonable to disseminate research findings in early stages to communicate them to interested peers and research communities. Second, the decision model is designed to cover a single period. In practice, in order to permanently ensure maximum of customer recovery, periodical assessments could be a possible extension of the decision model. Third, in the decision model it is assumed that the organization's decision regarding customer recovery investments is risk neutral. In reality, risk attitude can be context and branch specific, which should be further examined in future research. Fourth, future research can unfold the range between the attributes "dead" and "alive" to further approach the decision model for context- and industry-specific dependencies due to individual stages in the customer lifecycle. Finally, we assume that investing in an "alive" customer relation is not reasonable in terms of a recovery effect. In reality, recovery investments could also increase the satisfaction of "alive" customer relations.

However, besides these limitations and the identified need for further investigation, we consider the presented approach to be a valuable contribution to research and practice in order to enable data-driven recovery investment decisions. Accordingly, whether to invest in recovering a customer relation can be decided on the basis of a substantiated formal decision model. Moreover, by using digitally available customer data in the proposed decision model, organizations have the possibility to better meet digitization challenges in customer recovery.

Understanding Consumer Behavior in Electronic Commerce with Image Sentiment

Christof Naumzik[1], Stefan Feuerriegel[1], and Dirk Neumann[2]

[1] University of Freiburg, Freiburg, Germany
{christof.naumzik,stefan.feuerriegel,dirk.neumann}@is.uni-freiburg.de

1 Introduction

Customers in electronic commerce translate available information into buying decisions based on needs and behavioural tendencies. For this purpose, shopping sites provide detailed information on products and services ranging from simple figures (e.g., dimensions) to textual descriptions, user-generated reviews and visual images. All of the aforementioned sources of information may have a substantial impact on the decision-making of customers.However, little is known about the ways in which visual information is processed and used in decision-making. As a remedy, this research seeks to shed light on the informativeness of visual content in electronic commerce. This objective represents a highly relevant area of research, since visual information plays a major role in determining price, choice and thus willingness to buy (see [1], [2]). Unfortunately, such an undertaking is challenging as we are not aware of any existing methods for measuring the degree of informativeness of images. The main focus of visual sentiment analysis has been on the classification of the sentiment of images stemming from a fairly heterogeneous set. In contrast, we aim to build a model addressing a somewhat homogeneous set of images. In our case, we use photographs from real estate listings in order to predict the rent price. As an immediate implication, our findings show operators of e-commerce or recommender systems how to optimize the presentation of their products and services.

2 Dataset

In our paper, we demonstrate the added value of visual cues in electronic commerce. More precisely, we investigate how images in apartment listings can work as a predictor of the corresponding rent price. For that purpose, we utilize the data as follows: our dataset consists of 2,500 apartment listings for the Boston area, which we collected from Craigslist1 in June 2016. For each listing, we retrieved both the monthly rent and the size of the apartment, as well as the first picture shown on the webpage.

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Naumzik, C.; Feuerriegel, S.; Neumann, D. (2017): Understanding Consumer Behavior in Electronic Commerce with Image Sentiment, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1264-1266

3 Method Development

Figure 1 illustrates our research framework. We train different machine learning models to predict rent prices based merely on the image content. We chose to utilize both a Support Vector Regression (SVR) and a Random Forest (RF), as these models are already suitable for smaller datasets and allow for comparatively fast computation. To evaluate the predictive performance of our proposed method, we randomly partition our dataset into two subsets, a training set of 1800 and a test set of the remaining 700 listings.

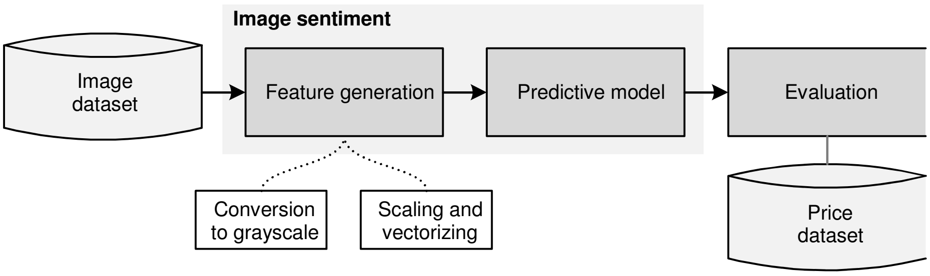

Figure 1. Research framework shows the steps of preprocessing for feature generation and the subsequent predictive model in order to calculate a sentiment metric for images.

4 Empirical Findings

The research framework shows the steps of preprocessing for feature generation and the subsequent predictive model used to calculate a sentiment metric for images. In table 1, we present the results from our predictive approach in comparison to our benchmark. We note that the SVR, as well as the Random Forest model, outperforms the benchmark by a substantial margin for both RMSE and MAE. The best results are obtained in the case of the random forest model, with improved prediction accuracy in terms of RMSE and MAE of 50.81% and 62.96 %, respectively. To provide a statistical underpinning for our results, we also performed a Diebold-Mariano test.

5 Contribution and Implications

This research paper contributes to our understanding of human behaviour in electronic commerce as well as, for instance, recommender systems. We propose an innovative approach to scoring the polarity of an image in a computerized fashion and introduce the concept of image sentiment, which refers to the positive or negative characteristics of the object in the image. In contrast to previous research, we avoid judgment as to whether humans perceive the object itself in a positive or negative manner. Instead, we suggest a sentiment measure that ranks images depicting the same object on a continuous scale from a low to a high appraisal.

We have implemented a predictive approach to forecast the price of objects on the basis of their product image. The above case study demonstrates that our predictions can considerably outperform a naïve baseline. This approach can be a viable extension to existing models that describe real estate prices, since the image sentiment is likely to make up for a substantial portion of the error term.

Overall, our research suggests numerous new applications, each of which can yield an immediate impact for professionals. Operators of e-commerce or recommender systems can leverage our method to optimize the presentation of their products and services. Such advances reveal the potential benefits and insights that can be derived from unstructured information.

Table 1. A validation set is used to assess the performance of our trained models. We compare these in terms of (1) RMSE and (2) MAE with the price per square foot in our validation set. Furthermore, we apply a Diebold-Mariano (DM) test to the trained models and the sample mean to test for the same forecasting accuracy.

Method	**RMSE**	**MAE**	**DM test** (test statistic)	**DM test** (p-value)
Benchmark				
Sample mean	1.1159	0.8549	—	—

Over-Paid Search: When Bricks-and-Mortar Retailers Should Not Use Paid Search

Darius Schlangenotto[1], Dennis Kundisch[1]

[1] Paderborn University, Faculty of Business Administration and Economics, Paderborn, Germany
{Darius.Schlangenotto,Dennis.Kundisch}@uni-paderborn.de

Abstract. Current research on paid search highlights its ability to enhance online as well as offline sales but is limited to pure online players and multi-channel firms. This paper presents a controlled field experiment which investigates whether paid search can increase sales for bricks-and-mortar retailers who solely sell their products via local stores and rely on informational websites to reach their customers. Results suggest that paid search increases the number of potential customers by enhancing the reach of online marketing initiatives. Yet, using a difference-in-differences analysis, our findings show that paid search fails to increase offline sales. Local store customers primarily use paid search as a navigational shortcut to the chain's website which they would have reached even without being exposed to paid search. Consequently, bricks-and-mortar retailers should approach paid search cautiously: whilst it can enhance the reach of marketing initiatives, it seems to have little effect on improving offline purchases.

Keywords: paid search, cross-channel behavior, substitution effects, field experiment, bricks-and-mortar

1 Motivation and Research Question

In this paper we investigate the question of whether paid searches are able to increase sales in local stores. Today, paid search – the mechanism of placing online ads in response to user search queries on search engine result pages (SERP) – is already the main source of Internet advertising revenue and expected to grow by 10% annually over the next four years [1].

As an emerging technology, paid search has spawned numerous new avenues for research especially in the fields of Information Systems and Marketing [2]. The current literature comprises, on the one hand, analytical studies, which focus on the paid search market as a whole and, on the other, empirical studies, which address the benefits of paid search for advertisers [3]. In the empirical stream of literature scholars either studied long-term effects of paid search such as brand perception [4] or short-term effects such as click-behavior of paid search users [5]. Investigating short-term effects, several studies focus on whether paid search has been able to increase online sales, so-called *own-channel effects*. The current body of literature suggests that paid search can be seen as a well suited mechanism to increase the reach of marketing campaigns [6]

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Schlangenotto, D.; Kundisch, D. (2017): Over-Paid Search: When Bricks-and-Mortar Retailers Should Not Use Paid Search, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1267-1270

and enhance online sales [7]. Up to now only a few studies [8] investigated the impact of paid search on offline sales, or so-called *cross-channel effects*. Early results suggest that paid search has the potential of enhancing offline purchases due to consumers' tendency to undertake online research prior to shopping in stores, so-called *research-shopping* [9]. However, current research on the cross-channel effects of paid search has so far only investigated the case of multi-channel firms that offer both online and offline shopping. In contrast, we are interested in finding out whether paid search initiatives could also benefit bricks-and-mortar chains that solely sell in-store and rely on their websites to promote their offerings. If paid search could be shown to have a positive effect on local store purchases, then bricks-and-mortar firms ought to consider investing in paid search in order to increase the reach of their marketing campaigns. With our study we intend to contribute to the current body of literature on paid search by analyzing the benefits of paid search for bricks-and-mortar firms. Hence, we pose the research question: *Do paid search campaigns pay off for bricks-and-mortar retailers?*

2 Methodology

To answer our research question we teamed up with a well-known bricks-and-mortar business-to-consumer (B2C) furniture retailer operating in Germany. The chain's website is primarily used to advertise the products sold in their six local stores. To quantify the cross-channel effect induced by paid search, one needs to address the endogeneity of marketing campaigns [10] as well as limited tracking possibilities between the online and the offline environment. To cope with both problems, in 2015 we conducted a field experiment applying a matched subject design while isolating the cross-channel effect of paid search using a trackable coupon. To identify the causal impact of paid search, we crafted an advertising campaign with Google AdWords in combination with geo-targeting [11] to ensure an appropriate experimental design setting. Throughout the experiment customers in the treatment regions were exposed to paid ads as opposed to customers belonging to the control regions who were not exposed to any paid ads. Based on 85,649 website visits we performed difference-in-differences analyses [12] to estimate paid search impact on user behavior in the online as well as the offline environment.

3 Results

Experimental results suggest that consumers tend to perform research-shopping by using the Internet as a search channel and the local store as a purchase channel. Yet, contrary to current literature [8], [13], our experiment reveals that at least in our case paid search fails to increase the number of cross-channel shoppers. In line with Blake et al. [6] who performed a similar experiment in a pure online environment, we argue that for a well-known bricks-and-mortar chain paid search is partly used by consumers as a navigational shortcut to the advertisers' website, and that cross-channel shopping is primarily performed by these customers. In our study, a paid search campaign is shown to increase the reach of online marketing initiatives, exposing additional customers to the offers, but these additional customers do not engage in cross-channel shopping. In other words, cross-channel shopping is primarily performed by customers who would have been exposed to the offers anyhow, without the firm's investment in paid search. With paid search shown as failing to increase sales, we are able to provide first evidence that it might has no direct sales impact for pure offline retailers.

For managers of bricks-and-mortar firms our study offers various practical implications. First, consumers do perform research-shopping and show cross-channel behavior by using an online coupon for offline purchases. This suggests that online offers might indeed increase local store sales. Second, paid search is able to broaden the reach of marketing campaigns as additional potential customers become aware of the chain's offerings. However, our results suggest that managers who mainly want to increase offline sales should approach an investment in paid search carefully. At least in our case paid search only serves as a costly substitute used by customers who would have performed cross-channel shopping even without being exposed to those ads.

Architecture and Evaluation Design of a Prototypical Serious Game for Business Information Visualization

Christian Karl Grund[1], Michael Schelkle[1], Max Hurm[1]

[1]University of Augsburg, Faculty of Business and Economics, Augsburg, Germany
{christian.grund,michael.schelkle}@wiwi.uni-augsburg.de

Abstract. Poorly visualized business reports may lead to wrong decisions caused by incomprehensible or misleading data. However, many companies still do not strive for adequate business information visualization (BIV), which may be due to a lack of knowledge about how to achieve it. To support managers in avoiding the pitfalls of incomprehensible reports, we are currently developing a serious game that helps players to learn about guidelines for adequate BIV. In this so-called "Dashboard Tournament", players compete across several minigames that address specific BIV guidelines. The aim of this paper is to provide an understanding of the prototype's architecture and to propose an experimental design for its evaluation. Researchers and practitioners may hence increase their understanding of how to design and evaluate serious games in the domain of business and information systems engineering.

Keywords: Serious Games, Business Information Visualization, Game-based Learning, Prototype.

1 Introduction

Poorly visualized business reports may lead to wrong decisions due to incomprehensible or misleading data [1]. Despite these threats, many companies still do not strive for proper business information visualization (BIV) [2]. One explanation for this is the lack of knowledge about adequate BIV practices and guidelines [3]. Experiential learning might be a way to sustainably increase this knowledge and therefore improve the way reports are designed [4]. Serious games are one form of experiential learning that has been used for decades to successfully convey business-related content by engaging players [5]. However, despite the plethora of different serious games described in literature, BIV has thus far not been a dedicated aspect of them [6, 7]. To fill this gap, we are developing a serious game called "Dashboard Tournament" that aims to increase BIV capabilities among players by letting them compete across several minigames [7]. Each minigame confronts players with insufficient BIV like pie charts, traffic lights, or crowded tables in reports. After describing the concept of the game in prior research [7], we aim to present its architecture and propose an experimental design for its evaluation in this paper. This may provide researches and practitioners with insights about how to develop and evaluate serious games in the domain of management reporting.

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Grund, C.K.; Schelkle, M.; Hurm, M. (2017): Architecture and Evaluation Design of a Prototypical Serious Game for Business Information Visualization, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1271-1274

2 Theoretical Background and Development Method

Since serious games are concerned with improving player capabilities as well as providing an entertaining experience [8], both learning and motivation theories are used in literature to explain the benefits of serious games [9]. For instance, they are often described as a form of experiential learning [4]. To explain the motivational effects of our game, we draw on self-determination theory [10]. According to this theory, video games in general foster intrinsic motivation by enabling perceived competence, autonomy, and relatedness [11]. We hence also expect to increase intrinsic motivation with our game by satisfying these needs. Perceived competence may be fostered by players succeeding in the different minigames and earning points for doing so. Relatedness may be achieved by letting players compete in the same room and using leaderboards that allow comparisons with other players. Last, a sense of autonomy may be achieved by players being able to choose their own approaches of how to succeed in the minigames. To develop the Dashboard Tournament, we employ the human-centred design process [7]. In the following, we describe the architecture of an evolutionary prototype that resulted from the first iteration of this development process.

3 Architecture of the Dashboard Tournament

The prototype of the Dashboard Tournament currently features a singleplayer mode that comprises four minigames [7]. To implement the prototype, we used the game engine Unity with C# as the programming language. An overview of the game's architecture is provided in Figure 1.

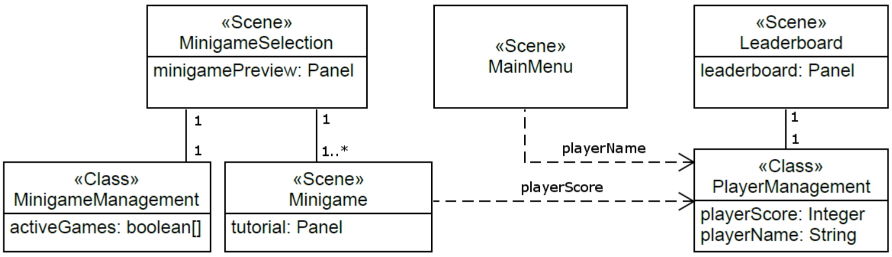

Figure 1. Architecture of the Dashboard Tournament

The game comprises different scenes (i.e., screens that players will access during the course of the game), classes that store the data necessary for the scenes to operate as well as several panels (i.e., graphical elements inside the scenes). First, players enter the main menu ("MainMenu") where they can enter their nicknames, which will be stored in the "PlayerManagement" class. Afterwards, a scene where the next minigame gets selected at random ("MinigameSelection") is shown. The different minigames are represented as "minigamePreview" panels in this scene. After the minigame that has to be played is selected, players access the respective scene for that minigame ("Minigame"). Each minigame features a tutorial panel that provides players with information regarding the objective of the current minigame and how to play it. When the minigame is finished, scores are saved in the "PlayerManagement" class and players enter a scene for displaying leaderboards ("Leaderboard"). Here they will find their score on a leaderboard panel. Afterwards, they return to the scene "MinigameSelection" as long as there are minigames left to be played. This information is stored in the "MinigameManagement" class. Although gameplay data is currently only available at runtime, a log file is going to be available on the server in later versions of the game for analysis purposes. Due to the prototype's component-based architecture, minigames may be added or removed in future iterations of the development process. In addition, multiplayer functionality will be added by defining one instance of the game as a host that selects minigames and keeps all clients synchronized.

4 Evaluation of the Prototype and Conclusion

To evaluate the game after its development will be finished (i.e., multiplayer functionality is added), we plan to conduct a laboratory experiment using a multivariate 1x3 between-group design (see Table 1). Power analysis revealed that for statistically significant results ($d = 0.8; \alpha = 0.05; 1 - \beta = 0.95$), each group should consist of 35 participants who are randomly assigned from a pool of students in business and economics programs (i.e., prospective managers and report designers).

Table 1. Experimental Design of the Evaluation

Group	Pretest	Treatment	Post-Experience	Posttest
1	Suggestions	Competition	Intrinsic Motivation	Suggestions
2	Suggestions	Singleplayer	Intrinsic Motivation	Suggestions
3	Suggestions	Presentation	Intrinsic Motivation	Suggestions

The treatments differ in how they aim to increase BIV capabilities. In the first treatment, participants play the Dashboard Tournament in a competition. The second treatment uses a modified version of the game, where there is no competition at all. This condition is used to isolate the effect of providing a competition: If the singleplayer version leads to the same benefits, the game may be easier to use in practice, since it would not require several managers to attend the same session. Last, there is a treatment with only a presentation about BIV guidelines, serving as a control group. To assess the motivational benefits of the game, we conduct post-experience questionnaires regarding perceived competence, autonomy, and relatedness as well as intrinsic motivation of participants by using the intrinsic motivation inventory [12]. To assess learning outcomes, pre- and posttests are going to address participants' BIV capabilities. For this purpose, participants are provided with different examples of business reports and are requested to suggest improvements. The provided reports suffer from inadequate BIV that is addressed by the guidelines covered in the different treatments. We can hence check whether improvements suggested by participants comply with the BIV guidelines. The pretests also help in determining prior knowledge of participants (e.g., courses or practical experience).

By comparing the post-experience questionnaires of all treatments, we may investigate whether playing the game leads to increased motivation compared to hearing a presentation. To examine the effect of setting up a competition, we may look for differences in motivation between providing a competition between players and simply playing the minigames (first and second treatment). We may also compare the learning outcomes in all treatments to see whether participants who play the game actually show increased BIV capabilities compared to participants only hearing a presentation. Last, we intend to examine correlations between motivation and learning outcomes.

In summary, this evaluation may show that the Dashboard Tournament leads to increased motivation as well as increased learning outcomes. This may encourage both researchers and practitioners to consider using serious games in the domain of management reporting. Since our approach appears to be the first serious game about BIV guidelines [6, 7], we intend to investigate its usage in this domain in future research. Especially the importance and effects of competition can be examined in further studies. By describing an architecture as well as proposing an evaluation of our game, we also aim to support building and evaluating these games.

Abstract. The widespread diffusion of electric vehicles (EVs) suffers from the lack of a well-developed public charging infrastructure, which currently is uneconomical to develop for investors. Many owners of EVs have private charging stations at their premises, which yield unlockable potential due to high idling times. In line with sharing platforms for other goods like accommodations and cars, we present the design, prototypical implementation, and evaluation setting of *CrowdStrom*, a peer-to-peer sharing service for charging EVs that networks individuals, their charging stations, and charging service customers.

Keywords: Electric Vehicle, Charging Infrastructure, Peer-to-Peer, Sharing, Design Science Research

1 Infrastructures for Electric Vehicle Charging

Clean, carbon-neutral transportation, fueled by electricity generated from renewable sources has been on governments' agendas for years. Central to these ambitious development plans is the potentially widespread diffusion of electric vehicles (EVs) [1]. While the German government, which is pursuing a target of one million registered EVs in Germany by 2020 [2], provides financial incentives for EV-buyers, registrations remain low with little more than 50,000 EVs registered by the end of 2015 [2]. In a circular pattern, customer adoption of EVs has been hampered by the lack of a well-developed public charging infrastructure [1], and the resulting limited demand for EVs deters investors from developing these infrastructures. Many owners of EVs have private charging stations at their premises, which yield unlockable potential due to high idling times. Peer-to-Peer (P2P) sharing has been proposed as way to increase the availability and use of existing resources by granting public access to individually owned resources [3]. P2P sharing facilitates IT-enabled economic transactions between individuals, where only temporary access to a physical resource is granted by a resource owner to others who need it in exchange for a monetary consideration [4]. The shift in

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Betzing, J. H.; von Hoffen, M.; Plenter, F.; Chasin, F.; Matzner, M.; Becker, J. (2017): One Plug at a Time - Designing a Peer-to-Peer Sharing Service for Charging Electric Vehicles, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1275-1278

consumer attitude from preferring ownership of a resource to preferring access to it has fueled the rise of IT-enabled P2P sharing services in domains such as transportation (e.g. *BlaBlaCar*) and accommodation (e.g. *Airbnb*) [3]. The central component of such services is a Web platform that brings together peer-providers and peer-consumers and that provides a framework for handling business transactions [5].

Against this background, we adopt the P2P sharing paradigm to enable individuals and businesses to share their private charging stations with other EV-drivers.

The remainder of the paper is structured as follows: section two sketches the research approach and the activities conducted in the course of the CrowdStrom project. Section three introduces the business model and the CrowdStrom platform, while the fourth section closes with the discussion of a comprehensive evaluation setting.

2 Research Approach

We adopt the Design Science Research (DSR) paradigm [6] to develop a business model and an instantiation of a P2P service for sharing EV-charging stations within a joint industry-and-academia consortium. In line with research guidelines on DSR [6], our work follows the cyclic process of the DSR Methodology (Figure 1).

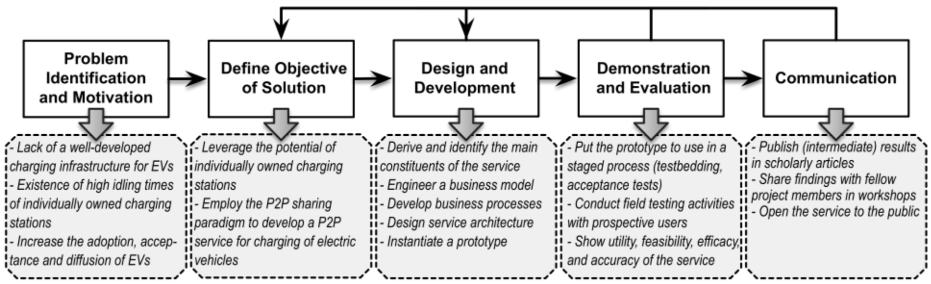

Figure 1. Overview of the DSR phases adopted for the CrowdStrom project

After identifying the mentioned societal problem, we further developed and communicated the project's objectives in multiple design cycles [7]. During the design and development phase, we addressed different issues of the EV-charging challenge ranging from customer-related (acceptance, willingness-to-pay), provider-related (incentives, organizational development), and legal aspects (energy provision, taxation) to service design (procedural/ technical design principles) [4]. We will subsequently conduct a comprehensive evaluation to advance the prototype into a mature solution.

3 The CrowdStrom Business Model and Prototype

The CrowdStrom service networks individuals and businesses that provide charging stations (peer-providers), and EV-drivers that require charging (peer-customers). Additionally, a service operator acts as intermediary that runs the central Web platform, handles transactions, and provides support services in return for a share of the revenue. The roles of the peer-provider and peer-customer are not mutually exclusive, i.e., users may both provide charging stations and use the ones of other users. Peer-providers connect their charging stations to the platform and define hourly prices according to location and power output. While the service is not intended to generate large revenue for peer-providers, it reduces the total cost of ownership of their already existing and individually bought charging stations. Furthermore, we identified a strong solidarity within EV-drivers and societal aspects to positive influence peers to become providers [7]. Peer-customers register at the service and then use the Web platform to search for and possibly reserve charging stations nearby. Additional filters for distance, price, charge rates [kW/h], plug types, green power, and customer ratings may also be applied to the search process. Peer-customers authenticate themselves at the charging station by means of RFID cards, text messages or the Web front-end. Charging sessions are recorded and fed back to the platform, so both providers and customers can have dashboards that transparently reflect their service usage (charging sessions, total energy transferred, current balance, invoices) and to facilitate an automated billing process that settles balances monthly.

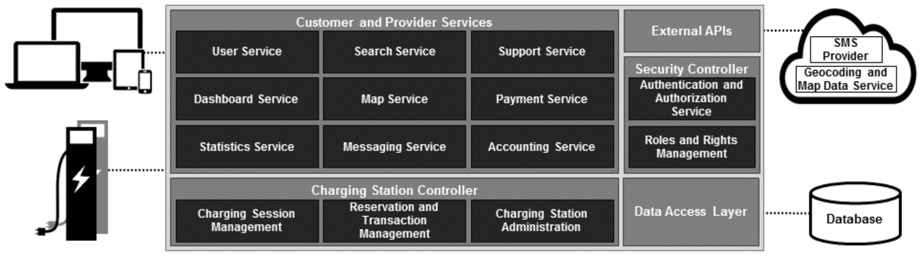

Figure 2. CrowdStrom Platform Components and Services Architecture

Figure 2 depicts the implemented solution design of the prototypical CrowdStrom platform. We leverage state-of-the-art open-source technologies (e.g. *AngularJS, Materialize*) for the responsive Web front-end and the server back-end (e.g. *Java EE, MySQL*). The charging station controller handles communication between charging stations and the platform, using the de facto standard *OCPP*. We rely on third-party providers for geocoding, cartographic material, and SMS handling. A central security service manages user authentication and authorization based on privileges and roles. Depending on the user's role, a range of functions and services is offered.

4 Evaluation and Outlook

VENABLE et al. define four evaluation strategies for DSR projects [8], from which we selected the *Human Risk & Effectiveness* strategy, as it focusses on socio-technical aspects of the service and on its real-world application. In earlier design cycles, we iteratively improved CrowdStrom's business model, processes, and service delivery mechanisms by conducting artificial formative evaluations in form of expert interviews, simulated experiments, and workshops with domain experts and technicians from our partnering local utility. For the final evaluation, we will conduct a naturalistic summative evaluation [8] in which we rigorously evaluate the validity and effectiveness of the prototype and its underlying design to ensure their utility in the real-world environment they were designed for. We will conduct two field tests for which we invite potential users to become peer-providers or peer-customers to gain insights regarding both roles.

For the first field test, we provide participants with a charging station to set up at their premises and connect to CrowdStrom in order to experience being a peer-provider for one day. During the course of the test, project members will mimic customers and perform charging sessions. Afterwards, we conduct semi-structured interviews with the participants to understand their experiences regarding the setup process, functionalities of the prototype, financial prospects, and interaction with test customers.

For the second field test, we scheduled 30 participants to perform a one-hour long test drive in an EV that entails comprehensive use of the CrowdStrom platform, i.e., search for a charging station, reserve it, visit it, and conduct a charging session. To assess the perceived ease-of-use of the solution, participants will answer semi-structured interviews. In addition, their interaction with the prototype will be screen-captured and monitored. Since both field tests will be very resource intensive (fleet of EVs, charging stations, personnel) the number of participants, especially on the provider side, will be rather small. Nevertheless, by closely monitoring and surveying the participants, we are sure to receive fruitful evaluation results that will help to improve CrowdStrom, reduce uncertainties about social and use issues, validate the ability of the design to solve the initially identified problems, and inform the launch of the platform.

Abstract. Eco-Driving Feedback Informationssysteme haben das Potenzial, auf sehr rasche und effiziente Weise zur Reduktion von Spritverbrauch und CO2 im Strassentransportwesen beizutragen. Vor allem neuere vernetzte Fahrzeuge bieten durch die zunehmende Digitalisierung der Cockpits viel Freiraum zur Gestaltung und Untersuchung von Eco-Driving Feedback. Neben klassischen „Spritverbrauchs-Tachos" findet man heutzutage auch eher abstrakte Formen der Informationsdarbietung, z.B. animierte Pflanzen, die in Abhängigkeit vom Spritverbrauch wachsen oder schrumpfen. Diese Möglichkeiten werfen wichtige Fragen auf: Welche Art der Informationsdarbietung ändert das Fahrverhalten kurzfristig und langfristig effektiver? Welche Fahrverhaltensweisen (z.B. Bremsverhalten) werden in welchem Masse beeinflusst? Hängen eventuelle Effekte von bestimmten Moderatoren ab? Um diese Fragen zu untersuchen, wurde ein Eco-Driving Feedback System entwickelt, welches den Spritverbrauch des Fahrzeugs auf klassisch „konkrete" Art einerseits und auf eher abstrakte Art andererseits anzeigt. Die Auswirkungen auf Fahrverhalten und Spritverbrauch sollen in einem Feldexperiment unter Alltagsbedingungen mit 72 Pannenservice-Fahrern untersucht werden.

Keywords: Eco-Driving, Persuasive Technology, Feedback.

1 Einleitung und Forschungsfragen

Die Möglichkeit, Personen und Güter über Strassen zu transportieren, war und ist ein entscheidender Faktor für Aufbau und Wahrung von Wohlstand und individueller Mobilität unserer heutigen Gesellschaft, geht jedoch auch mit substantiellen negativen Externalitäten einher: 2010 gingen nach OECD Angaben 17% des weltweiten CO_2-Ausstosses auf den Strassenverkehr zurück [1]. Als Reaktion darauf verschärfen viele Staaten ihre Regularien zum CO_2-Ausstoss für Fahrzeuge. Entsprechende Verbesserungen der Technik durch die Fahrzeughersteller sind jedoch sehr teuer und langwierig [2]. Als kosteneffizienter und schneller einsetzbar gilt es daher, das Fahrverhalten der Fahrzeugnutzer selbst zu adressieren. Eine spritsparende Fahrweise kann den Verbrauch und CO_2-Ausstoss schlagartig um bis zu 30% reduzieren [3]. Um

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Dahlinger, A.; Wortmann, F.; Tiefenbeck, V.; Ryder, B.; Gahr, B. (2017): Feldexperiment zur Wirksamkeit von konkretem vs. abstraktem Eco-Driving Feedback, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1279-1282

Fahrzeuglenker zu einem spritsparenderen Fahrverhalten zu bewegen, hat sich in Untersuchungen zumeist Echtzeit-Feedback, also die zielgerichtete Rückmeldung über verhaltensrelevante Informationen in der Situation, als die effektivste Interventionsmethode herausgestellt [4]. Aufgrund ihrer Möglichkeiten zur Informationsverarbeitung und -Darbietung bieten sich Informationssysteme (IS) optimal zur Gestaltung von derartigem Feedback zur Verhaltensintervention an [5]. Sie sind entsprechend auch schon seit Jahrzehnten in Auto-Cockpits zu finden (Abbildung 1a), wo sich derzeit jedoch ein fundamentaler Wandel ereignet.

Digitale Instrumentenanzeigen finden zusehends Einzug in heutige Fahrzeugcockpits [6]. Fahrzeughersteller nutzen diese Möglichkeiten bereits zur Implementierung unterschiedlicher Eco-Driving-Feedback-Informationssysteme (EDFIS). Besonders auffällig dabei ist, dass sich vor allem der Grad der Abstraktheit der dargebotenen Information unterscheiden kann. Einerseits finden sich EDFIS mit hohem Detailgrad und einer Fülle an Informationen zu Eco-Driving-relevanten Faktoren (z.B. Brems- und Beschleunigungsverhalten, siehe Abbildung 1b). Das andere Extrem bilden EDFIS, welche statt konkreter Zahlen abstrakte Repräsentationen der relevanten Information darbieten. Statt dem Spritverbrauch in Litern pro 100 Kilometern (l/100km) sieht der Nutzer dann zum Beispiel eine Pflanze, die gedeiht oder verwelkt in Abhängigkeit vom Spritverbrauch (Abbildung 1c).

Obwohl Fahrzeughersteller EDFIS seit Jahrzehnten anbieten, finden sich in der Literatur zu EDFIS folgende Forschungslücken: (1) Es finden sich kaum belastbare Untersuchungen zur Wirkung von EDFIS auf Spritverbrauch mit sauberen Forschungsdesigns [7]. (2) Ebenso fehlen trotz aktueller Relevanz Forschungsergebnisse zur Frage, welche Rolle unterschiedliche Designfaktoren für die Wirksamkeit von Feedback-IS spielen [8]. Forschung zur Construal-Level Theory deutet darauf hin, dass abstraktes zusätzliches Potential zur Förderung von spritsparendem Verhaltens bietet [9]. Um diese Forschungslücken zu schliessen, soll im Folgenden ein Prototyp eines EDFIS vorgestellt werden, welcher Feedback in „konkreter“ und in „abstrakter“ Art darstellen kann und mit dessen Hilfe in einem gross angelegten Feldexperiment folgende Forschungsfragen verfolgt werden: (1) Reduziert ein EDFIS den Spritverbrauch bei Pannenhilfefahrern? (2) Ist abstraktes Feedback wirksamer als konkretes?

(a) (b) (c)

Abbildung 1. Unterschiedliche EDFIS: (a) klassische Spritverbrauchsanzeige im BMW 7, Bj. 1982; (b) modernes EDFIS in Jaguar Land Rover Modellen mit detaillierter konkreter Information; (c) modernes abstraktes EDFIS der Ford SmartGauge mit animierter Pflanze

2 Beschreibung des EDFIS Prototyps und der Stimuli

Der verwendete EDFIS-Prototyp bestehet aus einem On-Board-Diagnostics (OBD2) Dongle, einem Smartphone mit App und einem Backend-Server. Der OBD2-Dongle wurde derart konfiguriert, dass er Fahrzeug-CAN-Bus-Daten mit einer Frequenz von 1-30Hz auslesen kann. Diese Daten werden über Bluetooth an das Smartphone gesendet, welches relevante Informationen über eine eigens entwickelte App dem Fahrer visuell darbietet und sie gleichzeitig über eine GSM-Verbindung, angereichert mit Smartphonedaten (z.B. GPS-Position, Uhrzeit), an ein Backend schickt, wo alle Daten verarbeitet und gespeichert werden.

Um die dargestellten Forschungsziele zu erreichen, wurden drei Feedback-Screens entwickelt, um die jeweilige Auswirkung auf das Fahrverhalten im Feldexperiment gegeneinander testen zu können. (1) Der „Eco-Baum"-Screen spiegelt den Spritverbrauch auf abstrakte Art wieder, indem ein Baum angezeigt wird, welcher in Abhängigkeit vom Spritverbrauch wächst bzw. schrumpft (Abbildung 2a). Als Referenzwert für den Baum wurde dabei der gleitende Mittelwert des Spritverbrauchs in l/100km über die letzten 3 Minuten herangezogen, um ein extremes Schwanken im Wachstum des Baums zu verhindern. Der kleinste Baum repräsentiert einen Verbrauch von 18l/100km, der grösste Baum repräsentiert 7l/100km. Der momentane Spritverbrauch wurde ebenfalls angezeigt, um die Nachvollziehbarkeit des Screens zu erhöhen. (2) Der „Eco-Tacho"-Screen zeigt den momentanen Spritverbrauch in Echtzeit in Form einer Tachonadel an (Abbildung 2b). Darüber hinaus werden Bremsung in Prozent (-1g=100%) und Gaspedalposition in Prozent (voll durchgetreten=100%) angezeigt. (3) Der „G-Radar"-Screen (Abbildung 2c) zeigt den Vektor aus longitudinaler (vertikale Achse) und lateraler (horizontale Achse) Beschleunigung in g in Form eines blauen Punktes auf einem Kreis an (Kreisrand entspricht Beschleunigung von 1g). Zusätzlich wurden Triplänge und momentane Geschwindigkeit angezeigt. Der G-Radar dient als Kontrollbedingung und sollte die Systemnutzung aufrechterhalten, ohne einen Einfluss auf Eco-Driving auszuüben.

3 Beschreibung des Feldexperiments

Für das Feldexperiment wurden 72 Pannenhilfe-Fahrzeuge mit unserem EDFIS ausgestattet. Die teilnehmenden Fahrer wurden per interner E-Mail rekrutiert. 72 von 92 angeschriebenen Fahrern nahmen freiwillig am Experiment teil.

Das Feldexperiment begann mit einer zwei-wöchigen Baseline-Phase. Während dieser sahen alle Fahrer den G-Radar. In der anschliessenden Interventionsphase wurden die Fahrer randomisiert einer von drei Gruppen zugewiesen: (1) die Kontrollgruppe sah weiterhin den G-Radar (N=25), (2) die Gruppe mit konkretem Feedback wechselte automatisch auf den Eco-Tacho (N=24) und (3) die Gruppe mit abstraktem Feedback wechselte automatisch auf den Eco-Baum (N=23).

In der Analyse sollen künftig die Spritverbräuche der drei Gruppen verglichen werden, um so Rückschlüsse auf die Wirksamkeit der unterschiedlichen EDFIS auf den Spritverbrauch im Sinne der dargestellten Forschungsfragen zu erlangen.

Towards a Software Prototype Supporting Automatic Recognition of Sketched Business Process Models

Manuel Zapp, Peter Fettke and Peter Loos

Institute for Information Systems at the German Research Center for Artificial Intelligence (DFKI GmbH) and Saarland University, Saarbrücken, Germany
{manuel.zapp,peter.fettke,peter.loos}@iwi.dfki.de

Abstract. The paper at hand presents a prototype that implements an approach to recognize the structure of business process models sketched on paper and whiteboards to create digital versions of those models. We explain the different steps from common photos of business process models sketched on paper or whiteboards to their digital version. We modified existing approaches from sketch recognition to fulfill the needs of sketched business process model recognition. Therefore, a dataset was generated that in turn is used to train different classifiers for different shapes within business process models.

Keywords: sketch recognition, BPM, computer vision, machine learning.

1 Introduction

In Business Process Modeling there has always been an interest in building tools assisting the modeler in creating business process models. Such tools aim at being user-friendly and intuitive. Nevertheless, pen and paper is still the predominant choice, especially in the early design phase of business processes. With no doubt using pen and paper is one of the most intuitive ways of creating business process models. Without manual work, these models can only be stored as pictures or archived on paper and not be transferred into existing modelling systems. To bridge this gap, we introduce a software system that fully automatically transfers sketched business processes into a digital format that can be interpreted by common modeling tools. This prototype is developed within the research project INDIGO in cooperation with a leading Business Process Management software provider, which has multiple customers that have expressed a strong interest in the functionalities of the prototype. Although we use the modeling convention Event-driven Process Chain (EPC) as a sample, our approach is generic and can be applied to other modelling conventions.

In our work, we want to implement an offline approach that is capable of constructing digital business process models from sketched ones on whiteboards or paper. Please note that this is work in progress. In this paper we concentrate on the structural recognition of business process models without solving the Hand Writing Recognition problem for labels that are usually present in sketched process models.

2 Related Work

In general, two approaches in sketch recognition can be distinguished – offline approaches and online approaches. In online approaches the process of sketching is observed, whereby the temporal order information of strokes is leveraged to reduce the search space [1]. Offline approaches are applied to images of finished sketches only and thus are much more challenging.

A lot of work has been done in the area of online sketch recognition, especially in the field of flowchart recognition [2–4], that is by means related to business process recognition. There is only one work available in that area that deals with an offline approach [1] and we refer to it.

To the best of our knowledge we are pioneers on the field of sketched business process digitalization. There exist some works that use post-it®s and create their own modeling conventions that are designed and simplified for later digitalization.[1] The major drawbacks of these systems are the modeling conventions that first have to be learnt by all persons involved as well as the limitations of the modeling conventions and the additional hardware that is needed in form of post-it®s.

3 Our Approach and Its Implementation

3.1 Overview

The prototype is designed as a web application that provides interfaces to prepare data in form of photos taken from sketched business process models to train the software system itself. Additionally, an interface is provided that allows a user to upload images of sketched process models and responds with a representation of the recognized model. Components that actually incorporate image processing and computer vision functionalities are built in C++, due to performance reasons and better handling of the OpenCV[2] library that is used. In the following the necessary steps for an automated recognition are explained.

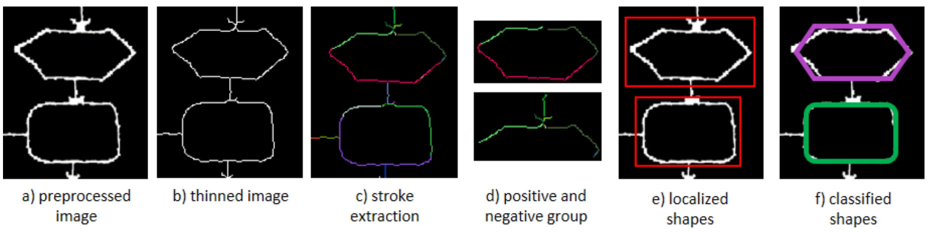

Figure 1. Different steps of processing

[1] http://www.symbioworld.com/de/produkt/produkt-portfolio/workshop-methode.html
[2] http://opencv.org/

3.2 Preprocessing and Stroke Extraction

In our work we target an end-to-end scenario. As we do not want to have unrealistic expectations at the initial quality of the images that should be processed, we allow the images to come from common hardware like smartphone cameras, but we demand sufficiently high contrast between the color of the used pen and the color of the surface the sketch is drawn on. As a consequence, some preprocessing to the initial image is necessary. We apply common filters from Computer Vision to get rid of artifacts in the image. The result of this process is a clean image where only white lines are displayed on a black background as shown in Figure 1a).

Since we follow an offline approach there is no structural information about strokes available. Based on the approach presented in [5] we reconstruct strokes from pixel data and adapt it to our needs. The authors propose to apply a Morphological Thinning algorithm [6] to the preprocessed image, so that all lines are reduced to a one-pixel width as shown in Figure 1b). The extracted strokes are sets of single pixels from the thinned image. Since these strokes may span over several different shapes, which is undesirable for our work we introduce a splitting algorithm. We trace the extracted strokes and at every *n-th* point and perform a principal component analysis on the last and the next *k* pixels of the actual stroke. The principal component analysis gives us the orientation of the last *k* and the next *k* pixels. If the angle between them exceeds an experimentally learnt threshold of 70 degrees, the stroke is split at that point. So all strokes extracted belong solely to one single shape in the process model as shown in Figure 1c).

3.3 Localization

To actually classify shapes into the right category we need to know which strokes form a shape. Common approaches extract rectangular regions from the image and test each against a classifier. Usually shapes contain text that leads to different appearances within the same type of shape. Thus we follow a technique presented in [1] that is called shapeness estimation. The authors propose a feature to construct a fast classifier that solely decides whether a set of strokes forms a shape or not. A group of strokes is a set of strokes that fulfils predefined constraints like spatial ones. The authors build the groups by breadth-first-search. We adopt their work for classical flow-chart recognition to also be able to detect sketched EPCs. Therefore, a dataset of 108 sketched EPCs was created by 36 people with expertise in business process modeling, all sketching 3 different EPCs including 24 shapes on average. The shapes were then extracted so we end up with nearly 2.600 labelled samples. Figure 1d) shows two stroke sets, where one forms a valid shape and, thus, got accepted by the shapeness classifier and an invalid and, thus, rejected one. In Figure 1e) the localized shapes are displayed.

3.4 Classification

The classification problem can be solved in different ways. We decided to choose the Histogram of Oriented Gradients feature since it is commonly used in sketch recognition [7]. We obtained best results in combination with Support Vector Machines. We train a classifier for each of the seven shapes (i.e. events, functions, application systems, organizational units and the three connector types) that are applied in the respective order to proposed stroke sets. If the maximum confidence exceeds a learnt threshold, the shape of the classifier with highest confidence is chosen otherwise the stroke set is dropped. Table 1 shows the accuracy measures for the overall model. We used 10-fold cross-validation to validate these results.

Table 1. Accuracy Measures

TP Rate	FP Rate	Precision	Recall	F-Measure	ROC Area
0.969	0.017	0.938	0.965	0.951	0.930

4 Conclusion and Discussion

We presented a prototype that implements an approach to construct common business process models based on the EPC modeling notation from sketched process models in terms of their structure. Our prototype is research in progress. At the moment, there is just a first evaluation of our prototype available. These first evaluation activities show that our approach is promising. Further evaluation is planned.

{soellner}@ unisg.ch

Abstract. Mobiles Lernen ermöglicht eine Integration von authentischen Lernszenarien in den Alltag und unterstützt somit den Aufbau von Problemlösungskompetenzen. Da zielgruppenspezifische Unterschiede die Nutzung von IT beeinflussen und sich Lehrkonzepte unterscheiden, muss die Zielgruppe bei der Entwicklung einer mobilen Lernanwendung (MLA) berücksichtigt werden. Dieser Beitrag zeigt eine iterative Prototypenentwicklung am Beispiel einer MLA für den Einsatz in chinesischen Berufsschulen. Auf Basis der IT-Kulturkonflikttheorie wird ein systematischer Gestaltungs- und Evaluationsprozess dargestellt. Die Ergebnisse zeigen, dass die systematische Zielgruppenanpassung den Erfolg einer MLA signifikant steigert.

Keywords: Mobiles Lernen, IT-Kulturkonflikttheorie, Zielgruppenanpassung

1 Einleitung

In China werden viele Ausbildungsberufe nicht in Form einer dualen Ausbildung mit einer engen Verzahnung zwischen Erwerb von Wissen und seiner praktischen Anwendung gelehrt, sondern in schulischen Einrichtungen unterrichtet. Insbesondere in Ausbildungsberufen, die neben theoretischen Kenntnissen auch Problemanalysefähigkeiten erfordern, fehlt es an realen Szenarien, um diese Kompetenzen aufzubauen. In Folge dieser Entwicklung erlebt China einen akuten Mangel an gut ausgebildeten Fachkräften. Mobiles Lernen (ML) kann dabei Teil einer Problemlösung sein. Es ermöglicht Lernenden Ort und Zeit von Lernaktivitäten frei zu wählen und mit Dozenten, Lernmaterial und Peers zu interagieren. In praktische Trainings eingesetzt, kann ML eine kontextuelle Wissensaneignung und direktes Feedback ermöglichen, um den Kompetenzerwerb zu unterstützen. Dennoch hat die Forschung gezeigt, dass in Kulturräumen wie China zum einen anders gelernt wird und zum anderen sich die Nutzung von Informationstechnologien (IT) unterscheidet, was eine Einführung von IT-Lösungen aus westlichen Ländern erschwert.

Ziel dieses Forschungsvorhabens ist daher die Entwicklung einer mobilen Lernanwendung (MLA), welche in der KFZ-Mechatroniker Ausbildung in China einen kontextuellen Kompetenzerwerb ermöglicht und zielgruppenspezifische Bedürfnisse

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Ernst, S.-J.; Janson, A.; Söllner, M. (2017): Mobiles Lernen für China - eine iterative Prototypenentwicklung, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1287-1290

berücksichtigt. Vorliegender Beitrag zeigt eine systematische Prototypenentwicklung auf, welche die Zielgruppe im Entwicklungsprozess berücksichtigt, um den Lernerfolg als abhängige Variable zu steigern. Vor diesem Hintergrund verweist die Forschung auf die IT-Kulturkonflikttheorie [1]. Diese besagt, dass die Rolle von Kultur in der Nutzung von IT nur bei Auftreten eines Konflikts sichtbar ist. Menschen sind sich nicht ihrer eigenen Kultur bewusst, bis es zu einem Konflikt mit einer „Gegenkultur“ kommt. Im folgenden Beitrag wird die IT-Kulturkonflikttheorie als Kerntheorie [2] verwendet, um die MLA während des Entwicklungsprozesses an die Werte der Zielgruppe anzupassen. Die Erhebung der Anforderungen basiert auf einer Analyse potentieller Konflikte, was wiederum eine gezielte Anpassung der MLA erlaubt.

2 Gestaltungsorientiertes Vorgehen

Das Vorhaben folgt einem gestaltungsorientierten Forschungsansatz [3], welcher eine iterative Prototypenentwicklung zeigt. Abbildung 1 veranschaulicht das Vorgehen.

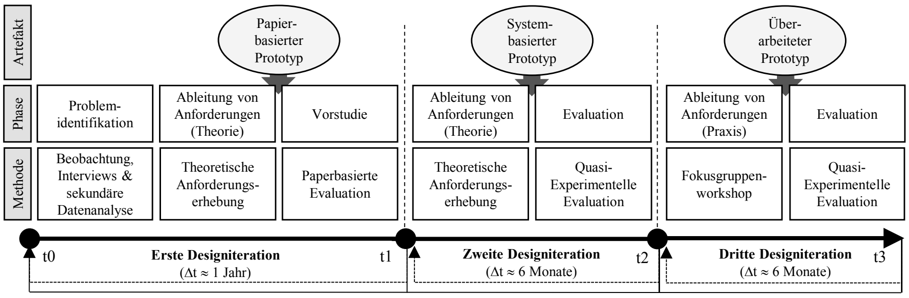

Abbildung 1. Iteratives Vorgehen zur Entwicklung der MLA

Die MLA ermöglicht kontextsensitives Lernen indem mit QR-Codes, welche an einem KFZ angebracht sind, interagiert wird. Dabei hat die MLA zwei Aufgabentypen: es müssen zum einen Autoteile gefunden und die dazugehörigen QR-Codes gescannt werden, um Basiswissen zu erwerben; zum anderen können Lösungsstrategien für Problemszenarien am KFZ durch Scannen bestimmter QR-Codes, welche jeweils für eine Fehlerursache stehen, entwickelt werden. Wissenstests ergänzen die Aufgaben.

Um die Zielgruppe im Entwicklungsprozess zu berücksichtigen, wurden in der ersten und zweiten Designiteration Anforderungen auf Basis der IT-Kulturkonflikttheorie aus der Literatur abgeleitet und somit Werte der Zielgruppe auf nationaler Ebene erfasst. Durch eine gestalterische Anpassung der MLA soll sichergestellt werden, dass die der MLA zugrunde liegenden Werte mit den IT-Werten (Vorstellungskonflikt) und generellen Wertvorstellungen der Zielgruppe (Systemkonflikt) vereinbar sind [1]. Sollte ein Konflikt zwischen den Werten auftreten, könnte dies eine nicht effektive Nutzung zur Folge haben [1, 4]. Der papierbasierte Prototyp beinhaltet hierbei Anpassungen mit Bezug zur Benutzerschnittstelle, wohingegen Konflikte hinsichtlich des Lernprozesses in dem weiterentwickelten systembasierten Prototyp instanziiert werden konnten. Die identifizierten Systemkonflikte beziehen sich auf einen lehrerzentrierten Unterrichtsstil, welcher dem nicht angeleiteten und freiwilligen Lernen des ML entgegenstehen könnte. Weiterhin sollten Nutzerdaten anonymisiert, um einen potentiellen Gesichtsverlust der Schüler bei falsch gelösten Aufgaben zu vermeiden und die Benutzerschnittstelle zielgruppenkonform gestaltet werden, da diese in verschiedenen Kulturen unterschiedliche Gestaltungselemente aufgreift. Der identifizierte Vorstellungskonflikt bezieht sich auf die IT-Werte der Zielgruppe, die ihre Smartphones primär für Unterhaltungszwecke, nicht aber zum Lernen nutzen.

Um die Werte der Zielgruppe ebenfalls auf gruppen- und individueller Ebene zu berücksichtigen, wurden in der dritten Designiteration Fokusgruppenworkshops durchgeführt. In den Workshops wurden in Gruppen weiterführende Änderungswünsche auf Grundlage einer unangepassten Basisanwendung erarbeitet.

In einem darauffolgenden Schritt wurden die jeweils erhobenen Anforderungen durch Designelemente adressiert. Um beispielsweise den zuerst genannten System- und den Vorstellungskonflikt zu adressieren, wurde ein virtueller Charakter in die MLA integriert, welcher neben Anleitungen, wie eine Aufgabe zu erfüllen ist (umgewandelt in ein Gamification-Element), direktes Feedback zu den Lernergebnissen gibt. Abbildung 2 zeigt die getesteten Prototypen aller Designiterationen.

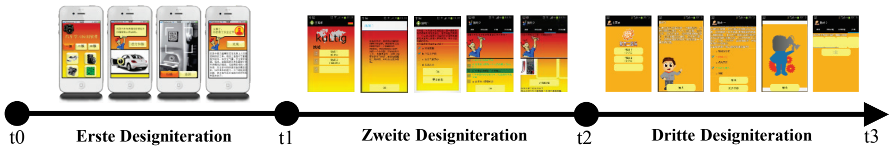

Abbildung 2. Iterative Entwicklung des Prototyps

Jede Designiteration schließt mit einer Evaluation des aktuellen Entwicklungstands. Ergebnisse sowie Feedback und Beobachtungen während der Datenerhebungen wurden zurück in das Gestaltungsvorhaben gespiegelt. So wurde beispielsweise ein Timer als Spielelement auf Grund der unkoordinierten und hektischen Nutzung der MLA revidiert und ein Männchen, das Lebensenergie bei Fehlern verliert, integriert.

3 Ergebnisse

Für die Evaluation wurden in chinesischen Berufsschulen, neben einer papierbasierten Evaluation (erste Designiteration), Quasi-Experimente (zweite und dritte Designiteration) durchgeführt. In den experimentellen Evaluationen wurde die angepasste MLA von einem Teil der Zielgruppe genutzt (Treatment) und von einem anderen Teil eine inhaltsgleiche Basisversion (Kontroll) ohne integrierte Gestaltungselemente verwendet. Während papierbasiert das Design der angepassten MLA mit dem Technology Acceptance Model [5] getestet wurde, konnte im Rahmen der Experimente neben der Technologieakzeptanz, der erworbene Lernerfolg anhand von Wissenstests erhoben werden. Das Experiment der dritten Designiteration wurde von einem Pre-Wissenstest, welcher aus 8 Wahr-Falsch Fragen bestand, eingeleitet, wobei eine Gleichverteilung zwischen Treatment- und Kontrollgruppe sichergestellt werden konnte. Die Evaluationen wurden mit einem N von 113 nach der ersten, 109 nach der zweiten und 201 Teilnehmern nach der dritten Designiteration durchgeführt. Die Teilnehmer aller Iterationen waren mehrheitlich männlich. Eine Teilnahme am Experiment war für Berufsschüler aller Jahrgangsstufen möglich. Die Evaluation des papierbasierten Prototyp (erste Iteration) zeigte eine signifikant positive Beurteilung hinsichtlich der wahrgenommenen Benutzerfreundlichkeit (Mittelwert = 5,26), wahrgenommenen Nützlichkeit (Mittelwert = 5,08) sowie der Nutzungsintention (Mittelwert = 5,12) im Vergleich zum Neutralwert der 7-stufigen Skala, was für die Tauglichkeit der MLA in China spricht. In dem Wissenstest der ersten quasi-experimentellen Evaluation (zweite Iteration), wobei Wissen anhand von Multiple-Choice Fragen erhoben wurde, konnte die Treatmentgruppe signifikant ($p < 0.001$) bessere Ergebnisse im Vergleich zur Kontrollgruppe erzielen. In der dritten Evaluation (dritte Iteration) wurde der Lernerfolg differenziert für deklaratives, prozedurales und fertigkeitsbasiertes Wissen erhoben. Für die Erhebung wurden Wahr-Falsch-Fragen sowie eine Fehlerbaumanalyse herangezogen. Es zeigten sich signifikant positive Auswirkungen der Anpassungen auf die Aneignung von prozeduralem ($p = 0.050$) und fertigkeitsbasiertem Wissen ($p < 0.001$), siehe im Detail Ernst et al. [6].

4 Fazit

Der Beitrag zeigt eine Theorie-geleitete Gestaltung und Evaluation einer MLA für Berufsschüler der KFZ-Mechatronik in China und trägt mit einer systematischen Evaluation zur gestaltungsorientierten Forschung bei [7]. Hiermit wird ein tieferes Verständnis für ML, die Anpassung an fremde Kontexte und die IT-Kulturkonflikttheorie aufgezeigt. Aus praktischer Sicht zeigt dieser Beitrag ein systematisches Vorgehen auf, um MLA zielgruppenspezifisch anzupassen.

Abstract. The personal and financial burden of asthma highly depends on a patient's disease self-management skill. Scalable mHealth apps, designed to empower patients, have the potential to play a crucial role in asthma disease management. However, the actual clinical efficacy of mHealth asthma apps is poorly understood due to the lack of both methodologically sound research and accessible evidence-based apps. We therefore apply design science with the goal to design, implement and evaluate a mHealth app for people with asthma, the Mobile Asthma Companion (MAC). The current prototype of MAC delivers health literacy knowledge triggered by nocturnal cough rates. We conclude by proposing a randomized controlled trial to test the efficacy of our prototype.

Keywords: Asthma Control, mHealth Apps, Asthma Disease Management

1 Introduction

Asthma, a chronic airway disease, ranks among the most prevalent noncommunicable diseases with an estimated 334 million people suffering from it globally. The yearly costs of asthma are estimated to be around 56 billion dollars in the US alone [1].

When patients are not able to control their asthma symptoms, it heavily impacts their quality of life and may even have life threatening consequences. However, successful maintenance of well-controlled asthma enables a patient to live with almost unimpaired quality of life [2]. Apart from the personal implications for patients, the degree of asthma (symptom) control profoundly affects the healthcare system from an economic point of view: A patient with uncontrolled asthma symptoms causes approximately 4.5 times the costs of a patient with well-controlled asthma, which is amplified by the fact that more than half of all asthmatics suffer from uncontrolled asthma [3].

In order to achieve asthma control, clinical guidelines emphasize the importance of an empowered patient with disease management skills [4]. Here is where mobile health applications (mHealth apps) can potentially decrease the personal and financial burden of asthma: in contrast to traditional asthma disease management programs, which

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Tinschert, P.; Barata, F.; Kowatsch, T. (2017): Enhancing Asthma Control through IT: Design, Implementation and Planned Evaluation of the Mobile Asthma Companion, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1291-1294

consist of multiple weekly face-to-face sessions guided by healthcare professionals, scalable mHealth apps can empower patients cost effectively by delivering disease management interventions to their smartphones as part of daily routine. Moreover, mHealth apps may exploit built-in smartphone sensors to objectively monitor disease symptoms and as a consequence identify windows of opportunities in which patients are particularly receptive and susceptible to respond to such interventions [5].

However, to prove the potential of mHealth asthma apps, clinical efficacy needs to be demonstrated in relation to the therapeutic gold standard (i.e. traditional asthma management programs). Systematic reviews in this field, which have indicated first promising results regarding the efficacy of mHealth asthma apps, strongly advocate for further research due to the low methodological quality of the available studies [6] and the low average quality of mHealth asthma apps, which often fail to consider clinical guidelines for asthma treatment [7].

We address this research gap by designing, implementing and evaluating our own mHealth asthma app, which is based on design science research [8]. We refer to our app as the Mobile Asthma Companion (MAC). Currently, the prototype consists of a disease management intervention focused on improving health literacy, which is triggered by, among others, automated cough detection.

The remainder of this paper is structured as follows: after introducing the applied justificatory knowledge and deriving the design requirements, we will describe the implementation of our MAC prototype. We conclude this paper by proposing an experimental study design, which will evaluate MAC's efficacy.

2 Conceptual Foundation and Design Requirements

Patients are responding particularly well to interventions when they are delivered just in time, or in other words, in the exact moment when patients demand them [5]. A state of demand is characterized, among others, by experiencing adverse health effects. For asthma, we argue that partially controlled or uncontrolled asthma indicate such a state of vulnerability. Thus, nocturnal cough rate, a valid marker for asthma control [9], could serve as an intervention trigger. We already delivered the proof of concept that cough can be monitored fully automated and accurately by means of a smartphone [10].

Requirement 1: The design artifact has to be able to monitor the nocturnal cough rate fully automated and use it to trigger just-in-time interventions.

Health literacy, or more specifically asthma education, is a key aspect of asthma disease management [4]. Research has shown that health literacy interventions are clinically efficacious in general and for asthma in specific [11].

For asthma health literacy interventions, first evidence was provided that an asthma mHealth app is able to improve asthma control significantly over the course of five weeks [12]. However, the single-arm study design and the monetary incentives for continuous study participation limit the explanatory power of the study results and the scalability of such an app. Therefore, in order to enable scalability, a user's engagement needs to be ensured without relying on financial incentives. Gamification features like point systems, badges or achievements are promising options in this regard [13].

Requirement 2: The design artifact has to deliver a health literacy intervention including educational asthma content implemented through gamification features.

3 Implementation

We implement our MAC prototype as a mobile application for Android smartphones based on the MobileCoach (MC) platform [14]. MC is an established digital health intervention platform, which provides the necessary user privacy and data security features when working with sensitive patient data. Currently, the MC based prototype offers two main functionalities: a chat and an alarm clock.

The requirement of automated nocturnal cough detection is met by expanding our prior work on cough detection [10] in order to detect cough rate overnight. The detection mode is enabled by setting an alarm, which defines a time frame from the moment the alarm is set until it rings. During this period, the detection algorithm operates in the background, automatically detecting and counting coughs.

Users will be instructed to set the MAC alarm directly before going to sleep and to place the smartphone near the bed (e.g. on a nightstand). Based on detected cough rates per night, users will be prompted to interact with MAC through push notifications. The likelihood of receiving such a notification is a function of the standardized cough rate within a user. In order to limit the burden of intervention, users can only receive up to two notifications per day. However, notifications will be sent at least twice a week to users with a particularly low cough rate who otherwise might not receive any notifications at all. Additionally, MAC is also accessible at will.

In order to address the second design requirement, MAC will interact with the user via a chat interface and provide educational material related to asthma health literacy topics in form of knowledge nuggets (e.g. video clips and quiz questions). This chat functionality is enabled by extending the current MC platform with the possibility to communicate with the user via an internet based chat client mobile application instead of a SMS based communication. Furthermore, the educational materials are fully congruent with the content of current disease management programs. The MC rule-based engine triggers the delivery of knowledge nuggets based on the nocturnal cough rate of the user. Finally, gamification features are implemented through badges which users can earn by viewing educational material and answering quiz questions correctly.

4 Study Design

We will evaluate the efficacy of our MAC prototype in a randomized control trial, the methodological gold standard for investigating efficacy. Adult asthmatics will be randomly assigned to two different groups: The control group will participate in a traditional asthma disease management program offered by local healthcare entities [4] whereas the experimental group will interact with MAC. The primary endpoint in this study is asthma control on a monthly basis. Asthma control is measured through a standardized test [15]. Study duration will be three months to account for lagged effects of the intervention on asthma control. Ideally, our study will show that MAC will perform at least as good as the control group in the measurement of the primary endpoint upon study completion (i.e. non-inferiority trial). We will consider seasonal differences in asthma by measuring asthma control additionally at study initiation. A follow-up measurement after three months will account for long-term effects.

Live Query – Visualized Process Analysis

Dennis M. Riehle[1], Steffen Höhenberger[1], Rainer Cording[1], and Patrick Delfmann[2]

Abstract. Business process management (BPM) becomes continuously challenging through a steadily increasing number and even more complex processes. For enabling an effective and efficient control of business processes, (semi-)automatic approaches are necessary as a supporting means. However, these approaches are often hardly applicable in practice since they lack a broad applicability or an acceptable ease of use. This work aims to close this gap by providing an approach that supports a widely applicable, (semi-)automatic analysis of business process models and makes the analysis comprehensible using a graphical visualization.

Keywords: business process analysis, model query, visualization, ease of use

1 Motivation

The view on value creation in companies has changed during the last decades off from the function perspective to the process perspective [1], [2]. Against this background, Business Process Management (BPM) is an indispensable part of business. However, this task becomes increasingly difficult due to a steadily rising number of more and more complex processes. Thus, it is becoming harder for supervisory bodies to prevent inefficiencies, compliance violations [3] or wrong executions due to lacking overview.

Process models that conceptually represent business processes using standardized modeling languages aim to provide a remedy for this issue. Nevertheless, if the processes exhibit growing size and complexity, the models become vast and confusing, too. Hence, manual control is hardly possible, and common understanding of processes gets lost. Actually, even process models cannot reduce the complexity of real processes.

This problem can be addressed by (semi-)automatic analysis approaches [4] that support an investigation of process models at design time. In the literature, there are plenty of those. Against that, these approaches do mostly not find their way into practice. Three critical aspects mainly cause this: lacking open availability, lacking wide applicability [5], [6] and lacking ease of use [7]. While open availability is the less problematic issue to be solved in most cases, wide applicability and a sufficient ease of use are core problems of many approaches. Approaches have to be widely applicable as different modeling languages are employed in different (and sometimes even in the same) companies. Moreover, there is no common understanding of processes, e.g., in terms of granularity or terminology in many cases. Hence, the

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Riehle, D.M.; Höhenberger, S.; Cording, R.; Delfmann, P. (2017): Live Query - Visualized Process Analysis, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1295-1298

companies require analysis approaches that can be customized to their situation and characteristics. Thus, an objective of a (semi-)automatic model analysis approach should be wide applicability in connection with easy handling. This way, an effective and efficient business process management can be sufficiently supported. This work aims to close this still existing gap.

2 Yet Another Analysis Approach?

Many model analysis approaches make use of model querying. In model querying, an issue to be searched (mostly a compliance violation, an inefficiency or another kind of flaw) is modeled in a specific modeling language and searched within process models by means of a corresponding algorithm. The effectiveness of an approach is based on the assessment if a detected issue structurally and especially content-wise, corresponds to the searched one. The efficiency depicts the required resources (e.g., the needed time). Albeit, their technical efficiency or effectiveness do not predominantly determine their adoption in practice. Their ability to be adapted to a company's needs and their actual usability figure much more prominently. Understandably, companies do (mostly) not employ approaches that do not support the prevalent modeling language, the issues to be searched for in models or that are too difficult to learn for the employees.

Thus, BECKER ET AL. [8] assess different model query approaches regarding their applicability for the detection of a variety of compliance violations. It becomes apparent that only five of the 27 identified approaches can handle different modeling languages. Furthermore, many of the approaches are restricted to search only for issues that exhibit a low level of complexity (i.e., the size and the amount of crosslinking the model subsection to be searched for can have). Some approaches retire at a medium complexity level, and only one approach can represent complex issues. In addition, only eleven approaches have been prototypically implemented, from which only one has been evaluated on real-world process models.

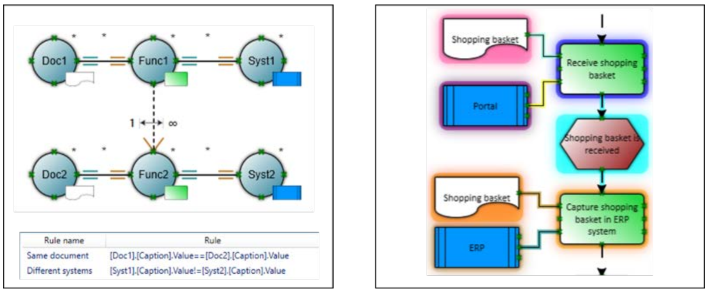
To focus on real-world problems and continuous improvement, we followed the Design Science methodology of PEFFERS ET AL. [9]. We proposed a model query approach under the objectives of wide applicability, independency of modeling languages, support of difficult and complex issues, and, at the same time, an appropriate ease of use [10]. This resulted in the *Generic Model Query Language (GMQL)*, which is based on set theory. Consisting of functions and set operators, it works independently of a modeling language and supports querying complex structural patterns (examples in [8]). An evaluation confirms the power and the utility of *GMQL* but also its amendable ease of use [11]. Though being generally applicable, the approach is inconvenient and overly complex, which prevents the application in practice.

Figure 1. Overall development process

Therefore, starting a new process iteration in our Design Science methodology, we introduced the *Diagramed Model Query Language (DMQL)* to keep the wide applicability of *GMQL* by simultaneously improving the ease of use [12]. With the prototype accompanying this paper, we provide an implementation of our *DMQL* approach. This leads to the overall development process as depicted in Figure 1.

Both approaches, *GMQL* and *DMQL* have been implemented as a plug-in for the meta-modeling tool called [εm]. Similar to *GMQL*, *DMQL* is an intelligent brute-force algorithm, which uses concepts from graph theory (like subgraph isomorphism) to find a query in process models automatically. In contrast, *DMQL* queries are modeled by using edges and vertices that reflect structural relations. Queries depict possibly occurring parts of process models that correspond to the initial real-world issue.

Regarding the main objective, the improvement of the ease of use, *DMQL* enables the visual creation of the queries. Hence, formulating a query in *DMQL* strongly resembles graphical process modeling "as usual." Furthermore, the plug-in supports querying models by using the *DMQL* algorithm with a real-time marking within the process models during the search process. An exemplary model query and a corresponding result are shown in Figure 2. Contextual requirements are included by using captions or attributes of the nodes. A detailed application of the plug-in is shown in the accompanying video. Finally, with the graphical specification of queries, the plug-in implementation is a promising approach to easy-to-use model querying.



Exemplary Query | Returned Result

Figure 2. Exemplary DQML Model Query & Returned Result

3 Conclusion

Summarizing, *DMQL* is an approach to provide a widely applicable and easy to use support for the analysis of (business process) models. It was developed following the design process stated above by passing through several evaluations. A comparison we made between *GMQL* and *DMQL* showed that both are usable independently from a modeling language [13]. In addition, a preliminary evaluation, where a group of modelers was asked to create the same query with both approaches, showed that the average creation time is 20 minutes for *GMQL* and 16 minutes for *DMQL* and modelers have reported to find *DMQL* more convenient, which let us presume a possible ease of use improvement. However, this was only an internal comparison and reliable numbers are still pending. While an in-depth evaluation is still part of future work, *DMQL* addresses the identified research gap with wide applicability and easy handling.

Additionally, the efficiency and effectiveness have been successfully evaluated by [13]. As already done during the past development process, evaluation insights and thereof upcoming ideas are taken continuously into account for further algorithm improvement are an improvement the approach. The latest published version of the approach and the video are accessible via www.conceptual-modeling.org.

Empowering Smarter Fitting Rooms with RFID Data Analytics

Matthias Hauser[1], Matthias Griebel[1], Jannis Hanke[1], and Frédéric Thiesse[1]

[1] University of Würzburg, Department of Business Management, Würzburg, Germany
matthias.hauser@uni-wuerzburg.de, griebelmatthias@gmail.com,
jannis.hanke@uni-wuerzburg.de, frederic.thiesse@uni-wuerzburg.de

Abstract. Smart Fitting Rooms offer great potential to enhance customer shopping experience in retail fashion stores. To this end, they leverage auto-id technology to detect product selections of customers and offer additional services based on these selections on screens within the Smart Fitting Room cabins (e.g., product recommendations or Omnichannel services). While current implementations mainly rely on hardware-based approaches to reliably detect customer's product selection, we investigate the applicability of software-based approaches to distinguish between products in individual cabins. In addition, we show that software-based approaches can be used to sort products in fitting rooms by relevance to the customer which is a valuable information for providing additional services.

Keywords: Data Analytics, RFID, Context Awareness, Internet of Things

1 Smart Fitting Room Opportunities

Internet of Things (IoT) technologies offer great opportunities to enhance customer shopping experience in retail fashion stores [1]. Such context-aware technologies have the potential to create pervasive retail systems that are able to accommodate user needs and wants when desired [2]. We consider Smart Fitting Rooms, which are an example of such context-aware environments. Such fitting rooms are not just cabins for trying on selected garments. Instead, they offer customers additional services on a screen within the cabin based on their product selection. Such services are for example (i) product recommendations or (ii) Omnichannel services.

Product recommendations facilitate cross- and up-selling and can lead to substantial sales increases for retailers [3]. Wong et al. [4], for example, provide such recommendations to customers in Smart Fitting Rooms at a fashion chain store in Hong Kong and find that they lead to sales improvements of more than 20%.

Omnichannel services, on the other hand, provide customers with a seamless shopping experience which can lead to a competitive advantage for retailers [5]. The smart fitting room offers various possibilities to bridge the gap between the different retail channels by, for example, offering customers to purchase products that are currently not available in the store from the online store in the Smart Fitting Room.

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Hauser, M.; Griebel, M.; Hanke, J.; Thiesse, F. (2017): Empowering Smarter Fitting Rooms with RFID Data Analytics, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1299-1302

2 Limitations of Current Implementations

Retailers have already started testing fitting rooms that offer additional services to customers. While some of these retailers provide customers with barcode scanners for the identification of items, others rely on Radio Frequency Identification (RFID) technology. RFID uses electromagnetic fields to automatically identify and track tags that are attached to objects. The technology is already commonly used in the retail supply chains for the automatic detection of logistical units in upstream and backroom processes. In contrast to optical barcode scanning, RFID tags not only enable the detection of the amount of items belonging to a specific product category but also permit the identification of each specific item. Moreover, RFID-based object identification does not require a direct line of sight between the tag and the reader device and thus allows for simultaneous bulk detection of multiple objects.

Thiesse et al. [6], Melià-Seguí et al. [7], and Wong et al. [4] describe pilot projects with Smart Fitting Rooms that rely on RFID technology. The application of RFID for such processes is, however, error-prone and challenging [8]. This is because in contrast to controlled processes in other parts of the supply chain, the sheer number and variety of simultaneously moving objects is very high. Complexity is further increased by the manner in which objects are transported, unpredictable customer walking paths, and suboptimal store layouts. To cope with these challenges, existing implementations mainly rely on hardware-based approaches. These approaches require the installation of one RFID reader system for each cabin and the use of shielding measures (e.g., shielding paint, thick fitting room walls from floor to ceiling) to ensure that only objects within the cabins are detected by the RFID systems. Another drawback of current implementations is that they are only able to detect all products within them but cannot distinguish between relevant products (e.g., products that are currently tried on) and others (e.g., products that hang on a coat hook). It is obvious that such information would be valuable for retailers as this would, for example, allow them to display only recommendations for items that customers are currently interested in.

3 Description of the Smart Fitting Room Artifact

We investigate the applicability of software-based approaches to tackle the previously mentioned limitations of current implementations. To this end, we follow the guidelines put forward by Hevner et al. [13] and develop an artifact that (i) detects garments within cabins without using shielding measures and (ii) sorts them by relevance to customers. Our current experimental setup considers three fitting room cabins (Figure 1).

The architecture of the artifact combines hardware and software components. The hardware component is a sensor infrastructure that collects sensor data that is then processed by the software components. We propose the use of a ceiling-mounted RFID system with a reader device and an antenna array with 52 far-field antenna beams which are mounted in one housing. Table 1 provides an exemplary data excerpt from the raw data gathered with the reader installation. Each row reflects a single tag read event triggered by one of the reader's antennas. Here, EPC is the unique identifier of the RFID tag, RSSI is the radio signal's power measured in dBm, Doppler is the frequency shift of the received signal at the reader due to relative motion between the reader and the tag, and Antenna is the ID of the antenna that read the tag.

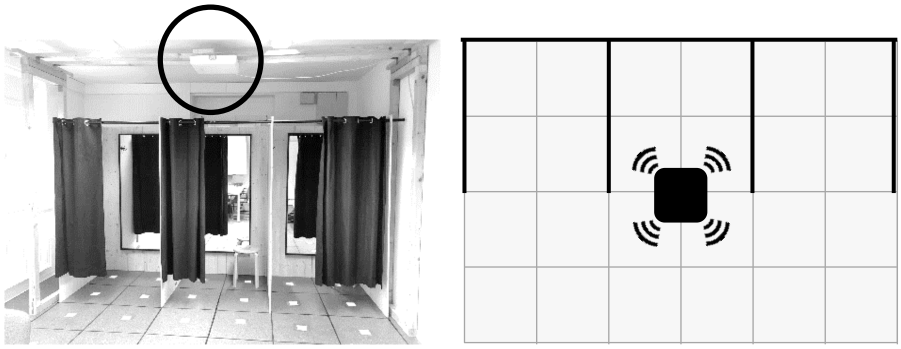

Figure 1. Test environment with ceiling-mounted RFID system and three fitting room cabins

Table 1. Exemplary data excerpt

EPC	***Timestamp***	***RSSI***	***Doppler***	***Frequency***	***Power***	***Antenna***
E28011606…	1465992659	-66.0	25.187	867.5	30.0	51
E28011606…	1465992660	-64.0	30.875	867.5	30.0	2

The first software component combines supervised machine learning and probabilistic models to detect items in individual cabins based on the low-level RFID data collected by the hardware component. In a first step, we determine the positions of tagged items using the indoor positioning technique “Scene Analysis”, which estimates the position of objects by matching their real-time measurements with “fingerprints” at different positions [9]. To this end, we apply multiclass classification techniques which necessitate dividing the fitting room area into grid fields and collecting training data for each of these fields. Here, the number of grid fields denotes the number of classes considered in the data mining model. In a second step, we consider the layout of the fitting room area and characteristics of the processes in fitting rooms to improve the positioning accuracy. The former comprises for example information about the location of fitting room walls, the latter builds on the assumption that some sequences of item locations within a certain time period are more likely than others.

The second software component relies on supervised machine learning techniques to sort garments in fitting rooms (i.e., the garments detected by the first software component) by relevance. To this end, we extract features from the raw data, which contain information regarding observed real-world events. The considered features are appropriately specific to RFID and must be developed based on knowledge of the particular business process. Examples are the number of tag reads, the standard deviation of the RSSI values, or the median of the Doppler frequency shifts of a particular tag within a certain time interval.

4 Expected Contribution and Future Work

Our initial study shows that current limitations of existing implementations can be tackled with software-based approaches. Our artifact is able to detect products in cabins (without the need of shielding measures) and sort these by relevance to the customer. Going forward, we want to evaluate our artifact in different test environments. Here, we want to focus on complex settings, such as high numbers of customers and products in reading range of the antennas or different customer movement speeds. Although first results are promising, we expect that additional tests will introduce new challenges. Our ultimate objective is to ensure feasibility of our approach under real-world conditions.

You can't buy my rating! On the pivotal effect of an unconditional gift on rating behavior

Abstract. The importance of online ratings on sales is widely acknowledged. Firms need to find ways of increasing the number of ratings and rating scores, but how they can achieve this effectively is less well established. In this paper we analyze the impact of an unconditional gift on customers' rating behavior in an online field experiment. Contrary to prevalent advice, our results suggest that providing a gift is not necessarily beneficial. Younger customers are significantly less likely to rate when exposed to an unconditional gift. Regression analysis reveals that age serves as a moderator and older customers even respond slightly positive to a gift. Having detected a negative effect of gifts on rating behavior provides first indicative evidence of a possible crowding out of intrinsic motivation in the context of online ratings. This has direct implications for practitioners considering the usage of gifts to elicit online ratings.

Keywords: online ratings, rating elicitation, reciprocal behavior, field experiment

1 Introduction

How many times have you received an email asking you to rate your recent online purchase but not acted on it? If your answer is "often", then you are in good company. Such email solicitations may be increasingly common but review rates remain stubbornly low, typically within one-digit percentage success rates (1.5%, as reported by Anderson and Simester [1]). Given that customer online ratings are a major driver of purchase behavior both online [2] and offline [3], by making it easier for customers to evaluate and compare the quality of a product or service, it is in the interest of businesses to increase review rates. This is supported by a considerable body of literature which, by and large, lends empirical evidence to the positive impact that online ratings have on sales in a variety of industries. This positive relationship is primarily driven by the volume of ratings [4] and the average ratings [5]. Consequently, obtaining a substantial number of ratings and achieving high average ratings has become a critical endeavor for firms both in online and offline markets.

Studies in the offline world have provided empirical evidence in support of the claim that customer feedback can be successfully elicited through monetary and nonmonetary

Gutt, D.; Schlangenotto, D.; Kundisch, D. (2017): You can't buy my rating! On the pivotal effect of an unconditional gift on rating behavior, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1303-1317

gifts, increasing both the amount of feedback [6], [7] as well as the average feedback value [8], [9]. Unconditional gifts in the offline world can be cash payments [6], [7]; [10], lottery tickets [7], charitable donations on behalf of the respondent [7], or fancy sweets [8]. While there is substantial evidence that gifts can increase and enhance feedback in offline environments, only a few recent studies involving field experiments on eBay have investigated how sellers can effectively elicit ratings in the e-commerce environment [11], [12]. Up to now it remains unclear, however, whether the results produced in the context of auction markets are transferable to conventional markets. In addition, the researchers in the aforementioned studies made use of *conditional* gifts which customers receive only in exchange for submitting a rating. For example, selling USB sticks on eBay, they employ pre-announced price discounts before purchase *conditional* on the customer’s rating [12]. Moreover, a related study found that the effect of conditional rebates on rating behavior and sales varies with the amount of discounts [11]. However, research findings from the offline world suggest that *unconditional* gifts offered to customers regardless of their subsequent action might be even better suited to elicit ratings [10].

This study, then, aims to analyze the impact of unconditional gifts on the rating behavior of customers in a conventional e-commerce environment. Unconditional rebates are provided as a gift via post-purchase emails in which customers are asked to rate their purchase. Investigating ways to gather and maintain good customer ratings is crucial for practitioners and scholars alike. This is especially true of post-purchase emails, which represent a cost-efficient - and now widespread - tool to obtain ratings. Thus we pose the following research question: *How do unconditional gifts in email elicitations affect the online rating behavior of customers?*

Previous insights on eBay [12] focused exclusively on the effectiveness of *conditional* rebates on rating behavior. With our research question we attempt narrowing the knowledge gap concerning *unconditional* rebates in a different market setting. Therefore we conduct an online field experiment and find a substantially heterogeneous treatment effect in response to unconditional gifts. Evidence suggests that emails offering unconditional gifts significantly decrease the rating volume provided by customers. This effect is moderated by customer age. While the first and second quartiles of the age distribution give significantly fewer ratings when receiving a treatment, the effect gradually lessens for the third and fourth age quartiles. Moreover, this effect is more pronounced for recurring than for new customers. Finally, we find no empirical evidence for unconditional gifts influencing the average rating.

Thus our research makes several contributions to the literature and carries valuable implications for scholars and practitioners alike. First, we add to the literature on online rating elicitation by broadening the scope from an online auction environment to conventional online business-to-consumer (B2C) commerce. Second, we add to the literature on reciprocal gifts by presenting empirical evidence suggesting that customers might perceive a gift as an attempt by a firm to influence their rating behavior, against which they then react in the form of a decrease in the rating volume. Finally, our results enable us to derive practical managerial implications. Managers intent on increasing rating volumes should be aware that email elicitations offering unconditional gifts do not automatically result in an increase in the number of customers providing ratings.

Rather, in the younger customer base (in our case, aged between 18 and 48) the emailed gift offer has the effect of decreasing the rating volume, whilst only slightly increasing the response rate of the older customers (aged 49-85). Managers might therefore want to design marketing interventions capable of exploiting this observed behavior by targeting them specifically at older customers.

2 Related Literature

A sizeable and emerging body of literature provides empirical evidence for the relationship between online ratings and business performance. One sub-stream identified the rating volume as one key determinant. The rating volume has been found to be positively associated with sales for books on Amazon [4] and movies on the basis of a variety of data sources [13]. Another sub-stream identified the rating valence as a crucial determinant. The rating valence, measured as the average rating obtained through ratings, has been found to be positively associated with revenues of a restaurant [3] and with sales in the online book market [5], [14] and the movie industry [15].

In the offline world a sizeable body of literature provides empirical evidence that customer response rates can be increased by offering monetary as well as nonmonetary gifts. Gifts (such as cash payments, lottery tickets, charitable donations, or sweets) have been found to increase the feedback volume [6], [7] as well as the feedback value [8], [9]. Singer et al. [6] find a positive effect of unconditional prepaid cash gifts on mail survey response rates. Warriner et al. [7] state that unconditional prepaid cash gifts can be even more effective than alternative forms as gifts such as lottery tickets or charitable donations. Moreover, Strohmetz et al. [8] find that unconditional chocolate gifts can significantly increase the tips given by customers. Comparing monetary gifts, James and Bolstein [10] conclude that an unconditional gift of $5 is more effective at increasing the volume of responses to a mail survey than a $50 conditional gift. In the online world, researchers have only started to investigate ways in which online ratings can be actively elicited. The current body of literature comprises research studies conducted in auction environments. Cabral and Li [12] argue that conditional gifts can trigger the reciprocal behavior of buyers and are thereby result in an increased rating volume and an enhanced average rating. In a related study, Li and Xiao [11], for example, conclude that conditional rebates lead to an increase in the number of sales and in the likelihood of obtaining a good rating.

We contribute to this literature by extending the investigation of rating elicitation towards unconditional gifts and towards a more generalizable non-auction e-commerce context. The impact of unconditional gifts on customer behavior is measured in terms of rating volume and average rating.

3 Theoretical Background and Hypotheses

Before analyzing the effect of an unconditional gift on rating behavior, we will review the literature on rating behavior in general, and specifically the role that gifts can play to influence such behavior.

One widely accepted stream of literature recognizes the positive relationship between the net utility a customer derives from the consumption of a product and the volume and average ratings they provide [2], [16], [17]. Theoretically, customers tend to publish a rating equal to the utility they derive from the obtained good. Yet, they will only provide a rating if they perceive its utility to be greater or equal to zero considering the costs incurred by the rating activity, such as the time needed to reflect on and compose a review [12]. However, observations in the field suggest that far from all customers who derive a positive utility give an online rating, and that ratings are given when the utility is either very high or very low [18].

The theory of reciprocity suggests that humans intuitively feel obliged to give back (reciprocate) in response to the actions of others. When a gift is presented to customers, reciprocal theory suggests that they will evaluate the gift and alter their behavior based on the psychological utility they derive from it. According to Falk and Fischbacher [19], utility from a reciprocal gift consists of three components. It comprises (i) the customer's perception of the gift-giver's intention, (ii) the value of the gift minus the gift-giver's outside option, and (iii) the reciprocation. Intention captures the notion that gifts can be based on disingenuous intentions, which hence lowers the value of the gift. The value of the gift minus the gift-giver's outside option reflects the differential between the value of the gift minus what the giver could have given. Reciprocation captures the value of the gift that prompts a reciprocally-acting individual's action by them returning the favor or rejecting it. Thus, reciprocity works both ways: customers respond positively to gifts perceived as genuine incentives and negatively to gifts that are seen as manipulative or disingenuous.

The total perceived utility a customer derives is constituted by the physical utility of consumption (the purchase and use of the contact lenses) plus the psychological utility due to the reciprocal gift which, in turn, consists of three components. From the perspective of a customer, one perception of a reciprocal gift could be that the customer (i) perceives the gift as genuine, (ii) values the gift and considers the gift giver's outside option as zero (because the retailer could have as well opted to give nothing at all), and (iii) reciprocates the kind behavior by giving a rating. This would result in a positive psychological utility and positive reciprocal behavior. The part of the utility derived by (iii) reciprocation is based on the idea that by giving something back, you feel better because you act fair [19] and thus you derive utility from acting reciprocally after receiving a gift. In that case, the perceived utility in the presence of the reciprocal gift is higher than in the absence of the gift.

In sum, current literature suggests that both rating volume and average ratings are driven by the perceived utility a customer derives from the obtained good. Introducing an unconditional gift to elicit ratings could either increase or decrease this perceived utility. In our research environment the gift should increase the overall utility in the minds of customers as they receive the gift in form of a rebate which was designed to be attractive in terms of its monetary value and which does not depend on a customer's action. Thus, we formulate our first set of hypotheses:

H1a: An unconditional gift increases the number of ratings received by the seller.

H2a: An unconditional gift increases the average rating received by the seller.

However, as stated by Falk and Fischbacher [19], customers could also perceive a gift as negative and respond to it accordingly, i.e. by refusing to act as requested. In our research environment, even when the gift does not depend on a customer action and is also considered attractive in terms of monetary value, customers might interpret the intentions of the gift-giver as being disingenuous. They might get the impression that the gift-giver wants to buy their rating. In these cases, the perceived utility of the gift could become negative, resulting in a negative impact of the gift on rating behavior. Consequently, we formulate a competing set of hypotheses:

H1b: An unconditional gift decreases the number of ratings received by the seller.

H2b: An unconditional gift decreases the average rating received by the seller.

4 Research Design

To evaluate the impact of an unconditional gift on rating behavior we teamed up with a German B2C contact lens retailer who uses emails to elicit online ratings from customers. Every customer who bought items in their shop receives a rating elicitation email three days after their items have been shipped. Obtained ratings are publicly accessible and can be viewed by all potential shoppers. We designed a well-controlled field experiment which leveraged the firm's practice of sending out rating elicitation emails, allowing us to identify the causal effect of an unconditional gift on rating behavior. As can be seen in Figure 1, whenever customers purchase items in the online contact lens shop they are randomly assigned to either the control or the treatment group. Customers assigned to the control group receive an email that asks them to rate their customer experience. When assigned to the treatment group, customers receive a modified email which presents an unconditional rebate as a gift. In order to ensure proper randomization, the assignment to either of the two conditions (treatment or control) is performed automatically. In every elicitation email, customers have the distinct choice to either rate the firm via a third-party website or refrain from rating (tested via hypothesis H1a/H1b). Customers who decide to give a rating can assign between one to five stars to the distinct categories, namely, delivery, product and service (tested via hypotheses H2a/H2b).

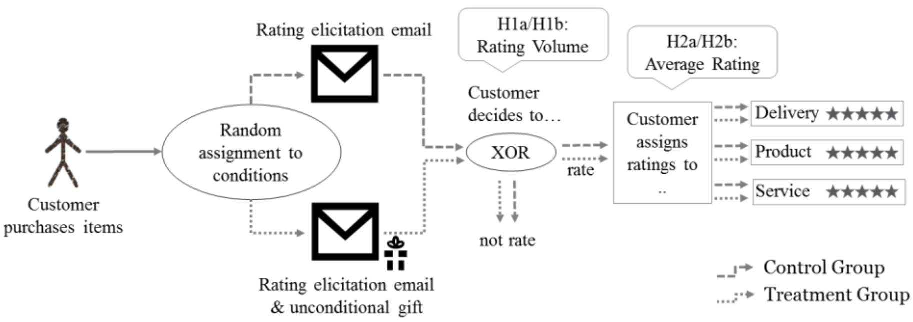

Figure 1. Research Setup

During the experimental period customers were equally likely to either receive the regular elicitation email (see Figure 2, Control) or a modified elicitation email which additionally offers an unconditional gift (see Figure 2, Treatment). While the subject ("Rate 'brand name' now!") of both emails was kept identical to rule out potential biases, the email content was altered in two ways. First, the headline differed: the treatment email only mentions the gift offered to the customer (see Figure 2, Treatment – [A]), whereas the control email only asks customers about the service they received ("how was our service?"). Second, below the rating-button an additional descriptive text was inserted in the treatment email, stating the importance of customer satisfaction to the firm and introducing the gift offer of five Euros in form of a rebate for the next purchase (see Figure 2, Treatment – [B]). These two modifications are used to advertise the unconditional gift and to trigger the reciprocal behavior pattern in customers. We chose a rebate of five Euros as it is considered to represent a substantial rebate on the average purchase basket. In addition, previous marketing campaigns have proven that customers of the contact lens shop respond positively to rebates and actively use them. Yet, in our research context no previous campaigns had tried to incentivize ratings via gifts. This means that prior to our intervention, the firm's customers would not have expected to receive a rebate in a rating elicitation email.

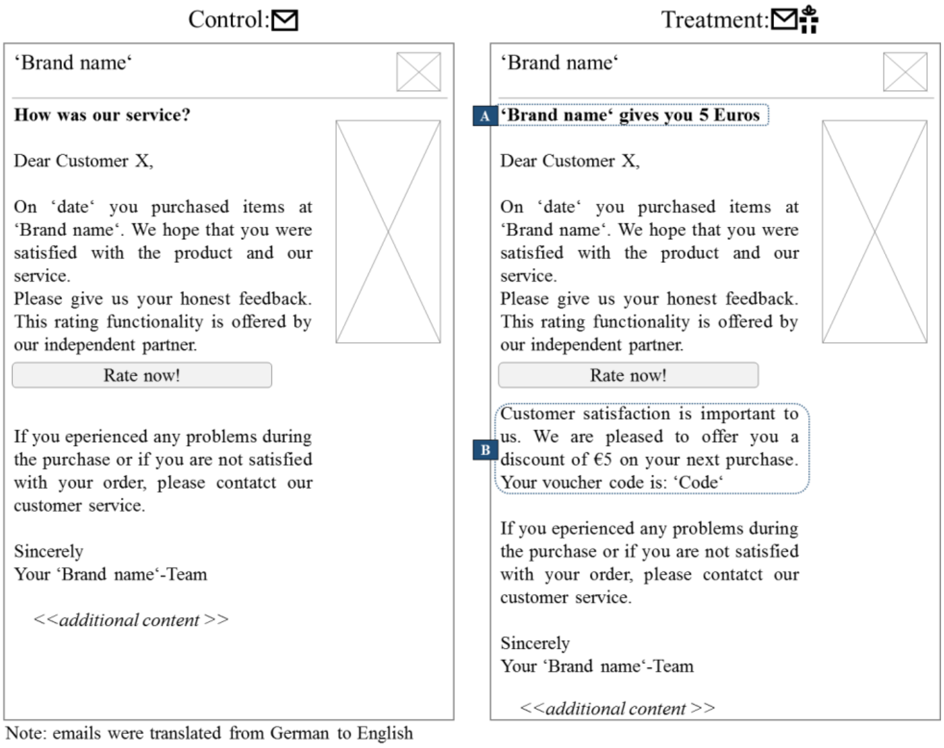

Figure 2. Rating Elicitation Emails

5 Empirical Model

Regression analysis is used to investigate the gift effect while simultaneously controlling for other potential confounding factors. Table 1 lists the variables considered in our regression analysis. Each customer *i* is randomly assigned to either a control group or a treatment group ($TREATMENT_i$) receiving a differently worded elicitation email (see Figure 2). We subdivide the sample of customers by their age so that every customer *i* is assigned to one of four 25%-quartiles (AGE_i) of the age distribution (see Figure 3). Customers are further distinguished by gender ($GENDER_i$) and by customer status ($CUSTOMER_i$). A customer could either be a new or a recurring customer. The rating behavior of every customer *i* is assessed first by whether they decided to provide a rating ($RATED_i$), and second, for those who did, whether they rated the category 'delivery' ($DELIVERY_i$), 'product' ($PRODUCT_i$) or customer 'service' ($SERVICE_i$) as the dependent variables of interest.

Table 1. Main Variables

Variable	Type	Description	Value range
$TREATMENT_i$	Independent	Every customer *i* is assigned to the control or treatment group	CONTROL/ TREATMENT
AGE_i	Control	Based on his age every customer *i* is assigned to an age quartile	Q1/Q2/Q3/Q4
$GENDER_i$	Control	Every customer *i* is either male or female	MALE/FEMALE
$CUSTOMER_i$	Control	Every customer *i* is either classified as a new or a recurring customer	RECURRING/ NEW
$RATED_i$	Dependent	Every customer *i* either rates (=1) or refuses to rate (=0)	[0,1]
$DELIVERY_i$	Dependent	Every customer *i* who rates can assign a rating to the quality dimension *delivery*	[1,5]
$PRODUCT_i$	Dependent	Every customer *i* who rates can assign a rating to the quality dimension *product*	[1,5]
$SERVICE_i$	Dependent	Every customer *i* who rates can assign a rating to the quality dimension (customer) *service*	[1,5]

By including all customer attributes as controls, we can distinguish between effects that are caused by the treatment and those that are driven by age, gender and customer type. Furthermore, previous studies suggest that a customer's age might be a pivotal determinant of their reaction to external marketing stimuli [20, 21]. We consequently include the interaction term between AGE_i and $TREATMENT_i$ to test for age-specific group differences. Hence we formulate the following model which is used as a logit regression for the dichotomously distributed rating volume and as an OLS regression to assess the average ratings:

$$Y_i=\beta_0+\beta_1 TREATMENT_i+\sum_{\tau=1}^{3}\beta_\tau\ AGE_i+\beta_3 GENDER_i+\beta_4 CUSTOMER_i+\sum_{\tau=1}^{3}\beta_{\tau i}\ (AGE_i{*}TREATMENT_i)+\varepsilon_i \quad (1)$$

6 Empirical Analysis

Throughout the 67 days of the experimental period, a total of 7,316 customers received elicitation emails three days after their products were shipped. As can be seen in Table 2, the majority of customers were recurring customers (78% or 5,697). Based on observable attributes, every customer was randomly assigned to either the control or the treatment group. To test whether the randomization of the treatment assignment worked properly, we performed a Mann-Whitney-Wilcoxon-test. The test yielded no significant group differences based on the attributes: customer type (recurring / new) and gender (male / female). Therefore, we find no indication to doubt the randomization applied in our experiment. Figure 3 depicts the age distribution of all customers, ranging from 18 to 85 years.[1] For every quartile an age group is built to allow for the observation of age-specific treatment effects.

Table 2. Received Elicitation Emails

Group/ Customer Attributes	Control	Treatment	Total
Recurring Customer	**2,820**	**2,877**	**5,697**
female	1,912	1,907	3,819
male	908	970	1,878
New Customer	**824**	**795**	**1,619**
female	558	569	1,127
male	266	226	492
Total	3,644	3,672	7,316

Table 3 presents customers' rating behavior during the experiment in respect of age quartiles. During the experiment 5.2% (379) of all customers chose to provide a rating. Their likelihood to rate increases with AGE, from 2% for the youngest quartile to 9.6%

[1] 55 customers had to be removed from the dataset as their age could not be determined.

for the oldest. These rating differences underline the need to differentiate customer behavior by age. In regard to the average rating given, customers tend to assign ratings close to the maximum value of five.

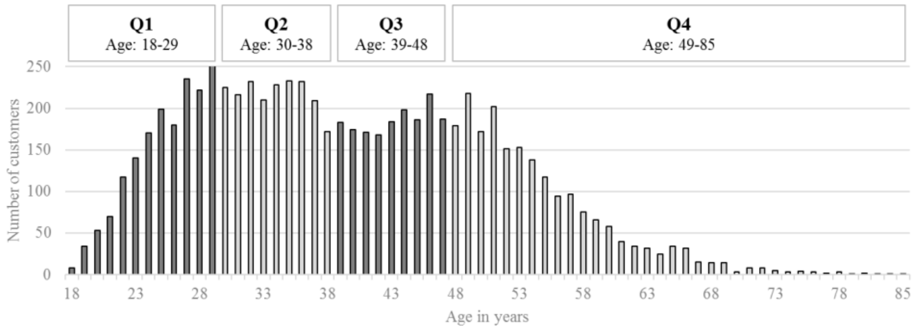

Figure 3. Age Distribution

For all the rating categories, ratings range from 4.7 to 4.9 (this is in line with high overall ratings as reported by [18]). In order to assess whether this observed rating behavior is influenced by the unconditional gift, the rating volume and the average ratings are analyzed separately.[2]

Table 3. Rating Behavior

Behavior / Age Quartiles	Rating Volume	Average Rating		
		Delivery	Service	Product
Q1	2.0%	4.9	4.8	4.8
Q2	3.1%	4.7	4.7	4.7
Q3	5.6%	4.9	4.9	4.9
Q4	9.6%	4.8	4.8	4.9
Total	5.2%	4.8	4.8	4.9

Notes: Rating Volume is calculated as: Number of ratings / Received elicitation emails
Average Rating is calculated for every dimension as: Number of assigned rating stars/Number of ratings

6.1 Rating Volume

Table 4 depicts customers' rating volume by their individual attributes. On average customers from the control group rated the firm in 5.5% of all instances as opposed to customers in the treatment group who provided a rating in 4.9% of all cases, indicating that the overall treatment effect is negative. The negative treatment effect is observed

2 Additional statistical analyses, extended variants of all regression models, incl. control variables are provided as an online resource: http://go.upb.de/Reciprocity

for recurring as well as for new customers. Table 5 presents the results of logit regressions performed according to the regression model specified in Equation (1).[3]

As can be seen in column (1) of Table 5, the treatment effect on the first quartile, comprising customers aged between 18 and 29, is significantly negative with a coefficient of -0.80. As logistic regression analyses are applied, coefficients cannot be interpreted as the direct impact on a change in the output variable for a one-unit increase in the respective predictor variable, while all other predictors remain constant. Instead, odds-ratios are more appropriate [22]. The odds-ratio indicates that the youngest group of customers in the data set are 55% less likely to provide a rating when exposed to an unconditional gift. In column (2), customers between the ages of 30 and 38 are also significantly less likely to respond to the gift with a rating, given their quartile's coefficient of -0.52. The odds-ratio here suggests that the second youngest group of customers is 41% less likely to rate in response to the gift. Customers between the ages of 39 and 48 also seem to be affected negatively, but the treatment effect is insignificant for this quartile. Only the oldest quartile of customers is not influenced negatively by the gift with logit results indicating a rather positive – if ever so slightly positive - response to the treatment.

Table 4. Rating Volume – Summary Statistics

Group/ Customer Attributes	Control (C)	Treatment (T)	Group Differences T-G
Recurring Customer	**5.2%**	**4.9%**	**-0.3%**
female	5.4%	4.5%	-0.9%
male	4.9%	5.5%	0.6%
New Customer	**6.7%**	**5.0%**	**-1.7%**
female	6.1%	4.7%	-1.4%
male	7.9%	5.7%	-2.2%
Total	5.5%	4.9%	-0.6%

From this we can conclude that customers' decision to provide a rating is indeed affected by the emailed offer of an unconditional gift, but in unexpected and differentiated ways: for the majority of customers, the gift not only fails to act as an incentive but rather as a deterrent, since these customer are less likely to submit a rating. The odds-ratio for customers who belong to the younger half of the sample suggests that they are 46% less likely to rate when they receive a reciprocal gift, compared with the control group. Consequently, based on the coefficients of TREATMENT in Table 5, we reject hypothesis H1a and accept the competing hypothesis H1b. Moreover, the interaction terms reveal a substantial heterogeneity of the treatment effect with respect

[3] To evaluate interaction effects between every age quartile and the treatment, four logit regressions are reported in which the particular quartile of interest is used as the respective base case. For example, in the column "Age Q1" the first age quartile is the base case.

to age. For age quartiles Q1, Q2 and Q3 the interaction effect remains insignificant which suggests that there are no significant differences in the treatment effect among the first three age quartiles. However, when comparing the first three quartiles to the fourth (see Table 5, TREATMENT*Q4) logit results yield significant group differences for Q1 and Q2. In column (1) of Table 5, comparing the treatment effect on the youngest quartile to the oldest, the latter significantly differs with a coefficient of 0.95 relative to the youngest quartile. In other words, the customers in the oldest quartile of the sample respond significantly differently. This effect is consistent across columns (1) and (2). In sum, our analysis of the interaction effects reveals that age is a pivotal determinant of a customer's decision to provide a rating in response to receiving an unconditional gift offer by email.

Table 5. Rating Volume – Regression Results

	Dependent Variable: Rated			
Model	Age Q1 (1)	Age Q2 (2)	Age Q3 (3)	Age Q4 (4)
TREATMENT	**-0.80****	**-0.52***	**-0.26**	**0.15**
	(0.38)	(0.27)	(0.21)	(0.15)
TREATMENT*Q1		-0.28	-0.54	-0.95**
		(0.47)	(0.44)	(0.41)

Controls	✓	✓	✓	✓
Observations	7,316	7,316	7,316	7,316
Log Likelihood	-1,419	-1,419	-1,419	-1,419
Akaike Inf. Crit.	2,858	2,858	2,858	2,858
Notes:	*p<0.1; **p<0.05; ***p<0.01; Standard errors in parentheses; Controls: AGE, GENDER, CUSTOMER			

Average Rating We performed a series of robustness checks. The results remained qualitatively unchanged when (i) we used different age groupings such as a median split, a fixed 20-year and a fixed 10-year interval, and (ii) we conducted estimations separately for recurring customers only. When restricting the logit regression to recurring customers, the observed negative treatment effect increases even further. In other words, recurring customers belonging to the younger half of the sample responded even more negatively to the treatment.[4]

6.2 Average Rating

Table 6 lists the average ratings appertaining to the quality dimensions of ratings provided on delivery, service and product. Group differences are close to zero and range from -0.3 for recurring male customers to + 0.3 for new male customers. Regression results do not yield any significant treatment effect either, as no differences in behavior based on a customer's age can be detected. In our experiment, an unconditional gift only affects the rating volume but has no effect at all on average ratings. Consequently, hypotheses H2a and H2b are rejected as no effect of TREATMENT on ratings can be found for any of the four age quartiles.

Table 6. Average Ratings – Summary Statistics

Group/ Customer Attributes	Control (C)			Treatment (T)			Group Differences
	Delivery	Service	Product	Delivery	Service	Product	∑T- ∑C
Recurring Customer	**4.8**	**4.8**	**4.8**	**4.8**	**4.7**	**4.8**	**-0.1**
female	4.9	4.8	4.9	4.9	4.8	4.9	0.0
male	4.8	4.8	4.7	4.7	4.6	4.7	-0.3
New Customer	**4.8**	**4.7**	**4.9**	**4.8**	**4.9**	**4.9**	**0.2**
female	4.8	4.8	4.8	4.7	4.9	4.8	0.2
male	4.8	4.6	4.9	4.8	4.8	5.0	0.3
Total	4.8	4.8	4.9	4.8	4.8	4.9	-0.1

7 Discussion

There is strong empirical evidence in the literature that the volume and the average of online ratings exert a positive effect on sales. Yet, little is known about how to elicit online ratings from customers effectively and the literature has only just begun to investigate this topic. This paper attempts to fill this gap in two ways: First, we add to the literature on rating elicitation by presenting results from conventional e-commerce markets, thus enhancing prior work that focused mainly on auction markets [11], [12]. Second, we shed light on the effectiveness of rating elicitations via unconditional gifts by means of our empirical field experiment. In general, our rating behavior analysis indicates that especially older customers (in our case, those over 49) are more likely to

[4] Regression results for all robustness checks are provided in our online appendix: http://go.upb.de/Reciprocity#robustnessChecks

rate firms and respond positively to an email elicitation. Rating volumes nearly quadruple between the youngest and oldest quartile of customers. However, our results suggest that providing unconditional gifts via emails fails to elicit ratings. On the contrary, such unconditional gifts tend to decrease the number of ratings, on average, and do not affect the ratings given. The observed negative impact on rating volume is substantially heterogeneous across age quartiles. Regression analyses reveal that the negative effect is mainly driven by the younger half of all customers who become 46% less likely to rate when they receive a gift in the form of an unconditional rebate offer. One potential explanation might be that, at least in our context, gifts (as external stimuli) crowd out the rater's intrinsic motivation. Crowding out of intrinsic motivation implies that utility can be constituted not only by consumption and by reciprocity, but additionally also by other individual-specific aspects or motives (e.g., helping potential customers, expressing themselves in public, showing power over the producer [23]). Unconditional gifts in the form of money might potentially erode these motives leading people to abstain from rating who would have otherwise rated due to their intrinsic motivation. The crowding out effect of intrinsic motivation has received quite substantive scholarly attention [24], [25]. Additionally, effort to redeem the voucher or the value of the voucher itself could contribute to the differences in rating behavior across age groups. However, to the best of our knowledge, this effect has not been observed in the context of online rating elicitation. In our field experiment, intrinsic motivation could be crowded out as raters might feel bribed by the gift and therefore refuse to provide a rating. From the perspective of reciprocity theory introduced in chapter 3, the negative treatment effect might be explained by the fact that costumers sense disingenuous intentions with the retailer for giving out rebates. Thus, the customers retaliate, i.e., abstain from rating. However, it is important to note that we have given out the gift unconditionally, which is not as "aggressive" as a conditional gift and should therefore mitigate the feeling of being bribed.

The results presented in this paper offer straightforward managerial implications and the potential impact can be substantial. Given the fact that spending on e-commerce advertisement has more than tripled during the past five years [26], e-commerce retailers need to find ways to economize on these expenses. Nevertheless, rebates and coupons sent out via emails are currently the preferred way of gift-giving to customers [27] and more than 78% of customers use rebate coupons more than once a year [28]. Therefore, discovering efficient ways to conduct rating elicitation via email transaction with customers can have a crucial impact for e-commerce retailers. Our evidence of a negative effect of unconditional gifts on rating behavior suggests that firms should resist the temptation of using gifts as a way of eliciting ratings. Our results point towards a possible crowding out of intrinsic motivation, with gifts having the exact opposite effect on the intended rating behavior. However, as our experimental data does not allow us to determine the root causes of this customer behavior, future research is needed to establish customers' true intentions. In general, though, firms considering the use of external marketing stimuli should be cognizant of our finding that customer age could be a pivotal determinant in behavioral responses to an external stimulus. At least in our case, customer age plays a decisive role and experimental evidence suggests that older customers react slightly more positively to gifts compared to younger customers.

Furthermore, as our results show that gifts significantly influence rating behavior, in one way or another, future research could evaluate alternative gifts such as nonmonetary incentives as a more effective instrument for eliciting rating behavior. As any research, this work also comes with limitations. Contact lenses are highly standardized and frequently bought by a single person, as opposed to a PC or a digital camera. Thus, our results are potentially limited to less complex repeat-purchase goods. Additionally, future research could also vary the shipping time of the product and the delivery of the elicitation mail to investigate possible effects of this relationship.

Abstract. Facts matter in financial communication, but academic research has revealed that soft information such as the tone and readability also impact the decision-making of investors and ultimately stock returns. Information Systems (IS) research has developed measures to quantify readability and tone of textual content, among which are techniques from statistical learning which are capable of extracting the most relevant words for investors. To make this knowledge accessible, we develop an IS prototype that guides communication practitioners to set the right tone in their investor communication. First, we identify relevant practitioner needs using requirements engineering. Second, we translate these needs into an IS prototype which seamlessly integrates into text editing processes and serves as a decision support system to steer readability and tone. Third, we pilot our IS prototype with 37 companies and successfully validate our prototype's capabilities in a survey with financial professionals.

Keywords: Decision Support Systems (DSS), Information Processing, Investor Communication, IS Prototype, Sentiment Analysis

1 Introduction

Financial markets are facing ever increasing information flows [1], [1]. On the one hand, this burgeoning data volume enables analysts to make more educated judgments on valuation and, thus, allows investors to make better informed investment decisions. On the other hand, the sheer amount of available information can be overwhelming for both individuals and companies [1], [1, 3]. Consequently, this inevitably calls for decision support systems in financial markets. Such decision support systems should be directed at all stakeholders involved in the dissemination of information in financial markets. By that, these systems should assist both senders of information (e.g. investor relations departments within companies, financial news agencies) and recipients of relevant information, such as financial analysts and investors [4], [5]. In fact, the latter group, i.e. investors as recipients of relevant information, already relies to a large extent on decision support systems. Examples include forecasting systems, text mining software and trading algorithms which support or improve decision-making.

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Alfano, S.; Pröllochs, N.; Märkle-Huss, J.; Feuerriegel, S.; Neumann, D. (2017): Setting the Right Tone: How Data Science Enables Investor Communication to Choose the Right Language, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1318-1332

The aforementioned systems partially originate from Information Systems (IS) research. IS research has made significant contributions to develop decision support systems for financial markets, especially for investors [6]. However, this is in contrast to the sending-side of relevant information for financial markets, typically investor relations departments.[1] This group typically lacks customized systems to support the process of preparing financial disclosures. Thus, they cannot rely on such a variety of decision support systems in order to tailor their news flow to the changing needs of capital markets [1].

Academic research has identified two key criteria characterizing high-quality investor communication: a positive tone and a high text readability [7–9]. In fact, many IS studies focus on the relationship between investors and textual information. Most of this research evaluates the tone of language in written communication as an indicator for its impact on investors [6], [9], [10]. Speaking broadly, one can refer to this tone of messages as *sentiment* which is a popular research topic in IS. However, as our understanding of tone of language in a financial market includes more than just the sentiment, namely the impact of language on the stock market, we refer to it as *tonality analysis* in the following. In contrast to sentiment analysis, our approach algorithmically computes the (positive or negative) perception of words to support authors in enhancing the tone. Needless to say, tonality and sentiment analysis are closely related, while the underlying methods can vary considerably [11].

In addition to a positive tonality, academic research reveals that companies must also communicate their messages clearly and concisely in order to reach investor attention. To measure the efficiency of information transmission in messages, readability measures are the quantitative lever of choice [8], [7].

This paper fills the gap of a lacking decision support systems for issuers of financial disclosures. Evidence-based support systems are of high practical value for corporate communication executives to facilitate, e.g. investor communication. This paper therefore suggests an IS prototype which builds on academic knowledge in the area of tonality and readability analysis for capital market communication. Accordingly, our IS prototype works as a decision support system that highlights words with a positive or negative tonality and then provides optional replacements with a better tone for the purpose of improving the readability and tonality of written communication[2]. In order to maximize usability, we pursue a rigorous requirements engineering with potential users prior to programming the IS prototype [12]. Finally, we successfully back-test the enhancements to tonality and readability of our IS prototype in a survey with 66 financial professionals.

The remainder of this paper is organized as follows: Section 2 describes the requirements engineering to identify the user needs. Based on these requirements, Section 3 outlines the textual analysis, while Section 4 describes our user interface

---

[1] Investor relations departments are in charge of communicating the performance of a stock-listed company towards financial markets. For investors, the news flow of a company is a highly relevant information source. Thus the way in which companies compose their investor updates, in line with existing regulations, acts as an important driver of share price movements.

[2] Regulatory disclosures must meet specific requirements regarding the content. However, they are typically not regulated in terms of actual word choice.

including available features. In Section 5, we present the results of validating the tonality enhancement of our IS prototype with financial professionals. Section 6 highlights the managerial implications of our IS prototype. Finally, Section 7 concludes and provides a research outlook.

2 Requirements Engineering

The fact that virtually all stock-listed companies have investor relations and corporate communications departments indicates the importance of communicating a company's performance to external stakeholders, including investors. However, practical knowledge of how investors perceive this communication is scarce as interviews with capital market communication practitioners reveal. Building on [12], we conduct a total of 18 semi-structured interviews with investor relations and communications departments of four global pharmaceutical companies headquartered in the UK, the US and Switzerland and with the investor relations associations of Germany, the UK and Austria.

During the semi-structured interviews, we collect unmet needs and requirements and cluster these into similar themes (e.g. integration into existing processes and simple-to-use interface belong to one such cluster). The interviewed practitioners particularly highlight that they currently lack a decision support tool to guide them how to write financial disclosures in line with the increasing automation of language processing by (automated) investors. Overall, we identify six requirement clusters (two non-functional, four functional), including the following two non-functional requirements:

- *(i) Objective fact base of investors' language perception.* To date, practitioners lack an objective fact base of how investors perceive the language in financial disclosures and process it. Yet, academic research shows that the tone of language matters to investors [7–9].
- *(ii) Defense mechanism against algorithmic trading.* The increasing importance of algorithmic trading, accounting for more than half of the market order volume [13], concerns investor relations practitioners. They particularly claim a misbalance with an increase in algorithmic trading based on language cues in financial disclosures [5], [14], while they do not dispose of tools to adapt their communication to automated trading based on the language used in corporate disclosures. Thus, making knowledge on how investors process language accessible would better equip investor relations against algorithmic trading.

In addition, we identify four functional requirements:

- *(iii) Compliance with insider trading law.* To ensure compliance with insider trading laws, the IS prototype must operate securely and reliably such that accessing confidential data is impossible. Hence, the IS prototype may not include any protocol that tracks information contained in a yet-to-be-published stock-market-relevant announcement. In addition, the tool should maintain its full functionality in the offline mode, e.g. to enable usage during travel.

- *(iv) Simplicity and integration into existing processes.* Practitioners stress the importance of a tool's simplicity and high usability and its seamless integration into existing writing processes. Writing processes shall not become complicated due to yet another tool, but rather be simplified with the help of a user interface that integrates directly into conventional text editors.[3]
- *(v) Collaboration-fostering design.* The process of drafting written corporate communication typically involves several departments (e.g. communications, legal, finance, media). To allow for cross-departmental collaboration, the tool needs to have a self-explanatory reporting dashboard. The dashboard further must be sharable via e-mail or as a PDF.
- *(vi) User-controlled change process.* Corporate disclosures are carefully written based on the available facts, legal requirements and corporate standards. Thus, all changes need to be initiated manually by users, to assure that the IS prototype does not unintentionally modify texts.

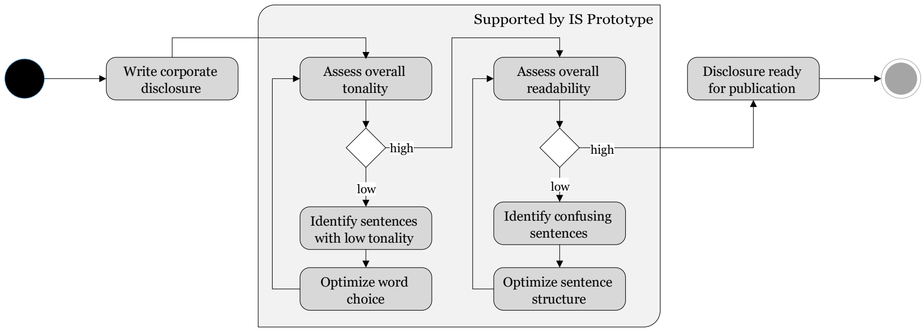

Figure 1. Activity diagram in UML notation showing the reference use case of our IS prototype.

Thus, the IS prototype is intended to support companies in achieving these targets. Moreover, it also incorporates the fact that the editing process of corporate disclosures is highly iterative. The reference use case that serves as the basis to guide our programming efforts and the design of the software system is visualized in a unified modeling language (UML) diagram in Figure 1.[4] As highlighted in the UML diagram, the initial step for companies is to write a first version of the corporate disclosure. Then, the IS prototype helps to assess the overall tonality. In the case of an unsatisfactory tonality, the IS prototype supports users in optimizing their language. In a second step, the IS prototype assesses the overall readability and highlights sentences with

[3] According to our interviews, the predominant text editor among corporate communications departments is Microsoft Word.
[4] The unified modeling language is a common standard to describe the design of a software system. See [15] for details.

optimization potential in case the readability is unsatisfactory. Once the tonality and readability are at satisfactory levels, the disclosure is ready for publication.

Next, we define the end-to-end process behind the development of our IS prototype (see Figure 2). After deriving the requirements of our IS prototype, we collect and pre-process a database of historic financial news disclosures. Then, we extract words that are statistically relevant to investors [11]. This results in a tailored tonality dictionary that contains positive and negative words with relative weights. Finally, we integrate this dictionary into a text editor that fits into existing writing processes. It is noteworthy that we entirely separate our text analytics from the user interface to bundle all computation-intensive analytics in previous processing steps. This ensures that users immediately obtain the correct tonality and readability scores. In the following sections, we further detail the way we generate tonality dictionaries and measure readability.

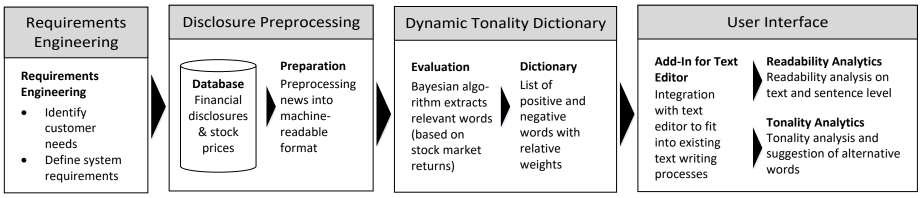

Figure 2. The above flow diagram shows the IS prototype development as an end-to-end process.

3 Data Analytics to Enable Evidence-Based Communication

3.1 Tonality Dictionary Generation

While financial sentiment analysis in IS research primarily counts the relative frequency of positive versus negative words based on standard dictionaries [9], [10], [16], tonality analysis identifies only words that have a relevant and causal effect on buy-or-sell decisions of investors. Among others, this *statistical* approach overcomes a methodological weakness of classical sentiment analysis which typically relies on *manually-selected* word lists that are not adjusted to domain-specific particularities.

For this purpose, we rely on a Bayesian learning approach from [11] that generates tailored dictionaries for the financial domain. Consistent with [17], the authors propose the so-called least absolute shrinkage and selection operator (LASSO) that entails several benefits for dictionary generation. First, this method features a variable selection property that filters out non-informative noise terms and thus, allows to pick only decisive variables in a regression model. Furthermore, the LASSO mitigates the issue of multicollinearity as present when estimating via ordinary least squares. Finally, the LASSO solves the problem of overfitting by finding a reasonable trade-off between bias and variance, which occurs if the model complexity is too high [18]. This results in parsimonious and interpretable models that are particularly suited to extract the words that are most relevant to investors.

As shown in Table 1, we utilize the LASSO approach to generate tailored tonality dictionaries for two different markets along with their corresponding disclosure regulations. First, we cover the U. S. market using a dataset of SEC regulated 8-K filings. Second, we employ a corpus of regulated ad hoc announcements written in English to generate an adjusted dictionary for the German market. In both cases, we measure the stock market reaction following the publication of each financial disclosure. Here, we use the common event study methodology that allows to assess the isolated effect of the financial disclosure on the value of a firm [19], [20].

Table 1. Utilized news sources to generate tailored tonality dictionaries for capital market communication.

Focus	*Market*	*Dataset*	*Benchmark*
Capital market communication	U.S. market	61,241 8-K filings from the years 2004 to 2013	Stock market return
Capital market communication	German market	14,463 ad hoc announcements from the years 2004 to 2011	Stock market return

Based on the input data, i.e. the financial disclosures and the stock market returns, the variable selection property of the LASSO chooses a subset of words that are statistically relevant to investors on the stock market. At the same time, non-informative noise terms are automatically discarded. The coefficient estimates of the LASSO then yields an individual tonality score $s_t \in [-\infty, +\infty]$ for each relevant word.

The resulting weighted word lists, i.e. the tonality dictionaries, allow to statistically assess the overall tonality of financial disclosures. For this purpose, we determine the tonality of a document d by calculating the tonality score $T_d = \sum_t s_t f_{t,d}$. Here, the frequencies $f_{t,d}$ describe how often term t occurs in the document d. The tonality metric T_d thus anticipates the market reaction to the language used in this document. In a next step, the dictionary in combination with the tonality metric can be used to enhance the perceived tonality of a document. For instance, one can exchange words with a negative tonality score with more positive replacements.

Compared to the state of the art, the presented statistical approach significantly outperforms frequently-utilized manually selected positive and negative word lists in terms of explanatory power and predictive performance [11]. Moreover, the generated tonality dictionaries are highly adjusted to domain-specific particularities in capital market communication. In contrast to existing dictionaries that postulate, by definition, an equal importance of all included words, the tonality dictionary also reflects a continuous bandwidth of tonality levels. However, the tonality dictionary only contains words which are used in a financial context and are found to have a statistical impact on the stock market price. Very rare words or words that are not generally used in financial language may be marked as neutral even if these may actually have an impact on reader perception.

3.2 Readability Analytics

An extensive body of literature finds that lower levels of readability reduce investors' reactions to news content [8], [7], [21–24]. Since investors face an ongoing and constant flow of new information, an easy-to-read representation of new information is essential to assure that investors can easily extract relevant information from new financial disclosures. Regulatory handbooks, such as the SEC Plain English Handbook [25], guide the editing of financial disclosures to a certain extent. However, the focus of such regulations is on what to communicate and only to a lesser extent on how to communicate the facts leaving significant freedom to communicators.

In order to fulfill the functional requirements of simplicity and a seamless integration into existing processes, we choose the readability metric based on these criteria. We implement the Automated Readability Index (ARI), as defined in [26], [27], to measure the readability of texts evaluated with our IS prototype. The ARI evaluates the readability of a written document by decomposing sentences into two structural components: the number of words in a sentence and the number of characters per word. The ARI is widely used in readability research [28–30]. In detail, the ARI's formula is defined by

$$ARI = 4.71\,\frac{\text{characters}}{\text{words}} + 0.5\,\frac{\text{words}}{\text{sentences}} - 21.43. \tag{1}$$

Other approaches, i.e., the Gunning fog index, rely on counting the number of syllables per word. However, this requires higher computational effort and results in a worsened error rate in the computation of the index. Thus, we follow [31] and choose ARI as a superior approach.

The readability information is used by practitioners to identify sentences with especially bad readability and to compare the readability of various documents to each other. Sentences with low readability may then be improved by either shortening the sentence or using shorter words within the sentence. While ARI provides a comprehensive and quick assessment of readability, it fails to assess more subtle dimensions of readability such as the usualness of certain words.

4 User Interface

As a result of our requirements engineering, the IS prototype should seamlessly integrate into the existing writing process to promote user adoption. We have therefore developed an IS prototype as an add-in for a conventional text editor, i.e. Microsoft Word. We select this text editor due to its predominance in corporate communication departments, but our IS prototype could be integrated into any other text editor as well (requirement (iv) in Section 2).

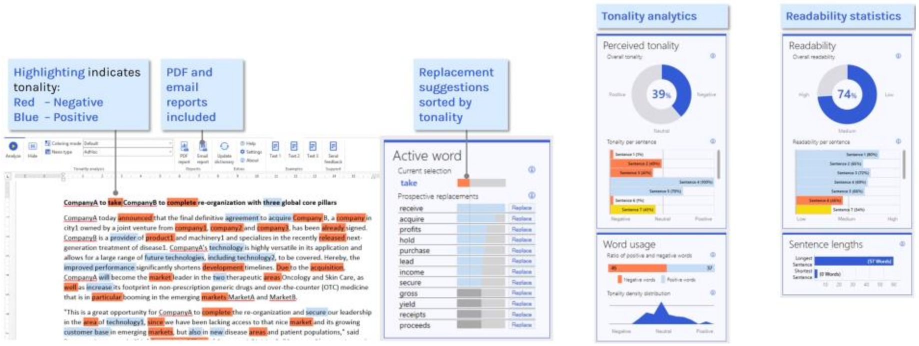

Figure 3. This screen-shot illustrates an exemplary text analysis with our add-in. The word *take*, with a negative tonality, is actively selected by a mouse click. As a result, the active selection panel suggests alternative words, such as the more positive and suitable *acquire*. The center shows the tonality analytics. The right view shows the readability dashboard.

Figure 3 presents our user interface. A drop down menu in the ribbon bar allows users to select a suitable dictionary for the purpose of the underlying communication. For instance, the current implementation of the IS prototype addresses the following domains: (a) a tonality dictionary for capital market communication in the U.S. and the German market following [11], (b) a domain-specific, static dictionary for capital-market communication based on previous research in [16]. This dictionary feature is the core of our application and fulfils the requirements (i) and (ii). The user interface consists of an add-in for a text editor with several functions. As a result of the requirements engineering, the menu (ribbon bar) contains few, but targeted, features. Features include the option to generate a PDF and e-mail report for collaboration (requirement (v)) and a dictionary update function. The dictionary update function allows users to regularly download updated dictionaries from a central server. For this purpose, the add-in automatically communicates with the server and checks for potential dictionary updates. In case updates are available, SSL encryption provides a secure way to transfer the data between server and add-in in line with requirement (iii). To ensure full offline functionality without the need for a continuous internet connection, the dictionaries are encrypted and stored locally after transmission.

Once a suitable dictionary is chosen, users are empowered to objectively analyze the tonality and readability throughout the whole writing process. The tonality analysis highlights words that investors perceive either negatively (highlighted in red) or positively (highlighted in blue). Our IS prototype suggests alternative words as a replacement[5] in case users want to modify the tonality of the underlying document (left

[5] The replacement function builds on the Thesaurus API of Microsoft Word. We perform a refinement to decide which words to display in the add-in. First, we use a part-of-speech tagger to obtain only context-related words. Then we order the prospective replacements according to their tonality score (from most positive to most negative). In the future, we plan to exclude words that are inappropriate in financial communication, i.e. words that not occur at least once in the financial disclosures corpus.

view of Figure 3). In order to ensure that users retain full control of the textual content, word replacements are never applied to the document automatically. Thus, users are required to manually decide whether individual suggestions are adequate and semantically meaningful. This also implies that users are still fully responsible to comply with the regulatory requirements as requested by requirement (vi).

An analytical dashboard displays the aggregated results of the overall tonality (Figure 3, center) and readability (Figure 3, right). The dashboard further reports the tonality and readability of each sentence to simplify the identification of text parts with a particular tonality or readability improvement potential. The dashboard is equipped with full interactivity. As such, a click on a sentence in the vertical bar diagrams lets the editor jump to the corresponding position and highlights the corresponding sentence in yellow color. In addition, we show a density estimation of the tonality scores t_i. A user can easily interpret this plot and verify if the content matches the actual polarity of the content. For instance, one can avoid the case where negative words describe positive information – by that threatening financial markets where readers and automated traders might interpret the information in a wrong way.

To validate and fine-tune our IS prototype, we collect feedback from demo users. The demo users are 49 investor relations and corporate communications professionals from 37 different companies.[6] We provided each demo user with a 2-minutes video tutorial to explain how the IS prototype may be used. We collected feedback on the installation, usability and benefits via a structured online survey. The results of the survey served to fine-tune the IS prototype.

5 Validation of the IS Prototype Through an Expert Study

One recurring concern of corporate communication professionals regarding our data-driven approach is the real-world validity of our algorithmically derived tonality and readability metrics. We encountered skepticism in various conversations with demo users of our IS prototype, despite that fact that we calculate our tonality dictionaries based on real world financial news. Furthermore, the algorithms only include words in the tonality dictionary which have a statistically significant impact on stock prices. As we do not only strive for statistical significance of our tonality dictionaries, but also for economic relevance, we back-test the impact of modifying texts based on our tonality algorithm and readability index with the typical audience of such communications.

We design a survey to gauge the tonality response of financial professionals to stock-market relevant news. The survey consists of eight questions, which cover some of the most frequent topics in financial disclosures [32], such as earnings reports or acquisition activities. In each question, we show an original extract of a published, regulatory filing

[6] The 49 demo users are 18 investor relations officers, 12 investor relations advisors (e.g. from financial communication agencies), 5 heads of investor relations, 4 business translators, 3 heads of media relations and communications, 2 capital market legal advisors, 2 consultants, 1 chief finance officer, 1 investor relations journalist and 1 investment fund manager.

published by stock-listed companies. We keep the original extract in its published form and only disguise the name of the respective company.

Seven questions validate the tonality metric, one question validates the readability metric. Among the seven tonality-related questions, five questions relate to text extracts with negative factual content and two questions relate to text extracts with a positive factual content. In each question, we alter either the tonality or the readability based on our tonality dictionary (cf. Section 3.1) and the ARI readability score (cf. Section 3.2). Thus, for each of the eight questions, we have a pair consisting of the original text extract and a text extract in which we enhance the tonality or readability with the user interface.[7] We ensure that the example remains semantically unchanged. As the thesaurus contains also semantically deviating replacement suggestions, the interface requires the active validation of the replacements by the user.

We conducted the survey among financial professionals between February 3, 2016 and April 4, 2016 in collaboration with a corporate communications service provider. We sent the survey link to more than 4,100 analysts and financial professionals by e-mail. In total, 70 financial professionals participated in the survey of which 66 completed the survey.[8] Across our eight questions, we collect a total of 511 observations, thereof 448 observations for the seven tonality-related questions and 63 observations for the readability-related question. The 66 participants left 17 (out of a total 528) questions unanswered. Overall, the results of the back-testing provide strong evidence for the practical validity of the tonality algorithm and the readability statistics used in the IS prototype.

Finding 1: *Financial professionals evaluate tonality-altered disclosures more positively.* In 70.8 (29.2) percent of the observations, survey participants provide a more favorable 'buy-' or 'sell-'recommendation for the tonality-altered (original) disclosure. This provides strong evidence that the tonality enhancement leads to a more favorable recommendation by financial professionals at a statistically significant level (*t*-statistics 6.064; *P*-Value < 0.001).

Finding 2: *Financial professionals are more sensitive to a better tone in negative than in positive news.* A more detailed analysis reveals that financial professionals react more sensitive to the negative tone in a disclosure with a negative underlying factual news content ('sell' recommendation case) than to the positive tone in a disclosure with positive underlying factual news content ('buy' recommendation case). For the five disclosures with a negative factual content, 76.0 (24.0) percent of the survey participants associate a stronger (weaker) 'Sell' recommendation with the original (tonality-altered) disclosure (*t*-statistics 10.897; *P*-Value < 0.001). For the two disclosures with a positive factual content, 57.5 (42.5) percent of the survey

[7] For negative factual news, we ask *Please select the statement that you associate with a stronger sell recommendation (contains information that is perceived as more negative).* For positive factual news, we ask *Please select the statement that you associate with a stronger buy recommendation (contains information that is perceived as more positive).* For readability, we provide the following question *Please select the statement perceived as easier to read.*

[8] Among the 66 participants, 11 are buy- or sell-side analysts, 7 in investment banking, 5 in communications, 13 in consulting and 30 in other finance-related areas, e.g. advisory. Participants could enter a draw of two Amazon vouchers worth 25 euros each.

participants associate a stronger (weaker) ‘buy’ recommendation with the tonality-altered (original) disclosure (*t*-statistics 1.698; *P*-Value < 0.05). This suggests that the effect of a more positive tone is stronger in negative disclosures. This finding is in line with the psychological negativity bias, which stipulates that human agents weigh negative stimuli more than positive stimuli [33], [34]. Thus, according to the negativity bias, negative information is weighted more heavily than positive information [35].

Finding 3: *Financial professionals rate the readability-altered disclosure as easier to read.* 77.8 percent of the survey participants rate the readability-altered disclosure as easier to read at a statistically significant level (*t*-statistics 5.261; *P*-Value < 0.001).

Table 2. Original and tonality- and readability-altered text pairs of back-testing validation survey (tonality-manipulated words highlighted in bold).

Focus	*Original text extract*	*Altered text extract*
Tonality (neg. factual content)	For the full year 2015, we now **expect** somewhat **weaker** growth for the global economy as well as global industrial and chemical production than was **forecasted** six months ago.	For the full year 2015, we now **anticipate** somewhat **retarded** growth for the global economy as well as global industrial and chemical production than was **predicted** six months ago.
Tonality (neg. factual content)	The oil price-related **decrease** in the Oil & Gas segment **dampened** earnings, while the Functional Materials & Solutions and Chemicals segments provided support through greater contributions.	The Functional Materials & Solutions and Chemicals segments provided support through greater contributions, while the oil price-related **headwinds** in the Oil & Gas segment **compromised** earnings.
Tonality (neg. factual content)	**Contrary** to the general market **expectation**, steel prices **continued to decline**, mainly **due to** a **further** decrease in quotations for Chinese steel exports.	**Different** to the general market **consensus**, steel prices **further fell**, mainly **caused by** an **additional** decrease in quotations for Chinese steel exports.
Tonality (neg. factual content)	The Q3 earnings before interest and taxes (EBIT) of approx. EUR 30 million **turned out significantly weaker than anticipated**.	The Q3 earnings before interest and taxes (EBIT) of approx. EUR 30 million **were behind plan**.
Tonality (neg. factual content)	The company said Thursday that currency fluctuations will **reduce** full-year profit by 85 million pounds, trimming an earlier **forecast** of 100 mio.	The company said Thursday that currency fluctuations will **lower** full-year profit by 85 million pounds, trimming an earlier **prediction** of 100 mio.
Tonality (pos. factual content)	Brew Co. **reported** a better-than-**expected** 7 percent **rise** in underlying third-quarter sales on Thursday, **helped by gains** in Africa and South America, and stronger growth in Europe, where unseasonably mild weather boosted demand.	Brew Co. **published** a better-than-**anticipated** 7 percent **increase** in underlying third-quarter sales on Thursday. **Gains** in Africa and South America, and stronger growth in Europe, where mild weather boosted demand, **stimulated the sales increase**.
Tonality (pos. factual content)	**Following** the transaction, UBM **expects** to **maintain** its investment grade status with the credit rating agencies.	**Succeeding** the transaction, UBM **anticipates** to **confirm** its investment grade status with the credit rating agencies.
Readability	This will be aggravated by losses of sales that are now expected and the consequently missing earnings contributions: the Company’s business prospects are being affected by the worsened economic conditions in China and Russia, which will probably lead to reduced demand, while U.S. business with the commercial vehicle industry as well as the amount of sales to some customers will likely not be at the previously budgeted level	This will be increased by reductions of sales that are now anticipated and the resulting lower earnings contributions. The Company’s business prospects are being affected by the impaired economic conditions in China and Russia, which will probably lead to lessened demand. The U.S. business with the commercial vehicle industry as well as the amount of sales to some customers will likely not be at the previously budgeted level.

Overall, the findings provide supportive evidence for the practical validity of our algorithm-based decision support system for capital market communication. One limitation of our approach is the low number of observations.

6 Managerial Implications

Our IS prototype offers several managerial implications for corporate communication executives. In particular, we have identified three particularly relevant managerial implications:

Implication 1: *Practitioner-friendly tonality analysis.* While current state-of-the-art tonality analysis requires in-depth methodological knowledge as well as advanced analytical skills, the proposed add-in enables any communications practitioner to perform state-of-the-art tonality analysis of disclosures before publication. The add-in thus gives practitioners an information advantage as the perception of texts by investors is forecasted immediately. Furthermore, practitioners are supported with replacement suggestions to improve the tonality and a holistic readability assessment.

Implication 2: *Quality compliance check.* Our IS prototype facilitates a natural compliance check in the writing process as overly negative or positive language is immediately flagged by the tonality assessment. Similarly, issues in the readability become visible when checking the readability metrics of a text. While regulatory frameworks, e.g. the SEC disclosure regulation, provide clear guidance on the content of stock-market-relevant announcements, they only give little guidance on how to write disclosures beyond using plain language [22] [25], [36]. Furthermore, a study of KPMG among investment professionals [1] finds that existing initiatives, such as the SEC Plain English Handbook, have an almost negligible impact in current industry practice. In fact, only 19 percent of the study participants report a positive impact of the plain English initiative on facilitating the disclosure process. In that context, our IS prototype could serve practitioners as a compliance check against regulatory frameworks and support practitioners in putting such regulatory frameworks into practice.

Implication 3: *Process efficiency gains.* The IS prototype integrates directly into conventional text writing processes and offers an objective assessment of the readability and tonality of texts. These assessment results can be easily shared with team members or other departments via the reporting features. Thus, the IS prototype contributes to accelerate the text writing process, especially in settings with multiple stakeholders (e.g. media relations, investor relations, legal, top management). In one interview, we have learned that disclosures of less than 400 words sometimes involve more than 100 iterations. Our tool addresses this process inefficiency by structuring discussions around individual word choices and the overall tone and readability that a company now can deliberately choose in its communication.

In addition, anecdotal evidence from pilot users of the IS prototype confirms the above implications 1 and 3. The director of investor relations at a UK-based pharmaceutical company shares his early user experience in an investor relations professional journal [37]: *"The add-in equips us with deep knowledge on the anticipated reaction of investors. We can now replace subjective feelings by actual evidence when discussing different wording for the very same story"*.

The overall contribution of this IS prototype is twofold: first, we open new avenues for making IS research accessible to practitioners. As such, the prototype serves as a statistically-validated tool to improve form and style of written corporate communication. Second, based on a collaborative approach, the insights and knowledge generated by the practitioners shall flow back to academia, which may then draw conclusions regarding the economics and value of IS on the usage of such a decision support system in practice.

7 Conclusion

In order to successfully compete for investor attention in light of ever-increasing information flows, companies need to ensure that their written communication conveys the relevant information in an easy-to-read manner. Previous research has identified readability and the tone of language as two key elements of successful and positive communication. However, as interviews with investor relations practitioners show, practical tools to steer the investor-specific tone and readability in capital markets communications are not yet available.

The results of the study suggest that improving the tonality of disclosures on basis of the tonality dictionaries leads to significantly more favorable evaluations of the disclosures by financial professionals. In summary, the prototype is a decision support system that not only describes and analyzes data, but directly suggests improvements to users to enhance the tone and readability whilst preparing financial market communication.

Abstract. Social media is becoming increasingly important during crisis situations. Affected people are now enabled to provide helpful on-site information, and emergency service organisations can use social media to inform people and communicate with them. This study addresses how different communication roles in social media affect sensemaking during crises situations. To this end, we conducted a study on Twitter during the Brussels attacks of 2016. We collected a sample of 3,223,197 tweets, which included a total of 1,535,943 participants. Our study reveals that, whereas information distribution dominates early crisis stages, attention-keeping gains in importance in subsequent stages. It is decisively depending on the characteristics and retweet behaviour of certain communication roles that information is being consulted by individuals in a situation of either lack of information or information overload.

Keywords: Sensemaking, Social Media, Twitter, Crisis Communication, Information Systems

1 Introduction

Crisis situations are characterised by ambiguity, confusion and feelings of disorientation. Thus, during disasters, people have a powerful occasion for sensemaking [1] to rationalise what is going on [2]. While sensemaking is the process of social construction by information seeking, sensegiving is a process by which attempts are made to influence the meaning construction and sensemaking of others towards a preferred interpretation of an occurrence [3]. People have a drive for sensemaking due to the motivation of simplification and the desire to construe the world in favourable ways [4]. From one of its first definitions, sensemaking is a process of social construction that occurs especially at that point, when discrepant cues interrupt individuals' ongoing activity in their real life. Thus, sensemaking involves the retrospective development of plausible meanings that rationalise what people are doing and making sense of a situation after it took place [2, 5]. To start

(Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1333-1347

their sensemaking process, individuals need information to connect different cues and draw a picture of the crisis situation.

Social media services such as Facebook or Twitter are increasingly used to communicate during crisis situations by individuals, members of the affected public, professional media and organisations [6, 7]. The microblogging service Twitter especially emerged as a widely used social reporting tool to instantly spread information on social crises [8]. Recent research shows that Twitter is a resilient and rapid information diffusion tool under large-scale crises such as natural disasters [9–11], terror attacks [12, 13] or social movements [14, 15]. Due to its short texting service interface on cell phones, Twitter turned out to be extremely rapid in tweeting situational reports to the online community [16], thus allowing first responders to collectively cope with the crisis situation [17]. During large-scale crises, it has become the norm for the incident to be initially reported by a local eyewitness with a mobile communication device. The report is rapidly distributed through social media services, and mainstream media involvement follows [12, 18]. However, especially in social media communication during large-scale crises, there might either occur the problem of information dearth or the problem of information overload, depending on the particular crisis situation [19]. Therefore, besides a general need for information, people also try to select incoming information in social media. Both the provision of information as well as information selection can be undertaken by hashtags [20], but also through opinion leaders in a social network [21]. Twitter users not only consume the incoming information from their network, but also broadcast the consumed information into their own network [22]. By that, the most active users might direct the public sensemaking process in a social media crisis communication by information selection and providing. In this context, recent research mainly focused on communication patterns during crises [22].

Recent research primarily focused on face-to-face situations [4, 23], though less on sensemaking processes in social media environments. Social media is used as an information source in crisis situations, because it provides fast and easy access [24]. On the one hand, there is a need for information when it comes to natural disasters or terror attacks to start the sensemaking process; on the other hand, communication systems, such as social media applications, might be overloaded with information [19]. Thus, information tends to be chaotic and uncontrollable and it is difficult to maintain a vast overview. This can cause rumours or false information in dangerous situations and might hinder emergency services to manage the crisis efficiently.

An Information-Systems-Journal article [20] identified collective sensemaking through Twitter during the 2011 Egypt Revolution. It could be monitored as the emergence of few hashtags out of many, which mainly brought together crisis-related information. Conclusively, the authors revealed that – besides hashtags – one can investigate whether power users, who receive the highest number of retweets by others [25], direct the collective sensemaking process. If the existence of power users can be confirmed, one can further analyse them and their characteristics. In this paper, we build on the conclusions and suggestions of [20] and address the collective sensemaking and its dynamics through roles and characteristics in a case study. We therefore aim to answer two research questions:

1. Which roles can be identified within the collective sensemaking process in social media during a crisis situation and how do they develop over time?
2. Which characteristics do these roles adopt in the collective sensemaking process in social media?

The remainder of this paper proceeds as follows: in Section 2, we present the status quo of the literature regarding (1) crisis communication in social media, and (2) sensemaking in crisis situations. In Section 3, we introduce our research design, which includes the case description, the data collection and our data analysis in detail. We then present the results of our case study in Section 4, followed by a discussion of our research findings in Section 5. The paper ends with a conclusion in Section 6, including limitations and an outlook for further research.

2 Theoretical Background

Crises are characterised by high levels of threat, situational uncertainty and decision-making pressure under time constraints. Therefore, a critical need for immediate and accurate information occurs in crisis situations, which are usually provided by experts, emergency management professionals, governmental organisations or similar authority figures. Besides the face-to-face-context and traditional media, in the past few years, social media use has also become a consistent feature in crisis response [7, 19, 26]. In a crisis communication process, social media tools are being more and more used by each actor of society, like individuals or media, but also increasingly by formal crisis responders [6, 7, 27]. People use and rely on official sources and other believable eyewitness accounts from which to source their information [28]. In this context [29], six types of information resources under different crises types can be distinguished on Twitter: eyewitness, government, non-governmental organisation, business, traditional and/or internet media and outsiders. While tweets from governments mainly advice or warn the public, tweets from the media offer information about crisis development, whereas outsiders produce information, although they are not personally affected by the event. Depending on the role type, the social media usage in a crisis communication can differ: individuals especially tend to use social media during disasters and post-disasters to investigate what is going on, check with family and friends or mostly direct, relay, synthesize or redistribute (existing) information [9]. Nevertheless, organisations (e.g., emergency management agencies like the police) use social network to spread important information to the public by using microblogging channels for two-way interaction [30–32]. This behaviour was observed during the Queensland Floods in 2010/2011 [33, 34], in the information-sharing behaviour of the US police departments [35] and during the Boston Marathon bombings of 2013 [36]. EMA use their social media channels mainly to broadcast accurate and simple messages to keep populations informed [31], [37]. Furthermore, [37] mention that a government's communication behaviour on social media is dependent on who is tweeting: the PR-department (formal, one-way-communication) or an employee (informal two-way communication). Especially during social crises, companies need to spread reliable information as early as possible to avoid rumours in social media crisis communication [17]. Overall, social media technologies mediate human communications in social crisis situations and present varying patterns of crisis communication [14]. In the social media context, e.g., in Twitter, users not only consume the incoming information from their own network, but also diffuse information to their own network. Furthermore, [21] showed through conducting an analysis of a 260 million Twitter dataset, that approximately 20,000 elite users (celebrities, media, organisations and bloggers) were responsible for 50 percent of the tweets. The authors suggest that people get their news directly through the elite users, who produce information, as well as through intermediaries (ordinary, non-elite users), which have a high follower count and distribute incoming information to their network [21]. Also, user characteristics, for example, the user's popularity, might be a driver for information diffusion [38], as well as URL and hashtag inclusion [39]. A social media crisis communication might involve users who seek information to start their sensemaking process, but also the ones who perform as sensegivers by information providing and sharing. Besides elite users and opinion leaders, in a case study about implementing an online platform for crisis communication, [40] suggest three different user types, which might play an important role for sensemaking in a social media communication: (1) inspectors, who define a certain event, (2) contributors, who provide media content and witness statements, and finally, (3) investigators, who verify media content by organising and sorting data and detecting missing information. In contrast, [41] distinguish the helper, reporter, retweeter and repeater as active user types on Twitter – each with their specific characteristic of producing, distributing and organising information.

Especially in crisis situations, people become highly suggestible and turn to others to find cues [42]. Collective sensemaking is manifested as the communication behaviours of active information seeking, offering and sharing among a like-minded group of people, which helps reduce the level of situational ambiguity and collectively defines an unfolding situation [20, 43]. Collective sensemaking can take place among emergent groups of actors, who interpret information together face-to-face [44], or remotely through social media [35, 45]. Through their ability to facilitate collective sensemaking, social media serves the purpose of filling in the possible information vacuum left by mainstream media [19] or other official channels. Crisis communication differs across media types like Facebook and Twitter [46–50], and therefore, the sensemaking process can also differ. But independent of the type of media and the leading roles, the direction of the sensemaking process is also dependent on the structure of a social network. During the 2011 Egypt Revolution, [20] detected the occurrence of collective sensemaking through collecting information and maintaining situational awareness via hashtags. In detail, the authors revealed that the Twitter space was structured around a few hashtags out of many, which can be related to the keynoting phenomenon [42]. Furthermore, during the 2011 Egypt Revolution, the hashtags' frequency changed over time and a content analysis showed that hashtags were used either as a symbol (to focus attention to a certain issue) or as a word in a sentence (to distribute information to a certain issue). Thus, [20] suggest that there are two characteristics of collective sensemaking through Twitter: (1)

maintaining a high level of awareness to a certain issue during an unstable situation (attention keeping), and (2) offering situational news and information about temporal events (information distributing). The authors conclude that, besides hashtags, one can investigate whether power users direct the collective sensemaking process and how these power users are characterised. In this context, power users could be defined as Twitter users, who receive the highest number of retweets [22], because retweet frequency can be seen as a measure of popularity for the message or its author [51].

3 Research design

In order to address our research questions, we conducted a case study and focused on the Brussels attacks in March 2016 as a type of a public crisis which generated a significant amount of attention and traffic on social media. We have chosen the microblogging platform Twitter as our data source, because recent research shows that Twitter as a social media application is frequently used for crisis communication in social crises or social change [14, 17, 20, 52]. Especially for the 2016 Brussels attacks, there is a direct link between Twitter and the crisis itself: in the first few hours after the bombings, the Crisis Center Belgium (@CrisiscenterBE) called on the people to communicate via social network sites, because mobile communication networks collapsed temporarily.

3.1 Case description

On the morning of 22nd of March 2016, three coordinated nail bombings occurred in Belgium: two at the Brussels Airport in Zaventem, and one at the Maalbeek metro station in Brussels. In the scope of the attacks, a total of 32 victims were killed. Furthermore, over 300 people were injured. Belgium raised the terror threat level to its highest, the public and air traffic of Brussels was suspended, and the population was told to stay where they were. As it was unclear who was responsible for the attacks and whether the suspects were still alive, the search and investigation went on. Thus, the population remained in uncertainty for nearly ten hours. Shortly after the attacks, the crisis communication began to spread over to social network applications.

3.2 Data collection and analysis

For our empirical analysis, we collected tweets regarding the Brussels attacks 2016 and examined the first 27 hours of the crisis, from March 22nd (8:00 am CET) to March 23rd (10:59:59 am CET), 2016. We collected the data through the Search API[1] of Twitter with a self-developed Java crawler, using the library Twitter4J[2]. We saved the collected data in a MySQL database, gathering all tweets that contained at least one of the following three keywords (including the hashtags): *brussels*,

[1] https://dev.twitter.com/rest/public/search, last access: 08-22-2016
[2] http://twitter4j.org, last access: 08-22-2016

brusselsattacks and *bruxelles* and merged them into one dataset. The keywords were selected based on their frequent usage on the platform. After collecting the data, we decided to divide the data into seven time slots in order to handle the large amount of Twitter data. The slots are of different lengths (slot 1-5 cover three hours, slot 6-7 cover six hours) because of the tweet volume and the beginning dynamics of the communication, which decreases over the examined overall time period.

For identifying the roles of participants in the crisis communication, and thus, to answer our first research question, we used methods from social network analysis. For each time slot, we analysed the graph given by the retweet network. The nodes (vertices) of our network are Twitter accounts and the edges are retweets. The network is therefore a directed network and the edge weights are the number of retweets. To analyse and visualise the networks, we used the open source tool Gephi[3]. To produce the visualisations for each time slot, we ran the layout algorithm ForceAtlas 2. The size and colour of each node represent the number of retweets from a node. Subsequently, we filtered each time slot with the aid of the Gephi filter Giant Component to remove all nodes which are not connected to the main network. Furthermore, we highlight the nodes with the highest indegree with their account names. Indegree is the value of how much a node has been retweeted, whereas the outdegree describes the value of how much a node has retweeted itself.

As an elementary assumption, we suggest that the phenomenon of keynoting is not only applicable to the utilisation of hashtags, but also to the determination of roles during crisis situations – especially under consideration of power users of a social network. The retweet function is one of the core functions of information diffusion on Twitter. The retweet activity not only shows reciprocal relations between different users, but is also suitable for identifying particularly active or strong connected users [53]. The decisive key figure to determine power users by the means of a network analysis using Gephi is the indegree measure. Since the available data is represented in a directed graph, the indegree indicates a node's prestige by quantifying its frequency of being retweeted. The retweet frequency for certain tweet messages can be seen as a measure of popularity for the message or its author [51]. For the purpose of arranging a significant sample of power users, we identified the top 20 power users for each time slot based on their indegree value. We focused on the top 20 users, because these users have the most impact on sensemaking in our case.

We also calculated the overall follower count, overall original tweet count, and betweenness centrality value based on the directed graph. Betweenness centrality measures the degree to which a node is in a position of brokerage by summing up the fractions of shortest paths between other pairs of nodes that pass through it [54]. The resulting set of power users are subsequently categorised into roles by all involved authors independently. Similar to [29], we adopted information sources such as traditional/internet media or the government as roles. In contrast to [29], we extended the source of outsiders to the role of private person and various kind of public persons to gain more detailed insights. The categorisation leads us to seven different role types. To complete the analysis regarding the first research question, identified roles

[3] https://gephi.org, last access: 08-22-2016

will be examined towards their development over time and how the presence of certain roles might shift during several crisis stages.

For the second research question, role characteristics are further examined. At that point, we combined findings from existing literature, in particular the definition of attention keepers and information distributors [20] with metrics of the Twitter network and the results of a detailed content analysis concerning all original tweets posted by the top 3 users of each role type sorted by indegree, hence the number of retweets received by those users. To obtain further insights on the characteristics, we conducted a qualitative content analysis [55], considering all original tweets (131) posted by the top 3 accounts of each role type (ranked by indegree). Indeed, 131 tweets represent less than 10 percent of the total number of tweets in the subdataset, but for two of the seven identified role types, there could be related only three user accounts each in the subdataset. Therefore, we decided to examine a smaller set of user accounts' original tweets, but with the same number of accounts per role (namely 3), instead of examining a larger set, but with a dissimilar number of related user accounts per role type. The 131 original tweets of the present selection by 21 user accounts (7 (roles) x 3 (top users)) were evaluated by all authors independently for the purpose of characterising the function each role adopts in the collective sensemaking process in a crisis situation. This includes the measure hashtag-use (symbolic/word) like [20] did, and furthermore, measures URL-use, which is a common measure to characterise tweet content [39], and the type of information (solicitousness, crisis information, opinion, other), which were partially adopted by [29] and further determined by the authors after exploring a random set of tweets out of the 2016 Brussels bombing dataset. We adopted relevant information types from [29], such as sympathy and emotional support, which we redefined as solicitousness. Furthermore, we applied caution and advice, as well as affected individuals, which we combined with infrastructure and utilities to general crisis information. Since we analysed the first 27 hours, and [29] argue that those are the most relevant information types in the early stages of a crisis, we excluded information types like donations and volunteering. Since neither information type addressed opinion sharing, we introduced another information type. Whether a hashtag is used as a symbol or as a word indicates the affiliation to either: 1) attention keeping or 2) information distribution. URL-use supports the designated characteristic of information distribution [39], whereas characterising the information type facilitates the understanding of role characteristics.

4 Findings

The results are split into two parts. The first part shows the results according to the first research question, including the results of the social network analysis and the analysis of the roles' development over time. The second part presents all relevant results to answer the second research question regarding the role characteristics. In total, we received a sample of 3,223,197 tweets, which includes a total number of 1,535,943 participants. In Table 1, the results for each time slot are summarised.

Table 1. Metrics of the directed network per each slot.

Day	Slot	Period (CET)	Edges	Nodes	Diameter	Giant Component (% of nodes)
22nd of March 2016	1	08:00-10:59:59	32620	33252	5	70.96%
	2	11:00-13:59:59	377116	265631	25	95.52%
	3	14:00-16:59:59	557533	386740	25	92.51%
	4	17:00-19:59:59	521538	383329	23	93.16%
	5	20:00-22:59:59	411192	318198	15	93.07%
23rd of March 2016	6	23:00-04:59:59	316421	234150	14	89.93%
	7	05:00-10:59:59	166365	134923	11	86.22%

First, we conducted a social network analysis to identify the top 20 power users ranked by indegree for each time slot. Figures 1-7 represent the social network analysis, which illustrate the top 20 power users for each time slot.

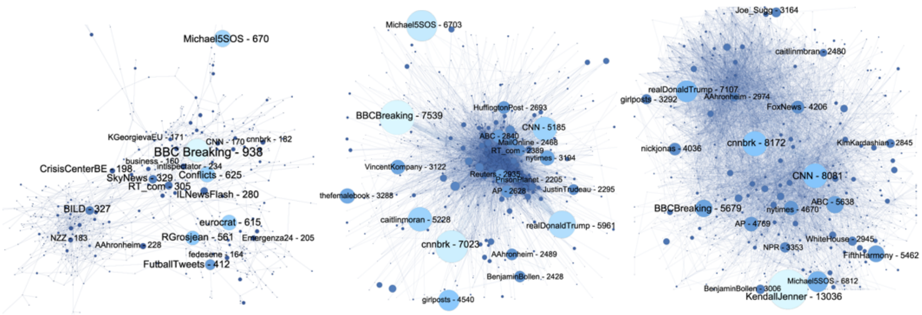

Figure 1. Social Network Analysis results: Time slots 1-3 (from left to right)

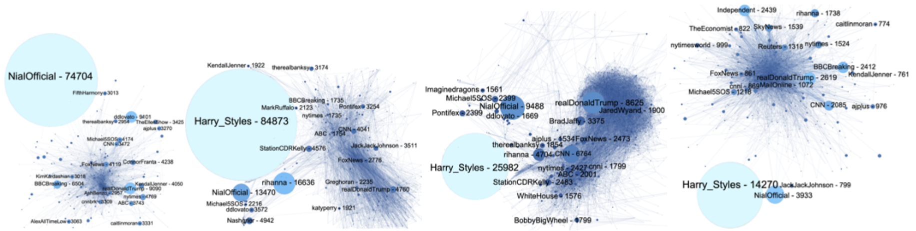

Figure 2. Social Network Analysis results: Time slots 4-7 (from left to right)

By analysing the accounts of the identified top 20 power users (ranked by indegree) of our dataset (table 2), we categorised them in seven distinct roles, derived from [29]: media organisations (e.g.: @CNN); 2) governmental organisations (e.g. @WhiteHouse); 3) private persons; 4) public persons (journalists); 5) public persons (celebrities) (e.g.: @Harry_Styles); 6) public persons (politicians) (e.g.: @RealDonaldTrump); 7) public persons (other) (e.g. @Pontifex).

Table 2. Top 20 users (ranked by overall indegree) categorised into roles

Rank	Role Type	Indegree	Betweenness Centrality (Rank)		Outdegree (Rank)		Follower Count
1	Public Person (celebrity)	125,125	0	(8)	1	(9)	28,6 m
2	Public Person (celebrity)	101,595	0	(8)	1	(9)	25,7 m
3	Public Person (politician)	38,162	0	(8)	4	(7)	9,48 m
4	Media Organisation	29,798	60433.41	(3)	36	(5)	25,57 m
5	Media Organisation	24,806	12677.3	(5)	23	(6)	23,6 m
6	Public Person (celebrity)	24,192	0	(8)	1	(9)	6,23 m
7	Public Person (celebrity)	23,079	0	(8)	1	(9)	62,3 m
8	Public Person (celebrity)	19,008	0	(8)	1	(9)	16,9 m
9	Media Organisation	18,686	41094.0	(4)	23	(6)	39,57 m
10	Media Organisation	18,347	166685.24	(2)	45	(3)	28,01 m
11	Media Organisation	15976	200576928	(1)	59	(1)	6.2 m
12	Media Organisation	14435	6173	(7)	50	(2)	9.4 m
13	Public Person (celebrity)	14342	0	(8)	1	(9)	36.9 m
14	Public Person (journalist)	11813	0	(8)	1	(9)	568 k
15	Public Person (celebrity)	8475	0	(8)	1	(9)	2.9 m
16	Private Person	7982	0	(8)	3	(8)	1.45 m
17	Public Person (other)	7832	0	(8)	1	(9)	6.19 m
18	Media Organisation	7396	6405.5	(6)	38	(4)	7.9 m
19	Public Person (celebrity)	6793	0	(8)	1	(9)	3.28 m
20	Public Person (celebrity)	5863	0	(8)	1	(9)	45.8 m

Second, we manually analysed the development of each role over time (Figure 3). For this step, we identified roles' total number of indegree for each time slot. The overall indegree of each role contains the number of indegree of every power user account, which could be assigned to the specific role.

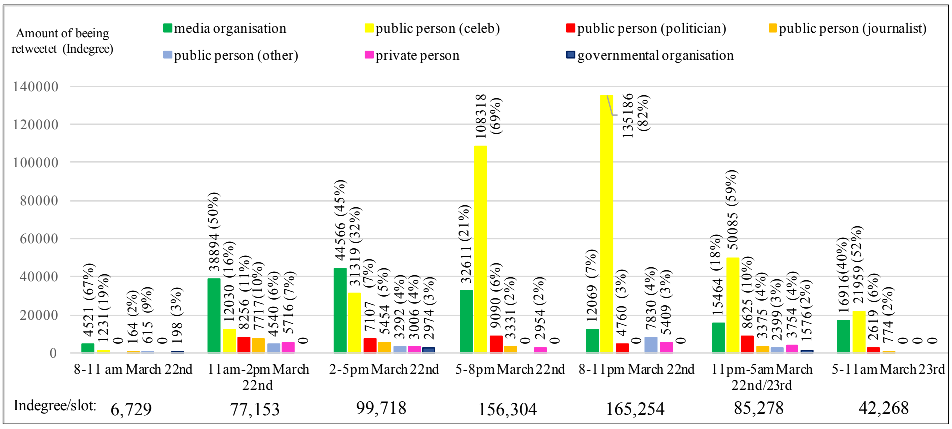

Figure 3. Roles' Development over time by indegree

In the dataset, we could identify two leading roles over time: 'media organisations' dominate over the first three time slots. Then, the role 'public persons' (celebrities) takes the lead until the end of the dataset. In the dataset, we could identify two peaks.

The first peak occurred on 22nd of March through the role media organisation, 2-5pm, the second on 22nd of March, 8-11pm, through the role public persons (celebrities).

As a second consecutive step of analysing upcoming roles in crisis situations, we defined role characteristics for participating roles during the Brussels attacks. Regarding hashtag-use, we found hashtags and keywords used as words within sentences far more often among all role types except governmental organisations (e.g. “All public transport in #Brussels shut down…”). The usage of hashtags as symbols was rather unusual concerning our sample (e.g., “I entrust to God’s mercy all those who lost their lives. #Brussels”). The usage of URLs, which is designated to serve as an indicator for information content, turned out to be non-existent among public persons, whereas media organisations dominated the dissemination of URLs on Twitter. To accomplish the content analysis, the information type of each original tweet was matched to one or more of following categories: 1) crisis information, 2) solicitousness/condolences, 3) opinion, and 4) other (everything what does not fit into category 1-3. Media organisations were found to primarily post crisis information, as well as public persons (journalists) and governmental organisations. Solicitousness and condolences were expressed by public persons (celebrities), private persons and public persons (others). Two-thirds of Tweets stemming from public persons (politicians) contained opinions, the other third contained solicitousness, and the remaining contained content.

Due to a high value in indegree, a high amount of shared crisis information and the usage of hashtags as words, following roles, could be found to be information distributors: media organisations, public persons (journalists) and governmental organisations. To the characteristics of attention keeping, public persons (celebrities), public persons (politicians), private persons and public persons (other) could be matched. As a subordinate characteristic, we defined central users who show a high indegree value and a high betweenness centrality at the same time. From all involved roles, only media organisations suited these special characteristics (see Table 2).

5 Discussion

This study provides findings regarding important sensemaking actors and their different contributions to the sensemaking process, which supports the findings of [20], according to which power users play an integral role during collective sensemaking one way or another. Although retweeting behaviour has various motivations, retweeted messages seem to have a higher informational value than non-retweeted ones [39]. Adopting this theory to power users, their tweets could be perceived with a higher informational value and therefore be selected by individuals for the sensemaking process among a social community. Our findings are consistent with [21], suggesting that people get their news through elite users, who are generally the producer of information. In this context, we identified seven roles, which play a role in the sensemaking process about the Brussels bombings 2016 communication in Twitter. The identified roles are partially consistent with the information sources by [29] regarding media organisations and governmental organisations. In this study, we extended the role of the outsider [29] – people that are not personally involved or affected by the event, to private persons and different kind of public persons like journalists, celebrities, politicians and others. While recent research mainly focused on sensemaking activities regarding information production and distribution [12, 22], our results support the findings of [20], according to which there are two characteristics of the collective sensemaking process. Even though celebrities seem to be important actors during the sensemaking process, their contribution to sensemaking differs from the attributes of media organisations. Media organisations, public persons (journalists) and governmental organisations could be primarily identified as information distributors. Public persons (celebrities or politicians or other), private persons, however, acted as attention keepers in the Brussel crisis communication, maintaining situational awareness by expressing their solicitousness or opinion. To relate these characteristics to the identified role types, we described them in a structural manner based on the Twitter network and the tweeted content. Besides the indegree value, media organisations can be characterised by a high betweenness centrality, a high outdegree, a high URL-use and a word-hashtag-use. In comparison, celebrities are characterised by no betweenness-centrality, a low outdegree, a high follower count, no URL-use and a word-hashtag-use. Contrary to [20], attention keepers in this study predominantly used word-hashtags rather than symbol-hashtags.

The follower count did not seem to predict the user's impact on sensemaking, since, for example, the user with the highest follower count was only on the seventh position in our top 10 ranking by indegree. Still, it is a determining factor for information diffusion, independent of the role type [38] and must be considered by examining online sensemaking. Additionally, a high overall betweenness centrality could be measured for the communication patterns of media organisations, while the betweenness centrality regarding tweets by public persons (celebrities) was nearly non-existent. Taking into account that the social network analysis was conducted for a retweet network, the betweenness centrality can be interpreted as a bridging function within the network that allows information to diffuse on the shortest routes. A non-existent score however emerges from not retweeting other user's content, while a high score identifies users, which are not only central to the social network, but also consumed and broadcasted other user's information. This is of high importance for the flow of crisis communication within a network and therefore for the sensemaking process [20, 43]. Those assumptions are reflected by the top 20 roles' outdegree. Whereas celebrities' indegree arose from one tweet alone, media organisations have an original tweet count varying between 23 and 45 tweets during the first 27 hours. In fact, media organisations posted on average at least one tweet per hour. The findings emphasise the influence of media organisations on public communication in social networks (as gatekeepers) and their role in the collective sensemaking process.

The observation of the role's development during the crisis moreover holds valuable information considering the sensemaking process. Similar to [29], our findings reveal that media organisations seem to be a dominant role during the early stage of a crisis, which can be defined as the event-breakout-phase [22], and is characterised by breaking news rather than local information avenues. Media organisations' high number of retweets can be explained by the public's need for information, which constitutes the starting point for the individual sensemaking process [1]. People turn to social media, since it serves the purpose of filling in the possible information vacuum left by mainstream media and therefore facilitates collective sensemaking [19].

Our findings are consistent with [29] stating that media organisations show the highest fraction of tweets in crises situations that are instantaneous like the Brussels bombings. Simultaneously, large-scale crises on social media can elicit the problem of information dearth or information overload, depending on the particular crisis situation [19]. People need to find a way to select the incoming information in a social media crisis communication, which can be comprehended by focusing on power users (as roles). In both cases, power users can either provide relevant information to fill the information gap or help start people's sensemaking process by sharing relevant content and distance themselves from social media noise. Adopting the suggestion by [42], according to which the sensemaking process consists of the chaotic milling and organised keynoting interactions, our study provides evidence that not only hashtags can facilitate keynoting interactions [20], but also power users e.g. celebrities drawing attention to the crisis by declaring solicitousness, or media organisations distributing information about the development of crisis, or establishing or distributing symbols (e.g. pictures) related to the crisis. These actors might help people overcome the chaotic situation when a crisis breaks out by providing and selecting relevant information. Consistent with [42], during the breakout-phase, media organisations seem to hold the most dominant voices, which emerge to override the chaotic opinions of the crowd (milling) by starting organised keynoting interactions.

However, the dominant sensemaking role of media organisations can only be observed for the early stages of the course of events. After a few hours, their number of retweets decreases, while the number of retweets of celebrities heavily increases. Their role in collective sensemaking in crisis situations has not been respected in recent literature yet, though our study provides evidence that elite users like celebrities contribute strongly to the people's sensemaking process. Celebrities' influence seems to be even greater than information provided by media organisations, since their indegree are significantly higher. Regarding the development of the roles, we observed that in the early stages of a crisis event, people turn to social media to gather and share relevant information for their individual sensemaking process. Roles, which act as information distributors, are dominant sensegivers at this point, as they try to support and direct the sensemaking of others [3]. After the event-breakout-phase, celebrities take over as dominant roles, acting as attention keepers by sharing solicitousness and opinions to influence people's meaning construction [3].

6 Conclusion

In this study, we analysed the Twitter communication of the Brussels attacks (2016). Through conducting a social network analysis, we could identify seven roles which are relevant for the collective sensemaking process during a crisis. Although some roles seemed to have a larger impact on sensemaking than others, every single categorised role contributed to the collective sensemaking process.

Given the complexity of human-involved collective sensemaking, focusing on retweets might not provide a holistic view. As the API is the only access point to large-scale Twitter data available to researchers outside of Twitter as a platform, there is no opportunity to independently verify the quality of the dataset. To mitigate this problem, [56] suggest creating more specific parameter sets with different users, bounding boxes, and keywords. We furthermore argue that a sample of 131 original tweets for content analysis is not large enough to generalise the different role characteristics we found. In the meantime, we analysed a bigger sample, but reached similar results. Nevertheless, for further research, we plan to expand the sample. We also note that our conclusions are case-specific and cannot be generalised without care and without examining a number of further crises, especially of different types.

Following the leading point of sensemaking through roles in crisis situations, the analysis of the case revealed significant aspects of social interaction in crisis communication. We contributed to the understanding of roles and their influence in social media during the sensemaking processes. Furthermore, this is one of the few studies that considers the dynamics of an event. In the underlying analysis, we detected a shift in the dominance of role characteristics regarding consecutive crisis stages. On a temporal layer, role characteristics alter from information distribution in early crisis stages to attention keeping in subsequent stages. The information being consulted by individuals decisively depends on the behaviour of major roles. In fact, information diffusion through retweets is a crucial means for collective sensemaking. If a situation generates a lack of information, (central) roles provide fast access to information, which can be immediately spread within a network or social cluster. In case of an information overload, the activity of roles in social media affects the selection of information to urge the sensemaking process. Through following the flow of information based on roles, the shaping of public opinion can be assessed more precisely.

Based on our findings, we recommend for further research to search for these role types in other Twitter networks automatically. Of course, these structural role descriptions have to be verified with other, larger datasets. Another approach that hasn't been addressed so far is the danger of upcoming rumours during crisis situation. [17] point out the importance of spreading trustworthy information as early as possible to avoid these. Since rumours are also part of the collective sensemaking process, one could examine the roles' impact on upcoming rumours in a social media crisis communication and the perceived trustworthiness by the public.

Abstract. Die Beratungsbranche sieht sich, genau wie ihre Klienten, ständig neuen Herausforderungen und sich verändernden Rahmenbedingungen gegenüber. Beratungsanbieter sollten daher ihr Leistungsportfolio immer wieder kritisch infrage stellen. Obwohl sie die Wettbewerbsfähigkeit ihrer Klienten durch innovative Lösungen stärken und dort maßgeblich an der Entwicklung neuer Konzepte zur Digitalisierung beteiligt sind, wird bei der Erbringung von Beratungsleistungen oft nur auf traditionelle Face-to-Face Ansätze zurückgegriffen. Ein virtueller Prozess ist demgegenüber ein Prozess, in dem die physische Interaktion verschwindet. Der Übergang eines physischen Prozesses hin zu einem virtuellen Prozess wird als „Prozess Virtualisierung" bezeichnet. Virtualisierung ist ein Trend, dem sich Beratungsunternehmen auch hinsichtlich ihrer eigenen Geschäftsprozesse stellen müssen. Theoriegeleitet sowie auf Basis ergänzender empirischer Forschung leiten wir in diesem Beitrag ein mögliches Vorgehen ab, um das Virtualisierungspotenzial von Beratungsprozessen (oder deren Teilschritten) im konkreten Fall ex ante beurteilen zu können.

Keywords: Virtualisierung, Digitale Transformation, Unternehmensberatung, Geschäftsmodellinnovation, Beratungsprozess, Beratungsforschung.

1 Grundlagen und Motivation

Unternehmensberatung (Consulting) kann definiert werden als professionelle Dienstleistung, die durch eine oder mehrere, im allgemeinen fachlich dazu befähigte und von den beratenen Klienten hierarchisch unabhängige Person(en) zeitlich befristet sowie meist gegen Entgelt erbracht wird [18]. Sie hat zum Ziel, betriebswirtschaftliche Probleme des beauftragenden Unternehmens interaktiv mit den Klienten zu definieren, strukturieren und analysieren, sowie Problemlösungen zu erarbeiten, und auf Wunsch ihre Umsetzung gemeinsam mit Vertretern des Klienten zu planen und im Unternehmen zu realisieren [18]. In diesem üblichen Verständnis ist Unternehmensberatung ein „people business". Dabei suchen Berater Klienten auf, um

Nissen, V.; Seifert, H. (2017): Ermittlung des Virtualisierungspotenzials von Beratungsleistungen im Consulting, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1348-1362

mit ihnen gemeinsam vor Ort interaktiv (Face-to-Face) unternehmensrelevante Problemstellungen zu bearbeiten.

Die Beratungsbranche ist, trotz positiver Umsatzentwicklung, mit neuen Herausforderungen konfrontiert. Einerseits nimmt die Konkurrenz mit Anbietern aus Billiglohnländern und Freelancern im Bereich von Standardleistungen zu. Daneben betreten neue Wettbewerber mit innovativen Geschäftsmodellen und technologiegetriebenen Beratungsansätzen den Markt. Auf der Klientenseite ist eine zunehmende Professionalisierung im Einkauf und Umgang mit Unternehmensberatung zu beobachten. Auch hat die Preis-Sensitivität zugenommen.

Die Virtualisierung von Beratungsleistungen kann, angesichts der beschriebenen Herausforderungen, eine innovative Strategie zur Sicherung des nachhaltigen Unternehmenserfolgs sein und klassische Angebote der Unternehmensberatung ergänzen. Virtualisierung zielt darauf ab, den Anteil direkter Face-to-Face Interaktion zwischen Berater und Klient durch den geeigneten Einsatz von Informations- und Kommunikationstechnologien (IKT) zu reduzieren [11] [20]. Sie kann damit als Strategie zur digitalen Transformation des Beratungsgeschäftes bezeichnet werden.

Notwendig zur Realisierung dieser ambitionierten Vision sind geeignete Artefakte, wie webbasierte Beratungsplattformen, mobile Beratungsapplikationen, semantische Technologien, Data Mining- und Kooperations-Werkzeuge. Ebenso werden Konzepte benötigt, wie die Virtualisierbarkeit von Beratungsprozessen beurteilt und Lösungen, die konventionelle und virtualisierte Beratung zu einem Ganzen verbinden, entwickelt werden können. Methoden und Techniken der Virtualisierung sind zu schaffen. Hier besteht noch erheblicher Forschungsbedarf [26].

Während die raumzeitliche Flexibilität bei der Virtualisierung zunimmt, kann die reduzierte persönliche Interaktion von Beratern und Klienten deren Beziehung beeinträchtigen. Ob Virtualisierung der richtige Ansatz ist, einen Beratungsprozess zu verändern und wie dies am besten geschehen kann, muss intensiv geprüft werden. Hier besteht heute jedoch ein Mangel an belastbaren Kriterien und Virtualisierungskonzepten. Daraus leitet sich die Forschungsfrage des vorliegenden Beitrags ab:
Wie kann das Potenzial zur Virtualisierung einer Beratungsleistung (oder eines Teilschrittes) anhand konkreter Kriterien ex ante beurteilt werden?

2 Inhaltliche Einordnung der Arbeit (Related Work)

Die hier bearbeitete Forschungsfrage ist dem Consulting Research [18] [19] zuzurechnen, worunter die wissenschaftliche Beschäftigung mit der Dienstleistung Unternehmensberatung, den Beratungsunternehmen als Organisationen und dem Beratungsmarkt mit seinen verschiedenen Teilnehmern auf Anbieter- und Nachfragerseite verstanden wird. Consulting Research hat zwei Anliegen [18]. Erstens, die wissenschaftliche Durchdringung des Themas Unternehmensberatung, wobei der von einzelnen Beratungsprojekten abstrahierende wissenschaftliche Erkenntnisgewinn im Mittelpunkt steht. Zweitens, die Übertragung wissenschaftlicher Theorien, Erkenntnisse und Methoden auf die unternehmerische Praxis mit dem Ziel, Aufgabenstellungen und Probleme im Umfeld von Beratungsprozessen und

Beratungsunternehmen besser als bisher zu lösen. Der vorliegende Beitrag ordnet sich schwerpunktmäßig beim zweiten Kernanliegen des Consulting Research ein, da letztlich eine Vorgehensweise entwickelt wird, die Beratungsanbieter bei der digitalen Transformation ihres Geschäftes unterstützen soll.

Gleichzeitig hat unser Beitrag eine gewisse Nähe zum Thema Service Modularisierung [7] [12] [25]. Durch die gezielte Anwendung von Standardisierung und Modularisierung wird die Virtualisierung von Einzelaufgaben und Teilprozessen in der Beratung vorbereitet. Diese Module können, gegebenenfalls bedarfsgerecht neu kombiniert, die Basis für innovative Beratungsleistungen bilden.

3 Methodik und Datengrundlage

3.1 Überblick

Zur Beantwortung der Forschungsfrage wird im ersten Schritt auf die theoretische Grundlage der *process virtualization theory* von Overby [23] [24] zurückgegriffen und diese in die Domäne Consulting übertragen. Ergänzend liefert eine großzahlige Studie zu den Einflussfaktoren des Virtualisierungspotenzials im deutschen Beratungsmarkt weitere Hinweise für ein sinnvolles Vorgehen. Im dritten Schritt wird eine strategische Perspektive eingenommen, die zusätzlich Chancen und Risiken der Virtualisierung auf Basis einer literaturgestützen Delphi-Studie mit Beratern und Klienten einbezieht. Im Ergebnis ergibt sich ein Analyseprozess in drei Schritten, der im weiteren Verlauf des Beitrages genauer dargestellt wird. Die methodischen Grundlagen dazu werden nachfolgend kurz dargelegt.

3.2 Prozessvirtualisierung – theoretische Fundierung

Ein virtueller Prozess ist ein Prozess, in dem die physische Interaktion zwischen den Menschen und/oder Maschinen verschwindet. Der Übergang eines physischen Prozesses hin zu einem virtuellen Prozess wird als „Prozess Virtualisierung“ bezeichnet. Overby [23] [24] entwickelte die generisch angelegte ‚Process Virtualization Theory‘ (PVT) und führte den Begriff der „Prozess Virtualisierbarkeit“ ein. Overby sieht die Nutzung/Akzeptanz und die Qualität der Prozessergebnisse als Basis, um die Virtualisierbarkeit eines Prozesses (als abhängige Größe) ex post messen zu können. Daneben benennt er eine Reihe von Einflussgrößen, die sich auf die Virtualisierbarkeit eines Prozesses auswirken und demnach für die hier angestrebte ex ante Beurteilung des Virtualisierungspotenzials von Beratungsprozessen grundsätzlich geeignet erscheinen. Die PVT erscheint als der passende theoretische Anker für diese Arbeit, weil sie im Gegensatz zur Theorie des Task-Technology-Fit nicht der Evaluation der Eignung einer Technologie für eine bestimmte Aufgabe dient, sondern vielmehr der Erklärung, wie gut sich eine Aufgabe (als Teil eines Prozesses) prinzipiell für den Technologieeinsatz eignet. Sie ist hier auch dem Technology-Acceptance-Model (TAM) vorzuziehen, da Beratungsleistungen als Co-Kreation von Berater und Klient primär aus Prozessperspektive (und nicht im Sinne reiner Technologieakzeptanz) zu betrachten sind [24]. Auch wurde das TAM bezüglich seiner mangelnden Relevanz und Nützlichkeit, zukünftige Systeme besser zu gestalten, stark kritisiert [2].

Gemäß der PVT wirken sich insbesondere die folgenden Prozesseigenschaften negativ auf die Virtualisierbarkeit eines Prozesses aus: hohe sensorische Anforderungen (da physische Interaktion entfällt), hohe Anforderungen an die persönliche Beziehungsebene der Beteiligten und daran anknüpfende Konstrukte wie Vertrauen, hohe Anforderungen an die Synchronität von Aktivitäten in der Prozessausführung und hohe Identifikations- und Steuerungsanforderungen im Prozess (da bei Virtualisierung die tatsächlich Interagierenden leichter verschleiert werden können).

Demgegenüber mildern die folgenden Eigenschaften des (IT-basierten) Virtualisierungsmechanismus die genannten Prozesscharakteristika und wirken sich somit auf die Virtualisierbarkeit eines Prozesses aus: die Fähigkeit der IT prozessrelevante Informationen darzustellen („representation"), die Fähigkeit der IT eine zeit- und ortsunabhängige Prozessteilnahme zu ermöglichen („reach"), sowie die Möglichkeiten durch IT eine Authentifikation der Prozessbeteiligten und Überwachung des Prozessablaufes zu gewährleisten („monitoring capability").

Balci und Rosenkranz [3] merken an, dass die Messbarkeit der Prozess-Virtualisierbarkeit bisher kaum empirisch untersucht ist. Sie finden in einer eigenen Untersuchung empirische Bestätigung für die PVT, sehen jedoch gleichzeitig Hinweise auf deren Unvollständigkeit. Demnach spielen auch Faktoren eine Rolle, die Merkmale der Prozessteilnehmer (z.B. IT-Kenntnisse) betreffen.

3.3 Kriterien der Virtualisierbarkeit – empirische Studie

Der Aspekt einer möglichen Unvollständigkeit der PVT wird für den Anwendungsbereich Consulting durch eine ergänzende großzahlige Befragung zu den Kriterien der Virtualisierbarkeit von Beratungsleistungen aufgegriffen. Befragt wurden, in Kooperation mit dem Bundesverband Deutscher Unternehmensberater BDU e.V., Gesellschaften aller Größen aus der gesamten Consultingbranche.

Im Rahmen der hier beschriebenen Studie wurden Daten online mit Hilfe der Umfragesoftware *Unipark QuestBack* erhoben. Mit Hilfe einer Online-Befragung ergeben sich zahlreiche Vorteile, wie die geringen Erhebungskosten, der Entfall der manuellen Dateneingabe oder die schnelle Verfügbarkeit der Daten [1]. Den Vorteilen bei Online-Befragungen stehen allerdings auch Nachteile gegenüber [13]. So entsteht aufgrund der Anonymität im Internet beispielsweise ein erhöhtes Risiko von Mehrfachteilnahmen. Dieser Aspekt wurde u.a. dadurch minimiert, dass der BDU aus seinen Kontakten Einladungen zur Teilnahme an die Mitglieder versendete. Da der BDU bezüglich seiner Mitglieder einen guten Querschnitt der deutschen Beratungslandschaft darstellt, sind hier Verzerrungen des Ergebnisses kaum wahrscheinlich. Weiterhin wurde viel Wert auf die Verständlichkeit des Fragebogens gelegt und dies im Rahmen eines Pre-Tests verifiziert.

Die Befragung der Teilnehmer wurde im Zeitraum vom 23. November bis 18. Dezember 2015 durchgeführt. Insgesamt klickten 765 Teilnehmer auf den Link zur Startseite der Online-Befragung, der zuvor in einer E-Mail versendet wurde. 654

Teilnehmer starteten die eigentliche Online-Befragung. In der anschließenden Editierung und Kodierung der Daten fand eine Datenbereinigung statt. Dabei wurden 102 Antworten ausgeschlossen, da sie die Anforderungen an Vollständigkeit nicht erfüllten. In Summe konnten so 552 Fragebögen für die weitere statistische Analyse berücksichtigt werden. Insgesamt wird der deutsche Beratungsmarkt nach Umsatz und Beratungsfeldern gut abgebildet, so dass von weitgehend repräsentativen Ergebnissen ausgegangen werden kann. Auch hinsichtlich Alter und Berufserfahrung der Befragten zeigte sich, dass das Meinungsbild von Beratern mit unterschiedlichen Erfahrungsniveaus erfasst werden konnte. Die Repräsentativität der Stichprobe ist insofern einzuschränken, weil die Datenerhebungsmethode bei allen Vorzügen nicht ganz unproblematisch. So setzt diese Methode voraus, dass Teilnehmer in der Lage sind, den Online-Fragebogen entsprechend zu nutzen. Teilnehmer, die wenig Internet-affin sind, könnten hier ausgegrenzt werden [13], was bei der Zielgruppe der Unternehmensberater jedoch kaum wahrscheinlich ist.

Die Befragung zielte insgesamt darauf ab, den Status Quo und die Perspektiven der digitalen Transformation in der Unternehmensberatung in Deutschland zu klären. In diesem Beitrag sollen jedoch nur Kriterien betrachtet werden, um das Virtualisierungspotenzial von Beratungsleistungen zu bestimmen. Hierzu wurde vorab eine strukturierte Literaturanalyse nach Webster und Watson [27] durchgeführt, um mögliche Kandidaten für solche Kriterien zu identifizieren. Neben der originären Literatur zur Beratungsvirtualisierung wurde auch in den Themenbereichen Telearbeit, Telekooperation, Computer Supported * Work, Task Analysis, E-Government und E-Services recherchiert, um auf das Consulting potenziell übertragbare Resultate zu identifizieren. Weiterhin sind Beiträge, die von Overby zitiert wurden oder die Overby zitieren, berücksichtigt worden. Insgesamt konnten 41 Beiträge für die Recherche genutzt werden. Durch die anschließende Literatur-Synthese und Erstellung einer Konzeptmatrix wurde eine Liste an Kriterien der Virtualisierbarkeit erarbeitet. Diese Kriterien lassen sich in die drei Gruppen *Klient*, *Beratung* und *Beratungsaufgabe* clustern. Die besondere Relevanz dieser drei Gruppen bei der Untersuchung der Virtualisierung von Beratungsleistungen wird in der Literatur von Autoren wie Wurdack [28] herausgestellt. Darüber hinaus wurden diese Gruppierungen bereits im Kontext der Standardisierung von Beratungsleistungen genutzt [10] und auch im Bereich der Modularisierung von Dienstleistungen als Schlüsselaspekte benannt [7].

Die Gruppe *Klient* beinhaltet alle Kriterien, die im Zusammenhang mit der Integration des Klienten stehen. Dies umfasst sowohl das Vertrauen des Klienten in das Beratungsunternehmen als auch die Akzeptanz des Klienten für die virtuelle Beratungsleistung. Ferner können die technischen Anforderungen des Klienten sowie die Erfahrung des Klienten mit virtuellen Beratungsleistungen genannt werden.

Die zweite Gruppe *Beratung* beinhaltet alle Kriterien, die im Zusammenhang mit der Beratungsorganisation, also dem Beratungsunternehmen selbst, stehen. Hierzu zählen sowohl die Erfahrung der Beratung mit virtuellen Beratungsleistungen als auch die Reife des Wissensmanagements. Weiterhin sind die Auslastung der Berater und die Seniorität der Berater bestimmend für die konkrete Virtualisierbarkeit.

Die dritte Gruppe *Beratungsaufgabe* deckt die Kriterien ab, die eine Evaluation des Virtualisierungspotenzials auf Ebene der Beratungsaufgabe ermöglichen. Dies umfasst sowohl die Kritikalität, d. h. das Risiko und Konfliktpotenzial der Aufgabe, als auch die Komplexität und mithin die Veränderlichkeit, Vielzahl und Vielfalt der Aufgabe. Ferner gilt es, die Dringlichkeit, also den Termindruck der Aufgabe sowie die Wichtigkeit, dass bedeutet die individuelle Bedeutung der Aufgabe, zu bestimmen. Weitere Kriterien, die in diese dritte Gruppe gehören, sind die Vertraulichkeit der Informationen und Aufgabe und die Interaktivität, d. h. die Frequenz, Dauer, Art und Intensität d. Berater-Klienten-Interaktion. Ein wesentliches und abschließendes Kriterium der Gruppe Beratungsaufgabe ist die Individualität und mithin der Anspruch des Klienten an eine individuelle Lösung.

Nach der literaturgestützten Herleitung dieses initialen Kriterienkatalogs galt es, die Kriterien im Rahmen einer großzahligen Befragung von Unternehmensberatern zu evaluieren. Um das Virtualisierungspotenzial praxistauglich beurteilen zu können, ging es hierbei auch darum, die Anzahl der bislang 15 Kriterien auf ein in den Unternehmen handhabbares Maß zu reduzieren.

Die Ergebnisse der Literaturanalyse bildeten die Grundlage einer entsprechenden Frage in der Online-Studie, bei der die Teilnehmer einerseits die Relevanz dieser Kriterien anhand einer 6-stufigen Likert-Skala beurteilen sollten, andererseits aber auch die Freitext-Möglichkeit hatten, weitere Kriterien zu ergänzen und zu beurteilen. Insgesamt konnten in unserer Studie hierzu die Aussagen von 374 Teilnehmern ausgewertet werden.

Um die Kriterien der Virtualisierbarkeit von Beratungsleistungen zu charakterisieren, bietet sich die Faktorenanalyse (EFA) als dimensionsreduzierendes Verfahren an. Hierdurch können latente Faktoren identifiziert werden, die entsprechend fokussiert die Einflussfaktoren wiedergeben [9]. In diesem Zusammenhang wurde für die 15 initialen Kriterienkandidaten auch Cronbach's Alpha berechnet, das grundsätzlich Werte zwischen 0 und 1 annehmen kann. Je höher der Wert von Cronbach's Alpha, desto höher ist die Korrelation zwischen den Indikatoren und damit die Interne-Konsistenz-Reliabilität [8]. Dementsprechend sollte ein Cronbach's Alpha Wert $\geq 0{,}7$ vorliegen [22]. Bei uns beträgt dieser Wert 0,83.

Für die Durchführung der EFA wurde zunächst der Datensatz mittels einer Complete-Case Analyse bereinigt und auf seine prinzipielle Eignung für die Analyse untersucht. Zentrale Kriterien, die darüber Aufschluss geben, ob ein Datensatz für eine EFA grundsätzlich geeignet ist, sind das KMO Kriterium und der Bartlett-Test [4]. Hierbei deutet ein KMO-Wert von über 0,5 daraufhin [15], dass die Daten grundsätzlich eine gewisse Korrelation aufweisen und damit für eine EFA genutzt werden können. Im vorliegenden Fall beträgt der KMO-Wert 0,81. Der Bartlett-Test deutet seinerseits bei einer Ablehnung der Nullhypothese auf eine grundsätzliche Eignung der Daten für eine EFA hin. Für die vorhandenen Daten ist dieser signifikant ($p < 0{,}001$) von Null verschieden. Die Nullhypothese, dass die Korrelationsmatrix nur zufällig von der Einheitsmatrix verschieden ist, kann also abgelehnt werden, womit auch der Bartlett-Test die Eignung der Daten für eine EFA bestätigt.

Der Tabelle 1 ist zu entnehmen, dass sich die Items recht trennscharf den einzelnen Faktoren zuordnen lassen, da jedes Item, mit zwei Ausnahmen, bei einem cutoff-Wert von 0,5 lediglich auf einen Faktor lädt. Gleichzeitig liegen bei den meisten Items Faktorladungen über 0,7 vor. Im Ergebnis lassen sich die 15 Kriterienkandidaten auf 7 Faktoren reduzieren, denen wir aussagekräftige Namen zu ihrem jeweiligen Fokus gegeben haben. Diese bilden nun die wichtigste Grundlage, um die Virtualisierbarkeit von Leistungen der Unternehmensberatung ex ante zu beurteilen.

Tabelle 1. Faktoranalyse zu den Kriterien der Virtualisierbarkeit von Beratungsleistungen.

Rotierte Komponentenmatrix	Komplexität	Verfügbarkeit geeigneter Berater	Akzeptanz d. Klienten	Reife d. Beratungs-organisation	Dringlichkeit d. Beratungsleistung	Vertrauen zwischen d. Akteuren	Interaktivität
Kritikalität	,888						
Komplexität	,856						
Vertraulichkeit	,770						
Individualität	,693						
Seniorität der Berater		,859					
Auslastung der Berater		,833					
Erfahrung des Klienten mit virtuellen Beratungsleistungen			,843				
Anforderungen des Klienten an die zu nutzende Virtualisierungstechnologie			,701				
Akzeptanz des Klienten für die virtuelle Beratungsleistung			,574			(,566)	
Erfahrung der Beratung mit virtuellen Beratungsleistungen				,859			
Reife des Wissensmanagements				,790			
Dringlichkeit					,888		
Wichtigkeit	(,546)				,627		
Vertrauen des Klienten in das Beratungsunternehmen						,896	
Interaktivität							,757

Extraktionsmethode: Hauptkomponentenanalyse. Rotationsmethode: Varimax mit Kaiser-Normalisierung. Die Rotation ist in 6 Iterationen konvergiert. Koeffizienten mit einem Wert von <0,5 wurden unterdrückt.

3.4 Chancen und Risiken der Virtualisierung – Literatur- und Delphi-Studie

Die klientenbezogenen Chancen und Risiken virtueller Beratungsleistungen wurden durch Nissen et al. [20] mittels einer Kombination aus strukturierter Literaturrecherche und einer Delphi-Studie mit Teilnehmern verschiedener Branchen untersucht. Es ergaben sich die folgenden, auf der strategischen Analyseebene relevanten Ergebnisse.

Klienten verknüpfen mit virtualisierten Beratungsangeboten die Chance auf größere Flexibilität und Verfügbarkeit, höhere Arbeits- und Reaktionsgeschwindigkeit im Projekt sowie die Hoffnung, Beratungsleistungen zu günstigeren Preisen zu erhalten. Weiterhin erhoffen sich die Klienten durch die intensivere Nutzung der Digitalisierung, Ergebnisse einfacher verarbeiten und wiederverwenden zu können. Auch sieht man die Chance, besonders innovative und teilweise automatisierte Beratungslösungen in Anspruch nehmen zu können.

Dem stehen jedoch Befürchtungen und Risiken auf Klientenseite gegenüber. Diese beziehen sich einerseits auf mögliche Kommunikations-, Koordinations- und Kooperationsprobleme sowie die stärkere Abhängigkeit von technischen Aspekten bei der Zusammenarbeit und damit verbundenen Gefahren wie Datenmissbrauch und Kontrollverlust. Andererseits wird befürchtet, die Ergebnisqualität könnte leiden, da die Beziehung zwischen Beratern und Klienten sich verschlechtert, Vertrauen und Loyalität sinken und die Individualisierung der Leistungserbringung abnimmt.

Die gewonnenen Erkenntnisse fließen nun in einen mehrstufigen Vorschlag zur Analyse des Virtualisierungspotenzials von Beratungsleistungen ein. Akzeptanz auf Kundenseite wird dabei in Übereinstimmung mit Overby [23] [24] und Bruhn [5] primär als Ergebnis der erfolgreichen Umsetzung von Virtualisierungspotenzialen angesehen, ist also ein Ziel.

4 Ermittlung des Virtualisierungspotenzials von Beratungsleistungen

4.1 Überblick

Die Erfolgskette [5] virtueller Beratungsleistungen beschreibt die Stufen, die zu absolvieren sind, um Virtualisierung in der Unternehmensberatung erfolgreich umzusetzen (Abb. 1). Das Angebot und die Gestaltung virtueller Beratungsprodukte führen im Idealfall zu einer hohen Akzeptanz seitens der Kunden. In Abhängigkeit von alternativen Beratungsmöglichkeiten, empfundenen Risiken und Vorteilen, kommt es dann zu einer Nutzung des Beratungsproduktes. Während der Inanspruchnahme der Leistung beurteilt der Klient die Qualität. Entspricht diese seinen Erwartungen, entsteht Zufriedenheit. Die Zufriedenheit der Kunden stellt eine Voraussetzung dafür dar, dass auf der letzten Stufe das Beratungsunternehmen einen Erfolg mit dem angebotenen virtualisierten Beratungsleistungsportfolio realisiert.

Um eine möglichst hohe Akzeptanz der Kunden zu erzielen und deren Nutzungsabsicht zu erhöhen, ist die Gestaltung der virtualisierten Beratungsdienstleistung von großer Bedeutung. Hierzu gilt es, das Virtualisierungspotenzial zunächst in der Analyse- und Gestaltungsphase einer virtuellen Beratungsleistung fundiert zu analysieren.

Im Ergebnis erscheint es sinnvoll, die Ermittlung des Virtualisierungspotenzials im Bereich der Unternehmensberatung in drei separaten Teilschritten vorzunehmen, die nun näher dargestellt werden (Abb. 1). Die erste Stufe, die Evaluation des prozessualen Virtualisierungspotenzials, basiert auf der *Process Virtualization Theory* von Overby und untersucht, wie die Eigenschaften des Beratungsprozesses das Virtualisierungspotenzial beeinflussen. Die zweite Stufe, die unternehmensbezogene Analyse, untersucht zentrale Faktoren innerhalb des Beratungsunternehmens und wie diese auf das Virtualisierungspotenzial wirken. In der dritten und strategischen Stufe werden Chancen und Risiken der Virtualisierung aus Kunden- und Beratungssicht im Rahmen eines Business Case untersucht. Für die spätere projektbezogene Umsetzung spielen dann die Qualitätserwartungen des Kunden eine erfolgsentscheidende Rolle.

Der Evaluationsprozess startet also in Schritt 1 mit den PVT-orientierten Einflussfaktoren. Die folgenden Evaluationsschritte wenden die restlichen Kriterien an und ergänzen sie um Ergebnisse zu Chancen und Risiken der aktuellen Virtualisierungsentscheidung. Der Evaluationsprozess wird im Verlauf immer spezifischer und mündet in einen Business Case des jeweiligen Beratungshauses.

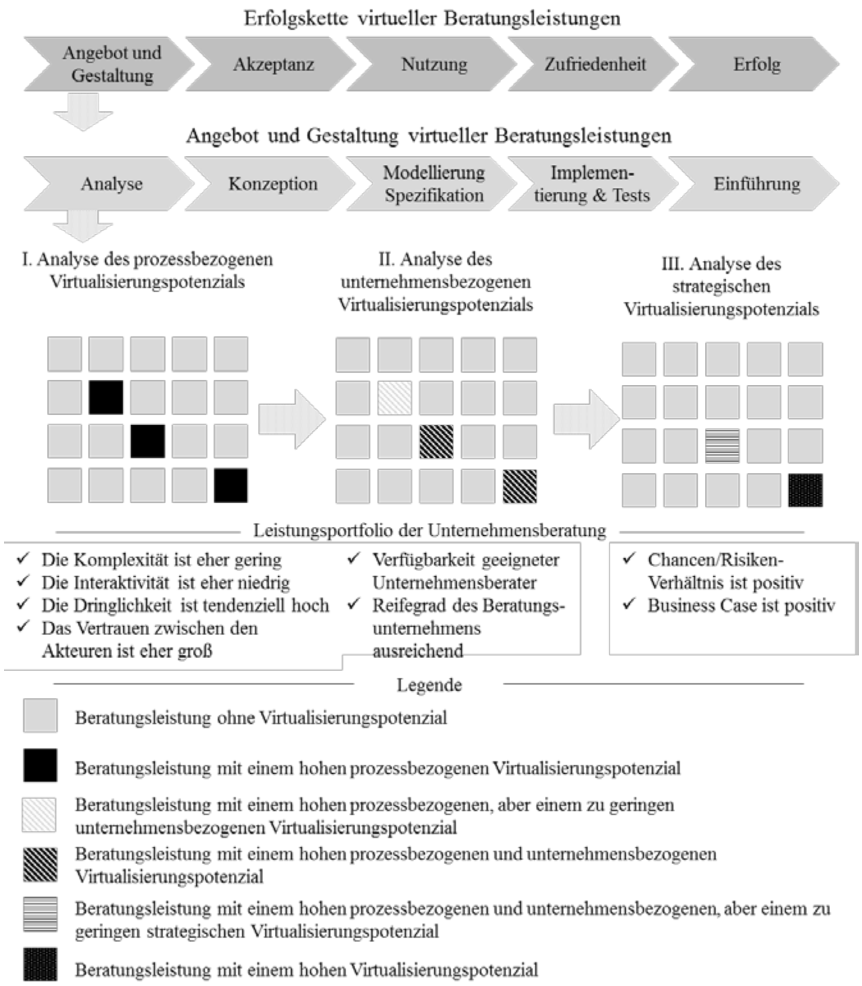

Abbildung 1. Schrittweise Analyse des Virtualisierungspotenzials von Beratungsleistungen

4.2 Analyse des prozessualen Virtualisierungspotenzials

Einfluss der Komplexität. Der erste Faktor, der für die Analyse des prozessualen Virtualisierungspotenzials entscheidend ist, ist die *Komplexität der Beratungsleistung*. Das prozessuale Virtualisierungspotenzial einer Beratungsleistung wird durch die sensorischen, beziehungsbezogenen, synchronitätsbezogenen und die kontroll-bezogenen Eigenschaften des Prozesses bestimmt. Hierauf wirkt maßgeblich die

Komplexität der Beratungsleistung. Komplexe Beratungsleistungen zeichnen sich u.a. durch eine Vielzahl von heterogenen Projektzielen, Stakeholdern, Projektstandorten und Technologien aus. Eine hohe Komplexität wirkt sich negativ auf das Virtualisierungspotenzial aus. In komplexen Beratungsszenarien sind die Anforderungen, die der Beratungsprozess an die Beziehung zwischen Berater und Klient stellt, hoch. Notwendig ist eine starke Berater-Klienten-Beziehung, die in der Lage ist, die Zusammenarbeit auch in kritischen Phasen innerhalb des Projektes zu gewährleisten. Zudem ist die Kritikalität oder das Risikopotenzial des Projektes zu beachten. Auch wenn in der Literatur bisher kein eindeutiger Zusammenhang zwischen Projekt-Komplexität und Projekt-Risiko nachgewiesen werden konnte, existiert eine verbreitete Vermutung, dass es eine Verknüpfung zwischen beiden Aspekten gibt [17]. Die Komplexität stellt zudem hohe synchronizitätsbezogene Anforderungen an den Beratungsprozess. Die Lösung komplexer Problemstellungen mit einer Vielzahl von heterogenen Informationen erfordert es häufig, zeitlich synchron miteinander zu arbeiten. Das bedeutet, Problemstellungen und Lösungen werden beispielsweise in Workshops kooperativ untersucht und generiert. Es ergeben sich zudem oft hohe sensorische Anforderungen, wenn Informationen unterschiedlichster Art verarbeitet werden müssen. Dazu zählen Sprachinformationen ebenso wie Grafiken oder Texte und insbesondere die Mimik und Gestik der verschiedenen Akteure. Komplexe Beratungsleistungen setzen auch die Kenntnis darüber voraus, wer mit wem gerade interagiert.

Einfluss der Interaktivität. Der zweite Faktor, der für die Analyse des prozessualen Virtualisierungspotenzials entscheidend ist, ist die *Interaktivität der Beratungsleistung*. Die Interaktivität der Beratungsleistung umfasst die Art, Dauer und Häufigkeit der Interaktion von Kunde und Berater sowie zwischen Beratern im Projekt. Eine hohe Interaktivität impliziert hohe sensorische und synchronizitätsbezogene Anforderungen, ebenso wie erhöhte kontroll- und identifikationsbezogene Anforderungen. Eine hohe Interaktivität schränkt somit die Virtualisierbarkeit ein. Durch die Wahl geeigneter Medien und Technologien kann dies teilweise ausgeglichen werden. Die Analyse der Antworten der Teilnehmer zeigte, dass die Interaktivität tendenziell höchstens mittelstark ausgeprägt sein sollte, damit man von einer guten Virtualisierbarkeit sprechen kann. Dieses Ergebnis ist in guter Übereinstimmung mit Erkenntnissen aus der Forschung zur Service Modularisierung. So verweisen z.B. Carlborg und Kindström [7] darauf, dass die Perspektive der Co-Kreation von Dienstleister und Kunden nicht vernachlässigt werden sollte. Starke Interaktionsanforderungen bauen auch aus Sicht der Service Modularisierung Hürden auf.

Interaktion umfasst ein breites Spektrum an Formen. Hier sollten Beratungsanbieter prüfen, welche grundsätzlichen Interaktionsformen bisher (traditionell) in einer gegebenen Beratungsleistung vorkommen: direkte persönliche Interaktion, mediale bzw. indirekte Interaktion oder automatisierte Interaktion. Häufige direkte, persönliche Interaktion zwischen Berater und Kunde deutet darauf hin, dass hier Virtualisierungspotenzial für synchrone Technologien, wie Konferenzsysteme, vorliegt [6].

Einfluss der Dringlichkeit. Die Dringlichkeit der Beratungsleistung, zu der auch die Priorität aus Kundensicht gehört, wirkt sich im konkreten Projektfall positiv auf das Virtualisierungspotenzial aus. Der Einsatz von Technologie zur örtlich unabhängigen Zusammenarbeit bringt zeitliche Vorteile mit sich, die bei dringlichen Problemstellungen tendenziell positiv wirken. Die örtliche Unabhängigkeit, die durch den Einsatz geeigneter Kollaborationswerkzeuge erreicht werden kann, fördert die schnelle und flexible Zusammenarbeit verschiedener, örtlich verteilter Projektmitglieder und ermöglicht einen schnellen Austausch von Informationen, die zur Lösung kritischer Problemstellungen benötigt werden.

Einfluss des Vertrauens. Das Vertrauen zwischen Berater und Kunde ist eines der Kernkriterien zur Beurteilung von Beratungsqualität. Die Virtualisierung von Beratungsleistungen führt zu einem veränderten Beratungsprozess, der den direkten Kontakt zwischen Berater und Kunde reduziert. Daraus resultiert ein Risiko für die Qualität der Beziehung von Beratung und Klient und insbesondere das dem Berater auf Kundenseite entgegengebrachte Vertrauen [20]. Das Vertrauen ist aus Sicht der Klienten besonders wichtig, da bei einer traditionellen wie auch einer virtuellen Beratungsleistung eine dienstleistungsspezifische Qualitäts- bzw. Informationsunsicherheit vorliegt und zum Zeitpunkt der Inanspruchnahme nur das Leistungsversprechen der Beratung existiert [20]. Großes Vertrauen der Kunden in den Beratungspartner, einerseits in das Beratungsunternehmen als Organisation und andererseits in den projektbezogenen, konkreten Berater als Person, wirkt sich positiv auf das prozessuale Virtualisierungspotenzial aus. Für die Virtualisierbarkeit von Beratungsleistungen ist es entscheidend, dass bei etablierter vertrauensvoller Zusammenarbeit zwischen Berater und Klient die beziehungs- und kontrollbezogenen Anforderungen des betroffenen Beratungsprozesses eher gering sind, da bereits eine entsprechende Berater-Klienten-Beziehung vorliegt. Die Akteure der Beratungsprozesse können daher weniger oft synchron und ohne den Bedarf häufiger Kontrollen der Zusammenarbeit miteinander interagieren. Bei stark virtualisierten Beratungsleistungen spielt vor allem das Vertrauen auf der organisationalen Ebene, also in das Beratungsunternehmen, eine Rolle. Hier kann das Reputationsmanagement der Unternehmensberatung einen wichtigen Beitrag leisten [14].

Es wird deutlich, dass die PVT alleine nicht genügt, um das Virtualisierungspotenzial praxisgerecht und nutzenstiftend bewerten zu können. Die Kriterien der PVT ermöglichen es jedoch, eine erste Einschätzung der grundsätzlichen Eignung einer Beratungsleistung für die Virtualisierung vorzunehmen. Im nächsten Schritt gilt es, dieses Urteil weiter zu schärfen und vor allem die unternehmensspezifischen Rahmenbedingungen sowie die Erwartungshaltung der Klienten zu berücksichtigen.

4.3 Analyse des unternehmensbezogenen Virtualisierungspotenzials

Einfluss des Reifegrads der Beratungsorganisation. Von großer Bedeutung für die Virtualisierbarkeit einer Beratungsleistung auf Unternehmensebene ist der Reifegrad des Beratungshauses in dieser Hinsicht. Ein hoher virtualisierungsbezogener Reifegrad eines Beratungsanbieters wirkt sich positiv auf das Virtualisierungspotenzial im konkreten Einzelfall aus. Weisen Beratungsfirmen einen hohen Reifegrad auf, dann impliziert das Erfahrungen und Know-how in der Digitalisierung von eigenen Geschäftsprozessen und Prozessen der Klienten. Dieses Wissen ist förderlich für die Entwicklung weiterer virtueller Beratungsprodukte. Firmen mit einem hohen Reifegrad können ihre Entscheidungen für oder gegen die Virtualisierung einzelner Prozesse/Prozessschritte basierend auf den schon vorliegenden eigenen Erfahrungen treffen. Das erleichtert es, das Virtualisierungspotenzial einzelner Leistungen nach Maßgabe der oben genannten Einflussfaktoren richtig zu bewerten.

Einfluss der Verfügbarkeit geeigneter Berater. Sollen virtualisierte Beratungsangebote in das eigene Leistungsportfolio integriert werden, so stellt dies Anforderungen an die Qualifikation der betroffenen Mitarbeiter. Virtuelle Beratungsleistungen erfordern neben den sozialen und fachlichen Fähigkeiten insbesondere Wissen in der Auswahl und Nutzung von passenden Informations- und Kommunikationstechnologien sowie Know-how über Formen und Besonderheiten der virtuellen Zusammenarbeit. Damit das prozessuale Virtualisierungspotenzial ausgeschöpft werden kann, müssen Berater die Wahl der passenden Medien und Werkzeuge unter Berücksichtigung der zuvor beschriebenen prozessualen Faktoren treffen. Bei der Zahl an relevanten Technologien ist hierfür fundiertes Wissen notwendig. Der Berater muss folglich in der Lage sein, die richtige Technologie für den richtigen Prozessschritt bei einem Kunden auszuwählen. Verfügt ein Beratungsanbieter über Mitarbeiter, die diesen Anforderungen gerecht werden, wirkt sich das positiv auf die Bewertung des Virtualisierungspotenzials aus. Ist das nicht der Fall, wäre es sinnvoll, zunächst in den Aufbau solcher Ressourcen zu investieren.

4.4 Analyse des strategischen Virtualisierungspotenzials

Der strategische Fit in Bezug auf das bestehende Leistungsportfolio des Beratungsanbieters ist wichtig für die Virtualisierung von Beratungsleistungen [28]. Demnach müssen Anbieter das in den bisherigen zwei Schritten identifizierte Virtualisierungspotenzial in der dritten Analysestufe auf die strategische Relevanz und Passfähigkeit prüfen. Hoher strategischer Fit wirkt sich positiv auf das Virtualisierungspotenzial aus. Die Idee einer Bestimmung des strategischen Virtualisierungspotenzials geht auf den Ansatz des strategischen Service Portfolio Managements zurück und zielt darauf ab, neue Beratungsleistungen im Hinblick auf die strategische Passgenauigkeit zum Service Portfolio des Beratungsunternehmens hin zu überprüfen und basierend darauf die Beratungsleistung und/oder das Portfolio strategisch neu auszurichten [16].

Die Forschung zur Service Modularisierung betont, dass es essentiell für Dienstleistungsanbieter ist, die Kundenwünsche zu verstehen und schon bei der Serviceentwicklung einzubeziehen [25]. Für die Entscheidung im konkreten Einzelfall ist es daher notwendig, neben den Vorteilen der Virtualisierung insbesondere deren Risiken aus Klientensicht, aber auch die Risiken der Beratung im Auge zu behalten und das Gesamturteil durch einen Business Case, der kurzfristige und langfristige Potenziale der Virtualisierung aufzeigt, weit möglichst zu objektivieren.

Die Bedeutung dieses strategischen Evaluationsschrittes wird auch durch die Analyse der Hemmnisse der Virtualisierung deutlich. So gaben 34 % der befragten

Teilnehmer der BDU-Studie an, dass der mangelnde strategische Fit ein Hemmnis der Virtualisierung in der Unternehmensberatung sei (n=493) [21].

4.5 Qualitätsanforderungen der Kunden an virtualisierte Beratung

Abschließend soll noch einmal die Perspektive des Beratungskunden betrachtet werden. Unternehmensberatungen vermarkten Leistungsversprechen in Bereichen, die für Klienten im Allgemeinen große Bedeutung haben und erhebliche Risiken mit sich bringen. Ein virtualisiertes Beratungsangebot kann langfristig nur dann erfolgreich sein, wenn die erbrachten Leistungen in ihrer Qualität die Erwartungen der Klienten erfüllen. Notwendig ist daher eine Qualitätsmessung. Dadurch kann überprüft werden, ob die Klientenerwartungen verfehlt, erfüllt oder sogar übertroffen wurden und somit die Beratungsleistung erfolgreich virtualisiert wurde oder nicht. Im letzteren Fall sollte kritisch evaluiert werden, ob die Virtualisierung generell unangemessen ist oder nur ein besserer Virtualisierungsmechanismus gefunden werden muss.

Die Untersuchung der Qualitätserwartungen von Klienten an virtualisierte Beratungsleistungen erfolgte in Nissen et al. 2015 [20] anhand einer strukturierten Literaturanalyse sowie einer anschließenden klientenbezogenen Delphi-Studie. Die von den Experten durchgeführte Evaluation und Priorisierung resultierte in einem integrierten Kriterienkatalog, der Kriterien traditioneller Beratungsleistungen und Kriterien elektronischer Dienstleistungen kombiniert. Die Delphi-Studie ergab auch, dass die Bedeutung der Qualitätskriterien für die Gesamtzufriedenheit der Kunden in Abhängigkeit des Virtualisierungsgrades variiert. So wird die Qualität einer hoch-virtualisierten Beratungsdienstleistung stärker anhand von Kriterien für die Qualität elektronischer Dienstleistungen gemessen, wohingegen eine Dienstleistung mit einem geringeren Virtualisierungsgrad stärker durch Qualitätskriterien von traditionellen Beratungsdienstleistungen bewertet wird.

5 Fazit und Ausblick

Die Akzeptanz, Nutzung und Zufriedenheit mit einer virtuellen Beratungsleistung sind gemäß Overby [23,24] die entscheidenden (ex post) Indikatoren für die Virtualisierbarkeit einer traditionellen Beratungsleistung. Damit wird aber vorausgesetzt, dass die virtuelle Beratungsleistung bereits entwickelt und im Einsatz ist. Sollen Beratungsleistungen erst noch konzipiert werden, lässt sich der zu erwartende Erfolg vorab nur schwer bestimmen. Folglich braucht es Indikatoren und ein analytisches Vorgehen zur ex ante Bestimmung der Virtualisierbarkeit einzelner Leistungen oder Prozessschritte.

Das vorgestellte dreistufige Vorgehen ist dazu ein theoretisch und empirisch fundierter Vorschlag, der sich allerdings im praktischen Einsatz erst noch bewähren muss. Hierzu sind Kooperationsprojekte mit Beratungspartnern gestartet worden, die in Kürze zu ersten konkreten Produkten führen werden. Im Ergebnis werden so Fallstudien entstehen, die den praktischen Wert der vorgestellten Methode in unterschiedlichen Beratungskontexten überprüfen und auch zeigen, inwieweit das

Vorgehen unternehmens- oder projektspezifisch konfiguriert werden muss, um den größten Nutzen zu erzielen.

Die Ergebnisse dieses Beitrags sind insofern einzuschränken, als die untersuchte Stichprobe nur den deutschen Beratungsmarkt betrachtet. Die Ergebnisse der zitierten Delphi Studien sind insoweit zu relativieren, als sie zwar den in der Literatur geforderten methodenspezifischen Umfang an Teilnehmern erreichen, dennoch aber nur das Meinungsbild einer überschaubaren Gruppe von Beratern und Klienten wiederspiegeln. Diese Ergebnisse gilt es in größer angelegten Studien in der Zukunft weiter zu vertiefen. In theoretischer Hinsicht erscheint es lohnenswert, die Themen Standardisierung und Modularisierung von Beratungsleistungen im Kontext der Virtualisierung noch einmal stärker aufzugreifen. Dabei existieren interessante Querbezüge, insbesondere zum Thema Service Modularität [7, 12, 25], wo schon verwertbare Ergebnisse vorliegen.

Virtualisierte Beratungsleistungen werden konventionelle Vor-Ort-Beratung nicht generell ersetzen. Sie sollten, dem dargestellten Entscheidungsprozess für oder gegen Virtualisierung folgend, aber als mögliche Ergänzung des Portfolios von Beratungsprodukten gesehen und fundiert analysiert werden.

Die digitale Transformation in der Beratungsbranche ist ein komplexes Unterfangen und schafft damit Barrieren gegen Wettbewerber. Wer frühzeitig relevantes Wissen akkumuliert und erfolgreiche, innovative Pilotprojekte vorweisen kann, wird langfristig voraussichtlich einen erheblichen Wettbewerbsvorteil generieren und über längere Zeit verteidigen können. Hier wird ein hohes Maß an Kreativität und strategischem Denken verlangt, das über die reine 1:1-Übertragung konventioneller Beratungsabläufe in die virtuelle Welt am Ende weit hinausreicht.

Abstract. This paper reports findings from an exploratory series of case studies undertaken to better understand the impacts of digitization on organizational and knowledge recombination. While 'digitalized firms' are expected to frequently update their knowledge (e.g., big data analyses, 'smarter' products) and organizational structures (e.g., agile team structures, open innovation approaches), we know little about the interrelations between recombining knowledge and organizational capabilities. Therefore, we collected data from 19 interviewees in 8 different firms from four industries. Our study integrates theoretical notions from the literature on organizational and knowledge recombination theory and categorizes the emerging shifts arising from digitization. Our results suggest that the identified changes in the digital age manifest as increased proximity to the customer (by fully digitizing the customer interface and digital co-creation) and celerity to the markets (cross-organizational teams, and collaborations with start-ups and competitors) affecting the whole organization.

Keywords: digital innovation, case studies, recombination, celerity, proximity.

1 Introduction

Ever since the seminal writings of Schumpeter, recombination is at the heart of innovation practices [1]. Schumpeter noted that innovation "consists to a substantial extent of a recombination of conceptual and physical materials that were previously in existence" [2, p. 88]. Accordingly, recent research commentaries on innovation in the digital age (e.g. [3]) also portray digital innovation in terms of recombination. Yoo et al. describe digital innovation as "the carrying out of new combinations of digital and physical components to produce novel products" [4, p. 725].

It is widely acknowledged that for a firm to 'go digital' will involve updating knowledge (e.g., big data analyses, 'smarter' products) and altering structures (e.g., agile team structures, open innovation approaches). Still, there is a need to better

Dürr, S.; Wagner, H.-T.; Weitzel, T.; Beimborn, D. (2017): Navigating Digital Innovation - The Complementary Effect of Organizational and Knowledge Recombination, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1363-1377

understand *what* components need to be recombined and to what extent there are interrelations between recombining knowledge and organizational capabilities. The innovation literature often scrutinizes the ability of firms to recombine resources in general [1], knowledge resources [5], IT resources with other resources [6, 7], or digital and physical components [8]. For example, Carnabuci and Operti [9] investigate recombinant capabilities of firms that allow them to recombine existing technologies for innovations.

However, the extant literature in the field of recombination and innovation mainly focuses on knowledge and component recombination, neglecting potential complementarities to the organizational perspective. Although Galunic and Eisenhardt [10] mention that delineations of competency areas may affect resource combinations, and Karim and Kaul [11] examine how the recombination of business units within a firm affects firm innovation, we know little about the interplay of recombining knowledge and organizational elements. We hence aim at identifying shifts in digitizing firms and disclosing how those firms navigate their knowledge and organizational capabilities from traditional waters into a digital environment by knowledge and organizational recombination. We are particularly interested in how this recombination affects innovation success, i.e. the commercialization of new knowledge in form of new products or services [12]. Following the recent call of Henfridsson et al. [13] that "it would, therefore, be useful to examine […] the relationship between organizational design and product design" [p. 39] our research question is: *How does the interplay of organizational and knowledge recombination relate to innovation success within a digital context?*

Methodologically, we conducted exploratory case studies with 19 interviews in 8 organizations to derive categories for organizational and knowledge recombination and identify complementarities among them. Theoretically, we build on Carnabuci and Operti's [9] distinction of recombinant reuse (recombination of familiar knowledge) and recombinant creation (recombination of unfamiliar knowledge). Concerning organizational recombination, we build on Karim and Kaul [11] but go beyond their notion of structural recombination by also considering inter-organizational relationships as identified by Mintzberg [14]. Together, this allows us to incorporate the largely neglected complementarities between the knowledge and organizational based perspectives in innovation research that, as the results show, shape the modern digital firm.

The next sections review the literature on recombination theory from a knowledge and organizational perspective, introduce and analyze the case studies and then discuss the main findings, their limitations, and implications for future research.

2 Recombination - A Theoretical Background

2.1 Recombinant Reuse and Recombinant Creation

Carnabuci and Operti [9] provide a granular perspective on recombination by distinguishing between recombinant creation and recombinant reuse. *Recombinant creation* is the "ability to envision and create combinations using technologies that […]

have never [been] combined before" [6, p. 1592]. An example is the "fitness tracking" services enabled by connecting Nike's running shoes and Apple's computing products, two technologies that the firms had never previously integrated [15].

Recombinant reuse is the "ability to refine and reuse systematically known technological combinations to solve new problems and develop new applications" [6, p. 1592]. Henderson and Clark [16] call this architectural innovation as the recombination is used to replace existing components because of an inferior cost structure and/or performance issues. An example of recombinant reuse is Apple realizing shortly after the invention of the iPhone that combining its operating system and its mechanical components, e.g. its camera, offered opportunities to develop a wide range of novel applications [17]. Thus, they progressively deepened their understanding of this technological combination and generated a string of advanced technological devices, including gyroscopes and accelerometers.

2.2 Organizational and Knowledge Recombination

Henri Poincaré pointed out that new knowledge stems from existing knowledge, and is (or builds on) the combination of existing knowledge [18]. Still, controversies remain on where the knowledge elements should be selected from. Some researchers (e.g. [19]) stress that industries are clearly divided and that various technical fields are strongly separate so that knowledge inside a field can hardly be understood by outsiders. Therefore, new knowledge is often built on existing knowledge elements within such fields [20]. In contrast, Hargadon [21] suggests that technical convergence through combining knowledge from different fields can create huge market returns. The idea is that combining more diverse knowledge sources challenges actors and existing concepts and thus stimulates innovation [22]. This notion is elaborated for the digital era by Lyytinen et al. [23] and Nambisan [3]. They emphasize that convergence and recombination of knowledge are particularly advantageous for digital innovations as the malleability of such technology [13] allows for greater flexibility in the alteration of digital products from a knowledge perspective.

Nevertheless, the recombination of knowledge from various fields may be obstructed by inter- and intra-organizational boundaries between firms, business units, or even departments [24]. Hence, Karim and Kaul [11] examine the effect of the recombination of organizational structural elements ("structural recombination") on innovation from an organizational perspective. They find that structural recombination complements knowledge recombination by dissolving unit boundaries, thereby enabling intra-organizational knowledge synergies. Similarly, previous work has shown that the transfer and sharing of knowledge across internal boundaries (i.e. amongst different units within an organization) is an important source of firm innovation and competitive advantage [1]. The essence of this strand of research is that a firm that wants to realize intra-organizational knowledge synergies beyond the explicit transfer of knowledge between units should alter its structure, dissolve internal boundaries and reshuffle activities among units [25]. Karim and Kaul refer to these changes as structural recombination, defined as "changes in business units as their resources and market activities are reorganized by merging units together, generally through the absorption of one unit into another unit or the formation of a new business unit by combining existing units" [19, p. 441]. This highlights that structural recombination is a subset of the larger set of organizational reconfigurations that have been studied in the prior literature and that include the addition and deletion of units as well as their recombination [26].

3 Methodology

We followed an exploratory case study approach to understand how the interplay of organizational and knowledge recombination is related to innovation success. We chose case studies as they are particularly suitable to answer "how" and "why" research questions and when the relationship between context and phenomenon is unknown [27][28]. For data collection, we conducted 19 interviews following semi-structured guidelines with open-ended questions to assure openness for every possible research direction. We contacted senior managers responsible for strategy, R&D, innovation, IT, or marketing/sales from various firms that may be expected to be key informants in the areas of interest. Usually, we collected data in a firm if three different senior managers agreed to participate. In case that one manager was able to cover the entire area of interest because of his background, we rested with one interviewee. The organizations were not limited to any industry in order to learn about differences in several sectors. Table 1 provides an overview of the cases, industries, and interviewee position:

Table 1. Case, Industry, ID, Interviewee Position and Length

Case	Industry	ID	Interviewee Position	Length [min]
A	Manufacturing	IP01	Innovation Manager	59
B	Financial Services	IP02	Innovation Manager	68
		IP03	Head of Product Management	66
		IP04	Chief Technical Officer	57
C	Publishing	IP05	Head of Business Development	72

		IP10	Chief Executive Officer	45
E	Manufacturing	IP11	Product Group Manager	91
		IP12	Head of Automation and Controls	121
		IP13	Director of Technology Management	54
F	Financial Services	IP14	Chief Digital Officer	57
G	Financial Services	IP15	Chief Executive Officer	65
H	Manufacturing	IP16	Chief Digital Marketing Management	53
		IP17	Chief Financial Officer	46
		IP18	Chief Marketing Manager	53
		IP19	Chief Executive Officer	45

We carried out the interviews mostly onsite involving two or three of the authors as interviewers. Our interview guideline is designed as follows: First, we asked about any recent digital initiative. We particularly probed into specificities of the company's innovation process, critical success factors, involved units, and the corresponding team structure. Furthermore, we gathered information on the wider organizational structure of the company, its governance, and leadership structure. The interviews took place from November 2015 to July 2016. All interviews were transcribed, and project documentations, related reports, company's financial statements, off-record notes, and observations were used to augment and triangulate the interview data. Data analysis proceeded through reiterations between looking for meanings in the data, writing descriptions, coding and revisiting literature. Following Miles and Huberman's [29] recommendations, this data analysis process was facilitated through the building of data displays in the form of tables and matrices (through coding in MaxQDA v.12.1.4) to refine the concepts identified, and the development of tentative conclusions to depict the emerging shifts.

The data analysis began with descriptive codes (or open coding) as soon as the first interviews were transcribed, and was done inductively, seeking to reflect the data as closely as possible. This stage led to the identification of over 280 descriptive coded statements. These statements were then organized into 27 different categories, such as firm specifics, initiatives due to digitization, agility, digital innovation, structure of an organization, organizational recombination, strategy etc. (these being the early interpretative codes). At this point, the focus was on interpreting the data to search for relationships and patterns and facilitate the next stage, pattern coding. The process was highly iterative, moving between data, interpretation, and theory. As our output, we identified two central emerging shifts that we structured in *knowledge recombination* and *organizational recombination.* Focusing on these shifts, we identified complementarities among them as we looked back at the data which are presented in the next section.

4 Results

4.1 Knowledge Recombination in the Digital Age

Collecting Data to Gain Knowledge about Customers in the Digital Age. In the conversations with the firms, we noted their necessity to collect increasing amounts of customer data to better understand customer needs and wants and to eventually adjust existing or create new services. Likewise, the CTO of a large online bank (IP04) remarks: "We want to gain more information about our customers […]. We'd like to gain knowledge about their living conditions and their financial situation […]. By today, we do not have the comprehensive view of the customer […] that we would like."

For this endeavor, the firm intends to track all digital activity of their customers through their connected digital products or digital services (e.g. usage data, transaction data, location data) and to combine it with their corresponding customer master data (e.g. profession, age). Another new challenge, according to the interviewees, is to complement their conventional user data (e.g. transaction data, product usage data) with secondary data that might initially seem unrelated (IP04: “We would even add further information such as weather data”) [30] but offer greater possibilities in predicting or concluding certain developments or desires of a customer [31]. To summarize, companies use new data sources to extend the knowledge on their customers for deeper analysis and to recombine this knowledge.

Knowledge Recombination via Recombinant Creation. Collecting primary data through tracking the digital activity of customers can lead to the development of new products or services as the behavior of customers may provide the firm with insights unavailable before [30–32]. Accordingly, the innovation manager (IP02) of a bank stated: “We collect all this data because it is an effective way to delineate innovations by identifying what is missing [for our customers] and where they have problems.”

This manager explained that his company analyzes when customers are aborting certain digital processes, and try to enhance these digital processes by providing their customers with, for instance, improved web page structures or more options to choose from. Then, such data is complemented by external data to further augment a firm’s knowledge about their customers and to create a comprehensive understanding of customer needs and wants. This, ideally, makes it possible to provide fitting offerings without requiring customers to enter lots of data: “In the future, [the customers] do not need to do anything because we will give [them] recommendations” (IP04).

Such recommendations can be innovative solutions that are being tailored based on the previously tracked and analyzed the digital activity of a customer combining knowledge from conventional (master data, digital behavior) and secondary (environmental) data. This way, firms add value by digitally engaging with their customers to get ideas for novel products, ideally, as we learned, in an automated way. It is of high priority to satisfy the customer’s needs following the core marketing idea of adjusting value propositions to consumer needs [33], and now this appears to be even more relevant as customer loyalty seems to become less important (IP14): “it does not matter if we want to [do this] or not. The customers will base their [banking choice] decision on where the banking experience is the easiest, most convenient or the greatest.” These insights indicate that companies try new combinations in products or services (recombinant creation) through recombining knowledge which is based on collecting and analyzing data through tracking the digital activity of customers (knowledge recombination).

Knowledge Recombination via Recombinant Reuse. Still, tracing digital activity is not only about becoming a “comprehensive advisor” but also about the co-creation with customers [33, 34]. This assumes that different entities (e.g. firms and consumers) cooperatively integrate their operant resources (e.g. knowledge, skills, and technology) [3] within a joint process to generate value [35]. A marketing specialist (IP11) introduces his organization’s practices as operated in the agricultural sector when they equip farms: “We do not develop one [stand-alone milking] robot per customer […]

[where the milking robot is just one component of the entire farm]. Yet, the information relevant to our sales process are how does the customer want his farm? What is his daily need? […] Therefore, we develop his farm in co-creation with the customer to ensure that he wants to have it."

He underpins that the company's approach to solving new problems (i.e. integrating a stand-alone milking robot) is using known combinations, i.e. through value co-creation with the respective customer. Therefore, the firm involves such customers as closely as possible to reduce technological uncertainty [36]: "We do not always know what we want to develop. Thus, we research a lot with our customers. We would run an algorithm in test mode to observe what this means to the customer. This way, we could improve a lot of functions, […] and increase performance" (IP11).

Hitherto, co-creation is not a novel concept [34]. But with digitization and being permanently connected to the customer it allows for co-creation on a large scale, as pinpointed in this statement (IP03): "For testing user satisfaction, we got our 'advisory customers'. This is an insider community of some five hundred customers which we survey continuously through digital channels."

From this testing, the company derives how customers use new products, and identify spaces for improvement. In the following, its CTO (IP04) explains how this improvement occurred in an agile way by recapturing the development of a successful app:

"We would try to only offer this core feature […]. This way, we can first test how the product is being perceived […] By now, I think, that the third version of the app is available – within only four or five months […]. Previously, we probably would have released the first version only late in summer, realizing all the other features that we have thought of. In this example, we have realized the very first functional version, and […] rereleased further functions."

Until recently, the traditional testing of products, i.e. imitating how clients will use products, was the means to identify potential weaknesses [37] and to ensure that new products conform with their intended functionalities [31]. In the digital age, however, companies monitor and improve their products continuously, i.e. they might compile real performance data from all products which may provide them with insights on design problems that the artificial testing did not reveal.

Accordingly, we observe that companies solve the problems of their customers (recombinant reuse) in digital co-creation through the recombination of known technological combinations supported by the collection and analysis of customers' digital activity (knowledge recombination). Further, we derive that these activities allow for greater proximity of a firm to every individual customer through digital technology in an unprecedented automatized way. *Proximity* connotes thoroughly analyzing the digital behavior of customers as a resource for innovation ideas, as a co-creator in the development and design of products and services, and as a user in testing the product or in helping other users to learn about the product or service [3]. This means that companies focus on creating market offerings after having digitally analyzed their customers' behavior (e.g. product usage via tracking digital activity [30, 31, 38]) and before tailoring specific affordances through a recombination of the gained customer knowledge (recombinant creation).

4.2 Organizational Recombination as the Complement of effective Knowledge recombination in the Digital Age

Restructuring the Organization in the Digital Age. In our eight case studies, we were sensitized that identifying new knowledge combinations through digital analysis, and solving problems of customers through digitally gathered knowledge, are associated with organizational recombination and eventually aimed at increased organizational agility. For instance, the agile development of products and services requires new units or functions [31, 39]. Likewise, the Chief Digital Officer of a retail bank (IP14) confers the sheer importance of becoming "more agile" and highlights how his firm's senior management team infuses his firm: "We have identified [digital] strategic fields which we elaborate on cross-divisionally, i.e. with teams created from the different areas of the company, with the aim to develop or identify a greater need for change."

By becoming more agile, firms want to be able to sense and respond quicker to customer-based opportunities [40, 41] to timely incorporate ('recombine') the knowledge gained from their digital activities. Besides, the CTO (IP07) of a large weekly explains another advantage of agile development approaches: "You just get more insight, you get insights faster, also when something goes out of control".

Following this prospect, firms may become more agile in various areas, such as customer-based processes or interactions with supply chain partners, or to increase competitiveness [41].

Organizational Recombination via Recombinant Creation. Firms have long tried new organizational combinations with external partners in various ways [11, 26]. Our case studies confirmed this practice, yet the objective slightly deviates. Hence, companies would continue with the traditional integration of external partners by acquisition [11] ("Fintechs[1] are integrated with quite banal cooperation models. We honestly cooperate with Fintechs for many years" (IP14)), but at the same time they are trying to adopt the agile spirit of start-ups: "It is of interest for us to experience entrepreneurship. The spirit, the gut decisions, this enthusiasm […]. I believe this 'spirit transfer' in the sense of digital transformation is extremely important. Especially for larger companies."

This spirit appears to complement the co-creation between a firm and its customers (knowledge recombination) and may strengthen through solutions integrated through collaborations with startups or competitors (organizational recombination). The rationale is that startups or competitors may provide novel, legacy-free solutions for the customers of a "traditional" firm that the incumbent may have difficulties to develop due to a lack of skills, its strong hierarchy, or slow decision-making processes [14]. Hence, all firms reported integrating startups, while a subset creates incubator structures (in cases A, B, F, and G) to attract and support startups at their very founding stage [42]. Firm A also launches small spin-offs to save resources (e.g. cost, and manpower) as internal efforts are being decreased, and allow for more agile realizations compared to those of his organization due to "less organizational legacy". However, a

[1] Fintech is a synonym for start-ups in the financial industry.

product group manager (IP11) also introduced us to their shift towards operating on platforms on which they collaborate with their competitors, aiming at providing the customer with solutions to their individual problems regardless where the solution is coming from:

"We see farmPage[2] as a platform. We would appreciate if our competitors would be on it, too […]. The more customers, […] the more valuable is what you can analyze from it." With these words, the manager highlights the notion of collaboration with competitors. He further notes that in the digital age customers are less involved with minding the origin of a solution to their problems, rather than having an organizational combination that provides them with a solution. Besides, the last part of the quote underlines how the collaboration with customers and competitors may serve as a new source for knowledge recombination. Hence, we note that companies form various new organizational combinations (recombinant creation) through the integration of external partners, i.e. start-ups, incubators, spin-offs or competitors, to increase the celerity in developing innovations.

Organizational Recombination via Recombinant Reuse. Besides forming new organizational combinations with external digital partners, the interviewed firms alter their internal structures by creating cross-functional teams. This brings knowledge resources closer together that were previously separated, and removes internal boundaries between them thus increasing the likelihood of knowledge recombination [43]. One manager (IP02) sketches how such teams are constituted in digital initiatives: "We do not have these silos anymore, which we had […]. Now, all parties are in the product development: marketing, IT, legal and product managers." This structural recombinant reuse (forming cross-organizational teams) within the organizational structure (organizational recombination) fosters the thorough engagement with a firm's customers as the analysis of customer data and environmental data can be facilitated by various experts from heterogeneous fields (knowledge recombination) allowing a new view on existing products) [9].

In addition, the companies restructured their physical workspace to further support this cross-functional collaboration. With wide spaces without boundaries and people mingling together, knowledge is more easily shared within units than between them [44], even when activities within a unit are distant from each other [45]. One manager illustrated this for his firm (IP03): "We have started to completely restructure many of our workspaces. […] We created larger spaces because many small offices existed in which employees got lost […] Now, the people focus on one topic, and the cycles of product development shrunk significantly […]. In addition, the workspace development is very, very good for our staff […] captured on the balance sheet." Overall, fewer divisional boundaries enable greater and wider exploration of knowledge through richer communication and joint development [46] by forming cross-departmental teams, and by co-locating people.

In the digital era, another emerging shift comes from the formation of new positions, and dedicated managers to consolidate the digital activities of a firm [30, 31]. Hence,

[2] Software product name changed to assure anonymity of all interview partners and related firms.

several managers (IP02, IP08, IP04, IP14, IP16) told us they were hired to introduce initiatives to make their company more "digital". Other companies (cases E and F) even instantiate new digital structures, such as a digital office equipped with the competence to make their company more agile. Correspondingly, a newly appointed chief digital officer (IP14) describes his current position: "Our Chief Digital Office reports directly to the CEO. I am a member of a six-member management team in the CDO department [...]. Since May last year, we made an organizational change, [...] so that I get the space to deal with the major disruptive changes in our business [...]. Now I deal with the digitization [...]. In particular, the management of innovation and in this context the exchange with startups, but also with other potential partners in the digital context."

He summarizes how the integration of external partners is fortified through the firm's internal restructuring. This is complemented by digitizing the customer interface for digital customer analyzes (aimed at knowledge recombination) because it simplifies the integration of external partners (organizational recombination). Through the digitization of an interface, a firm defines certain standards (i.e., APIs) which also can be used when incorporating startups, respectively their solutions into a company.

Overall, we note that companies recombine their internal organizational structure, responsibilities, and functions (organizational recombination) to be quicker at solving problems in the digital age (recombinant reuse) and to form new organizational combinations with external partners (recombinant creation). Digital co-creation (knowledge recombination) may even support this by spurring quicker product or service releases for the customers if the organization uses agile methodologies in heterogeneous teams (organizational recombination), which is reportedly integrated into the daily business practices by all managers. Our findings are depicted in Figure 1:

Recombinant Type	Area of Recombination		
	Knowledge Recombination	Organizational Recombination	
Recombinant Creation	[a] Digitizing the customer interface (**Smart Customer Analysis**) Reported in: A, B, E, F	[b] Becoming more open to external partners **(Startups, Competitors)** Reported in: A, B, C, D, E, F	
Recombinant Reuse	[c] Solving problems through digitally gained knowledge (**Digital Co-Creation**) Reported in: B, E	[d] Becoming more agile in development (**Cross-Organizational Teams**) Reported in: B, C, D, F, H	
Identified Complementarities	Smart customer analysis [a] enhances in cross-organizational teams [d]		IP02
	Digital Co-Creation [c] improves through integrating solutions of Startups or Competitors [b]		IP11
	Digitizing the customer interface [a] simplifies the integration of Startups or Competitors [b]		IP08
	Digital Co-Creation [c] is quicker realized in agile development [d]		IP06

Figure 1. The Emerging Shifts in the Digital Age and their Complementarities

5. Discussion

We theoretically and empirically analyzed complementary organizational and knowledge capability recombination as pillars of a firm's digitization initiative. The results reveal consistent shifts in organizational and knowledge recombination.

Organizations recombine knowledge elements based on customer analysis identified in an unprecedented way which is enabled through fully digitizing the customer interface, to achieve greater proximity for deriving innovations, and to co-create products which are quickly realized. As product co-creators, customers often develop and refine product and service features that the firm incorporates into future versions [47]. Finally, customers who become expert users often discover new ways to use the product as well as shortcuts and other methods to enhance the overall value of the product.

Organizations recombine organizational elements by forming cross-functional teams, and by collaborating with external partners to achieve greater celerity in developing new products reflecting the customer preferences identified with the help of digitalized customer interfaces. Celerity echoes the imperatives of fast, recurrent product design, continuous product operation, and ongoing product upgrades [39] that create a need for new functional groups. In the software industry, collaborative and cross-functional software development methods like scrum have long been established. They bring together software engineers and R&D staff with IT, manufacturing, and service staff who deal with operational matters [31]. This approach rests on teams that manage product updates, shorten product cycles, and deliver new services and enhancements after the sale.

In this manuscript, we theoretically and empirically analyzed the complementarities of organizational and knowledge capability recombination. Thus, we contribute to existing research in organizational and knowledge recombination in two ways: First, we highlight that not only intra-organizational recombination of organizational elements but also inter-organizational recombination plays a role in the digital age. In addition, we extend this notion by exploring that not only investigating unit boundaries is necessary going beyond the work of Karim and Kaul [11]. Second, looking for key shifts for firms in the digital age we identify celerity and proximity as pillars of a firm's digitization initiative. Further, the results highlight complementarities between knowledge and organizational recombination for innovation that have only attracted scant recognition in the literature so far [13]. Our cases indicate that these complements may exemplify ways of becoming faster and more agile when developing digital innovations.

The results suggest some interesting implications and avenues for future research on the recombination of complementary knowledge and organizational elements (cf. Figure 1). For knowledge elements, the number of accessible knowledge elements constitutes a knowledge recombination space. Hence, combination means building networks of knowledge elements, and recombination means creating new networks. Analogously, a firm's organizational elements (i.e. structural elements such as units, teams, and cross-functional teams, both inter-organizational and intra-organizational, power distribution, and decision-making modes [14]) constitute the organizational recombination space. Recombination then means managing boundary conditions and interventions that influence the creation of new knowledge networks [11, 48]. Drawing on the knowledge management and enterprise governance and change literature, the findings could offer a first framework for more theoretical and empirical work on digitization.

For practice, the results imply that firms increasingly pursue agile methodologies to spur faster results and use digital channels to either more thoroughly analyze or engage with a firm's customers, competitors or partners. These practices may provide direction for practitioners when navigating the enterprise into digital waters.

Future research may increasingly aim at each dimension of the emerging shifts in the digital age as illustrated in Figure 1. Hence, further organizational elements such as an organization's culture or power structure may shift in a digital context. It will also be necessary to transcend our focus on European companies and include firms from other continents and cultures.

Our research needs to be reflected in the light of its limitations. We did not use a chronological order nor an order based on popularity due to the heterogeneity of our interview partners. Instead, we ordered the findings by forming a theoretical lens (cf. Figure 1), and by following this lens' aspects to classify the identified shifts. Second, there may be a bias as two, respectively three, people attending the interviews may have intimidated the interview partners. However, we avert this by selecting one main interviewer to not overcharge the interviewee.

6. Conclusion

Our research question was: "*How does the interplay of organizational and knowledge recombination relate to innovation success within a digital context?*" The analysis mainly shows that organizational and knowledge recombination complement each other leading to increased proximity to a firm's customers and to increased celerity to markets to develop novel innovations when navigating in an increasingly digital environment.

Why should Incumbent Firms jump on the Start-up Bandwagon in the Digital Era? – A Qualitative Study

Nihal Islam[1], Peter Buxmann[1], and Nicole Eling[1]

[1]TU Darmstadt, Information Systems, Darmstadt, Germany
{islam,buxmann,eling}@is.tu-darmstadt.de

Abstract. Due to ongoing digitalization, the traditional business models of incumbent firms are threatened by the innovation performance of start-ups. Therefore, a few incumbent firms have established programs to collaborate with start-ups in order to receive relevant impulses from them. However, empirically, there has barely been any insight into the specific role that start-ups play for incumbent firms. For this purpose, we present the key findings of our qualitative study, which has been built on interviews (n=35) with experts. Our results reveal that incumbent firms and start-ups have equally environmental factors affecting their decision-making in pursuit of digitalization. However, they differ in their technological and organizational factors. According to our findings, we have emphasized that collaboration between incumbent firms and start-ups could be an opportunity to meet the challenges of the digital era. They can build on these identified enabling factors of the partner and overcome their own inhibiting factors.

Keywords: Digitalization, Enabling and Inhibiting Factors, TOE Framework, Collaboration between Incumbent Firms and Start-ups, Qualitative Study

1 Introduction

Over recent years, new digital technologies have enabled lots of physical products and services to be turned into intangible digital content, such as the integrated usage of maintenance recommendations based on the vehicle data of a connected car in real time. Another example is the payment via a mobile wallet that promises infinitely more comfort in the daily life of consumers [1], [2]. The work environment has changed significantly as well. In particular, work models have become flexible and mobile, opened up by smartphones, tablets, and laptops so that individuals are no longer bound to any specific work space [3]. Last but not least, our present modes of communication have created a space for sharing and exchanging information on social media platforms [4].

The growing opportunities due to digital technologies – characterized by trends in information technology such as Social, Mobile, Analytics, and Cloud [5] – are forcing incumbent firms to rethink and realign their business models, and especially to change their operational processes and functional structures [6], [7]. Various conferences and expos focus on this issue, for example, Thinking Digital 2016 in the UK, Cebit 2016

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Islam, N.; Buxmann, P.; Eling, N. (2017): Why should Incumbent Firms jump on the Start-up Bandwagon in the Digital Era? - A Qualitative Study, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1378-1392

in Germany, the CEO2CEO Summit 2015 in the US, and even the annual meeting of the world economic forum in 2016. What is new in these discussions is that digital technologies have become the primary driver of innovation and reach the sphere of all industries and dissolve the market boundaries between industries. In particular, innovative products and services – especially those in digital form – have increasingly been placed in the center of consideration and are becoming a critical factor for success in the digital era [7], [8]. In addition, new entrants – especially start-ups from various industries – are represented in greater numbers than ever before. For instance, in 2015, the number of start-ups rose sharply, and it has been rising especially in Silicon Valley, London, and Berlin for the last several years [9]. Thereby, while start-ups are known as a major source of innovation because they use new technologies to invent products and services, and especially to develop digital innovations, incumbent firms are beginning to address the opportunities and challenges of digitalization [6], [10], [11], [12].

In the literature, the topic of digitalization in organizations is reflected in different ways. However, a holistic view of the connection between incumbent firms and start-ups in the context of digitalization has barely been investigated. As digital innovation is seen as crucial to the success of firms in creating new value for their business [8], a study is needed in order to analyze the pursuit of digitalization in incumbent firms and start-ups. Against this background, we have approached this field of interest with an observation about the causes of their opportunities and challenges in context of digitalization. In our study, we have used the adoption of digital technologies to create digital innovation as an outcome measure of digitalization. Information Systems (IS) research has broadly researched technology adoption at the individual and organizational levels. However, none of these studies have explained the adoption of digital technologies with specific relevance to creating digital innovation by comparing incumbent firms with start-ups. By taking these observations together, the addressed research question is: ***What factors influence the decision to adopt digital technologies in order to create digital innovations by incumbent firms and start-ups?*** To generate insights into this emergent phenomenon of digitalization and an understanding of the different perspectives of experts, we conducted an exploratory study based on interviews with 23 executive managers (most of them CEOs and CIOs) from various incumbent firms, as well as with 12 founders of start-ups. The objective of this study was to retain the richness of the phenomenon while studying the linkage between known but less researched factors of incumbent firms´ and start-ups´ decision-making in the context of digitalization. Thereby, the variety of the identified factors was sorted by the technology-organization-environment (TOE) framework, which is suited to our understanding of the affects of these factors. In particular, based on our findings, we have illustrated what role start-ups play for incumbent firms and why collaboration between both is a great opportunity to meet the challenges of the digital era.

The paper is structured as follows: First, we provided a brief overview of the theoretical background and related work to mark off the research field. Then, we described how the exploratory study was designed and how the interviews were executed. Thereby, we have presented our sample of 23 executive managers of incumbent firms and 12 founders of start-ups. In addition, we have presented the empirical results and integrated our findings by utilizing the TOE framework in a sorted form. Therefore, the results of our paper provide a holistic view of the enablers and inhibitors that are relevant for incumbent firms and start-ups in the digital era. Afterwards, we discussed our key findings and illustrated an approach to future work. Finally, we concluded by describing the limitations of and contributions to research and practice.

2 Theoretical Background and Related Work

The sociotechnical process of applying new technologies to broader social and institutional contexts comprises the term "digitalization" [2], [13]. Currently, there is a new wave of digitalization because the growing role of digital technologies is changing the way firms relate to their customers [14]. The objective of today's discourse on digitalization is not only to improve efficiency based on new technologies, but also to create new business value with innovative products, services, or business models – especially in the form of digital innovation, which is embodied in or enabled by IT [8], [12]. In particular, SMAC can serve as a holistic basis and equip an organization to create digital innovations in context of digitalization [5]. Thereby, an organizational innovation is defined as the first use of an idea in terms of a product, process, or service that is new or improved to the organization adopting it [15], [16], [17].

In IS research, there have been some studies conducted and empirical evidence found for the impacts of digitalization on organizations. For instance, IS researchers have investigated the IT-enabled transformational change in organizations, the importance of a digital business strategy, changes in the producer-consumer relationship, and the managerial tasks of a chief digital officer [6], [7], [18], [19]. In addition, there are concepts for classifying organizations into types of digital maturity levels [e.g. 20]. However, research in the field of digitalization with a focus on whether incumbent firms and start-ups – despite culture clashes – fit together well can hardly be found. Only a few studies exist that have made collaboration between incumbent firms and start-ups a subject of discussion; however, the specific role of start-ups for incumbent firms has not been investigated in this context. Rather, it has been found by researchers that, when both work together, it is a balancing act, as it is a cooperation and competition at the same time. In addition, it is also about strategies for dealing with emerging cooperative competitive tensions [21]. Although some incumbent firms have a great interest in cooperating and although they have great advantages in open innovation [22], [23]; another study has resulted in a more differentiated result: The choice of the wrong cooperation partner does not promote the innovation of both sides. Above all, startups, by and large, are dissuaded from cooperation with multinational firms [24].

To illustrate the specific characteristics of start-ups related to incumbent firms, the life-cycle approach could be used. This approach is based on the assumption of the ideal-type stages of a firm: introduction, growth, maturity, and decline. Start-ups can be categorized into the introduction and growth stages. These stages characterize high investment costs via extraction of necessary resources, which usually causes low turnover [25]. Besides that, there are lots of start-ups that have very low investment costs, as they only sell digitized products or services without huge production costs.

Generally, start-ups are not bound to a specific industry. However, a distinguishing characteristic of start-ups can be the degree of innovation. An innovative start-up has a solid foundation for creating technology-specific innovation. In particular, high flexibility and digital know-how enable start-ups to quickly implement ideas as the innovative digital products and services [26], [27], [28]. In the growth stage, firms successfully penetrate the market. The growing size of firms indicates the standardization and professionalization of all the operational systems and processes. Incumbent firms are located at the end of this growth stage when reaching the maturity stage [25]. Thereby, incumbent firms are characterized by their good position in the market [29]. Despite incumbent firms and start-ups differing on characteristics, it can be assumed that both address the opportunities and challenges of digitalization [30]. With this in mind, a holistic view of the factors influencing the adoption of digital technologies in consideration could be useful for understanding the decision-making in the context of digitalization from the two parties' perspectives. A broadly used framework in the field of organizational technology adoption is the TOE framework. Accordingly, technological innovation decision-making is influenced by technological development, organizational, and environmental dimensions. The TOE provides a set of factors that are relevant: The technological context includes the availability and characteristics of technologies. Factors in the organizational context are formal and informal linking structures, communication processes, firm size, and slack. The environmental context describes factors outside of the organization. These include in particular industry characteristics and market structure, technology support infrastructure, and government regulation [31]. Previous studies provide relevant factors as well [32], [33], [34], [35], [36], [37]. However, a holistic view of the factors that influence a specific kind of organization's adoption, such as that which compares incumbent firms with start-ups directly of a particular technological innovation (e.g., digital innovation), is missing. Furthermore, to our knowledge, existing studies have not focused on incumbent firms and start-ups with a holistic view or with the aim to analyze how these different factors of incumbent firms and start-ups could fit together. Following this line of thought, the applicability of the TOE framework supports our research by integrating our findings in a sorted form.

3 Research Study

The qualitative study presented here was a research project that investigated effects on and outcomes of digitalization in business and science. In this paper, we have presented relevant factors influencing decision-making in the context of digitalization – identified by statements from incumbent firms and start-ups – with the aim to gain insights about the role of start-ups for incumbent firms.

As described earlier, this study is focused on a relatively new phenomenon. Against this background, we decided on qualitative research with an explorative design. The explorative approach allowed us to analyze data material in areas in which only limited knowledge exists [38], [39]. Our qualitative study has been built on interviews with experts. Generally, an expert is a person with special knowledge of a subject area [40]. For the interviews, a semi-structured guideline was used with questions that were designed to generate comparability of results and were selected in order to preserve the exploratory character [38]. This guideline ensured that all interviews covered the main topic, and it allowed us to address the peculiarities of the respective firms' contexts.

In the following, the sample and data collection process, as well as the data analysis method, are described in detail.

3.1 Sample and Data Collection Process

The focus of this paper is to present the differences between incumbent firms and start-ups by identifying the influencing factors for adopting digital technologies in the context of digitalization.

Interviewees were first asked about the importance of digitalization in their organizations, then about the activities in the areas of projects in terms of digital innovations, strategy, processes, leadership style, and culture. Thereby, the interviewees would give insights into their own field of activities, as well as a holistic view of their organization across all departments.

Firstly, we concentrated on interviews with executive managers (most of them CEOs and CIOs) of well-known and well-established firms from various industries, such as consulting, product-oriented, and service-oriented firms. With the intention of developing a uniform and industry-nonspecific picture of firms, experts were selected from various industries. Within the incumbent firms, we decided to interview managers from the strategic level because they determine the strategy of the firm and have a holistic cross-functional organizational overview. This view is crucial, as digitalization affects all functions of a firm [6], [7]. In addition to these interviews with managers of incumbent firms, we conducted interviews with founders of various start-ups. The start-ups interviewed were required to have technology-based business models with the focus on business-to-business (B2B) and business-to-consumer (B2C). This was because of the assumption that they would demonstrate a high degree of innovation performance in context of B2B and B2C [10], [11].

The expert interviews were conducted during the period between June 2015 and August 2015. In total, the sample was comprised of 35 interviews with 23 executive managers (hereby abbreviated as "IF" for "incumbent firm") and 12 founders of start-ups (hereby abbreviated as "SU" for "start-up"). All the interviewees from the incumbent firms had a proactive role and extensive staffing/budget responsibility within their firms at the time of the interview. Beyond that, all the founders of start-ups interviewed had been managing their business for at least one year. Table 1 provides an overview of the 35 experts interviewed. Thereby, we ranked each group by founding year, because, in all likelihood, the older the organization, the more established the existing business model.

Table 1. Overview of experts interviewed

The interviews were held in private spaces and lasted an average of 45 minutes. All interviews were recorded. For easier analysis, the recorded material was transcribed. This process resulted in 309 DIN A4 format pages of transcripts.

3.2 Data Analysis Method

The aim of the data analysis was to retain and provide essential contents by abstracting a manageable collection of data that still illustrated a reflection of the data material. Characteristic of this type of examination is the methodological technique "content analysis" [41]. Thereby, we have used an inductive approach, as we have not had theoretical assumptions in context of our research. Against this background, the categories were derived inductively from the transcribed interviews and, thus, were not predefined or derived from existing theory. Based on the content analysis technique and following the reducing code rules, the data material was reduced into an abstract form in order to paraphrase and generalize the data material by maintaining only the parts of substantial content, which was finally divided into categories [42], [43]. For instance, the quotation of an expert *"Each new project, such as one based on digitalization to create digital innovation, always presupposes a well-realized application platform. […] we have a well-functional basis that provides a functional IT System within our firm."* (IF-19)" was coded – after a paraphrasing and generalizing process – to category 'Solid IT Infrastructure'. As required, corresponding points in the material were assigned to the newly formed categories.

To achieve reliability in our analysis, multiple people (three in total) coded and analyzed the data material by using a software tool [44]. Thereby, we have combined all the categories together and marked only those that were coded by all. Afterwards, we have filtered them by factors that are relevant in each respective incumbent firm and start-up. Finally, the categories were filtered again by relevance in terms of representing insights into factors influencing incumbent firms´ and start-ups´ decision-making in context of digitalization.

4 Empirical Results

To illustrate our key findings in a comprehensive view, the relevant categories were summarized into thematically related groups. For instance, the categories ‘solid IT infrastructure’ and ‘access to broadband’ were summarized into **‘Available Technical Equipment’**. As a result, these groups stand for 15 influencing factors for each respective incumbent firm and start-up that exist across all industries. In particular, we found that factors can be enablers or inhibitors and differ partially, depending on the incumbent firm or start-up. Thereby, enablers help to promote the adoption of digital technologies, while inhibitors prevent their adoption [45]. It is possible that the same factors may be rated differently depending on the organization in which they occur, as is presented in our study.

Due to the variety of the identified factors, in the following, the influencing factors have been sorted into an aggregated form based on the TOE framework. Accordingly, the factors were classified as technology, organization, and environment, whereby these mutually influence each other. As illustrated in Figure 1, the factors of incumbent firms and start-ups have been sorted by enabling factors (the symbol “+”) and inhibiting factors (the symbol “-”). Thereby, the symbol “+” means that the identified factor has an enabling effect, and the symbol “-” means that the factor has an inhibiting effect on the decision-making of incumbent firms and start-ups in the context of digitalization.

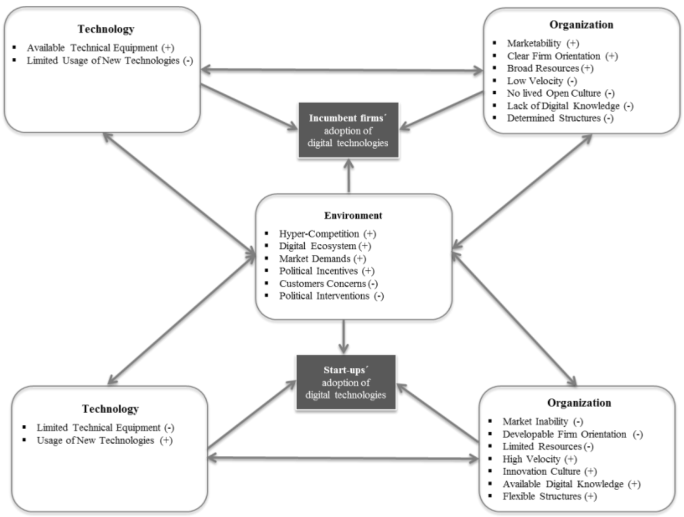

Figure 1. Influencing factors for decision-making in the context of digitalization

The factors illustrated above mark the enablers and inhibitors that pave the way for understanding the similarities and differences between incumbent firms and start-ups. As the factors originate from the statements from the interviews, the definitions of the factors can be derived from the explanations of the experts interviewed. In the following, we have described some examples of each technological, organizational, and environmental factor in incumbent firms and start-ups.

The technological context includes the internal and external technologies that are available for an organization and that fit with an organization´s current technology. For many IT solutions to work, firms need **'Available Technical Equipment'**, which allows the performing of digital-based projects. Some experts from incumbent firms stated that a 'solid IT infrastructure´ is a highly relevant enabler for them to operate without problems. Furthermore, 'access to a broadband connection' is a basic prerequisite for and enabler of efficient use of modern IT solutions in the digital era. In particular, for projects to develop digital products and services, available technical equipment is needed in order to build upon on this foundation. In contrast, **'Limited Technical Equipment'** causes start-ups to be restricted in their business actions. Some start-up interviewees stated that their 'IT infrastructure was not comprehensive` and hindered them in implementing further digital solutions based on existing ideas. Furthermore, some founders of start-ups stated that a 'reduced broadband connectivity' led to fewer additional digital services within their business models.

The organizational context encompasses the characteristics and resources of an organization. Thereby, **'Marketability'** is an essential factor for incumbent firms. This means that 'capability due to experience in business' enables incumbent firms to operate in the market with perseverance. Moreover, they have an understanding of environmental dynamics. Furthermore, 'product and service portfolio' is an enabler that represents a solid foundation for extending functional business to a digital business model. However, start-ups are not able to act in their business field due to '**Market Inability'**. This is attributable to their 'lack of experience in business' and 'difficult access to customers', as mentioned by some founders of start-ups interviewed.

The environmental context includes, among others, the competition pressure in the course of ongoing digitalization. Thereby, **'Hyper-Competition'** especially leads to the rapid escalation of competitive tactics. Against this background, the executive managers of incumbent firms indicated that there were 'new entrants from various industries'. The founders of start-ups used the same line in relation to 'other start-ups'. Both indicated that hyper-competition enables the adoption of digital technologies, as it is crucial to keep a competitive advantage.

For a closer look at the results, we compared the factors of incumbent firms and start-ups and analyzed our key findings with a focus on the role of start-ups for incumbent firms. In the following, the factors are represented with sub-factors in order to highlight the relevance – stated by the interviewees – of the enabling and inhibiting factors. Thereby, relevance has been considered based on the following point-allocation: ■ = very high relevance (p=4), ▣ = high relevance (p=3), ⊡ = low relevance (p=2), and ☐ = very low relevance (p=1). The findings have been rated according to the following formula: $\sum$**p/n**, with n=number of mentions per executive manager with respect to start-ups. In Table 2, the average relevance is shown for each respective factor.

Table 2. Merging both groups*

Incumbent Firms		Incumbent factor	Incumbent category		Start-up category	Start-up factor		Start-ups
Technology								
Enabler	■	Solid IT Infrastructure	**Available Technical Equipment**	↔	**Limited Technical Equipment**	No comprehensive IT Infrastructure	■	Inhibitor
Enabler	▣	Access to Broadband Connection				Reduced Broadband Connection	■	Inhibitor
Inhibitor	■	Legacy IT Systems	**Limited Usage of New Technologies**	↔	**Usage of New Technologies**	IT-Based Innovative Tools	■	Enabler
Inhibitor	▣	No Broad Utilization of Cloud Computing				Full Utilization of Cloud Computing	■	Enabler
Organization								
Enabler	■	Capability Due to Experience in Business	**Marketability**		**Market Inability**	Lack of Experience in Business	▣	Inhibitor
Enabler	■	Product and Service Portfolio				Difficult Access to Customer	■	Inhibitor
Enabler	■	Digital Business Strategy	**Clear Firm Orientation**	↔	**Developable Firm Orientation**	Strategic Goal Still in Development	■	Inhibitor
Enabler	☐	Process Orientation				Non-professional Flowcharts	☐	Inhibitor
Enabler	▣	Comprehensive Workforce	**Broad Resources**		**Limited Resources**	Mini Manpower	⊡	Inhibitor
Enabler	⊡	Available Budget				Scarce Budget	■	Inhibitor
Inhibitor	■	Hierarchical Structures	**Low Velocity**		**High Velocity**	Flat Organization	■	Enabler
Inhibitor	▣	High Quality Requirements				No Long Discussions	▣	Enabler
Inhibitor	■	Longstanding Methods				Agile Working Methods	■	Enabler
Inhibitor	▣	Missing Entrepreneurial Spirit	**No lived Open Culture**		**Innovation Culture**	Willingness to Dare	■	Enabler
Inhibitor	⊡	Older Top Management		↔		Trial-and-Error Attitude	■	Enabler
Inhibitor	■	Aging Workforce	**Lack of Digital Knowledge**		**Available Digital Knowledge**	Digital Natives	■	Enabler
Inhibitor	▣	Limited Experiences in Big Data				Deal with Big Data	▣	Enabler
Inhibitor	■	Low Availability of IT Professionals						Enabler
Inhibitor	■	Inefficent Interaction of Business and IT	**Determined Structures**		**Flexible Structures**	Jack of All Trades	■	Enabler
Inhibitor	▣	Fixed Workplaces				Co-working Spaces	▣	Enabler
Environment								
Enabler	■	New Entrants from Various Industries	**Hyper-Competition**			Other Start-ups	■	Enabler
Enabler	■	Knowledge Exchange with Start-ups	**Digital Ecosystem**			Knowledge Exchange with Other Start-ups	■	Enabler
Enabler	☐	Platforms for Digitalization Topics				Platforms for Start-ups	▣	Enabler
Enabler						Venture Capital Investors	■	Enabler
Enabler	■	Customer Expectations	**Market Demands**			User Entrepreneur	■	Enabler
Enabler	☐	Funding Programs	**Political Incentives**			Funding Programs	⊡	Enabler

Inhibitor						No Openess Due to Unknown Name	▣	Inhibitor
Inhibitor	■	Law Protection of Data	**Political Interventions**			Law Protection of Data	■	Inhibitor
Inhibitor	⊡	Regulatory Requirements				Bureaucratic Expenditure	⊡	Inhibitor

**A list of all the factors, with corresponding descriptions, is available from the authors upon request.*

As seen in Table 2, incumbent firms and start-ups share equal environmental factors in the digital era. For instance, interviewees from both positions stated that **'Hyper-Competition'** is a great enabler for promoting decision-making in the context of digitalization in their own firms. Aside from that, they had been facing 'Customer Concerns', which inhibit incumbent firms and start-ups equally. However, although the environmental factors of incumbent firms and start-ups are equivalent, the factors of technology and organization differ significantly. Thereby, the technological and organizational enabling factors identified in incumbent firms are similar to the inhibiting factors of start-ups, and, likewise, the inhibiting factors of incumbent firms are similar to the enabling factors of start-ups. For instance, the organizational enabling factor **'Marketability'** for incumbent firms is missing in start-ups and can be compared with the inhibiting factor **'Market Inability'**. Beyond this, there is also the indication that the inhibitors of incumbent firms can correspond directly with the enablers of start-ups. For instance, the technological inhibiting factor **'Limited Usage of New Technologies'** for incumbent firms can be compared with **'Usage of New Technologies'** for start-ups: While incumbent firms would have liked to implement a higher level of cloud computing if they had not had concerns about their data, start-ups did not have concerns about using cloud computing solutions.

5 Discussion of Findings

To illustrate and discuss the new findings of our research, we have compared our results with those of existing studies. We have drawn on relevant studies with respect to the specific context of the organizational adoption of technological innovation, which can be associated with digital technologies. These include in particular adoption of cloud computing, customer-based interorganizational system (IOS), e-business, e-commerce, and mobile business. An overview of the relevant factors is provided in Table 3.

Table 3. Overview of the relevant factors

		Innovation
Technological factors	Complexity [32], [35]	Cloud Computing
		Customer-Based IOS
	Compatibility[32], [35]	Cloud Computing
		Customer-Based IOS
	Technology Competence (e.g., IT-Infrastructure) [33], [36], [34]	E-Business
		E-Commerce
	Unresolved Technical Issue [36]	E-Commerce
	Interoperability [36]	
Organizational factors	Top-Management Support [32]	Cloud Computing
	IS Experience [32]

		Mobile Business
	Trading Partner Readiness [33]	E-Business
	Consumer Readiness [33]	
	Customer Interaction [35]	Customer-Based IOS
	Legal Issue [36]	E-Commerce
	Regulatory Support [34]	E-Business

In a comparison of the factors presented above with our findings, it can be noted that there is at least one newly identified factor in each dimension of the TOE separated between incumbent firms and start-ups: In the technology context, the factors **'Limited Usage of New Technologies'** in incumbent firms and **'Usage of New Technologies'** in start-ups have been identified; **'Marketability'**, **'Low Velocity'**, **'No lived Culture',** and **'Determined Structures'** in incumbent firms and **'Market**

Inability', **'High Velocity'**, **'Innovation Culture'**, and **'Flexible Structures'** in start-ups have been identified as organizational factors; and **'Digital Ecosystem'** in both represents an environmental factor. The rest of our findings can be found in a similar form in existing literature.

Besides the new identified factors, based on our key findings, we have been able to investigate whether incumbent firms should collaborate with start-ups in the digital era. Basically, the bigger a firm, the higher the probability – despite sufficient relevant resources, such as budget and technical equipment – that they will have lower innovative performance, due to, for example, inertia [29], [46]. In contrast, start-ups have relevant enablers for adopting digital technologies to create digital innovation, which are important in the digital era. However, incumbent firms have several inhibiting factors for adopting digital technologies to create digital innovation; hence, collaboration with start-ups can be an opportunity to balance these factors. In addition, incumbent firms also have relevant enabling factors that start-ups need for expanding their efforts in the field of digital innovations.

It has become visible that incumbent firms and start-ups complement each other perfectly and have the potential to collaborate with each other in an appropriate form. Against this background, the approach of open innovation can be an option for initiating collaborations between incumbent firms and start-ups. This potential was also emphasized by some of the executive managers of the incumbent firms: "*We are definitely interested in working with start-ups"* (IF-18). Start-ups are seen as providing a chance to create innovative products and services, as pointed out by one interviewee in following words: *"It is a great opportunity for large firms to work with start-ups – you can find your missing impulses right there"* (IF-13). These and other quotations paint a picture of incumbent firms being interested in collaborating with start-ups, as well as hoping to learn from them. In particular, incumbent firms can use start-ups to create an entrepreneurial organization with the aim to stimulate the expansion of competence and, across all departments, to build up the ability to act and operate entrepreneurially. Moreover, with collaboration with start-ups, new business areas can be pursued [47], [48].

However, when it comes to a concrete activity on which to collaborate with start-ups, start-ups have criticized incumbent firms' restricted openness towards collaboration. One founder of a start-up described it this way: *"Cooperation partners are very important for achieving drive in our target market. However, discussions with potential partners do not lead to positive results"* (SU-11). In the same line of thinking, some founders of start-ups stated that incumbent firms had *"difficulties with cooperation because they do not understand our innovative product and services"* (SU-02). This reproach could be explained by the assumption that *"potential cooperation partners do not really see the potential of our business model"* (SU-04). To sum it up, while some incumbent firms want to collaborate with start-ups, there are apparently some noticeable hurdles. This conflicts with some popular views and raises a fundamental question concerning the usefulness of collaboration between incumbent firms and start-ups to pursuing increased innovation performance on both sides. Currently, the design of corporate start-up programs is being intensely examined, especially with regard to the joint development of new and innovative ideas [23]. At the same time, many programs are promising success, in which the start-ups should profit from the experience and resources of the incumbent firms.

Often, however, studies on this topic have mainly been based on the experience of the incumbent firms, or on the prerequisites and recommendations for successful collaboration for managers of incumbent firms [22].

6 Conclusion, Limitation, and Outlook

On the grounds of reflection on the enabling and inhibiting factors influencing the incumbent firms´ and start-ups´ decision-making in the context of digitalization, we have been able – in our opinion – to present newly identified influencing factors that were sorted by the TOE framework. Alongside this, we have analyzed the similarities and differences between incumbent firms and start-ups: In particular, we have found out that the technological and organizational enabling factors in incumbent firms are similar to the inhibiting factors in start-ups, and the corresponding inhibiting factors in incumbent firms are similar to the enabling factors in start-ups. In consideration of how inhibitors can develop into enablers, incumbent firms as well as start-ups can approach each other to overcome their respective inhibiting factors. There are already a few incumbent firms trying to establish structures in which to collaborate with start-ups. For instance, corporate-startup programs, namely, accelerator programs like the accelerator program "Microsoft Ventures" and the newly founded "InnoJam++" event from SAP in cooperation with Volkswagen. However, there are lots of incumbent firms that have not yet recognized the opportunity of cooperating with start-ups to meet their challenges in the digital era. Against this background, we assume that our results could have an impact on the reinforcement of incumbent firms' willingness to collaborate with start-ups.

As in any study, our qualitative research has been constrained by some limitations. However, at the same time, these limitations provide avenues for further research. Due to the interpretive nature of our research, the results we have described represent the sense-making process of the researchers. Subjective personal judgments cannot be ruled out completely, even though we took great care to reflect the subjects' opinions as correctly as possible. Moreover, the factors have been derived from the views stated by the interviewees. It cannot be ruled out that there are more factors that we have not identified in our study. Besides that, it is difficult to make quantitative predictions. Therefore, it is necessary to validate our results with an extensive investigation based on a quantitative study. Nevertheless, despite the limitations, our study makes three major contributions: *Firstly*, we have illustrated influencing factors that are relevant to incumbent firms´ and start-ups´ decision-making in pursuit of digitalization. In particular, we have provided new findings related to enabling and inhibiting factors from a holistic viewpoint as a basis for the research discussion. *Secondly*, for practitioners, we have shown the potential of start-ups as cooperation partners and have emphasized that incumbent firms should collaborate with start-ups in order to be competitive in the digital era. *Thirdly*, we have indicated that hurdles exist in efforts to collaborate, which should be investigated in detail in future research. Against this background, it would be interesting to analyze the following main question: What factors, and how do those factors, influence collaboration between incumbent firms and start-ups in the context of the digital era? Thereby, the dyadic relationship should be considered in this investigation, with the primary aim of figuring out what factors are relevant from a two-sided perspective, as our results have illustrated that there remains an area of tension. Thus, it is advisable to examine precisely which hurdles exist in order to determine a balance that can be crucial for the success of the collaboration between incumbent firms and start-ups.

robin.knote@uni-kassel.de

Abstract. Patterns are becoming increasingly prominent in the field of Information Systems (IS). They contain good practice solutions to recurring problems and are therefore especially valuable for systems development. Although a huge amount of patterns for nearly every problem in systems development (and even in many fields of IS such as enterprise information management or security) exist, literature still misses a systemized overview on how such patterns are developed. Approaches in practice exist but are either methodologically imprecise or lack a scientific foundation. This contribution is devoted to review the state-of-the-art on how patterns are designed. The findings of our systematic literature review reveal approaches for pattern development which we consolidate, structure and critically reflect. Since we argue that patterns can be considered design artifacts, we apply a design science research (DSR) lens to these approaches, highlight potential gaps and show needs for future development in theory and practice.

Keywords: pattern, pattern development, sociotechnical systems engineering, design science research

1 Introduction

The ongoing digital transformation causes great technological and societal challenges and opportunities. Consequently, the complexity of systems engineering is exponentially increasing. On the technical side, systems have to be able to communicate with an unknown number of different systems and subsystems, offer individualized services to the user and even change their behavior during runtime based on context information. On the societal side, systems have to be accepted by the users, which require privacy, trust, usability or legal considerations as well as the offering of added value. Therefore, the main challenges for systems engineering are identified as complexity, multidisciplinarity and user focus. Accordingly, systems development, in order to be efficient and effective, has to include heterogeneous and multidisciplinary stakeholders to analyze their requirements and offer proper designs [1]. A profitable approach for eliciting, understanding and applying multidisciplinary knowledge and experience within systems engineering are patterns [2–5]. Patterns

Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1393-1404

focus on making good solutions to recurring problems accessible and comprehensible and thus, prevent the applier from ‘reinventing the wheel’. Capturing multidisciplinary knowledge related to certain design problems, patterns may decrease cost and effort when solving the problem. Thus, they ensure that already identified requirements and good designs are used (avoidance of potential mistakes), reveal knowledge in an understandable form for all stakeholders and provide a common vocabulary for experts to communicate about design questions. Furthermore, they lead to more transparency of the problem context, as they entail information about structural relations and dependencies that would otherwise probably be neglected [2, 6–8]. Therefore, the use of patterns, has a high impact on the performance of systems, services and organizations, leading to economic benefits and increased competitiveness. Prominent examples of patterns are the Design Patterns by the Gang of Four, which contains patterns about good software engineering [8].

However, although a lot of pattern repositories and catalogues exist and patterns are used in systems engineering practice, the question of how patterns are developed to reach certain design goals (such as quality, applicability or utility) remains unclear. Furthermore, since pattern development is a practical problem and is mostly focused by practitioners or practitioner-oriented communities, existing approaches still lack a scientific foundation. However, we suggest that such a methodological underpinning is necessary in order to have patterns becoming an acknowledged topic for IS and adjacent research fields. We believe that pattern development, underpinned by methodology, can have a strong impact and offer new solutions to existing design problems, as well as increasing their added value through best possible development. From a practical point of view, a clear methodological approach on how to develop patterns is suggested to resolve issues concerning pattern structure, quality and utility.

To solve these problems, we are undertaking a systematic literature review to identify, cluster and structure pattern development approaches. Thus, our work is devoted to structure the field and can be considered a first step towards approaching pattern development from a scientific base.

Our paper is structured as follows. Section 2 gives deeper insights about patterns and pattern development. Our research methodology is described in section 3. The findings of the literature review are given in section 4 and further discussed in section 5. We conclude with our contributions, limitations and future outlook in section 5.

2 Background

2.1 Patterns in IS

The idea to establish and apply patterns originally stems from the field of architecture. Alexander [9] defines patterns as specifications of recurring problems and proven solutions to these problems. Hence, a pattern comprises applied and established knowledge on how to solve a certain design problem. In the mid 1990’s, the pattern concept was first introduced for system development by Gamma et al. [10] who described design patterns for object-oriented software development. Since then, the acceptance and use of patterns has increased tremendously. Nowadays, a huge amount of patterns can be found for different fields of IS, such as human-computer interaction, security, requirements engineering and enterprise integration. Due to the wide circulation of pattern publications, the pattern community is continuously becoming larger. Today, many workshops on scientific conferences (such as RePa[1]) or even entire conferences (e.g., PLoP[2] conferences) are devoted to pattern development and dissemination.

Across all disciplines, the main goal of patterns is reuse of established knowledge for specific problem contexts [11]. Therefore, patterns contain templates for problem specification and other relevant information in tabular form, including a unique pattern name, meta data (e.g., author), conditions of pattern applicability and relations to other patterns [7, 12]. Thus, patterns should contain at least five central elements: a description of *problems* and *forces* to describe the problem and why it is difficult to solve (problem domain), a description of the *solution* and possible *consequences* to demonstrate what happens when the solution is applied (solution domain) and a description of the *context* in which the pattern is applicable [13].

2.2 Pattern Development

Although nowadays many patterns exist for various application domains, literature about how to systematically develop them is scarce. Wellhausen and Fießer [13] introduce the topic by explaining what patterns are and how to identify them with regard to IS disciplines from a practitioners point of view. Furthermore, Withall differentiates between a systematic (inductive) and a theory-based or opportunistic (deductive) approach for pattern development [7]. According to his work, following a systematic approach, is appropriate in case enough satisfactory solutions exist for a problem. In this case, these solutions (e.g., design guidelines) are collected, aggregated and generalized in a pattern format. The opportunistic approach is applicable if no or few solutions exist. Pattern development is then based on relevant experiences and theoretical insights (e.g., empirical data). However, the process itself still lacks a theoretical and methodological foundation which is important for pattern development in a scientifically acknowledgeable manner. Thus, Petter et al. consider the 'scientific' way of pattern development a design science approach, in which the pattern becomes the design artifact [14]. A design artifact is a solution to a problem, which creates value while being used. To ensure the quality of an artifact and therefore its value, it iterates within three different cycles until it creates a satisfactory value. These cycles can be assigned to pattern development for developing satisfactory, value adding, patterns. The Design science research (DSR) cycles can be described as follows [15]. The *relevance cycle* is about identifying the problem

[1] International Workshop on Requirements Patterns held on the International Requirements Engineering Conference. http://re16.org/pages/conference/workshops/#WS08 (accessed October 12, 2016)

[2] Pattern Languages of Programs conferences. http://hillside.net/conferences (accessed October 12, 2016)

domain, eliciting requirements and, after the solution is built, field-testing the artifact. In the *rigor cycle* a common knowledge base is created and other relevant research (e.g., other pattern repositories) is screened to derive design considerations. The goal of the *design cycle* is to build the artifact and validate it against preliminarily defined evaluation criteria. In this work, we follow this logic, since other research present DSR as a suitable way for pattern development [16]. Hence, the conceptual model for our literature review is divided into relevance (identify problems), rigor (include existing knowledge), design (build artifacts) and evaluation (assure value).

3 Methodology

To identify approaches for pattern development, we conduct a systematic literature review [17, 18]. According to the taxonomy given by Cooper, our review is characterized as follows [19]: We focus on approaches for but not the results of pattern development (i.e., the actual patterns). We thereby understand an approach as a technique or type of (collaborative) work, that is used for developing patterns. The goal is to identify pattern development approaches and to integrate them within the DSR framework. The findings will be clustered and organized on a conceptual level. Our target audience are scholars and practitioners. The coverage of this research is representative and should identify common approaches.

The search for relevant articles was conducted in February 2016. For identifying relevant databases and search phrases, a brief research was done based on the aforementioned foundational work including a short forward search. The following databases were chosen, as they cover the PloP conferences, fit the targeted domain of systems engineering and Requirements Engineering: ACM, SpringerLink, IEEE Xplore und AISeL. The predominant phrases in the context of pattern development are: *pattern mining* [7, 20–22], *pattern writing* [7, 22–24] or *pattern authoring* [24, 25]. Unsuitable phrases were *pattern detection* [27, 28] and *pattern discovery* [29], since they are predominantly used in Data Mining or technical pattern detection and hence were excluded from our search. The search was conducted in title, abstract and keywords, which led to 1156 hits. In a first step title, abstract and keywords were screened and unsuitable articles disregarded. In the second step the remaining full articles were read thoroughly to further sort out non-relevant articles. In general, articles were disregarded if they were purely technological, did not mention any approach or were not available in German or English. In the end, a total number of 28 articles were selected for further analysis.

The initial list of possible approaches found in the relevant articles contained 76 items. A four phase process was used to cluster these items into useful and relevant approaches. First, all items were analyzed regarding their abstraction level, which resulted in disregarding very abstract approaches (e.g., Grounded Theory). Second, the meaning of each remaining approach was summarized in a short description- Approaches with similar meaning were clustered in a third step. Fourth, all approaches that did not have at least three hits were disregarded. Since our way of clustering approaches is comparable to coding in qualitative content analysis (i.e., interpretative nature), two researchers clustered the findings independently to establish inter-coder reliability [30]. The clustered approaches were finally analyzed regarding their fit into DSR elements as mentioned above.

4 Approaches for Pattern Development

The findings of the literature review are presented in Table 1. In general, it can be observed that inductive approaches (i.e., observing the specifics of a context and moving towards generalization) are more commonly used to identify and design possible patterns, whereas deductive approaches (i.e., starting from generalized insights and moving towards specifics of a context) are used to structure and validate them in different practical contexts [21, 23]. For example, Schadewitz and Jachna used an inductive approach to find reoccurring issues in student teams' interactions and communications as well as a deductive approach to discover possible connections between these issues and to compare them within different contexts [26]. Another general finding is the importance of collaboration and communication. It urges the meaning of the community and inclusion of interdisciplinary stakeholders for actively creating and sharing comprehensible patterns [24, 25].

Table 1. Pattern Development approaches

Approach	Hits	Relevance	Rigor	Design	Evaluate	Sources
development workshop	15	●	○	●	○	[21, 23–25, 31–41]
enhancement workshop	15	○	○	●	●	[21, 23–25, 31–41]
guided development	15	○	○	●	○	[7, 24, 25, 31–33, 36, 42–46]
shepherding	9	○	○	●	○	[21, 23–25, 32–34, 36, 41]
expert interview	8	●	○	○	●	[26, 32, 33, 35, 39, 41, 43, 47]
observation	8	●	○	○	○	[21, 23, 26, 31–33, 40, 43]
open channel	6	●	○	○	●	[21, 24, 25, 36, 41, 43, 44]
literature review	4	○	●	○	○	[32, 32, 36, 42, 48, 49]
collaborative learning and development	3	●	○	●	○	[33, 35, 39]
pattern mapping	3	●	○	●	○	[21, 26, 32]
pattern writing	3	●	○	●	○	[23, 31, 35]

○ = not applicable / unknown; ● = applicable

Shepherding and workshops are state-of-the-art pattern development approaches and are frequently used on pattern conferences [25]. They are both sharing a highly interactive character. A workshop is a cooperation of a group of people, while shepherding is a cooperation between a shepherd (experienced pattern author) and a sheep (pattern author). A general benefit of a workshop is the attendance of multiple participants which leads to a harmonization of different views [32]. The workshop can target a wide range of goals, from creatively coming up with new pattern ideas to finalizing one definite pattern. Accordingly, there is no generic workshop approach. We suggest two different approaches. First, the pattern development workshop, which is used to mine (collect, categorize and summarize) patterns [23]. For example, Iacob uses a set of workshops to confront designers with a set of problems. The design process is analyzed and transformed into design issues, which are then counted. Their degree of recurrence is calculated to identify pattern candidates [21]. The output of the development workshops are pattern candidates or patterns. Hence, development workshops can be used to find relevant issues and design pattern artifacts. Second, the enhancement workshop, which is about giving and getting feedback on a pattern (evaluation) and using this to improve the pattern until its final form. To continue with the example from Schadewitz and Jachna, their design issues were evaluated in workshops with novices and experts. The insights from those workshops were used for further development. Experts can actively interact with design suggestions, while novices can offer great insights about the actual quality of the pattern [41]. One technique, "fly on the wall", is described very often and helps exemplifying the intention of the enhancement workshop: the pattern author is listening to a group of participants which discusses the pattern he developed without being allowed to intervene or rectify. The goal of this approach is to evaluate the understandability of patterns as stand-alone, self-explaining artifacts [6]. Therefore, the enhancement workshop can be used to design and evaluate patterns.

Shepherding is much more focused on pattern specific knowledge and the artifact itself. It usually takes place over several months and is an intense interaction between the shepherd and the sheep. This makes it a very valuable approach for the design phase. In practice, it is often used in advance of pattern conferences, which offer a wide range of approaches to support pattern development. They contain multiple approaches like workshops, discussions, presentations and shepherding.

Collaborative learning and development, is an effective approach to start pattern mining, as it teaches domain experts and novices about patterns and how to develop them. While understanding the nature of patterns and their use, participants start recognizing and can support each other in developing first patterns. This approach raises pattern awareness, which helps finding relevant issues and supports the design of first patterns.

Guided development is mainly used to support designing the actual pattern as it informs about possible formats (even offers tool supported templates), steps to do while writing a pattern or best practices with useful recommendations. It makes particular pattern development knowledge available to be used by authors. The approach comprises elements such as step-by-step guides, pattern templates and checklists.

Expert interviews are interactive meetings of two people or a small group to gather each subject's personal views and experiences within their context. The interviewees are either experts of a certain domain and thus act as source for issues within their expertise (relevance) or future pattern appliers who give feedback on pattern designs (evaluation).

A not necessarily interactive approach for investigating people and/or technology within their realworld environment, is observation. It was also used for first patterns by Alexander [50] and is highly applicable in identifying relevant issues for pattern development. Especially for non-communicable complex situations and contexts this approach is highly effective.

The open channel approach implies communication between all stakeholders of a system. A continuous discussion between stakeholders leads to two main benefits: Already discovered patterns are being continuously evaluated and new issues for pattern development might arise within a simple discussion. Therefore, the open channel approach is inherent in most of the presented approaches. However, its core intention is to focus on being open for discussion at all other phases as well. Fehling et. al. posit that patterns evolve continuously through discussion in a community [44].

Pattern mapping is used to structure codes, elements or domains of patterns with regards to their relationships. This approach supports the design of patterns as it sheds light on interdependencies between different patterns. Additionally, it can be used to identify relevant issues or missing solutions for new patterns as it reflects the structure of the underlying problem domain. [32].

The literature review approach is a systematic research of existing knowledge about existing solutions, a theoretical base or adjacent patterns. A literature review can access a multitude of resources from wikis, scientific and practitioner-oriented outlets or pattern repositories [32]. Pattern repositories, as an important resource for pattern development, comprise different patterns for certain problem domains or applications [48]. However, due to the vast amount of potential sources, a pattern-oriented literature review may be a difficult task.

Pattern writing is the actual process of creating the pattern artifact, but it is also an approach for identifying relevant patterns as it reveals new facts by adding additional experiences or asking the authors to express more of their implicit knowledge [23].

5 Discussion

It can be observed that most of the identified approaches are applicable in the design cycle. Thus, it may be inferred that this is the core to the very practitioner-oriented and less scientific state-of-the-art of pattern development. However, we second the opinion that this phase is the most crucial part of a pattern development process. However, high number of approaches can be applied in the relevance cycle as well, which again highlights that pattern development is practically-driven process. Not many approaches were found applicable for the rigor or evaluation phase. Although a vast amount of pattern repositories exist that can potentially be used in the rigor cycle, the search for patterns relevant to a specific development problem is often a complex endeavor. This is mainly caused by a lack of structuration as well as nonexistent formatting standards for patterns and pattern repositories. Furthermore, validation of patterns as usually conducted in the design-evaluation phase of DSR has yet widely been neglected. This issue is also manifested in the vague definition of when a recurring solution can be considered a pattern: the pattern community calls for at least three good implementations, without specifying what 'good' means. Hence, based on our findings, we call for rigor in (1) screening existing relevant knowledge that may be useful for pattern design and (2) validate patterns and evaluate them in the problem context. We believe that both are necessary to give pattern development a stronger scientific impact besides its practical relevance.

6 Conclusion and Research Outlook

Our research embodies a first step towards a clearer understanding of pattern development approaches from a design science perspective. To the best of our knowledge, we are the first to structure existing approaches for pattern development by conducting a systematic literature review. With this contribution we aim to make the following contributions: From a scholarly perspective, we made steps towards an operationalization of DSR for pattern development, which leads to the creation of both prescriptive and descriptive design knowledge [51, 52]. From a practical viewpoint, pattern authors can use our findings to enhance their own pattern development. Our findings serve as a guide through necessary phases of pattern development and highlight applicable approaches for each phase. Furthermore, the description provided for each approach supports pattern authors in choosing the best fit for their context. This may lead to patterns with improved quality and more efficient and effective pattern development.

However, since our research is only a first step towards structuring the field it does not come without limitations. Although we are sure in having covered the most relevant approaches with our orientation towards the pattern community, literature search should be extended to more scientific and pattern-related outlets and databases in future research in order to reveal complementary approaches and enhance the presented findings. Furthermore, future research may build up on our results by creating (reference) processes for pattern development. Finally, evaluation of our approach in specific problem contexts is necessary to prove our results in field.

Abstract. Ideencommunities haben sich als effektives Tool zur Erhöhung der Innovationskraft von Unternehmen etabliert. Ein Aspekt, dem bislang wenig Aufmerksamkeit geschenkt wurde, ist die Ideenevaluation in Ideencommunities. Ein Problem im Rahmen der Evaluation ist die Vielzahl an Ideen, die in solchen Communities entsteht und Unternehmen zunehmend vor neue Herausforderungen stellt. So verfügen Unternehmen in der Regel nur über eine begrenzte Kapazität, um das vollständige Potenzial solcher Ideen nutzbar zu machen. Eine Lösung für dieses Problem bieten sogenannte Text Mining Verfahren, die in Verbindung mit neuen Informations- und Kommunikationstechnologien Unternehmen dabei unterstützen können, Ideen effizienter auszuwerten sowie neue Datenzusammenhänge und somit wertvolle Information zu erkennen. Vor diesem Hintergrund untersucht der Beitrag welche Phasen der Ideenevaluierung am effizientesten durch ein Text Mining Tool unterstützt werden können und leitet daraus konkrete Gestaltungsempfehlungen für ein Text Mining Tool für Ideencommunities ab. Der Beitrag umfasst dabei konkrete Gestaltungsempfehlungen, die Praktiker bei der Umsetzung eines solchen Tools unterstützen sollen. Der theoretische Beitrag liegt in der Erweiterung des Erkenntnisstandes hinsichtlich neuer Methoden zur Unterstützung der effizienten Auswertung von Ideen im Crowdsourcing

(2017): Text Mining in Ideencommunities: Gestaltungsempfehlungen eines Text Mining Artefakts zur Unterstützung der Ideenevaluation, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1405-1416

1 Einleitung

In jüngerer Vergangenheit hat Crowdsourcing immer mehr an Popularität gewonnen [1]. Eine spezielle Form des Crowdsourcing, die von Unternehmen zunehmend aktiv eingesetzt wird, sind sogenannte Ideencommunities. Es handelt sich dabei zumeist um Plattformen, die es Unternehmen ermöglichen bestimmte Probleme zu posten und in Zusammenarbeit mit der Crowd Lösungen in Form von Ideen zu generieren. Das Ziel von Ideencommunities ist es dabei, von den Erfahrungen und Ideen der Kunden zu profitieren und dadurch die Innovationskraft des Unternehmens zu erhöhen. Die Vorteile von Ideencommunities wurden in der Literatur umfangreich belegt [2]. Das Unternehmen Lego kann hierbei exemplarisch für den Aufbau einer solchen Ideencommunity hervorgehoben werden [3]. Durch das interaktive Kollaborieren und Zusammenwirken der Crowd wird der dem Ansatz zugrunde liegende Kerngedanke des Nutzbarmachens der sogenannten „Weisheit der Vielen" deutlich [4, 5].

Trotz der genannten Vorteile, die Ideencommunities mit sich bringen, ist deren effiziente Nutzung auch mit großen Herausforderungen verbunden. So entsteht durch die rege Teilnahme an Ideencommunities eine Vielzahl an Beiträgen. Das Resultat ist eine große Menge an unstrukturierten Daten. My Starbucks Idea umfasst beispielsweise über mehrere Kategorien hinweg ca. 150.000 Ideenvorschläge, Dell Idea Storm über 25.000 (Stand: September 2016). Die große Menge an textuellen Informationen macht es dabei in der Regel schwierig das volle Potenzial von Ideencommunities zu nutzen [6, 7]. Unternehmen, als Betreiber solcher Ideencommunities, sehen sich dabei mit der Herausforderung konfrontiert, dass sie nur über begrenzte Ressourcen und Kapazitäten verfügen, um diese Daten auszuwerten. Die beschriebene Problematik wird in der Literatur unter dem Begriff Absorptive Capacity thematisiert. Hierunter wird die Fähigkeit verstanden, Wissen aus externen Quellen zu identifizieren, assimilieren und anschließend anzuwenden [8]. Die Mengen an unstrukturierten Daten, die im Rahmen von Ideencommunities generiert werden, stellen eine besondere Herausforderung für die Absorptive Capacity von Unternehmen dar. Eine Möglichkeit, Unternehmen bei der Auswertung von Ideencommunities zu unterstützen, bieten moderne Informations- und Kommunikationstechnologien. Neben der effektiven Einbeziehung von Kunden bergen diese das Potenzial Organisationsroutinen und die Koordinationsaktivitäten von Unternehmen zu verbessern und Kosten zu senken [9, 10].

Ein vielversprechender Ansatz, um Unternehmen bei der IT-gestützten Auswertung von Ideen zu unterstützen, bilden sogenannte Text Mining Anwendungen [41]. Es handelt sich dabei um Tools, die eine Kombination aus computergestützten linguistischen, statistischen und mathematischen Verfahren anwenden, um Wissen aus großen Mengen an unstrukturierten Textdaten heraus zu filtern und neue Zusammenhänge zu erkennen [11]. Obwohl von einem hohen Potenzial von Text Mining Lösungen für Ideencommunities ausgegangen werden kann, blieb eine kombinierte Betrachtung dieser beiden Forschungsgebiete bislang unberücksichtigt [1, 12]. Demnach wurde lediglich partiell abgedeckt, wie sich eine Text Mining Lösung systematisch für Ideencommunities nutzen lässt. Vor diesem Hintergrund ist es Ziel dieses Papers potenzielle Einsatzgebiete und Unterstützungspotenziale eines Text

Mining Tools zur Ideenevaluierung in Ideencommunities zu identifizieren und Unternehmen Gestaltungsempfehlungen für ein Tool zur automatisierten und somit effizienteren Ideenevaluation an die Hand zu geben. Das generelle Vorgehen im Rahmen der Studie orientiert sich dabei am Design Science Research (DSR)-Ansatz nach Vaishnavi und Kuechler [13].

Der sich hieraus erschließende Beitrag bezieht sich auf zwei Bereiche. Zum einen geben wir Praktikern Empfehlungen zum Einsatz und zur Gestaltung eines Text Mining Tool an die Hand, die darauf abzielen den Prozess der Ideenevaluierung in Ideencommunities zu automatisieren und Unternehmen bei der Analyse von Ideen zu unterstützen. Der theoretische Beitrag dieser Arbeit liegt in einer Erweiterung des Erkenntnissstandes zur Ideenauswertung im Crowdsourcing. Das Ziel hierbei ist es die Phase der Ideenauswertung näher zu beleuchten. Speziell die einzelnen Prozessschritte, die mit der Phase der Ideenevaluation einhergehen, werden in der vorliegenden Arbeit betrachtet, da die genaue Untersuchung dieser Thematik in der Literatur bisweilen noch keinen Eingang fand. Darüber hinaus soll gezeigt werden, wie ein Text Mining Tool in den einzelnen Prozessschritten am besten unterstützen kann. Wir setzen hierbei an vorangehenden Arbeiten zum Crowdsourcing an, die zu der Erkenntnis kommen, dass die Phase der Ideenevaluation ein großes Potenzial für die Effizienzsteigerung und die breite Anwendung von Crowdsourcingaktivitäten birgt.

Das folgende Paper gliedert sich wie folgt. Nach der Einführung des theoretischen Hintergrunds wird die zugrunde gelegte Methode in Form des DSR-Ansatzes genauer erläutert. Im Anschluss an die Ermittlung des Einsatzpotenzials eines Text Mining Tools zur Unterstützung der Ideenevaluierung und der konkreten Ableitung von Gestaltungsempfehlungen, welche ein Text Mining Tool erfüllen muss, werden die weiteren geplanten Schritte für die Entwicklung dieses Tools dargelegt. Das Paper schließt mit einer Zusammenfassung und dem erwarteten Beitrag für Praxis und Wissenschaft.

2 Theoretischer Hintergrund

2.1 Absorptive Capacity Theorie

Das Grundkonzept der Absorptive Capacity wird in der Fachliteratur als Fähigkeit von Unternehmen definiert „to recognize the value of new, external information, assimilate it, and apply it to commercial ends“ [8]. Aus der Definition ist abzuleiten, dass sich die Absorptionsfähigkeit in sequentielle Teilfähigkeiten differenzieren lässt [14].

Zunächst beschreibt es die Fähigkeit eines Unternehmens neue, externe Informationen zu identifizieren und dabei den zu schöpfenden, potenziellen Wert zu erkennen. In einem weiteren Schritt müssen im Zuge der Assimilationsfähigkeit die Informationen an die Bedürfnisse adäquat angepasst bzw. an das bestehende Wissen des Unternehmens angeknüpft werden. Abschließend kann das Wissen angewendet bzw. kommerziell eingesetzt werden [8, 15]. Dieses klassische Konzept zur Absorptive Capacity nach Cohen und Levinthal [8] wurde in den darauffolgenden Jahren insbesondere durch die Beiträge von Zahra und George [16] sowie Todorova und Durisin [17] theoretisch diskutiert, konkretisiert und erweitert. Lane et al. [18] verstehen Absorptive Capacity als eines der zentralen Konstrukte, wie Unternehmen oder Organisationseinheiten Wissen einarbeiten, welches sich außerhalb ihrer Grenzen befindet. Im Zuge des Trends Richtung Open Innovation werden Kunden in die Gestaltung von Innovationsprozessen der Unternehmen aktiv integriert [19]. In diesem Zusammenhang werden Ideencommunities als Instrumente eingesetzt, um Ideen bzw. Wissen zu generieren. Die Herausforderung liegt explizit darin, die Unmengen an unstrukturierten Daten den Bedürfnissen eines Unternehmens anzupassen, um anschließend relevantes Wissen absorbieren und anwenden zu können. Zur effizienten Steuerung der Informationen im Unternehmen legen Roberts et al. [9] den Einsatz von Informationstechnologien dar, welche in Form von automatisierten Anwendungstools in den Absorbierungsprozess integriert werden. Das vorliegende Paper setzt sich mit der Verwendung eines Text Mining Tools auseinander, welches unter Berücksichtigung der Effizienzsteigerung im Absorbierungsprozess eingesetzt werden soll.

2.2 Grundlagen zum Crowdsourcing

Der Neologismus aus den beiden Wörtern „outsourcing" und „crowd" wird in Anlehnung an Leimeister [20] als ein Interaktionsprozess definiert. Eine Unternehmung, Organisation, Gruppe oder ein Individuum, auch Crowdsourcer genannt, bietet einer nicht genauer definierten großen Gruppe, den sogenannten Crowdsourcees, die Möglichkeit der Bearbeitung einer Aufgabe über einen offenen Aufruf. Ziel ist es, sich das aggregierte Wissen der Masse zu Nutze zu machen. Die Crowdsourcees, welche sich ebenfalls aus Individuen, formellen sowie informellen Gruppen, Organisationen oder Unternehmen zusammensetzen können, übernehmen anschließend die Aufgabenbearbeitung [20].

Eine besondere Ausprägungsform dieses genannten Ansatzes sind von Unternehmen initiierte und betriebene, IT-basierte Ideencommunities. Sie ermöglichen die Teilnahme von Individuen außerhalb des Unternehmens, insbesondere von Kunden, am unternehmerischen Innovationsprozess [7]. Kunden haben auf Ideencommunities die Möglichkeit, eigene Erfahrungen, Verbesserungsvorschläge sowie Innovationsideen bekanntzugeben, Vorschläge anderer zu bewerten, interaktiv mit Hilfe von Kommentar- und Wiki-Funktionen weiterzuentwickeln und auf diese Weise aktiv zur Produkt- und Serviceentwicklung beizutragen [7].

Die Anwender und Nutzer der Ideencommunities generieren im Rahmen dieses interaktiven Prozesses eine Menge an Ideen, die als textuelle Informationen gespeichert werden. Dieses wird bisher in einem ressourcenintensiven, manuellen Verfahren durch User sowie Experten evaluiert. Die auf eine Person begrenzte und wertvolle Arbeitskraft, die für diesen Auswertungsprozess benötigt wird, steht anschließend nicht mehr für die angemessene Analyse der vielen Beiträge und Ideen zur Verfügung. Darüber hinaus kann die Analyse der Ideen aufgrund der Masse an textueller Information nicht adäquat vorgenommen werden, denn häufig fokussieren die am Analyseprozess beteiligten Experten unbewusst auf einige wenige Ideen, ohne dabei die Gesamtheit der Ideen zu berücksichtigen. Aufgrund dieses zeitintensiven und subjektiven Auswertungsvorgehens gelingt es Unternehmen folglich nicht das gesamte Potenzial der Ideen zu nutzen. Eine Möglichkeit den zuvor genannten Problemen zu begegnen und dabei die Absorbierungsfähigkeit von Unternehmen zu unterstützen, bildet der Einsatz eines automatisierten Text Mining Tool.

2.3 Grundlagen zum Text Mining

Der Begriff Text Mining bezeichnet einen Ansatz, welcher sich aus verschiedenen Verfahren zusammensetzt. Durch die Anwendung unterschiedlicher Techniken werden neue Informationen aus unstrukturierten Texten generiert und diese automatisch extrahiert [21]. Text Mining wird dem Bereich des Data Mining zugeordnet, mit dem Unterschied, dass Informationen im Gegensatz zum Data Mining aus unstrukturierten Daten gewonnen werden [21, 22]. In der Literatur wird überwiegend ein Prozessverlauf thematisiert, welcher das Text Mining Verfahren in zwei Phasen aufteilt [23, 24].

Die erste Phase stellt hierbei die Datenvorbereitungsphase dar. Der unstrukturiert vorliegende Text muss in ein Format transferiert werden, aus dem ein Text Mining Algorithmus Informationen gewinnen kann. Dieser Vorbereitungsprozess bedient sich dabei computerlinguistischer Methoden in Form der morphologischen, syntaktischen und semantischen Analyse [23]. Im Bereich der morphologischen Analyse wird durch die sogenannte Tokenisierung (Entfernen von Satz- und Leerzeichen; Generierung von Tokens), das Filtern (Stoppwortentfernung) sowie das Stemming (Rückführung der Wörter zu Wortstämmen) der Text für den weiteren Verlauf vorbereitet [24, 25]. Ferner behandelt die syntaktische Analyse den Textinhalt und versucht durch Worterkennungen mit Hilfe syntaktischer Regeln einzelne Phasen in strukturierte Syntaxbäume zu bringen. Darüber hinaus werden hierdurch das Verhältnis sowie die gegenseitige Modifikation einzelner Phrasen erkannt [26]. Die semantische Analyse hingegen behandelt Mehrdeutigkeiten der einzelnen Wörter und deren Bezug zum Gesamtkontext [27]. Das Ziel dieser ersten Phase ist demnach die Komplexitätsreduktion, um einen bereinigten und nur aus potenziell interessanten Wörtern bestehenden Text zu erhalten, der in einem nächsten Schritt bearbeitet werden kann [28].

In der zweiten Phase ist es nun durch das Nutzen von Mining-Techniken möglich, wichtige Informationen aus dem überarbeiteten Text zu gewinnen. Daten können hierbei vordefinierten Klassen durch Verfahren wie Naïve Bayes, Logistic regression, Entscheidungsbäume, Neuronale Netzwerke, Support Vector Machines, MARSplines, k-nearest neighbors zugeordnet werden [29, 30, 31, 32, 33]. Clustering-Methoden wie das k-means Clustering [25] können sowohl einzeln, als auch in Kombination mit anderen Methoden angewandt werden, um Gruppen mit denselben Inhalten zu bilden.

Abschließend wurde herausgearbeitet, wie sich Text Mining Methoden auf den Kontext von Ideencommunities anwenden lassen, um aus einer unstrukturierten Menge an Daten wichtige Informationen zu extrahieren, diese in einem Prozess für die weiteren Bearbeitungsschritte zu selektieren, um schlussendlich einen Beitrag für eine effiziente Ideenevaluation leisten zu können.

3 Methode

3.1 Design Science Research

Das vorliegende Paper bezieht sich auf den DSR-Ansatz nach Vaishnavi und Kuechler [13]. Dieser Ansatz konzentriert sich auf die Konstruktion sowie Evaluation von sogenannten Artefakten, welche zur Lösung eines vorab definierten Problems beitragen [35, 36]. Artefakte können hierbei mehrere Ausprägungen annehmen, wie beispielsweise Konstrukte, Modelle, Methoden, Instanziierungen oder wie unserem Fall Design-Guidelines [37].

Das Ziel dieses Papers ist es, Einsatzgebiete und Unterstützungspotenziale eines Text Mining Tools im Rahmen der Ideenevaluierung zu identifizieren, sowie entsprechende Gestaltungsempfehlungen in Form von Design-Guidelines für Unternehmen abzuleiten. Die Design-Guidelines dienen als Basis für die Gestaltung eines Text Mining Tools zur Unterstützung der Ideenanalyse in Ideencommunities. Das Tool soll dabei konzipiert werden um eine große Menge an unstrukturiert vorliegenden Textdaten automatisiert aufzubereiten und auszuwerten. Es dient dabei, Experten in der Ideenevaluation zu unterstützen, indem es eine effektivere Nutzung des Potenzials vorhandener Daten erlaubt.

Vaishnavi und Kuechler [13] untergliedern den DSR-Ansatz in fünf Phasen: Awareness of Problem, Suggestion, Development, Evaluation und Conclusion. In unserem Fall wurden die ersten drei Phasen konkret bearbeitet.

In der ersten Phase, *Awareness of Problem*, wurde zunächst der Prozess der Ideenevaluierung in Ideencommunities mit Hilfe einer systematischen Inhaltsanalyse abgeleitet, um anschließend Probleme in den einzelnen Prozessphasen identifizieren zu können. Insgesamt wurden im Rahmen der Analyse die folgenden fünf Ideencommunities untersucht: My Starbucks Idea, SAPiens, Dell Ideastorm, LEGO Ideas und Tchibo Ideas. Bei den Betreibern der Plattformen handelt es sich um Unternehmen aus unterschiedlichen Branchen, die mit ihren Ideencommunities primär Endnutzer (B2C-Bereich) ansprechen. Darüber hinaus ähneln sich die betrachteten Communities stark im Hinblick auf ihren Aufbau und ihre Struktur. So erlauben es alle Communities Probleme zu posten und Ideen durch User generieren und bewerten zu lassen. Die Analyse folgte einem iterativen Vorgehen, indem 3 Autoren die oben genannten Plattformen unabhängig voneinander untersuchten und anschließend Probleme im Hinblick auf die Ideenevaluation identifizierten.

In der zweiten Phase, *Suggestion*, wurden im Zuge von Interviews mit drei Crowdsourcing Experten potenzielle Einsatzgebiete von Text Mining im Ideenevaluierungsprozess erarbeitet. Bei den Crowdsourcing Experten handelte es sich um Spezialisten mit umfassender Erfahrung hinsichtlich der Durchführung von Crowdsourcingprojekten sowie um Personen, die sich umfassend mit dem Thema aus praktischer und wissenschaftlicher Sicht beschäftigt haben. Als Grundlage für die Interviews dienten der zuvor abgeleitete Prozess und die identifizierten Probleme.

In der dritten Phase, *Development,* wurden auf Basis der zuvor identifizierten Probleme konkrete Gestaltungsempfehlungen in Form von Design-Guidelines abgeleitet. Zur konkreten Ausgestaltung des Text Mining Tools wurden Interviews mit drei Text Mining Experten geführt. Hierbei handelt es sich um Spezialisten auf dem Gebiet der Entwicklung und Implementierung von Text Mining Lösungen. Ein Interview wurde mit dem Geschäftsführer eines Unternehmens geführt, welches sich auf Text Mining Lösungen spezialisiert hat. Die beiden weiteren Interviewpartner verfügen über langjährige Erfahrung in der Implementierung von Text Mining Lösungen und mit der Betreuung von Text Mining Projekten.

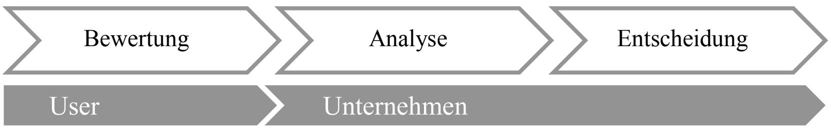
Die weiterführenden Prozessphasen, *Evaluation* und *Conclusion*, werden in Kapitel 5 betrachtet.

3.2 Vorläufige Ergebnisse (Anforderungen an ein Text Mining Tool)

In diesem Paper können wir bereits vorläufige Ergebnisse präsentieren, welche die Ziele und damit einhergehenden Anforderungen eines Text Mining Tools in Bezug auf Ideencommunities kennzeichnen.

In dem ersten Prozessschritt *Awareness of Problem* wurde zunächst, auf Grundlage einer systematischen Inhaltsanalyse von mehreren Ideencommunities, der Prozess zur Ideenevaluierung abgeleitet (siehe Abbildung 1) und damit einhergehend potenzielle Problemfelder beleuchtet.

Abbildung 1. Bisheriger Prozess der Ideenevaluation



Wie in Abbildung 1 ersichtlich gliedert sich der Prozess der Ideenevaluierung in drei Phasen. In Phase eins, *Bewertung*, erfolgt eine initiale Bewertung der Ideen durch die User. Dies geschieht über das Verfassen von Kommentaren oder durch die Anwendung von Bewertungsmechanismen wie Ratingskalen. In Phase zwei, *Analyse*, werden die Ideen durch das Unternehmen analysiert. Diese Phase ist dadurch gekennzeichnet, dass Unternehmen eine Vielzahl an Beiträgen und Kommentaren analysieren sowie bewerten müssen. In Phase drei, *Entscheidung,* entscheidet das Unternehmen, wie und mit wem die Ideen weiterentwickelt bzw. welche Ideen weiterverfolgt werden. Wie aus der obigen Abbildung ersichtlich werden Beiträge und die daraus resultierende Menge an unstrukturierten Textdaten im bisherigen Prozesses der Ideenevaluation durch User und durch Experten evaluiert. Dem Prozess liegt dabei eine stark subjektive Betrachtung- und Vorgehensweise zu Grunde.

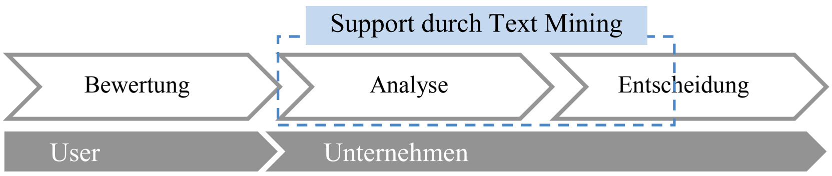
In einem weiteren Schritt wurden die Problemfelder im Prozess der Evaluierung von Ideen näher betrachtet. Während bei My Starbucks Idea, Dell Ideastorm und LEGO Ideas eine hohe Anzahl an generierten Beiträgen auffallend ist, weist SAPiens und Tchibo Ideas bisher noch keine bzw. eine beschränkte Themenkategorisierung der Beiträge auf.

Im anknüpfenden Prozessschritt, *Suggestion*, wurde der abgeleitete Prozess der Ideenevaluation und die identifizierten Probleme im Rahmen von Interviews mit

Crowdsourcing Experten diskutiert. Die identifizierten Probleme beziehen sich hauptsächlich auf die Analyse Phase des Ideenevaluierungsprozesses.

In den mit den Experten geführten Interviews wurden die zuvor identifizierten Probleme bestätigt und konkretisiert. Die Experten kamen dabei zu dem Schluss, dass vor allem die Vielzahl an Beiträgen und fehlende Themenkategorisierung die Unternehmen vor große Probleme stellt. Durch die subjektive Betrachtung einerseits und das arbeits- sowie zeitintensive manuelle Vorgehen andererseits werden Organisationen an Kapazitätsgrenzen geführt. Der Einsatz von automatisierten Auswertungsverfahren im Sinne von Text Mining Tools war den Experten bei Ideencommunities nicht bekannt. Ferner konnte in den Experteninterviews erarbeitet werden, welche Phasen im bisherigen Ideenevaluationsprozess das höchste Potenzial für die Unterstützung durch ein TextMining Tool bergen.

Abbildung 2. Unterstützende Funktion eines Text Mining Tool in der Ideenevaluation



Aus den Interviews mit den Experten lässt sich dabei ableiten, dass ein Text Mining Tool insbesondere in der Analysephase einen strukturierten bzw. gesamtheitlichen Überblick über die Ideen darlegt. Indirekt unterstützt das Tool die Entscheidungsphase, da Unternehmen zusätzliche Informationen erhalten, die Unternehmen bei der Wahl der geeigneten Ideen helfen.

Nach der Identifizierung potenzieller Einsatzgebiete und Unterstützungspotenzials eines Text Mining Tools im Rahmen des Prozesses der Ideenevaluierung wurde in der *Development*-Phase in Zusammenarbeit mit Text Mining-Experten die konkrete Ausgestaltung eines Text Mining Tools, in Form von Design-Guidelines, erarbeitet.

Tabelle 1. Darstellung konkreter Probleme und dazugehörige Design-Guidelines

Kategorien	**Probleme**	**Design-Guidelines**
Dokumenten-aufbereitung	Unaufbereitete textuelle Daten	Tool soll Textdokument bereinigen.*
Themen-kategorisierung	Vielfalt an aufbereiteten textuellen Daten	Tool soll Schlüsselwörter extrahieren (Keyword Extraction), deren Häufigkeiten ermitteln und anschließend gewichten.

	Überflüssige/identische Informationen	Tool soll identische Ideen eliminieren.
	Unterschiedliche Formulierungen einer identischen Idee	Tool soll identische Themen-bereiche erkennen und entsprechende Oberkategorien bilden.
Priorisierung	Vielfalt an gegensätzlichen User-Bewertungen	Tool soll Bewertungstendenzen innerhalb der Themenbereiche erkennen (Sentiment-Analyse).
	Relevante Informationen erkennen	Tool soll Themenbereiche sowie Ideen innerhalb dieser Bereiche priorisieren/ gewichten.

*Morphologische, syntaktische und semantische Analyse: a) Entfernen von Zahlen, Satz- und Leerzeichen, b) Behandeln von Groß- und Kleinschreibung, Rechtschreibung, c) Entfernen von Stoppwörtern, d) Stemming, e) Erkennen von Satzgrenzen, f) Durchführung des Part-of-Speech-Tagging, g) Bildung von Wortgruppen, h) Durchführung des Parsing und Junking, i) Erkennen von Synonymen, Mehrdeutigkeit der Sprache (Dialekt).

Hierzu wurden in einem ersten Schritt Probleme textueller Daten identifiziert. Die Anforderung der Aufbereitung dieser Daten liegt darin, das Textdokument mit Hilfe einer morphologischen, syntaktischen und semantischen Analyse zu bereinigen. Die Probleme zwei bis vier können der Themenkategorisierung zugeordnet werden. Zunächst liegt der Fokus auf der Vielfalt an textuellen Daten. Hierbei soll das Tool Schlüsselwörter extrahieren, indem durch eine Häufigkeitszählung bestimmte Wörter identifiziert, geclustert und entsprechend gewichtet werden. Des Weiteren sind die unterschiedlichen Formulierungen einer identischen Idee sowie überflüssige als auch identische Informationen in einem Evaluationsprozess als problematisch einzuordnen. Das Tool soll zum einen identische Ideen eliminieren können. Zum anderen soll es identische Themenbereiche erkennen und Oberkategorien bilden. Die Probleme fünf und sechs, der Kategorie Priorisierung zuzuordnen, zielen auf die Vielfalt an widersprüchlichen User-Bewertungen sowie auf das Erkennen von relevanten Informationen ab. Demnach soll das Tool Bewertungstendenzen innerhalb der Themenbereiche erkennen (Sentiment-Analyse) und anschließend die Themenbereiche sowie Ideen innerhalb dieser Bereiche priorisieren bzw. gewichten können.

Anhand der angesetzten Strukturierung der Probleme konnte ein Prozess mit Anforderungen aufgestellt werden. Diesen gilt es zu erfüllen, um das gesetzte Ziel einer automatisierten und effizienten Ideenevaluation zu erreichen.

4 Geplante weitere Schritte für die Entwicklung eines Text Mining Tools

In dem vorherigen Abschnitt haben wir die vorläufigen Ergebnisse in Bezug auf die notwendigen Gestaltungsanforderungen eines Text Mining Artefakts konkret herausgearbeitet. Die geplanten weiteren Schritte für die Entwicklung dieses Text Mining Tools in Anlehnung an den DSR-Ansatz sehen wie folgt aus: In der vierten Phase, *Evaluation*, werden die Gestaltungsanforderungen durch zusätzliche Interviews mit Plattformbetreibern bezüglich der potenziellen Anwendung bzw. Nutzbarkeit analysiert. Ferner wird das Tool entwickelt und in einem abschließenden Schritt erneut evaluiert. Das gewählte Vorgehen zielt darauf ab, den Prozess der Ideenevaluation effizienter zu gestalten und folglich die Nutzung bzw. Verwertung der Ideen aus Ideencommunities zu unterstützen. Aus diesem Grund wird das Tool auf Effizienz im Sinne von Geschwindigkeit untersucht. Mit Hilfe einer einfachen Zeitmessung könnte man die benötigte Dauer des Ideenevaluationsprozesses durch Anwendung des Tools ermitteln und anschließend dem zweistufigen manuellen Prozess durch User und Experten gegenüberstellen.

5 Zusammenfassung

In dem vorliegenden Paper haben wir uns mit der Gestaltung eines Artefakts auf Grundlage des DSR-Ansatzes nach Vaishnavi und Küchler [13] auseinander gesetzt. Das Ziel hierbei war es die Phasen der Ideenevaluierung näher zu beleuchten, Unterstützungspotenziale durch ein Text Mining Tool in den einzelnen Phasen zu identifizieren und auf Basis dessen die konkreten Anforderungen an ein solches Tool abzuleiten. Der sich anschließend hieraus ergebene Beitrag bezieht sich auf die zwei Bereiche Praxis und Wissenschaft.

Zum einen liegt der praktische Mehrwert unseres Beitrags darin Unternehmen Handlungsempfehlungen zum effizienten Einsatz und zur Implementierung eines Text Mining Tools zur Unterstützung der Ideenanalyse in Ideencommunities zu geben. Die Vorteile einer solchen Lösung liegen auf der Hand. So erlaubt die Implementierung einer Text Mining Lösung dem Plattformbetreiber die Ausschöpfung von Automatisierungspotenzial, das zu internen Ressourceneinsparungen in Form von Kosten und Arbeitskapazität führt. Zusätzlich bietet eine Text Mining Lösung den Unternehmen die Erkennung von neuen, bisher nicht entdeckten sowie relevanten Zusammenhängen und dient diesen folglich als Informations- und Entscheidungsunterstützung. Folglich kann das vorhandene Potenzial der vorliegenden Daten besser ausgeschöpft werden.

Der theoretische Mehrwert unseres Beitrags liegt in der Erweiterung des Erkenntnissstandes der bestehenden Crowdsourcing Literatur. Dieser wird einerseits erreicht durch die gezielte sowie der tiefergehende Betrachtung und Analyse der Ideenevaluierung im Crowdsourcing. Bisherige Studien zu dem Thema beschäftigten sich primär damit wie sich die Crowd in die Evaluation von Ideen einbinden lässt [38] und welche Individuen sich am besten für die Bewertung von Ideen eignen [39]. Zum anderen wird die bestehende Literatur durch die in dieser Studie vorgestellten Gestaltungsempfehlungen für ein Text Mining Tool um eine neue Forschungsperspektive erweitert. Unser Beitrag liefert dabei eine Design Theorie [40] zur Gestaltung eines Textmining Artefakts zur effizienten Unterstützung der Ideenevaluation im Crowdsourcing.

{pascal.stegmann,marin.zec,matthes}@tum.de

Abstract. Many newly founded companies fail due to a lack of experience of the founders, a missing connection to mentors, investors or other valuable contacts, or building a product without a real market need. Formalized frameworks like Lean Startup suggest that there is a structured way of evaluating ideas and building companies that increase the chances of success. In this paper we investigate and identify potential for software support in managing new venture creation. We conducted 10 semi-structured interviews with employees at business incubators and startup founders. Based on our observations we derived high-level guidelines that need to be taken into account for a software to provide added value for management activities of venture creation processes.

Keywords: Entrepreneurship, Venture Creation Process, Knowledge Management, Social Software

1 Introduction

Evaluating an idea for a business model and ultimately building a company is a complex and high risk undertaking. After earlier research on the different stages of venture creation [1] which suggested a predictable, chronological venture creation process, more recent research acknowledges the complex, dynamic and often unpredictable nature of the venture creation process [2], [3]. Focusing on the early phase, i.e. the process between initial conception of an idea until a product or service is sold to customers, Bhave [4] developed a process model with distinct sequential steps while at the same time emphasizing the iterative and non-linear character of the process. Abstract models like this help to isolate and understand different factors increasing the chances for success like having experience [5], operating in a favorable environment [6] or having a strong social network and personal relationships [7-12] but are not necessarily helpful for founders as they do not provide a prescriptive model.

By combining multiple current management trends such as Agile Development, Lean Thinking and Customer Development, various methods emerged in the last years aiming to provide guidance and a conceptual framework to manage the complexity of the venture creation process.

For instance, the Lean Startup method [13] promotes an iterative process involving short feedback loops between founder(s) and potential customers. The underlying

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Stegmann, P.; Zec, M.; Matthes, F. (2017): Assessing the Potential Value of Software-Support for the Venture Creation Process, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1417-1428

assumption of the Lean Startup method and similar approaches is that there is some sort of a prescriptive blueprint process model or best-practice patterns such as certain practices or artifacts for creating a new business. Given this formalization of the venture creation process, the topic of software support becomes more and more relevant to support founders in implementing these frameworks, increase transparency in the process and support communication amongst involved parties.

The objective of this paper therefore is to investigate and identify potential for software support in managing new venture creation, thereby providing a basis for future research on software support of the venture creation process.

To prevent potential premature generalizations due to conceptual bias towards a particular potentially narrow conceptual framework and existing preconceptions about venture creation processes, we chose an inductive, qualitative research approach.

2 Research Approach

We conducted 10 semi-structured interviews with startup founders and employees at different business incubators. The interviews centered around the following four themes:

1. Which general characteristics describe the venture creation process?
2. How is knowledge transferred and a lack of experience compensated in this context?
3. How are tools and artifacts used over the course of the venture creation process?
4. What characterizes the social exchange during the venture creation process (e.g. networking and access to experts)?

2.1 Research Design & Method

We followed an exploratory approach based on 10 semi-structured interviews. This way, we were able to cover common questions and themes as well as remain open to issues brought forward by our interview partners. The interviews were conducted in two rounds with two types of interview partners (see section 2.2 for more details).

As suggested by Mayring [14], the interviews were transcribed as detailed as necessary to capture important information and enable further processing. The transcriptions were coded using the four themes mentioned above as codes (i.e. *general characteristics*, *knowledge exchange*, *tools/artifacts* and *social exchange*). To end up with the final observations we followed an approach presented by Miles and Huberman [15], by marking certain patterns in the extracted text segments and subsume particular aspects into more general observations.

In a final step, we abstracted from the descriptive observations to derive prescriptive guidelines for venture creation management software which address one or more of the observations. This was done by collecting underlying problems for each observation. By grouping these problems, we could again subsume particular aspects of these problems into general problems that a software support needs to address. These general aspects consequently represent the design guidelines.

2.2 Sample Selection & Description

The interviews were conducted in two rounds using different interview guidelines to account for the different characteristics of the types of interview partners (see table 1). The first round involved employees at business incubators since we assumed that business incubators tend to follow a (semi-)structured approach to company building and supporting the venture creation process of startups. Further, we assumed that employees at business incubators would be likely to observe and recognize potential patterns of startup founder experiences since they interact with multiple startups.

Table 1. Description of Interview Partners

	No	*Code*	*Role*	*Description*
Round 1	1	PM1	Project Manager	Publicly funded incubator program, thematic focus, 1-5 years old
	2	IL	Innovation Lead	Corporate incubator/research lab, industry focus, 1-5 years old
	3	PM2	Program Manager	Publicly funded incubator program, industry focus, <1 year old
	4	COO 1	Chief Operating Officer	University affiliated accelerator program, technology focus, <1 year old
	5	CM	Community Manager	University affiliated incubator program, focus on scalable business models, >5 years old
	6	COO 2	Chief Operating Officer	Independent company builder, focus on scalable business models, >5 years old
	7	CEO	Chief Executive Officer	Independent accelerator program, focus on scalable business models, <1 year old
Round 2	8	TF	Technical Founder	Platform in e-commerce space, before scaling phase, received first financing round
	9	BF1	Business Founder	Media startup, validation phase with internal beta test, no funding
	10	BF2	Business Founder	Media startup, validation phase with public beta test, no funding

To pick the interview partners of business incubators, a list of business incubators in Germany containing 58 entries was created. Subsequently, the initial list was reduced to a shortlist of 22 business incubators that covers a broad spectrum of possible approaches to business incubation. Business incubators on the shortlist were contacted, from which seven ultimately agreed on participating in the research project. The business incubation programs differed in terms of age of the program, industry focus, objective of the organization, phases of admitted startups as well as duration and degree of involvement of the business incubator.

In a second round we interviewed startup founders to get reports on first-hand experience with entrepreneurship. We focused on first time founders to get insights into the problems of unexperienced founders as they would benefit most from software support. In terms of business models, we made sure that there is a significant amount of technology involved and frameworks such as Lean Startup are potentially applicable.

3 Observations

We found several challenges and characteristics that define the environment of a potential system support. In this section, we present our observations structured according to the four themes of interview questions, presented in our research approach (*general characteristics*, *knowledge exchange*, *tools/artifacts* and *social exchange*)[1].

3.1 General Characteristics

An important observation influencing the venture creation process is the resource restrictions startups face. Their critical resource is most often available time. Thus, many activities fall short because of lower priority and due to low perceived value for the startup. Founders have to take a pragmatic approach and as mentioned in the interviews, unnecessary tasks or too much formalization and fixed processes may produce too much overhead that is not valuable and are therefore rejected.

O1 - ***Founders face resource restrictions and have only limited time available.*** (2 of 10; COO2, PM2)

It was often mentioned that each startup is unique and as one interview partner put it *"there is no blueprint"* (COO2) of how to build a company. Given the fact that by definition a startup is doing something new and innovative and further considering the different influencing factors, the result is often an unstructured, chaotic and fast changing environment with low predictability of outcomes. There is seldom a protocol or process to follow, but rather a pragmatic approach has to be taken to handle the high degree of uncertainty a startup faces. This manifests itself in a required high degree of flexibility, how a process evolves, which tasks to perform, which information to capture, etc.

O2 - ***Each startup is unique and requires a high degree of flexibility with regards to the performed tasks and processed information.*** (6 of 10; CM, COO1, COO2, IL, PM2, TF)

As mentioned by employees at business incubators, providing support for the founders is necessary and helpful, but the initiative ultimately has to come from the founders, i.e. an advisor cannot push a team to be successful if they do not have the drive to achieve success themselves. Most often the support is therefore on a request basis, as one

[1] The number in parentheses represents the number of interviews this observation is based upon, i.e. 7 of 10 means that this was mentioned by 7 interview partners out of the total 10 interviewed persons. The codes in parentheses refers to the interview codes as introduced in the methodology section in table 1 and indicate the source of information.

incubator mentioned "*we see ourselves as a service provider for the startups and only give recommendations, the decision has to come from the startup itself*" (COO1). This also seems to be an important trait to be successful in the long-term and the alternative can be counterproductive if a team is just executing what someone else tells them. Founders themselves mentioned they want to remain in control and drive the development and not be forced by a process or third party to do something or use some tools they do not want. This has to be balanced as they still have to be receptive to feedback and ultimately make the right assessment.

O3 - *Founders want and need to take the initiative and have the deciding power.* (7 of 10; CM, COO1, COO2, IL, PM1, PM2, TF)

3.2 Knowledge-Related Observations

Given the complexity of the venture creation process and the required tasks at hand it is hardly possible to acquire all the required knowledge in advance. Especially unexperienced founders lack process knowledge, i.e. what to do and how to do or approach things. As mentioned, they try to use their own judgment what to do or try to educate themselves, but often due to a lack of time (see O1) it is not possible to perform an elaborate research on the best practice for a specific task. They rather resort to trial and error and incorporate gained experience and knowledge over time. Even experienced founders face situations where they may not be knowledgeable due to the uncertainty of the process.

O4 – *Founders often lack relevant knowledge about the venture creation process and best practices.* (4 of 10; BF1, CEO, COO1, IL)

The most valuable knowledge is often tacit and, thus, hard to explain or codify. Such kind of knowledge is built from experience and for example comprised of the ability to assess a situation with limited information and still provide a promising recommendation. It is often not possible to break this decision making process down into simple and generally applicable rules, due to the complexity of influencing factors that have to be taken into account. This is a value add of advisors and mentors and why the personal interaction and support by experienced people is considered to be important in this context. One founder emphasized that they did not lack any support in the beginning besides advisors: "*we could have needed that (advisors) from the beginning ... someone who raps our knuckles ... we underestimated this*" (TF). Experienced-based knowledge might be a differentiating factor as it is difficult to replicate.

O5 - *Valuable knowledge is often tacit and based on experience.* (4 of 10; BF1, COO1, COO2, TF)

Besides tacit knowledge, certain information on specific topics is documented and accessible via the internet. The challenge is often to make an effort to find it. As mentioned, the scattered information makes it burdensome to find a specific information and assess the validity and applicability in a given situation.

O6 - *Certain information and knowledge is spread across different sources and difficult to find.* (3 of 10; CEO, CM, TF)

Many challenges are unique to each startup and depend on the specific context (e.g. product, business model or degree of innovation). However, it was mentioned that overall there are also problems that are recurring across startups. A startup may only face this problem once or a few times and therefore sees no need to document such knowledge. Although it could be helpful for other startups there is no real incentive to share this. An example could be how to set up a legal structure, which is only done once in the beginning. Such knowledge is often provided by people interacting with multiple companies like mentors or incubators that can transfer such knowledge between companies. As an example, incubators use strategy days or simple lists describing what to consider when founding a company to distribute this knowledge.

O7 - *Certain problems are recurring between startups but not necessarily within a single startup.* (4 of 10; CM, COO2, PM1, PM2)

Different types of knowledge exist and are subject to different frequencies of change. Legal topics were given as an example for quite static knowledge. As a contrast, topics like online marketing or new emerging technologies were mentioned as topics that are subject to frequent changes, which makes it difficult for documented knowledge to remain relevant. The difficulty therefore becomes to balance the efforts of collecting and formalizing such knowledge with the created value of doing so.

O8 - *For certain domains, new knowledge is created often or existing knowledge is subject to frequent changes.* (3 of 10; CM, COO1, COO2)

3.3 Tools- and Artifacts-Related Observations

Founders tend to feel overwhelmed by the amount of offered software tools for the various tasks they need to perform like prototyping, business modelling, analytics, etc. They have difficulties identifying relevant and useful ones. One founder mentioned: "*I think there are too many tools, we are testing tools all the time*" (BF2). Some software tools are trending or considered standard in certain areas. However, it remains up to the founder to assess the suitability for a given situation.

O9 – Multiplicity of software tools for the various tasks of a founder are available, which requires a continuous assessment of suitability. (5 of 10; BF2, CM, COO1, PM2, TF)

Various artifacts are created and used over the course of the venture creation process. As an example, for business modeling purposes a pitch deck, Business Model Canvas or some form of business plan is created but mostly by using generic data processing software that does not provide much structure. Therefore, the structuring needs to be provided by the user, e.g., by using other example documents as templates.

O10 - ***Multiple types of artifacts are created over the course of the venture creation process. However, little structural support is provided as mostly generic software is used.*** (5 of 10; BF1, BF2, CEO, COO1, TF)

Some artifacts such as the Business Model Canvas or a business plan are perceived as a standard amongst startups. For some business incubators they are mandatory to assess the business model: "*In the beginning we have an assessment center, where we use a Business Model Canvas*" (COO1). However, sometimes there seems to be a lack of experience of how to create and work with these artifacts. One founder mentioned, he used the Business Model Canvas but "*besides filling things in boxes … it did not provide much value*" (BF1). The idea of most artifacts is to convey a certain thinking about a problem by providing a structure. However, if people do not know how to effectively use this structure or are not provided with any form of guidance the artifacts lose their purpose.

O11 - ***Founders do not necessarily know how to effectively use certain artifacts.*** (3 of 10; BF1, IL, TF)

Pen-and-paper tools seem to play an important role for specific artifacts and project management purposes. Value is still perceived in using these forms instead of working digitally only. Especially in agile methods and when applying the Lean Startup approach, the use of posters of boards and special artifacts is prevalent as supported by the empirical data. It is more suitable for group work and in-person discussions, due to better visibility. However, there remains a gap when trying to integrate the physical pen and paper artifact into a digital workflow. As mentioned by one founder, the pen and paper versions get outdated ("*the one (Business Model Canvas) as it is hanging on the wall is not up-to-date anymore*", BF2) and lose its usefulness if the form is switched from physical to digital.

O12 - ***Founders see value in pen-and-paper tools, but it is difficult to keep physical and digital versions in sync.*** (3 of 10; BF2, CEO, TF)

3.4 Social Exchange-Related Observations

Due to the knowledge often being tacit and advice being contextual, various types of interaction for knowledge transfer are required, such as personal meetings and discussions. As was mentioned in the interviews, the exchange benefits from a more informal setting and that is often why incubators organize events or try to have startups be co-located to foster exchange, as it increases the willingness to share information. As one incubator mentioned: "*The teams being co-located proved to be a major* *strength, as they are communicating a lot amongst each other … we were almost surprised how well it works*" (PM2).

O13 - *Exchange of knowledge and experience is often informal, i.e. through relatively unstructured personal interaction between peers and advisors/mentors.* (8 of 10; BF1, CM, COO1, COO2, IL, PM1, PM2, TF)

Most valuable knowledge is often tacit and held by experts, such as experienced founders or investors. Due to their expertise, these experts are usually sought out by many people seeking for help and are therefore difficult to get in touch with. Even before an initial contact, it may be difficult to identify the right expert who might be a good fit, as there is not always transparency about the area of expertise and actual knowledge that the person could provide. As mentioned by business incubators, this matchmaking process is one of the most important value adds, i.e. identifying the right fit and giving introductions to overcome this barriers founders usually face. They usually provide this through alumni networks or other forms of partner networks.

O14 - *Founders often lack access to experienced people like mentors/experts/etc.* (7 of 10; CM, COO1, COO2, IL, PM1, PM2, TF)

In interaction with advisors, mentors and other people that need deep insights into the company to give useful advice, sensitive information is shared. Especially in the beginning when there is often not more than an idea, founders fear revealing proprietary information and get their intellectual property stolen. As one interview partner mentioned: "*startups need to have trust in their mentors … startups have to decide themselves who they can trust and who they want to share it (information) with*" (CM). Founders may be hesitant to document and share certain information and knowledge, as they want to have control over who has access to it. In a similar way, advisors might share confidential material too, to provide examples of documents or information that might be helpful for founders but need to be kept confidential.

O15 - *Sensitive information needs to be handled and bears the fear of founders of revealing proprietary information.* (3 of 10; CM, COO1, TF)

4 Design Guidelines

To address the mentioned observations, design guidelines for the IT support of the venture creation process were developed and are presented in this section. The reference code in parentheses indicates the observations the guideline is based upon.

DG1 - *Integrate system usage into existing workflows:* Due to the high resources restrictions startups face, additional work needs to be minimized in order to increase the acceptance and adoption of a tool. The effort to use a system can be minimized by integrating system usage into existing workflows and not add additional process steps. (O1)

DG2 - ***Enable contextual accessibility of knowledge:*** On a similar note, to minimize the barrier and required effort of switching between learning and doing something, relevant knowledge should be provided in a specific context, i.e. where and when it is needed or should be applied. The alternative would be to provide all available knowledge in a central location thereby having increased switching costs to access the knowledge. (O1)

DG3 - ***Provide functionality to set goals:*** Given the complexity of the venture creation process, focusing too much on individual steps can be counterproductive. Instead, by supporting the setting of goals and milestones collaboratively with stakeholders, accountability can be created without compromising on the flexibility of the actual implementation compared to a fixed defined process. (O2, O3)

DG4 - ***Enable structuring flexibility:*** To further account for the complexity of the process and not be too restrictive, flexibility and adaptability of the system needs to be ensured, with regards to captured data, information and structuring capabilities of the process to address the individuality of the startup. (O2, O3, O10)

DG5 - ***Provide support on a suggestion basis:*** Any form of decision support needs to remain on a suggestion basis. Control and final implementation needs to remain with founders to increase the acceptance of a support by not restricting the founder's freedom of action. As an example, possible next steps in a certain situation could be suggested based on collected data but which actions to implement ultimately has to be decided by a human. (O2, O3)

DG6 – ***Support bridging medium gap between analog and digital tools:*** Given the perceived value of analog tools and artifacts, bridging the medium gap between analog and digital tools should be enabled to combine the benefits of both forms, i.e. ease of creation and interaction of analog forms with ability to share and collaborate across locations of digital forms. As an example, results of a brainstorming on a flipchart could be captured with a camera and further processed in a digital workflow. (O12)

DG7 – ***Enable knowledge emergence through usage:*** Given the resource restrictions, taking time to formalize created knowledge is not necessarily the highest priority. Therefore, the emergence of knowledge and best practices through the use of the system should be enabled to minimize the effort of knowledge explication. This could be achieved through providing structuring flexibility (see DG4) and afterwards analyze the usage for patterns to use as suggestions for the future. (O1, O5, O8)

DG8 – ***Incentivize knowledge explication:*** In addition to automate some form of knowledge creation, explication and sharing of knowledge needs to be incentivized to keep the knowledge base up-to-date with valid knowledge and thereby relevant for the founder. (O1, O5, O8)

DG9 – *Provide shared knowledge base with common information:* A shared knowledge base with relevant information for the venture creation process (e.g., best practices for common processes, suggested tools for use cases, etc.) to compensate for the difference in knowledge and establish a common understanding needs to be provided. As mentioned, this could be a central repository or wiki to collect all knowledge, though providing context for the knowledge is important (see DG2). (O4, O6, O7, O9, O11)

DG10 – *Ensure adaptability of knowledge:* As some knowledge might be changing it needs to be adapted to stay relevant and provide value to the users. Mechanisms need to be provided to easily adapt the knowledge base to account for the changing nature of information and knowledge while still ensuring the validity of the knowledge, possible through some form of version control and consensus mechanism. (O8)

DG11 – *Provide functionality to share information amongst stakeholders:* To foster collaboration amongst stakeholders easy sharing of information with other stakeholders should be enabled to lower the barrier of knowledge transfer and simplify creating a context for discussion. This could be achieved through providing access rights to certain information collected in a system or using of existing communication channels to distribute information. (O1, O13)

DG12 – *Foster social exchange and relationship building:* Given the mentioned barrier to formalize and capture certain knowledge, an additional way of knowledge exchange is through social interaction. Therefore, social exchange and engagement between users needs to be incentivized to support relationship building and improve the knowledge transfer of tacit knowledge. This could be achieved by encouraging the initial interaction amongst users and further through lowering the technical barriers of engagement, i.e. make it as easy as possible to connect and interact with each other. (O5, O13)

DG13 – *Simplify identification of experts with relevant knowledge:* As mentioned, there is often a lack of access and possibly a lack of transparency about the capabilities of a certain person. Therefore, the identification and access to people with relevant knowledge and expertise should be simplified to enhance the matching process and reduce the necessity for human intervention. (O14)

DG14 - *Create a digital space providing trust and confidentiality:* As confidential information is often handled in this context, formalizing and submitting such information to a third party system could pose a high barrier to system usage. To overcome this issue a space of trust and confidentiality needs to be created by giving transparent access control to the data owner to support the willingness of users to share information. (O15)

5 Conclusion

At a rather abstract level, common features between different venture creation processes could be identified such as the use of a business plan or Business Model Canvas. However, there are considerable differences in the way of usage and perceived value of applying certain methods or using certain types of artifacts. From the perspective of our interview partners, venture creation processes are perceived to be idiosyncratic. Furthermore, their application and usage does not necessarily seem central to success.

Our study suggests that the venture creation process is dominated by three characteristics: (1) the unpredictability in the way it evolves over time, (2) a (perceived) lack of knowledge and experience among most founders and (3) its social nature to get access to valuable resources and enable transfer of experienced-based knowledge between different stakeholders. According to our interview partners, knowledge and social exchange may compensate for a lack of formalization and are perceived to be increasing the likelihood of success.

In the present study, we derived guidelines based on our observations to inform the design of software systems for venture creation management. While the focus of this study was to gain insights into entrepreneurial practice, we acknowledge the yet hypothetical nature of the guidelines. Given the limited sample, a thorough validation and possible adjustment of the derived design guidelines is subject to future research.

Looking at different paradigms as a basis for such software support, Business Process Management (BPM) comes to mind as a way to support the management of the venture creation process. However, given our empirical findings, the high uncertainty and contextual dependency of the process, the focus on predefined process steps does not seem like a viable solution.

The uncertainty of the process and the context dependency on the knowledge and decision of the user calls for a more social and flexible approach such as Adaptive Case Management (ACM) seems more appropriate. It aligns with the goals driven approach presented in the guidelines and the focus on artifacts that are used in the process. It further emphasizes collaboration and social interaction rather than a step-by-step process. Still further research should provide a thorough discussion and investigation of the suitability of this paradigm.

Given the multitude of involved stakeholders, we think it is important to focus on those who would benefit and/or contribute the most to reduce the complexity. However, there seems to be an asymmetry of incentives between those benefitting and those contributing to such a system. We see two main directions to extend the research: 1) identification of stakeholders who would benefit most from software support and 2) research on incentive mechanisms which would drive engagement towards and adoption of a venture creation management system.

TOOLS FOR OPEN SERVICE DESIGN
An Analysis into Existing and Future Methodologies

Andrew Cooney[1], Timo Zink[1], Dr. Julia Jonas[1]

[1] Friedrich Alexander Univeristy, Information Systems 1, Erlangen Nuremberg, Germany
{andrew.cooney, timo.zink, julia.jonas}@fau.de

Abstract. The growing importance of the service industry in today's information technology-oriented domain is indubitable. In contrast to the manufacturing industry, which has had time to develop, mature and standardise processes, there exists in the service industry a dearth of standardised design methodologies. In analysing an extent of relevant new literature, this illustrative case study examines three service design tools chosen on the basis of their applicability to open innovation. One tool is thus selected and applied to a currently existing, but hitherto under used, technology. The purpose of this illustrative case study is to expand the service design repertoire of service innovation managers in the field of open innovation.

Keywords: Open Service Design, Prototyping, Open Innovation, Service Innovation, Co-creation

1 Introduction

The importance of the service industry in the global context is a relatively new phenomenon; with a broad definition of services and its components still contested among academic communities. Services comprise more than 70% of aggregate gross domestic product and employment in the Organization for Economic Cooperation and Development countries [24]. Moreover, increased globalisation, in concurrence with the increased access to the internet [5], has accelerated competition and challenged companies to be more agile in light of increasingly complex consumer demands [26].

Open innovation is a concept that is gaining more traction within service design thinking and can help companies achieve the growth in service revenues they seek [10]. A firm achieves this by developing outward-looking strategic approaches to research and development in the attempt to leverage potential value from a broader environment [24]. However, the methodologies in regards to utilising this concept and resulting complexities are, until now, not yet widely investigated within the realm of service design. With the increasing popularity of open innovation, service innovation managers may have to learn how to effectively interact with the consumers for whom they create services.

This paper addresses the challenges and opportunities that service innovation managers may face when approaching open service design. This is achieved through an evaluation of the opportunities and limitations of a set of existing service design tools and recommending the best fitting tool with which service innovation managers can most effectively respond to this challenging environment. Thereafter this recommended design tool is applied to an emerging technology to demonstrate how the challenges and opportunities relating to service design could be minimised and leveraged respectively.

Cooney, A.; Zink, T.; Jonas, J. (2017): TOOLS FOR OPEN SERVICE DESIGN An Analysis into Existing and Future Methodologies, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1429-1440

2 Research Methodology

The work that ensues has made use of an illustrative case study [35] to establish a conceptual discussion of prototyping within open service design. Initially, theory regarding select service design tools is examined in the context of open innovation. Following this the reader is exposed to possible use case studies in which prototyping has been applied. Lastly, future uses of prototyping is posited in the use of currently-available, however not widely used, technology.

3 Theoretical Background of Open Service Design

Until recently limited attention has been paid to developing systems that can address this changing situation, and specifically to the issue of new service development [26]. New internet technologies have not only increased the reach of information but also exposed hitherto non-internet users to a much wider "virtual" market [5]. Consequently consumer demand has evolved to reflect this increasing complexity. As Peter Drucker, in his interview with Chesbrough [10], states "What the customer buys and considers value is never a product. It is always utility – that is, what a product does for him." This trend towards consumer-centricity has pushed companies to engage in new forms of research development; looking at how to integrate external stakeholder knowledge into product and service development [24].

One such approach is open innovation. This recognises and builds on the changes in the dynamics of the consumer's interaction with the company from simply a consumer of pre-determined services to that of value co-creation with the company. By engaging outside knowledge through open innovation, companies can achieve the growth in market share and in revenue that they seek [10]. However, it is often the case that activities performed by managers are inconsistent with the demands of the consumer they try to meet [39]. Consequently, a plethora of tools and methodologies have been developed under the broad umbrella of service design to better equip stakeholders, such as the company and consumer, in better visualising and articulating their specific needs and demands.

3.1 Tools available for Open Service Design

Service design is a useful framework for maintaining the perspective of the outside world of consumers as the leading element in selecting and elaborating ideas for potential innovation [13]. Service innovation managers have available a wide range of tools designed to engage various stakeholders in new service design. In the context of an open innovation approach to service design, companies attempt to engage 'outside in' innovation [10]; where outside stakeholders are actively brought into the design process [2].

In contrast to product design, where the end result is something tangible, a service is an intangible offering developed ultimately by a service innovation manager, an individual or a company [26]. This design process usually takes place behind closed doors, from service innovation managers working on their assessment of the consumers' requirements, traditionally informed by passive and reactive methods [18]. Increasingly, however, the lone ingenious designer, who could do everything by him/herself is rapidly becoming history [2] as it becomes more common for firms to search for knowledge existing beyond the boundaries of the company [24]. In line with increasingly complex customer demands, engaging with market-based partners such as customers and suppliers can help to better specify market requirements for specific services and to spread the costs and risks of the innovation process [24].

The following section discusses three potentially relevant design tools that are frequently used in service design. These are: **Lead User Research, Crowdsourcing and Prototyping**.

These tools have been selected on basis of their potential applicability to open service design. Academic research on service design is to date limited [1], especially so in the context of open innovation. The following section will hence discuss the possibilities and limitations of each of the selected open service design tools. One tool will then be selected that appears to best suit the open innovation approach to service design.

Lead User Research applied to Open Service Design. A term first coined by Eric von Hippel [16], lead user research focuses on individuals who are experiencing needs that are yet to be known to the wider public. These individuals, through intense use of certain company value propositions, often adapt existing value propositions to enhance the benefit they obtain from them. They typically have a strong intrinsic incentive to innovate on their own account [13] and are not necessarily bound by profits, organisational structures and production capabilities [12].

As stated by [13], integrating lead users into service design can be highly profitable and, in turn, can be valuable to involve lead users in the exploration stages of the innovation processes. Von Hippel [16] identifies lead users as possessing the following characteristics: (i) they face needs that will be in a general marketplace – but face them months or years before the bulk of that marketplace encounters them and (ii) they are positioned to benefit significantly by obtaining a solution to those needs. This principle follows the line of "necessity is the mother of invention", whereby lead users will engage in necessary problem solving to ensure that their needs are met. Market research with normal consumers is constrained by the familiarity of the product, its attributes, and the real-world experience to which the consumer has already been exposed. Therefore market opportunities, if any, uncovered by market research, represent incremental improvements in a product with reference to company competition rather than a consumer focus. However, since lead users' needs are often very specific, perhaps niche, adopting lead user research still leads to uncertainty when applying the service to a larger market.

Expecting success based on advanced and innovative users of a product, which is what lead users typically are, does not necessarily foreshadow general market adoption. Using lead users for open service design needs to therefore be approached with caution. Applying the needs of the few to the general community could result in a service being too complex to be feasible; straining a company to provide resources that could go beyond the needs of the wider community. Additionally, the specific consumers who can be lead users can be especially difficult to find. They may exist outside of targeted markets, be consumers of rival products, or, due to their rapidly evolving needs, could have already moved on to the next innovation by the time they are identified [16].

Crowdsourcing applied to Open Service Design. Although only officially recognised in 2005, engaging crowds in the generation of new ideas has been a useful open innovative tool used throughout history. The ever increasing availability of internet access and reach, however, has accelerated the range and complexity of consumer demands; making it more difficult for companies to address them behind closed company doors [32]. Companies are responding by giving more attention to gaining knowledge and insights from crowds, potential and actual consumers for example, as opposed to only from competitors [21]. The transition to 'outside-in' knowledge [10] goes against long-established approaches, in which companies typically considered their research and development efforts as the sole source of new technologies and products [12].

The utilisation of crowdsourcing within a company leverages economies of scale to solve problems that have been too resource-demanding to solve internally. Further, it is also used to generate ideas that will come closer to consumer expectations; creating, in turn, a lasting relationship between consumer and company as the opinions of consumers are listened to and acted upon. Companies engaging in crowdsourcing no longer see themselves only as resource providers, rather they are positioning themselves as community hubs - bringing together consumers and, for example, manufacturers and/or service providers [29].

The theoretically mass-directed approach that crowdsourcing permits does raise the question of product quality. Questions are also raised in response to its non-monetary incentive insofar that participants are less likely to commit for small, or no, financial incentive. Additionally, as the crowdsourcing participants are typically large in number, companies are required to engage resources (internal or outsourced) to direct, regulate and speak to participants, with a commensurate increase in management time and cost overheads [8]. While crowdsourcing may in principle work for new product development, services are intangible which involve processes and experiences that are difficult to define [18]. Although crowdsourcing is a useful tool for idea generation, its voluminous nature may complicate clear visualisations of services that provide value.

Prototyping applied to Open Service Design. Prototyping can be defined as the conceptualisation of abstract thoughts and specifications into tangible realisations. Where a prototype is the manifestation of ideas and the assumptions behind them, prototyping is an activity and a mindset [30] seeking to answer one or two questions at a time as opposed to the entire system [11]. Originally applied to manufacturing, prototyping in services faces intrinsic difficulties relating to a service's intangible nature. For this reason, prototyping in service design differs from its use in manufacturing in the sense of being a representation of a future situation [6].

Despite this apparent limitation, prototyping is a powerful service design tool that is able to identify current, future and perceived expectations of a service. Its nature is centred on participatory design and focuses largely on making ideas explicit by directly engaging stakeholders, particularly users of the service and others who will be impacted by the service, in the development of an effective design solution [17]. Engaging stakeholders in the development of services encourages multi-disciplinary input; removing the organisational barriers that can sometimes exist as remnants of the importance that corporate internal research and development once possessed [27]. The effect of prototyping is twofold: (i) from the management perspective companies gain inputs from divergent mindsets that would otherwise not have been discovered under traditional organisational structures (ii) by having participants demonstrate what a favourable service consists of they are breaking down the intangible complexities of a service. Such activities allow companies to address expectation gaps in turn minimising wastage of company resources. Giving permission to explore new behaviours - the tangible presence of a new thing, the prototype, itself encourages new behaviours, relieving individuals of the responsibility to consciously change what they do [11]. Hence the ideas generated are typically better representations of actual consumer demands and are better situated to address the improvement of a stakeholder experience.

While prototyping offers an empirical, user-centred, rapid solution, it is a practice still not easily understood nor applied in the service domain [30]. This is partly because services exist in stages with a multiplicity of touch points [37], thereby making it difficult to visualise and imagine how a service may be of benefit. Therefore the result of prototyping is constrained by the participants' ability to visualise the complexities of a service. The risk in this regard is the time and resources used to create a prototype [33] which may not be a real representation of the needs and wants of the wider community.

Flexibility within prototyping allows for this consumer involvement. However it does require that a company maintains open channels of communication between all stakeholders. Such an investment into new service design thinking requires a company to focus less on passive and reactive forms of research, rather more so on engaging with, listening to, and acting on stakeholder comments.

Summary: Crowd Sourcing, Lead User Research, & Prototyping.

	Possibilities	**Limitations**
Lead User Research	- Ahead of the mainstream market - Belong to a niche of innovators - Insights that may foreshadow future market trends	- Ahead of the mainstream market; assumed adoption - Potential overly complexity - Time expenditure with identifying lead users
Crowd-sourcing	- Company as a hub; pooling ideas from a large resource base - Outside-in approach breaking down company walls - Scale of knowledge reached far greater than internally possible	- Crowd dictates direction of the idea – possible misdirection - Difficulty in articulation with respect to service visualisations - Extra staff needed to manage incoming information flow
Prototyping	- Accurate visualisations of services. Breaking down services to a series of processes - Multidisciplinary input - An activity and mindset that is embodied in the thought process	- Dependent on participants ability to visualise - Multiplicity of touch points in services – difficultly in thinking broadly - Limited practical research

Figure 1: Identified possibilities/limitations of chosen service design tools

The importance of service design within the context of an increasing reliance on technology is indubitable. The preceding investigation into possibilities and limitations of the selected design tools, and their applicability to open service design, favoured prototyping as the most suitable in the context of co-creation and open service design. Prototyping's unique adaptability stems from the unique characteristic of stakeholder interaction and involvement; achieving a level of subconscious and 'in-use' reactions that the other tools lack. This real-life experience improves the speed at which consumers respond to stimuli in addition to providing visualisations of the experience that are closer to, if not the actual, demands of the consumer. The effect of which mitigates effects of misdirection and the saving of company resources [6]. Through participatory design companies switch their focus from providing a service they deem to be of value, rather allowing the consumer to tailor their own perspective of value. As ancillary developments in technology become more advanced, the integration of prototyping in conjunction with augmented and virtual reality will allow for scale and reach to broader markets.

Consumer interaction is typically characterised by passive and reactive methods to experiences [18], utilising retrospective descriptions to gain insight into consumer behaviours. Through interaction and involvement, prototyping in open service design allows companies to see how value is perceived from an outside-in perspective [10], transcending the intangibility of services. Although crowdsourcing is directed at large scale participatory involvement, it still exists within the context of passive and reactive interactions between company and customer. In this regard its capacity for participatory design are both the strength and weakness, in that it has the ability to engage scale, however only in a backdated capacity. Lead user research also encourages participation and involvement from consumers however lacks the scale of participants; assuming that the wider community will be receptive to a group of innovators.

The intangible characteristic of services contributes to the difficulty from which the visualising of services can occur. Prototyping engages stakeholders in intense visualisations, making ideas more tangible, complexity more readable and alternatives shareable [30]. Within service design it shows how different touchpoints, along with their associated actors and customer groups [37], fit together sequentially [30] making public services and hospitals, as examples, more accessible. Crowdsourcing lacks this ability to intensely visualise services as, due to its strength in scale, it can only exist in an online arena governed by moderators attempting to control the flow and direction of the innovative process. Consequently, and as Jonas et al. [18] argue, service industries are still lacking an open space for transparent, interactive value creation to include, on a large scale, customers, other potential future users, non-users and ordinary people. With lead user research, issues rise again regarding its adoptability from the general user community. As lead users' demands exist only within a select niche [13], it could be thought that integrating their ideas into open service design would serve to complicate services unnecessarily. Creating a service from such an advanced niche could create superfluousness, potentially straining company resources. In contrast prototyping in open service design is oriented around user-centred thinking. This implies that the walls between customer and company are, during prototyping in open service design, removed. The result of which is a collaboration of co-created effort leading to the realisation of a service that is both feasible and desired from the company and customer perspective respectively.

4 Executing Prototyping in Open Service Design

As services are experiences and a result of human-to-human interactions, service design is about communication [23]. In service innovation the challenge is to not only to identify the consumers' needs and wants they can express, but also to enable the consumers to tap into their subconscious desires [22] by instinctively interacting with their environment. Therefore, the role that the end-consumer plays is integral to prototyping within service design [22]. Dodgson [14] describes prototyping as the company's embodiment of open innovation and its direction towards the inclusion of an outside-in stream of knowledge. The following section will elaborate on the importance of prototyping and its methodologies to the service innovation manager [22]

4.1 How the Service Innovation Manager guides the process

Prototyping can be viewed as a tool that aligns the efforts of stakeholders such as companies or end-customers. Services are tested by having the users of the prototype interact in collaborative, explorative, iterative and open-ended ways. At the same time factors that could interfere with the service delivery and the user experience need to be taken into account as well [7]. Hence, service innovation managers can be seen as actors playing a key role as translators in the network of participating stakeholders. They ensure the user-centred design of the service by avoiding passive and reactive observations. Instead, they attempt to understand unrecognised needs of the customers and in turn propose relevant service solutions [4].

Service solutions offer value for the consumer in two ways: a customer evaluates a service (i) by its ability to fulfil a functional outcome and (ii) by its experiential offering [4]. As fulfilling functional targets is likely to lead to the consumer's satisfaction, providing an enjoyable experience during the process of a service may lead to a consumer's loyalty [4]. By prototyping the service experience, service innovation managers work towards meeting functional and experiential targets by proposing solutions and examining the results in a trial and error process; thereafter the result are refined in collaboration with the consumer. Buchenau & Fulton Suri [9] explain however that prototyping is not about using a toolkit or a set of techniques, rather about creating an attitude and language for communicating with the consumer in order to solve design problems.

4.2 Creating a Communication Tool Using Prototyping

The service design process is carried out in a number of phases [23]: Discovering, Concepting, Designing, Building and Implementing. Buchenau & Fulton Suri [9] write that prototyping is of value in understanding existing user experiences, exploring and evaluating design ideas, and communicating services to an audience. Participatory design, prototyping and co-creation are integral in the concepting, designing and building phases [23], and are ongoing activities throughout the design process [7]. Meanwhile, operating in the background, prototyping is functioning as a mechanism for knowledge transfer [23, 36]; hence breaking down the complexity of service systems into easier-to-visualise segments.

The consumer experiences a service as a journey in which interactions between consumer and service innovation manager are dynamic, complex, subjective, and go beyond concrete sensories [9]. Prototyping enables the identification and targeting of key touch points within this journey. Thus allowing both the service innovation manager and consumer to collaboratively break down a service experience into smaller segments. The cocreation thereafter is directed towards the improvement of smaller segments as opposed to the entire service system.

4.3 Leveraging Interaction and Involvement through Prototyping

Prototyping in service design provides the opportunity to describe, discuss and develop services efficiently. It achieves this, by (i) integrating customers as co-creators that can partake in creating services and (ii) contributing explicit and subconscious needs [18]. The different ways in which prototyping can be carried out are based on interactions between the users and emphasises giving voice to actors who may previously not have been involved in the innovation process. Through the process of doing and refining and by customer participation it is possible to create differentiated services [3].

4.4 Possible Caveats using Prototyping in Open Service Design

The inconsistent nature of services has implications on the prototype and the way people interact with it. The presentation of a technology-based prototype is the same each time, whereas a human-delivered prototype can vary even if the same people are involved [7]. This inconsistency could impact the validity of the produced prototype, hence risking the position of the service innovation manager, the collaborating consumers, and the relationship between them.

Awareness of fictitious scenarios could also influence the authenticity of the prototype. As people are privy to the role-playing scenario, there is a possibility that they behave differently in a real service situation. Additionally, it is possible that participants new to prototyping are unaware of relevant methodologies (e.g. theatre play, bodystorming, etc.). Hence resources of the service innovation manager may be required to train new participants and actively enourage open-minded participation in the service design process.

All the stakeholders of a service should ideally be present already at the prototyping stage in order to improve how similar test and implementation contexts are [7]. As the service experience is ultimately subjective, producing only one prototype would not be considered sufficient. Therefore, several prototypes would be necessary to validate the consistency and authenticity of the service design.

4.5 Open Service Design in Practice

(Open) service innovation as a research field is a relatively young topic that is receiving increasing traction. Meanwhile, an increasing number of 'service innovation labs' (c.f. Fraunhofer ServLab[1], JOSEPHS®: The Service Manufactory[2] or the Service Innovation Corner[3] among others) are interesting approaches where prototyping methodologies in the development of new service concepts are applied.

Service innovation labs equipped with sophisticated technology enable abstract ideas to transcend into a tangible reality. Positioned as an engagement platform between service innovation manager and consumer, they apply the principles of prototyping through active participation and collaboration. This in turn encourages and promotes cocreation of services from different stakeholders early in the innovation process.

The Service Innovation Corner – University of Lapland, Finland. The SINCO lab is described as a technology-aided prototyping environment for user experience in which tools and devices support the concretisation of ideas, testing and agile co-creation [33]. It is an ideal example of how prototyping as a service design tool can approach the aforementioned challenges of services. The focal point of this approach is to map the divergent touchpoints in a consumer's experience of a service. Technology is hence used as an aid to create a 'transferable model' of a service prototyping environment [23].

SINCO identifies factors that need to be considered during prototyping. Thus the list below can be seen as a guideline for service innovation managers:

- Understanding challenges: users, environment and technologies involved,
- Creating empathy for and co-operating with the users,
- Including clients, other stakeholders and customers in the process,
- Prototyping, improving and visualising methods during the whole process and,
- Implementing, maintaining and continuous development at later stages.

The service labs extensive technological capabilities enable the creation of a 'Servicescape[4]', thus simulating the real service experience to help overcome authenticity and validity difficulties. Additionally, a skillful group leader and technical expert are necessary to include new participants and real consumers who are unfamiliar

[3] The Service Innovation Corner (SINCO), University of Lapland: http://sinco.fi/
[4] An artificial and physical environment of the place in which a service is provided (Bae & Leem, 2014)

with the concept and enable them to freely immerse themselves into a creative state that is required for prototyping [36]. Through the combination of new technology with prototyping in the SINCO lab, agile collaboration with users is easily achieved [22].

JOSEPHS® - The Service Manufactory. JOSEPHS® - The Service Manufactory, located in the heart of Nuremberg, Germany, is a non-profit innovation laboratory and an innovation ecosystem for the development and testing of novel service concepts and prototypes. The goal of the experimental initiative is to provide an intermediary platform for consumers and companies to actively engage in co-creative and collaborative innovations [34]. This is achieved by means of alternating exhibitions, or theme worlds, in which members of the public have a chance to view, interact with, and leave feedback for companies displaying their novel service or product prototypes. This offers users a rare glimpse into the thinking behind the company and thus allows users to play a (pivotal) part in the early stages of product or service development.

Opening up the prototyping process to the public means that companies operating through JOSEPHS® are able leverage participatory scale. Moreover, through the regular hosting of diverse events in the Denkfabrik (Thinking Factory), JOSEPHS® offers a platform for forward-thinking innovators as well as everyday consumers to collaborate with companies. Furthermore, companies have the chance to enact agile-like methods on their products and services based on the nature of feedback received. Hence the product or service remains in a dynamic state until the end of a company's three-month tenure at JOSEPHS®. This in turn allows for the development of a valid and authentic product or service before launching into broader environments.

5 Future Outlook: Prototyping in Virtual Reality

In the past, 'virtual worlds' or 'computer-simulated realities' were mainly used for public entertainment, cultural projects, virtual museums etc. [3]. Advances in computer hardware and gaming technology in the last decade have given rise to a new generation of virtual world applications running on desktop computers [19]. This new dimension adds another way in which service innovation managers and consumers can practice prototyping in open service design. Consequently, the application of collaborative virtual environments (CVEs) [38] in service-oriented fields is increasing and becoming more diverse. By means of high-immersion displays, haptic virtual environments, and other sensory-devices [28], virtual worlds are able to provide exceptional depth in a collaboration-driven prototyping experience. This is in contrast to simple online environments which often cannot provide the suitable relational depth of experiences and emotions needed for constructive co-creation [18].

5.1 Application and Relevance to Open Service Design

From a practical standpoint, virtual reality prototypes can, due to their novel use in the service industry, be more time consuming and costly compared to traditional prototyping tools. Additionally, users, just as with programmers designing service platforms, require new mindsets to become part of a structure in a virtual service organisation [15]. Therefore, the realistic presentation of a service scape and concept demands high effort and resources for scenery composition and programming from the service provider's side and an affinity for virtual worlds from the user's side [31]. Regardless, the hitherto status quo for gaining consumer knowledge is through market research, whereby statistical studies are regarded as being more scientific. Yet, it is known that asking the customer, particularly through structured questionnaires, only reveals a superficial layer of attitudes and behaviour, rather than root motivations [15]. In contrast, virtual worlds are inherently interactive, allowing users to interact with simulated artefacts [20] as they would in real settings. Thus this process of interaction creates possibilities for service innovation managers to easily integrate users in the development process of a service [31].

Virtual worlds are powerful platforms for designing novel collaborative design environments [20] and have been used frequently in architecture and organisational and interior design spaces [25]. Furthermore, virtual worlds uniquely allow users the embodiment of another character through avatars. The added persona enables users to be more than just viewers of a virtual space. Rather, through their observable motions and actions they are able to express both verbal and non-verbal forms of communication and awareness. According to Koutsabasis [20], "the avatars' position and orientation communicate where they are and what are they looking at; their appearance can usually be modified to express the user's personality, or even to denote the role of the user in a collaborating team; their animated bodies communicate their current activity; in some virtual worlds the avatars may also use facial expressions and gestures as an additional means of communication. All these abilities are important for the quality of the remote communication and coordination of a design team." Thus, virtual worlds provide an interactive platform for service innovation managers and users in which prototyping can be iteratively practiced producing a refined service innovation.

5.2 Adaptability of Virtual Worlds to Subjective Service Experiences

Virtual worlds enforce the characteristics of prototyping without having to rely on a user's physical presence. Therefore, by eliminating mitigating factors such as presence, weather, or proximity, a whole new service design paradigm could be conceptualised from the comfort of one's own home. As service innovation managers would be able to record and analyse more than just traditional and retrospective market research, they would be confronting and overcoming the intangible and experience-driven characteristics of a service.

Moreover, virtual worlds offer their own scripting language to be used for extending the real world's functionality and defining specific object behaviour. This makes them customisable and allows developers to design and implement application-specific tools whilst taking advantage of the existing visualisation, interaction and communication infrastructure of the virtual worlds [20]. Therefore programmers and service innovation managers with the suitable skill set can deconstruct, reuse, and rebuild platforms based on the size of their existing graphic and source code libraries. In addition to providing numerous cost efficiencies, this would be particularly useful for a service innovation manager working across a number of industries.

6 Conclusion and Postulations for Future Research Directions

The importance of service design in a service-dominant economy is undeniable. With the rapid developments of, and reliance on, information technology, the service innovation manager is faced with a difficult role in catering for increasingly complex demands of consumers.

Open service design is an open innovation technique that encourages non-traditional involvement from outside stakeholders. Through the analysis of three different service design tools it was suggested that prototyping was not only the most appropriate tool in the service designer's arsenal, but matched open service design as an ideology.

Given the intangible and complex nature of services, prototyping still faces challenges of validity and authenticity, particularly with unfamiliar participants. Institutions such as SINCO and JOSEPHS® are approaching these challenges by encouraging and fostering an outside-in stream of knowledge. Both institutions display interesting and innovative methods in which service innovation managers can test the validity and authenticity of a service idea.

Integrating prototyping into future technologies such as virtual worlds have the potential to alter methodologies in service design; potentially reaching a larger audience from which to apply prototyping iteratively. The inclusion of novel technology has been designed to provide a real world scenario where participants can actively participate without having to leave the comfort of their own homes. Looking to virtual worlds may therefore answer the question as to how services, with their characteristic multiplicity of touch points, can be fully visualised.

In lieu of the wide-scale availability of virtual worlds, it could be suggested that more documentation and research is needed into the processes of prototyping in open service design. Namely, at which particular stage of open service design is the prototyping process most vulnerable to inauthenticity and lack of validity? Or, what contextual factors are companies and consumers most subject to in order to collaboratively prototype a service that can benefit both parties? Literature in this direction would develop further the field of research in service innovation, prototyping and open innovation. Additionally, it would ultimately help service innovation managers engage and collaborate more effectively with their consumers.

Zielgruppendilemma des gleichzeitigen stationären und Online-Handels: Eine experimentelle Studie am Beispiel des Facebook-Auftritts eines Mode-Einzelhandelsunternehmens

Mario Porst, Sven Dittes, und Stefan Smolnik

FernUniversität in Hagen, Hagen, Deutschland
mporst22@gmail.com,{sven.dittes,stefan.smolnik}@fernuni-hagen.de

Abstract. Immer mehr traditionelle Einzelhandelsunternehmen sehen sich mit den Auswirkungen der Digitalisierung konfrontiert und eröffnen eigene Online-Shops, um mit E-Commerce-Plattformen wie Amazon und Zalando mithalten zu können. Hierbei setzen sie zumeist auf die über Jahrzehnte stationär aufgebaute Marke, unter der sie dann auch den Online-Shop führen. Darüber hinaus haben diese Unternehmen auch Social-Media-Plattformen wie Facebook als kosteneffizienten Marketingkanal für sich entdeckt. Da über diese Kanäle jedoch sowohl die Kunden des stationären Kaufhauses als auch die des Online-Handels erreicht werden, stellt sich vielen Unternehmen die Frage, wie sie mit demselben Online-Auftritt beide Zielgruppen adressieren können. In diesem Beitrag wird eine Fallstudie vorgestellt, mit deren Hilfe dieses Zielgruppendilemma untersucht wird. Darauf aufbauend wird eine experimentelle Studie konzipiert, um festzustellen, ob Beiträge auf sozialen Medien von beiden Zielgruppen unterschiedlich bewertet werden. Die Ergebnisse können von Unternehmen verwendet werden, um ähnliche Zielgruppendilemmata zu adressieren und die eigenen Aktivitäten auf Social-Media-Plattformen strategisch und fundiert zu planen.

Keywords: Social Media, stationärer Handel, Online-Handel, E-Commerce, Facebook

February 12-15, 2017, St. Gallen, Switzerland

Porst, M.; Dittes, S.; Smolnik, S. (2017): Zielgruppendilemma des gleichzeitigen stationären und Online-Handels: Eine experimentelle Studie am Beispiel des Facebook-Auftritts eines Mode-Einzelhandelsunternehmens, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1441-1452

1 Einleitung

Social-Media-Plattformen (SMP) wie Facebook und Twitter, aber auch neuere SMP wie Pinterest und Instagram haben sich im privaten Leben zum Zweck des Informationsaustauschs und der Vernetzung mit Freunden etabliert [1-5]. Die sich daraus ergebenden Möglichkeiten haben auch Unternehmen erkannt, die zunehmend auf diesen Plattformen mit eigenen Profilen und Auftritten vertreten sind. So stieg der Prozentsatz der Unternehmen, die SMP einsetzen, von 42% im Jahr 2008 auf 88% im Jahr 2012 an [6]. Nachdem Social Media bis vor einigen Jahren nur als „Marketinghype" von einigen Online-Spezialisten betrachtet wurde, ist es heute ein akzeptierter Marketingkanal [7]. Laut einer Studie von Bruhn, Martin und Schnebelen [8] schreibt mehr als die Hälfte der befragten deutschen Unternehmen sozialen Medien einen relativ hohen oder sehr hohen Stellenwert zu.

Das B2C-E-Commerce-Wachstum setzt sich laut dem Handelsverband Deutschland (HDE) weiter fort. Dieser prognostiziert für das Jahr 2016 einen Umsatz ohne Umsatzsteuer von 46,3 Milliarden Euro. Dies entspricht einem Wachstum von fast 300% in den letzten zehn Jahren[1] [9]. In einer weiteren Studie des HDE wurden Händler befragt, ob sie bereits einen Online-Shop haben oder planen, in den nächsten zwölf Monaten einen Online-Shop zu eröffnen. Fast jeder dritte (28,9%) stationäre Händler hatte in der Befragung bereits einen Online-Shop aufgebaut. Weitere 8,8% planen die Eröffnung in den nächsten zwölf Monaten [10]. Ein Vorteil von E-Commerce gegenüber dem stationären Handel ist, dass das Einzugsgebiet vergrößert wird, da Online-Shops über das Internet überregional erreichbar sind. Für Unternehmen mit regional fokussiertem stationärem Handel bedeutet dies eine Ausweitung des Einzugsgebiets.

Dieses Potenzial hat auch ein Mode-Einzelhandelsunternehmen erkannt, das im weiteren Verlauf des Beitrags als Fallstudienunternehmen dient. Dieses stationär regional fokussierte Unternehmen hat 2006 einen Online-Shop eingerichtet, um seine Modeartikel auch überregional verkaufen zu können. Jedoch sind mit dieser Ausweitung auch Herausforderungen verbunden. Beispielsweise ist die Zielgruppenansprache auf SMP nicht trennscharf umzusetzen. Wenn z.B. die regionalen Fans der entsprechenden Facebook-Seite des Unternehmens in der Regel eher an Informationen über das Unternehmen und dem stationären Ladengeschäft interessiert sind, sind – aufgrund der überregionalen Reichweite des Online-Shops – die Fans, die nicht im stationären Einzugsgebiet leben, eher an Angeboten und Informationen, die den Online-Shop betreffen, interessiert. So entstand für das Fallstudienunternehmen ein Zielgruppendilemma auf diesen Plattformen: Entweder werden die regionalen Kunden zufriedengestellt und die überregionalen Kunden mit nicht relevanten Informationen, wie z.B. Aktionen im Ladengeschäft, konfrontiert oder es werden den regional interessierten Kunden zu wenig Informationen über das stationäre Ladengeschäft mitgeteilt. Facebook-Seiten sollten ihren Fans jedoch interessante, unterhaltsame und innovative Inhalte liefern [11]. Dieser Beitrag adressiert dieses Zielgruppendilemma des Fallstudienunternehmens und hat das Ziel,

[1] 15,7 Milliarden Euro ohne Umsatzsteuer im Jahr 2006

eine wissenschaftliche Grundlage zu erarbeiten und eine Lösung zu finden, wie mit diesem Problem umgegangen werden kann.

Im Folgenden wird zunächst das Fallstudienunternehmen vorgestellt, das sich gerade in einem Zielgruppendilemma hinsichtlich seiner Marketingstrategie für Facebook befindet. Aufbauend auf den Erkenntnissen aus dem Fallstudienunternehmen werden in diesem Beitrag die Ergebnisse einer experimentellen Studie vorgestellt. Aufgeteilt in zwei Gruppen wurde eine Umfrage bei Facebook-Nutzern durchgeführt, bei der die Teilnehmenden zunächst jeweils in ein unterschiedliches Szenario eingeführt wurden. In einem Szenario wurde den Teilnehmenden eine Facebook-Seite eines Mode-Einzelhandelsunternehmen vorgestellt, das sie nur als Ladengeschäft kennen, und in einem anderen Szenario nur als Online-Shop. Beiden Gruppen wurden Bilder derselben Facebook-Beiträge eines fiktiven Unternehmens vorgelegt, die schließlich von den Teilnehmenden bewertet wurden. Als Ergebnis der Studie werden Unterschiede hinsichtlich der Bewertung der Facebook-Beiträge präsentiert. Auf Basis dieser Ergebnisse werden Hypothesen bezüglich der festgestellten Unterschiede formuliert und Handlungsempfehlungen für Unternehmen abgeleitet.

2 Theoretische Grundlagen

2.1 Facebook-Seiten und deren Möglichkeiten

Mit einer Facebook-Seite können Unternehmen ihre Kunden und Interessierte mit verschiedenen Arten von Informationen versorgen. Sie haben die Möglichkeit, die Kunden und Interessierten selektiv, sogar auf personalisierter Ebene, über ihre Produkte und Dienstleistungen zu informieren, sie mit interessanten oder nützlichen Inhalten zu erreichen oder die Facebook-Seite als einen Kundenservice-Kanal zu nutzen [12]. Unternehmen können auf ihren Facebook-Seiten Beiträge veröffentlichen, die Anekdoten, Fotos, Videos, Veranstaltungen, Hyperlinks oder anderes Material beinhalten. Ihre Fans können mit diesen Beiträgen dann interagieren, indem sie auf „Gefällt mir“ klicken oder die Beiträge kommentieren sowie teilen [13]. Weiterhin gibt es eine Reihe von zusätzlichen Möglichkeiten für Unternehmen wie z.B. das Schalten von Werbeanzeigen.

Grundsätzlich können auf die sozialen Medien klassische Marketingprinzipien angewendet werden [14]. So besteht die Aufgabe von Werbemitteln darin, dass die vom Unternehmen gewollten Botschafts- bzw. Beitragsinhalte mit der gewünschten Wirkung an den Nutzer (Rezipient) herangetragen werden [15]. Daher müssen auf SMP Inhalte geliefert werden, die den Nutzern (Fans) angenehme Erfahrungen bieten, sodass diese wiederkommen und aktiv mitwirken [16]. Hierzu schreiben Castronovo und Huang [16], dass eine virale Kampagne eher erfolgreich ist, wenn der Inhalt der Nachricht stark auf die Zielgruppe abgestimmt ist und somit auf die Motivation zum Teilen dieser Informationen einwirkt. Des Weiteren stellen Heller-Baird und Parasnis [17] fest, dass Unternehmen Erlebnisse bereitstellen müssen, die den Kunden und Interessierten einen konkreten Mehrwert im Gegenzug zu Zeit, Aufmerksamkeit, Unterstützung und Daten bieten, um das Potenzial von Social Media erfolgreich zu nutzen.

2.2 Wahrnehmung, Einstellung und Reaktion auf Facebook-Beiträge

Um messen zu können, wie ein Beitrag auf die Rezipienten wirkt und ob dieser einen Mehrwert liefert, wird im Folgenden auf das Konzept des (Botschafts-) Involvements zurückgegriffen. Trommsdorf [18] definiert Involvement als den „Aktivierungsgrad bzw. die Motivstärke zur objektgerichteten Informationssuche, -aufnahme, -verarbeitung und -speicherung“. Weiterhin unterscheidet Trommsdorff diverse Kategorien von Involvement. Ob eine Botschaft subjektiv mehr oder weniger interessant ist, beschreibt dabei – unabhängig vom Produkt, für das die Werbung gemacht wurde – der Grad des Botschaftsinvolvements [18]. Im Folgenden soll der Begriff Involvement für das Botschaftsinvolvement stehen und damit beschreiben, ob die Facebook-Beiträge des Untersuchungsobjekts für die Betrachter subjektiv mehr oder weniger interessant sind.

Um das Involvement auf verschiedenen Ebenen abzufragen, wurden die drei Bereiche *Wahrnehmung*, *Einstellung* sowie *Reaktion* festgelegt. Die *Wahrnehmung* (kognitive Komponente) ergibt eine *Einstellung* (affektive Komponente), die wiederum zu einer *Reaktion* (konative Komponente) führt. Um die Wahrnehmung und den Wert von Werbung im Internet zu messen, hat Ducoffe [19] verschiedene Dimensionen definiert: *Informationsgehalt*, *Unterhaltung*, *Verärgerung* und *Werbewert*. Weiterhin wird die *Einstellung* zu den Beiträgen gemessen. Innerhalb des Bereiches *Reaktion* wird die Intention zu jeweils „Gefällt mir“, „kommentieren“, „teilen“, „klick auf Link“ oder „Interessiert“ abgefragt. Reaktionen auf Beiträge werden von Werbetreibenden und Marketer als Metriken für die Erfolgsmessung von Kampagnen herangezogen [20]. Im Rahmen der nachfolgend beschriebenen Fallstudie werden diese Dimensionen innerhalb verschiedener Gruppen von Rezipienten gemessen, analysiert und miteinander verglichen.

3 Fallstudie

Das Mode-Einzelhandelsunternehmen ist seit über 100 Jahren in einer deutschen Metropolregion ansässig und stark mit der Region verwachsen. Seit der Einrichtung des Online-Shops wird über die Region hinaus Ware angeboten. Die Untersuchungen innerhalb dieser Studie beziehen sich auf die 2010 erstellte Facebook-Seite des Unternehmens. Am 10.02.2016 weist diese ca. 90.000 „Gefällt mir“-Angaben auf. Die Geschlechterverteilung der Fans der Seite ist laut Facebook-Seitenstatistik am 06.03.2016 mit 83% Frauen und 17% Männern angegeben. Mit 41% hat die Gruppe der 18- bis 24-Jährigen den größten Anteil der Fans, gefolgt von den 13- bis 17-Jährigen mit 27% und den 25- bis 34-Jährigen mit 20%.

Die Facebook-Seite wird derzeit als relevanter Marketingkanal für Kunden und Interessierte sowohl für den überregionalen E-Commerce als auch für den regionalen stationären Handel genutzt. Aus diesem Grund befindet sich das Unternehmen in einem Zielgruppendilemma und stellt sich u.a. folgende Fragen:

- Wie und in welchem Maße sollten beide Kundengruppen angesprochen werden?
- Werden Beiträge mit E-Commerce-Inhalten von der Zielgruppe der Kunden und Interessierten des regionalen stationären Handels schlechter bewertet?
- Werden Beiträge mit Ankündigungen zu stationären Aktionen von der Zielgruppe des überregionalen E-Commerce schlechter bewertet?
- Werden neutrale Inhalte, wie z.B. zu Trends und Styling-Tipps sowie Entertainment, von beiden Zielgruppen gleich bewertet?

Diese Studie soll ein besseres Verständnis über das Zielgruppendilemma schaffen und damit dazu beitragen, Lösungsansätze zu finden, wie dieses Problem zu adressieren ist. Dazu konnten im Vorfeld gemeinsam durch Interviews mit relevanten Stakeholdern des Fallstudienunternehmens folgende Ziele identifiziert werden:

- Reduktion von Kosten bzw. effizientere Nutzung von vorhandenen Ressourcen
- Beide Zielgruppen gleichermaßen erreichen
- Beide Zielgruppen zielgruppengerecht ansprechen
- Strategisch ausgerichtete Social-Media-Aktivitäten auf Basis von wissenschaftlicher Forschung

4 Methodisches Vorgehen

4.1 Voruntersuchung

Um den Status-quo der Aktivitäten auf der untersuchten Facebook-Seite zu extrahieren, wurde deren Inhalt analysiert. Hierfür wurden alle Beiträge im Zeitraum vom 01.11.2015 bis zum 31.01.2016 betrachtet und klassifiziert. Die Zahl der analysierten Beiträge in diesem Zeitraum beträgt 308. Dabei wurden die Beiträge nach dem *Inhalt*, den ausgewählten *Typen* von Beiträgen und der *Ausrichtung* kategorisiert. Tabelle 1. zeigt sechs Kombinationen der identifizierten Beitragscluster.

Tabelle 1. Ausgewählte Kombinationen von Beiträgen

	Inhalt				*Typ*			*Ausrichtung*	
	E-Commerce	*Trends & Styling-Tipps*	*Stationäre Aktion*	*Enter-tainment*	*Bild*	*Link*	*Veran-staltung*	*regional*	*über-regional*
Beitrag #1	x				x				x
Beitrag #2	x					x			x
Beitrag #3		x				x		x	x
Beitrag #4			x		x			x	
Beitrag #5			x				x	x	
Beitrag #6				x	x			x	x

Auf Basis dieser Voruntersuchung wurden sechs entsprechende Beiträge aus dem analysierten Zeitraum ausgewählt, die daraufhin in der Fragebogenstudie verwendet wurden. Im folgenden Kapitel wird das Vorgehen bei der experimentellen Fragebogenstudie beschrieben.

4.2 Experimentelle Fragebogenstudie

Im Rahmen der Studie wurden in einem Online-Fragebogen den Teilnehmern Bilder von Facebook-Beiträgen gezeigt. Die Beiträge wurden auf Basis der Analyse beim Fallstudienunternehmen ausgewählt (siehe Tabelle 1). Für die Beiträge #2 und #3 wurden, da es sich um Beiträge mit Inhalten zu Produkten, Styling-Tipps und Trends handelte, jeweils eine Version für weibliche und männliche Probanden genutzt und die Ergebnisse aggregiert.

Alle sechs Beiträge wurden mithilfe von 5-Punkt-Likert-Skalen von den Teilnehmenden bewertet. Es wurden Konstrukte für die drei Bereiche *Wahrnehmung*, *Einstellung* sowie *Reaktion* untersucht (siehe Abschnitt 2.2). Tabelle 2 zeigt eine Übersicht über die in der Studie erhobenen Konstrukte sowie die Items und die Quellen, aus denen die Items abgeleitet wurden.

Tabelle 2. Übersicht der verwendeten Konstrukte und Items

Bereich	*Konstrukt*	*Item*	*Quelle*
Wahrnehmung	Informationsgehalt	Dieser Facebook-Beitrag ist eine gute Informationsquelle.	Brackett und Carr [21] Ducoffe [19]
		Dieser Facebook-Beitrag gibt mir relevante Informationen.	
		Dieser Facebook-Beitrag beinhaltet aktuelle Informationen.	
	Unterhaltung	Dieser Facebook-Beitrag ist unterhaltsam.	Brackett und Carr [21] Ducoffe [19]
		Dieser Facebook-Beitrag ist angenehm.	
		Dieser Facebook-Beitrag ist ansprechend.	
	Verärgerung	Dieser Facebook-Beitrag ist störend.	Brackett und Carr [21] Ducoffe [19]
		Dieser Facebook-Beitrag ist lästig.	
		Dieser Facebook-Beitrag ist irritierend.	
	Wert des Beitrags	Dieser Facebook-Beitrag ist nützlich.	Brackett und Carr [21] Ducoffe [19]
		Dieser Facebook-Beitrag ist wertig.	
		Dieser Facebook-Beitrag ist wichtig.	
Einstellung	Einstellung zu dem Beitrag	Ich finde diesen Facebook-Beitrag gut.	Burton und Lichtenstein [22]
Reaktion	Intention „Gefällt mir“	Ich würde „Gefällt mir“ bei diesem Beitrag klicken.	Alhabash et al. [20]
	Intention „kommentieren“	Ich würde diesen Beitrag kommentieren.	
	Intention „teilen“	Ich würde diesen Beitrag „teilen“.	
	Intention „Interessiert“ bzw. klick auf Link	Ich würde auf „Interessiert“ bzw. den Link klicken um weitere Informationen zu erhalten.	

Die Fragebogenstudie wurde in zwei Schritten durchgeführt. Im ersten Schritt wurde die Umfrage bei den Fans des Mode-Einzelhandelsunternehmens der Fallstudie durchgeführt (im Folgenden als „echte“ Umfrage betitelt). Die Beiträge waren hier nicht verfremdet und mit dem Firmenlogo (Profilbild) versehen.

Im zweiten Schritt wurde der experimentelle Teil der Studie durchgeführt, indem die Teilnehmenden zunächst in das jeweilige fiktive Unternehmen „MODE haus“ eingeführt wurden. Die Facebook-Beiträge wurden hierfür anonymisiert umgesetzt. So wurde sichergestellt, dass eine Beeinflussung durch die Marke auszuschließen ist. Die Teilnehmenden wurden randomisiert auf zwei verschiedene Gruppen aufgeteilt. Zu Beginn des Fragebogens wurden die Teilnehmenden jeweils in ein Szenario eingeführt: Das Szenario 1 suggerierte, dass die Teilnehmenden das Unternehmen nur als stationäres Geschäft kennen und noch nie online bei dem dazugehörigen Online-Shop eingekauft haben. Szenario 2 suggerierte den Teilnehmern, dass sie noch nie vor Ort waren und keinen Bezug zum stationären Ladengeschäft haben, jedoch bereits beim dazugehörigen Online-Shop eingekauft haben. Bei allen drei Versionen der Umfrage wurden die gleichen Beiträge verwendet.

Der experimentelle Teil der Fragebogenstudie wurde im Zeitraum vom 08.05.2016 bis zum 23.05.2016 durchgeführt. Der entsprechende Fragebogen wurde am 08.05.2016 mittels eines Facebook-Beitrages über private Facebook-Profile veröffentlicht, sowie am 10.05.2016 über den Verteiler der Stiftung Begabtenförderung berufliche Bildung gGmbH (SBB) an 4227 E-Mail-Adressen versendet. Am 19.05.2016 wurde über den SBB-Verteiler eine Erinnerung gesendet. Das Online-Befragungswerkzeug wies den Teilnehmenden randomisiert eines der beiden Szenarien zu. Die „echte“ Umfrage war nicht Bestandteil der Randomisierung und wurde daher über einen separaten Hyperlink am 10.05.2016 mittels einer Facebook-Anzeige über das Unternehmensprofil des Fallstudienunternehmens veröffentlicht. Um die Beteiligungsquote zu erhöhen, wurden bei allen Umfragen Anreize in Form von Verlosungen von Sachgeschenken und Gutscheinen eingesetzt.

5 Ergebnisse

Von 580 abgeschlossenen Umfragen der Fragebogenstudie haben 489 Teilnehmende angegeben, dass sie ein Facebook-Profil für private Zwecke besitzen. Von diesen 489 hatten 414 Teilnehmende ein Aufmerksamkeits-Item korrekt beantwortet. Die nachfolgenden Ergebnisse stellen daher nur die Ergebnisse dieser 414 Teilnehmenden dar. In der Abbildung 1 werden die Ergebnisse der erhobenen demografischen Merkmale dargestellt. 75,85% (n=314) der Teilnehmenden waren weiblich und 24,15% (n=100) waren männlich. Auf die „echte“ Umfrage entfielen 129 ausgefüllte Fragebögen, auf die Umfrage des Szenarios 1 151 und auf die Umfrage des Szenarios 2 134. Die demografischen Merkmale der Umfragen waren ähnlich verteilt und daher vergleichbar. Weiterhin entsprechen die Daten in etwa der Verteilung der Fans der Facebook-Seite des Mode-Einzelhandelsunternehmens (siehe Abschnitt 3).

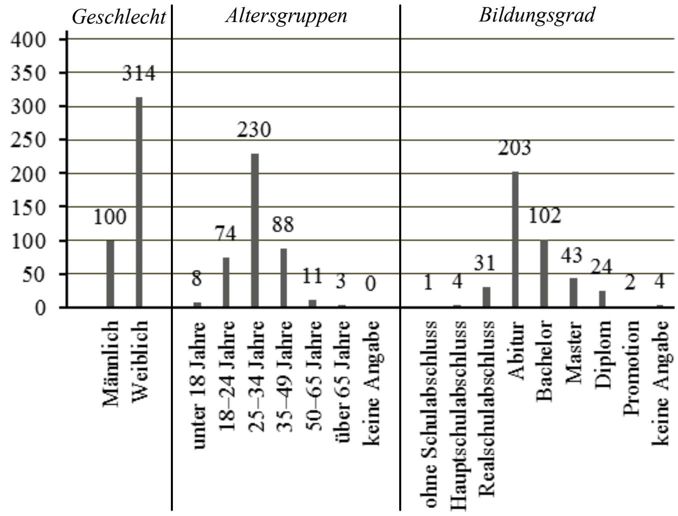

Abbildung 1. Demografische Ergebnisse in absoluten Zahlen (n=414)

In Tabelle 3 werden jeweils die auf zwei Stellen hinter dem Komma gerundeten Mittelwerte der Ergebnisse der drei Umfragen („echte“ Umfrage, Szenario 1 des experimentellen Teils der Studie sowie Szenario 2 des experimentellen Teils der Studie) dargestellt. Bei den vier Konstrukten *Informationsgehalt*, *Unterhaltung*, *Verärgerung* und *Wert des Beitrags* werden die aggregierten Mittelwerte über die drei jeweiligen Items pro Konstrukt aufgezeigt. Die Skalen haben ein Minimum von 1 und ein Maximum von 5. Um mögliche Unterschiede zwischen Szenario 1 und 2 statistisch zu identifizieren, wurde mithilfe der Statistik-Software IBM SPSS Statistics eine multivariate Varianzanalyse (MANOVA) durchgeführt. Als Ergebnis dieser Analyse werden in der Tabelle 3 die entsprechenden Signifikanzlevel der Unterschiede (p-Wert) aufgeführt.

Tabelle 3. Ergebnisse der Beiträge

Bereich		*Echt*		*Szenario 1*	*Szenario 2*	*p-Wert*
Beitrag 1 (E-Commerce; Bild; überregionale Zielgruppe)						
Wahrnehmung	Informationsgehalt	4,05		3,50	3,35	0,234 n.s.

6 Diskussion

Die Analyse zeigt, dass die Ergebnisse der „echten“ Umfrage – teils deutlich – von den Ergebnissen der Szenario-Umfragen abweichen. Diese Unterschiede zeigen sich konsistent in allen Bereichen. Die z.T. deutlichen (positiven) Abweichungen könnten auf eine starke (positive) Beeinflussung der Ergebnisse durch die Marke erklärt werden. Hieraus lässt sich folgende Hypothese ableiten:

H1: Marken beeinflussen die Wahrnehmung, Einstellung und Reaktion hinsichtlich Facebook-Beiträgen stark.

Des Weiteren zeigt die Analyse der Umfrageergebnisse, dass die Beiträge mit regionalem Bezug bei den Teilnehmenden des überregionalen Szenarios 2 schlechter bewertet werden. So sind vor allem bei Beitrag #5 – der eine reine stationäre Verkaufsveranstaltung bewerben soll – signifikante Unterschiede gemessen worden. Es kann daher die folgende Hypothese formuliert werden:

H2: Stationäre Aktionen werden von einer überregionalen Zielgruppe schlechter bewertet.

Anders war dies bei überregional ausgerichteten Beiträgen. Dort wurde die Aussage widerlegt, dass überregionale Beiträge mit E-Commerce-Inhalten von einer regionalen Zielgruppe schlechter bewertet werden. Bei beiden E-Commerce-Beiträgen #1 und #2 konnten keine signifikanten Unterschiede zwischen den Zielgruppen gemessen werden. Es folgt daraus die Hypothese:

H3: Überregionale Beiträge mit E-Commerce-Inhalten werden von einer regionalen Zielgruppe nicht schlechter bewertet.

Bei den neutralen Beiträgen #3 und #6 konnten – wie erwartet – keine signifikanten Unterschiede zwischen den Zielgruppen gemessen werden. Daher konnte folgende Hypothese abgeleitet werden:

H4: Neutrale Inhalte, wie z.B. Trends und Styling-Tipps sowie Entertainment, werden von beiden Zielgruppen ähnlich bewertet.

Aus diesen Erkenntnissen können Unternehmen mit einem ähnlichen Zielgruppendilemma schließen, dass bei überregionalen Beiträgen keine Differenzierung vorgenommen werden muss, regionale Beiträge jedoch gezielt eingesetzt werden sollten. Facebook bietet dazu bei den kostenpflichtigen Werbemöglichkeiten an, eine Zielgruppendefinition nach Standort vorzugeben. Damit sind diese Werbeanzeigen nur für Nutzer sichtbar, die sich an den vorher definierten Standorten aufhalten. Als Auswahlmöglichkeiten ist es möglich, ein oder mehrere Länder, eine Region, eine Provinz, einen Ort, einen Wahlbezirk oder eine Postleitzahl einzugeben [23]. Diese Möglichkeit beschränkt sich jedoch auf die Bewerbung eines Beitrags, jedoch nicht auf die (reguläre) Darstellung der Beiträge selbst. Daher sollte bei regionalen Beiträgen grundsätzlich überlegt werden, ob die Inhalte bzw. die Aktion „wichtig“ genug sind, um diese der ganzen Fangemeinde anzuzeigen. Folglich sollte bei diesen Beiträgen auch besonders auf den Inhalt geachtet werden.

7 Fazit und Ausblick

Ziel dieses Beitrags war es, das Zielgruppendilemma zwischen stationärem Handel und E-Commerce hinsichtlich der Marketingaktivitäten von Unternehmen auf Facebook zu untersuchen. Es wurde zunächst ein Mode-Einzelhandelsunternehmen als Fallstudie vorgestellt. Basierend auf einer Analyse des Facebook-Auftritts des Unternehmens wurde eine experimentelle Studie entworfen, um festzustellen, ob Beiträge von Kunden des Online-Shops und des (stationären) Kaufhauses unterschiedlich bewertet werden. Hierzu wurde neben demografischen Daten, das Involvement auf den Ebenen *Wahrnehmung*, *Einstellung* und *Reaktion,* bei verschiedenen Beiträgen, abgefragt. Als Ergebnis konnten vier Hypothesen abgeleitet werden.

Bei der Durchführung dieser Studie wurden erprobte und wissenschaftlich akzeptierte Methoden eingesetzt, jedoch kann die Wirkung von Werbung nur bis zu einem gewissen Grad durch herkömmliche Konsumentenbefragungen ermittelt werden. „Die durch Markenkommunikation entstehende Bedeutung der Marken ist den Kunden nicht explizit bewusst“ [24]. Zudem besteht hinsichtlich des Aufbaus des experimentellen Teils der Studie die Möglichkeit, dass die Einführung der Szenarien nicht ausreichend war, um die Teilnehmenden wie gewollt zu beeinflussen. Die Ergebnisse könnten zudem von situativen Faktoren beeinflusst worden sein, da es aufgrund des online erhobenen Fragebogens keine standardisierte Umgebung gab.

Die Ergebnisse der Umfrage könnten als Ausgangspunkt für weiterführende Studien verwendet werden. So sollten die aufgestellten Hypothesen einer konfirmativen Studie unterzogen werden. Zusätzlich könnten durch den Einsatz von Strukturgleichungsmodellen auch Korrelationen und Abhängigkeiten zwischen den Bereichen *Wahrnehmung*, *Einstellung* und *Reaktion* analysiert werden. Schließlich könnte auch der in dieser Studie deutlich erkennbare Einfluss einer Marke auf das Involvement im Social-Media-Umfeld weiter analysiert werden.

Abschließend können die Ergebnisse von Unternehmen verwendet werden, um ähnliche Zielgruppendilemmata zu adressieren und die eigenen Aktivitäten auf Social-Media-Plattformen strategisch und fundiert zu planen. Zudem kann der Ansatz in dieser Studie als Blaupause für weitere experimentelle Studien verwendet werden, um die Wahrnehmung von Social-Media-Inhalten beim Rezipienten zu untersuchen.

Co-Creation and User Involvement in a Living Lab: An Evaluation of Applied Methods

Theodor Beutel, Julia M. Jonas, Kathrin M. Moeslein

Friedrich-Alexander-University Erlangen-Nuremberg, Information Systems 1, Nuremberg, Germany
{theodor.beutel;julia.jonas;kathrin.moeslein}@fau.de

Abstract. Living labs are only recently developing to facilitate active user involvement in an interactive setting. Research on the methodological facilitation of co-creation and user feedback in such open physical spaces is still scarce. The objectives of this paper are to identify applied methods as well as to investigate the level of user involvement in living labs to further develop theoretical insights on living labs as well as on method implementations for co-creation. A qualitative explorative approach in the form of a case study on the living lab JOSEPHS in Nuremberg is applied. This paper finds that applied methods serve either of two purposes: 1) Collecting data for innovation research, or 2) adapting co-creation to living labs. Combined accordingly, methods cover both purposes and increase user involvement. Furthermore, six factors that determine user involvement are proposed. Implications for living lab managers are provided.

Keywords: Co-Creation, Living Labs, User Involvement, Methods, ICT

1 Introduction

In an era of sophisticated information and communications technology (ICT) with empowered users and blurring organisational boundaries, innovation procedures in new product and service development (NPSD) undergo a fundamental transformation. Firms actively loosen conventional boundaries through the inclusion of external actors in their NPSD activities [1]. As part of such open innovation approaches, major importance is devoted to users. Whereas users only recently received major attention in open innovation research [2], the emergence of user innovation research dates back as far as four decades [3, 4]. Among open innovation practices, co-creation with users is one of the most important and proves to be widely adopted among firms [5].

Today, many tools of open innovation are driven by ICT [6]. Benefiting from low cost and large scale, also co-creation is often implemented online [7]. However, building trust [7] and providing context [8] proves to be challenging over the Internet. Here, real life settings play to their strengths [9, 10]. Living labs (LL), endorsed by the

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Beutel, T.; Jonas, J.M.; Moeslein, K.M. (2017): Co-Creation and User Involvement in a Living Lab: An Evaluation of Applied Methods, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1453-1464

European Union [11], are a rather new approach to foster NPSD and co-creation with users in real life settings. LLs are described as a "new way to manage the new product development process" [12] and fit into the idea of arenas for co-creation by Bhalla [10]. LL are considered as a conceptualisation of extra-organisational open innovation [2, 8].

However, it remains rather unclear *how* users can and should be involved in the context of LLs. In contrast to the firms' and the users' roles, the role of intermediaries in open innovation is less illuminated [13, 14]. Furthermore, recent innovation research has covered broadly *where* but less *how* to search for external knowledge [15]. It is particularly questioned how methods involving the user in a LL should be chosen and implemented. Such lack of knowledge may be attributed to the novel nature of LLs as an area of interest. However, the importance of user involvement specifically in LLs has been highlighted by scholars for more than a decade [16]. Mulder and Stappers [17] state that LLs are not living up to their full potential of active user involvement in real life settings. Hence, this paper aims to identify applied methods and to investigate the emergence and intensity.

2 Theoretical Foundation

2.1 Co-Creation for Innovation Purposes

As real and physical spaces, LLs can be used for open innovation by facilitating co-creation with users [2, 18, 19]. Co-creation for innovation purposes in NPSD is only one out of several applications for co-creation [20] and is framed within the concept of co-creation of value. While traditionally, the process of value creation was coined by independently value-adding firms, which led to demand from passively consuming users, value is now jointly co-created from firms and users. When users go beyond mere consumption and become active contributors in NPSD, they co-create and extract value for their own good [21]. Through the active role of users, the changed user-firm relationship implies a new locus of value creation, which lies in interaction and experience [22].

In this paper, co-creation is defined as "an active, creative and social collaboration process between producers[1] (retailers) and customers[2] (users)" [24]. It is argued that users place importance primarily on the value that (eventually) emerges while the process is of little account to them [29]. Consequently, Snyder et al. [29] propose to view outcome and process separately. However, it is not to be neglected that users create value during co-creation processes [30], e.g. benefit from enjoyment and learning [26]. It is therefore useful to shed more light on processes and methods of co-creation.

For a firm, the most important benefit of co-creation with users lies in an improved access to need information, as need information tends to be sticky. Thus, better access to user preferences leads to more effective NPSD [24].

[1] The literature contains varying terminology, such as "company" [as in 21, 23] and "producer" [as in 3, 24]. This paper confines the word choice to the term "firm" [as in 1, 2].

[2] Likewise with footnote 1, this paper employs the term "user" [as in 3, 25] in place of "consumer" [as in 26, 22], "customer" [as in 21, 24], "citizen" [as in 27, 28] and "visitor" [as in 23].

2.2 User Involvement

The involvement[3] of users is a fundamental dimension to co-creation [22] as well as to open innovation [2]. User involvement can be defined as a user's influence on the idea, development and launch processes in NPSD [25]. Similarly, Piller, Ihl, and Vossen [24] see co-creating users actively involved during NPSD processes, but add that they are performing "an act of company-to-customer interaction which is facilitated by the company" [24]. Depending on their role, users engage in different intensity, varying in time and effort. User activity in NPSD processes can range widely among users as a passive source of information, a co-creating contributor, and a designing innovator [33].

2.3 Living Labs

LLs provide a novel way to connect firms with users and help with "closing the gap between open and user innovation" [34]. Compared to other innovation approaches, LLs differ in two dimensions [8]. Firstly, LLs are capable of providing novel structures for user involvement [35]. They involve users in an interactive and empowering way, enabling them to become co-creators, and thus go beyond user-centred approaches that only involve users passively [36]. Secondly, a particular strength of LLs lies in their real life offline setting. In this regard, they overcome hurdles in knowledge transmission relating to sticky information and tacit knowledge [37]. Therefore, LLs can be considered as "a user-centric research methodology for sensing, prototyping, validating and refining complex solutions in multiple and evolving real life contexts" [38].

Methods applied in Living Labs. Bergvall-Kåreborn and Ståhlbröst [27] argue that LLs are methodologically designed in two levels. While a general framework provides stability and continuity, a second level beneath allows spontaneity within projects [27]. Similarly, Dell'Era and Landoni [12] argue that a framework both allows and determines the implementation of methods within a LL. The LL methodology draws from co-creation techniques as well as from traditional innovation research methods such as questionnaires, in-depth interviews, or focus groups. Depending on the domain and its method, a different type of knowledge and originality can be expected [39].

Distinguishing itself from other approaches, the LL methodology stands out in active user involvement and realism [17, 37]. Real life environments set LLs apart from controlled environments. A real life setting is usually designed through the use of contextual methods and/or with the aid of physical artefacts [12]. It is argued that methods applied in LLs should adapt to the distinct advantages in interactivity and real life environments and thus should go beyond traditional methods of innovation research [35, 40]. However, only few studies evaluate methods applied in LLs in relation to the distinct features of LLs, whereas traditional methods have been researched extensively [27]. All in all, distinct attributes of LLs and advantages over other innovation approaches have been emphasised sufficiently [8, 9, 35, 37]. However, studies linking

[3] This paper uses the term "involvement" [as in 25, 30, 31], whereas the literature interchangeably employs the terms "participation" [as in 3, 26] and "integration" [as in 24]. However, it is not referred to committing oneself emotionally as in "commitment" or "dedication" [32].

methods applied to LLs to these attributes are sparse and tend to focus on NPSD phases [18, 41] or single methods [42, 43]. Consequently, this paper conducts a comprehensive analysis of methods and their characteristics. Accordingly, it is questioned:

(1) *Which methods are implemented in a living lab and how are they characterised according to the level of user involvement?*

User Involvement in a Living Lab. While involving users is only one factor among many that promote co-creation in a LL [19, 44], it is considered quintessential to the LL concept [12, 35]. In LLs, firms are often one stakeholder among many [45]. Hence distinguishing between stakeholders is required. Due to LL's roles as intermediaries in innovation, Piller, Ihl, and Vossen's [24] understanding of a *firm-user interaction* is altered to *intermediary-user interaction*. This adjustment seems appropriate because the co-creation process takes place *in* and *with* the LL, acting as an agent for the firm. Nevertheless, the firm is still considered to facilitate the co-creation process [24].

Regarding voluntary user involvement, many questions remain for future research [46]. A dearth of methods and tools adapted to the distinct attributes of LLs has been emphasised [27]. As a first step, methods applied in a LL are examined for the level of user involvement [28]. As a result, it is proposed to shift from user-centred to user-driven methods. However, Gray et al. [28] do not present further implications concerning the application of co-creation methods in LLs. To date, only few studies evaluate methods applied in LLs specifically in relation to user involvement as a distinct feature of LLs, while observed LLs cases vary widely [28, cf. 40, 41, 47]. Hence, the second research question of this paper is as follows:

(2) How does user involvement differ and how is it determined?

3 Research Design

A qualitative explorative approach in the form of a holistic single-case study is applied. To gain in-depth insights on co-creation methods and user involvement in LLs, qualitative case study research is a suitable methodology [48]. Further reason lies in the opportunity to illuminate contextual conditions and processes [48, 49]. The LL serving as unit of analysis of the present case providing a unique setting and the LL landscape being rather diverse [12, 50] further justifies a single-case design [48]. Hence, this paper focusses on an in-depth analysis rather than aspiring general claims [48].

3.1 The Case

The case study is implemented at JOSEPHS® – Die Service Manufaktur, a LL centrally situated in Nuremberg in southern Germany. Within its premises, which also include a coffee shop and a workshop area, the LL devotes an openly accessible area to five distinct co-creation spaces, used by five companies simultaneously. Six days a week during regular shopping hours, any passer-by is invited to come in; LL visitors await the opportunity to engage themselves interactively in firms' NPSD processes. Just as

LL visitors are expected to share their feedback, companies are advised to be equally open and cooperative. Firms can utilise JOSEPH's real life environment to test (physical and digital) ideas and prototypes under simulated conditions with a diverse, self-selected crowd of users. Since the LL's launch in 2014, users had been able to co-create about 60 diverse products and services at the LL. The firms utilising the LL come from a broad variety of backgrounds, ranging from start-ups in consumer products, to technology providers and larger enterprises even in business-to-business industries.

3.2 Data Collection and Analysis

This case study took place during summer 2016 and is based on primary data in the form of physical artefacts and seven semi-structured expert interviews as well as on secondary data from documentation material such as reports and photo documentation.

To utilise the expert's knowledge effectively and ensure comparability, an interview guide allowed open responses within a predefined field of interest [48, 51, 52]. All interviews were audio recorded, transcribed following the rules proposed by Misoch [52], and analysed using the qualitative data analysis software MAXQDA [49, 53]. The challenges of quality in interview data lie in potential biases, poor recall, or inaccurate articulation [48]. These are addressed through a diverse sampling of interview partners who occupy various perspectives and positions in three different organisations as well as through complementary data from documentation and artefacts [51].

While the interviews constitute the main and most important source of information, including documentation and artefacts both forms a reliable starting point for the case and allows to verify and contextualise interview data in a complementary way [48, 49]. Press releases, photo documentation and various publicity materials as well as internal documents by the LL are analysed. Due to the importance of context, physical artefacts such as the LL itself and objects within the LL are included in this case [54].

As part of the data analysis process, raw data from all three data sources was approached through open coding and iteratively complemented with existing literature [49, 51, 55]. Upon completion of the coding process, all codes, code segments and comments were exported from MAXQDA to Microsoft Excel for further analysis.

4 Empirical Findings

A range of applied methods is identified. The variety stems from a discrepancy in purpose, as shown in Table 1. Whereas one group of methods is utilised primarily to have the user answer specific questions, the other group of methods primarily aims to stimulate the user's experience in the LL. Ultimately, all methods serve the purpose of innovation research. While the former contribute directly to data collection, the latter do indirectly – complementing the former with beneficial LL-specific characteristics.

Methods of innovation research are threefold. Questioning methods of quantitative and qualitative nature as well as observational methods including technology-assisted tracking are applied. Some of these traditional innovation research methods such as questionnaires or voting mechanisms involve the user in a rather passive and theoretical way. In order to involve the user in a more active and practical way, a single co-creation space can be equipped with several complementary methods, as one expert phrased as follows: "*[If I] should test something, or tinker with something, then there is an active involvement which is what we want, but which can be achieved through [traditional] innovation research methods only then, if there is an app to try out, for instance.*"

Purpose	Innovation Research			Complementary
Type	Quantitative questioning	Qualitative questioning	Observing	
Methods	Price assessments, Questionnaires, Usability-tests (quantitative), Voting	Focus Groups, Interviews, Open feedback, Personas, Usability-tests (qualitative), Workshops	Observation and shadowing, Tracking	Artefacts, Storytelling, Information material, Toolkits, Prototypes, Prototyping, Service staging

Table 1: Characterisation of Applied Methods

The experts consider involving users actively as crucial, one stating that "*we try to involve the user as much as possible, so you would rarely see a yes-no-query as the only method, but rather as a supplement.*" It is also described as a prerequisite to generating data for innovation research. Furthermore, it does not only make it easier for users to give feedback but also increases their willingness to do so. Methods differ regarding the facilitation of active user involvement in methods, as Figure 1 illustrates.

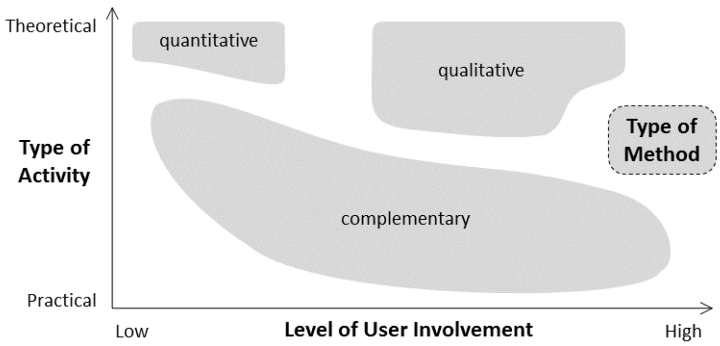

Figure 1: Differing User Involvement and Activity in Applied Methods

If considered individually, quantitative and qualitative methods of innovation research involve the user predominantly on a theoretical level. They require the user to answer questions, hence to think about a certain subject. Quantitative methods result in a low to medium level of user involvement in terms of activity and variety. Qualitative methods, on the other hand, rank substantially higher in user involvement. However, they are equally constrained to theoretical activities. Methods with beneficial LL characteristics may complement these innovation research methods. Examples include the provision of context and haptic experience in the case of physical artefacts, and testable prototypes with a high level of practical activity, as two experts explain: "*Whenever possible, we hand something over to the user […] if it is a physical thing or so*", because "*through mere haptic experiences, [the user] becomes more involved*".

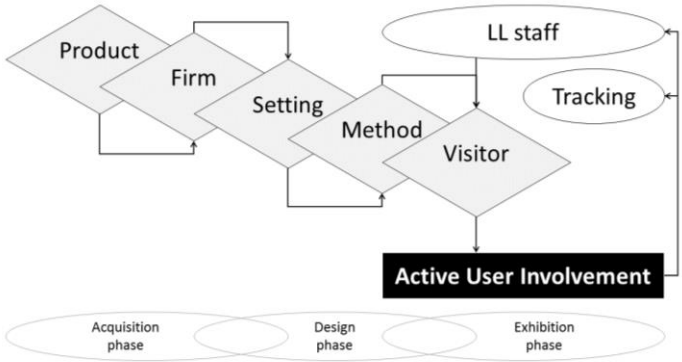

Figure 2: Factors and Conditions Determining Active User Involvement

Figure 2 outlines several factors, which are proposed to influence the emergence of active user involvement beforehand. In this model, each of the six factors product, firm, setting, method, LL staff, and users are dependent on all previous factors, with several conditions respectively as shown in Table 2.

Factor	Product	Firm	Setting	Method	User	LL staff
Conditions	Fit for co-creation, Functio-nality	Strategic fit, Willing-ness	Context/ artefacts, Appeal, No barriers	Facilitating activity	Type, Effort, Time, Motivation	Enabling/ motivating

Table 2: Factors Determining Active User Involvement

5 Discussion

Contributing to the discussion about method application and development for new methods in LLs [27, 40], this paper proposes a combinatorial approach. Several complementary methods lead to the desired outcome of data for innovation research in a more effective and more appropriate way than traditional innovation research methods on their own. Complementing methods can adapt to the distinct features of LLs and thus benefit traditional methods of innovation research through more richness and quality in data. These findings are in line with Tang and Hämäläinen [41] who argue that combining methods can lead to a better understanding of users.

A predominant use of traditional innovation research methods like interviews and surveys in LLs is observed, congruent with Tang and Hämäläinen [56]. However, it is frequently argued that ICT is underused in LLs [7, 9, 18, 41, 57, 58]. Use of ICT, however, could contribute to an improved realisation through shortening the feedback loop between users and corporate designers in iterative processes [58], enabling a true firm-user interaction beyond the intermediating LL. Equally, ICT could connect users with LLs when they are not on site. Either way, higher user involvement can be expected, as the level of activity would increase both time and effort spent.

While no systematic approach to using ICT was identified, general technology use as part of the co-creation process occurs at times. In line with previous authors, this study finds technologically sophisticated methods and tools being used infrequently besides mobile handsets for usability-tests. Counterexamples include a 'thumbs up'-voting mechanism using a Microsoft Kinect camera for gesture recognition and virtual reality (VR) applications using a Google Cardboard. Besides, tracking technology is implemented, which the user, however, is not concerned with as this is an unobtrusive way of collecting data [41]. Notably, it is found that technology use may also impede user involvement. If a lack in technology acceptance, unfamiliarity, or technical failure is present, this can keep users from becoming actively involved in the envisaged way.

This study proposes users as the chronologically last, thus deciding factor in involving themselves actively. Holding the position of a co-creating partner, LL visitors are entitled to both include and exclude themselves from the co-creation process whenever they want and without having to give reasons [59]. In an open LL, the idea of incentivising outsiders to become a LL visitor suggests itself at first sight. Dutilleul, Birrer, and Mensink [45] even ask if incentives are needed in order to attract and sustain a desired amount of LL visitors continuously. However, based on the principle of self-selection, this study argues that such mechanisms may distort results and question their validity. Previous studies find that material and financial rewards are not important to users [46] while importance is attached to the value that users experience in the course of co-creation [60]. Instead of giving financial incentives, it is proposed to improve on the co-creation space, particularly the appeal of its setting in order to provide an experience to LL visitors that is as much beneficial and pleasant as possible.

Managerial Implications

Implementing digital technology for an automated acquisition of implicit, behavioural data as well as explicit, articulated data would arguably not only support LL staff and let them focus on interpersonal communication but also accelerate the data analysis process, thus increasing efficiency. For example, a customised mobile handset that runs a digital content management system could record interviews, capture questionnaires, and aggregate contextual data (e.g. place, date, time, duration). Most importantly, LL staff needs to be provided with enough expertise in order to carry out semi-structured interviewing and other methods of qualitative innovation research.

In the design process of co-creative activities, a firm's requirements serve as the starting point and may imply certain methods. However, some firms have false expectations or request mostly quantitative methods. During communication with customer firms, it is advisable to follow a threefold strategy of selecting appropriate firms fitting the LL methodology, undertaking expectation management on the innovation research outcome, and consulting firms in order to utilise a LL's strengths.

Particularly in iterative or continuous NPSD processes in LL, the use of ICT may be of help. ICT could bridge the gap to a firm without the necessity of sending an employee physically to a LL. With an employee being available on call, all LL visitors had the chance to deepen their input. On the other hand, ICT are able to reach LL visitors before and after their physical co-creation engagement. For instance, a web interface could be a way for LL visitors to contribute even in hindsight. It does not seem too farfetched to assume that users might come up with new ideas after they left and had the opportunity to rethink their contribution, but also find their additional input not worth a second (physical) visit. In terms of a real life setting, storytelling proves beneficial for creating overall context. Combining ICT and the method of storytelling with augmented reality (AR), Snapchat, a story-based social media application, could fit LLs with changing themes quite well. Its contribution to user involvement in activity and variety is yet to be evaluated. However, it might be a way to involve younger users in particular.

6 Conclusion and Outlook

The first contribution of this paper is a review on methods that are applied in LLs. Characterising these, two primary purposes emerge. The first group of methods directly contributes to data collection for innovation research, while the second group contributes indirectly and primarily complements former methods with beneficial LL-specific characteristics in providing a real life setting and enabling user involvement.

The second contribution of this paper is a proposed model of six consecutive factors and several conditions that influence user involvement. It is proposed that these factors influence user involvement firstly in its emergence, and secondly in its intensity. If a factor allows user involvement at all, it further limits its maximum intensity that subsequent factors are able to draw on.

Concerning this study, several limitations apply. Firstly, the form of a holistic single-case study induces an in-depth analysis, which does not permit generalisation but requires comparison across multiple cases of LLs. Secondly, while this paper focuses on contributing to the intermediary perspective of LLs and is conceptualised accordingly, both the user and the firm perspective are not particularly addressed.

Exploring the field as a first step, this study indicates promising niches worth further quantitative research. Above all, the proposed model on factors influencing user involvement demands quantitative validation with proof of causal effects. Furthermore, future studies should ask whether combinations of methods with a higher level of user involvement result in superior validity or efficiency [35]. Here, studies should contribute with other perspectives than the intermediary's. As part of the firm, the rates of adoption for further development and profitability might contribute to the question which level of user involvement is considered ideal. Assuming a high level of active user involvement, it is of interest to know which kinds of firms benefit the most. Simulating and enhancing a real life setting, new technologies, such as AR and VR, seem promising. It should be evaluated if they are beneficial to the level of user involvement as well as to the co-creation process as a whole. Do these technologies lead to more motivation and willingness among LL visitors through improved experience and a higher perceived value? Although LLs differentiate themselves with their offline real life settings from Internet-based technologies, ICT usage within LLs is worth further research. While LLs utilise the Internet only rarely [35], the combination of online-offline methods could lead the way for the future of LLs. Finally, in providing *Co-Creation as a Service*, the intermediary perspective needs further research [14]. In line with Schweitzer, Gassmann, and Rau [31], it is argued that reciprocal effects of goal setting, chosen methods, and user involvement require further qualitative and quantitative modelling.

7 Acknowledgments

We thank all interview partners, the JOSEPHS team, and the anonymous reviewers for their valuable contributions to this research paper. The paper is part of current research projects funded by the Fraunhofer IIS-SCS within its "Service Innovation" initiative.

Abstract. Cloud certifications are a good means to assure users of high level of security and reliability of certified cloud services. However, cloud environments are highly dynamic due to the challenging cloud characteristics and fast technology life-cycles. We believe that current certifications fail to cope with an ever-changing cloud environment because assessments are based only on manual expert assessments and periodic spot checks. We argue that continuous service certification (CSC) is required to assure reliable and trustworthy cloud services. To understand and enhance CSC's rate of adoption, we examine the adoption process of CSC from the perspective of certification authorities by building on the Diffusion of Innovations theory and the Technology-Organization-Environment framework. Our findings reveal that the innovation's characteristics, organizational and environmental influences will affect the adoption of CSC by certification authorities. We advance the understanding of the CSC adoption process by providing a synthesis and discussion of important factors.

Keywords: Continuous Certification, Cloud Services, Diffusion of Innovations Theory, Technology-Organization-Environment Framework

1 Introduction

Several cloud service certifications have recently evolved and attempt to assure users of a high level of security, availability and legal compliance of the certified cloud service. Certifications aim to reduce cloud customers' concerns, increase trust as well as to enhance transparency in the cloud service markets. These cloud service markets have become increasingly popular because they offer a vast selection of IT services (e.g., online storage, office software and collaboration tools) that are instantly available and that can withstand unexpected fluctuations in demand for the service, e.g., quickly spin-

ning up new resources when demand increases. Certifications in general are well-recognized means for organizations to assess goods and services [1, 2], and their importance and number steadily increase in recent years [3].

Yet, current research has primarily focused on identifying and assessing the effectiveness of certifications at a given point in time, and thus they are essentially regarded as static snapshots of attributes of providers and their services [4–6]. However, cloud service environments are highly dynamic, resulting from challenging cloud computing characteristics (e.g., on-demand provisioning and entangled supply chains), fast technology life cycles and ongoing architectural changes [6–8]. Likewise, cloud services are faced with dynamically emerging environmental challenges and with changes in legal landscape which might threaten certification effectiveness and reliability in the medium to long term.

We believe that current certifications fail to cope with an ever-changing cloud environment because certification assessments are based only on static, manual expert assessments and periodic spot checks, and may not be actually valid for longer periods of time since certification. Therefore, we argue that continuous service certification (CSC) is required to assure reliable and trustworthy certifications and cloud services.

CSC is beneficial for cloud certification authorities, service providers and customers altogether [7, 8]: certification authorities can actively detect and investigate critical certification deviations as they occur, thus increasing certification reliability over today's approaches; cloud providers can constantly improve their cloud services by evaluating ongoing feedback from certification authority about their performance; and finally CSC can counteract customers' worries due to lack of control of cloud infrastructure by increasing the transparency of providers' operation. With increasing reliance of organizations on cloud service providers, the necessity for continuous reliable, trustworthy and meaningful certification gains importance. Yet, CSC remains currently underexplored, not well test marketed and evaluated only in trials, resulting in a low adoption rate by certification authorities [8].

To understand and enhance CSC's rate of adoption, and therefore ultimately pave the way for continuously reliable and secure cloud services, we examine the adoption process of CSC from the perspective of certification authorities by conducting a thorough literature search, and building on the Diffusion of Innovations theory [9] and the Technology-Organization-Environment framework [10, 11]. Our work helps to answer the research question: *What influences certification authorities to adopt CSC?*

Investigating how the characteristics of an innovation as well as organizational and environmental factors will affect CSC's rate of adoption can be of great value to understand and enhance actual adoption processes [9]. With this study, we advance the understanding of the CSC adoption process by providing a synthesis and discussion of relevant factors that influence adoption rate of certification authorities. In addition, we provide a theoretical model to be tested in future research for validation.

The paper proceeds as follows. We provide a background on cloud service certifications and highlight the need for CSC, followed by a brief presentation of our research approach. Thereafter, we discuss how the characteristics of CSC, organizational, environmental, risk and cost factors influence the adoption process. We then discuss our findings and conclude with directions for future research.

2 Theoretical Background

2.1 Cloud Service Certifications

Cloud computing offers ubiquitous, on-demand access to a shared pool of configurable IT resources (e.g., servers, storage and applications) that can be rapidly provisioned and released with minimal management effort or service provider interaction [12]. On the one hand, cloud services offer an attractive alternative to traditional IT usage for organizations, and on the other hand they challenge contemporary security and privacy risk assessment approaches. Therefore, cloud services face a broad range of risks including lack of accessibility, reliability and virtualization vulnerabilities, privacy and control issues as well as issues related to data integrity and segregation [13].

One widespread strategy to reduce customers' uncertainties is to adopt certifications, which is particularly important for small and medium-sized cloud providers [1]. A certification is defined as a third party attestation of products, processes, systems or persons that verifies the conformity to specified requirements [14]. During a certification process, independent and accredited auditors perform comprehensive, manual checks to test adherence according to a defined set of certification criteria. If a provider adheres to the specified requirements, the certification authority awards a formal written certificate. A variety of certifications has already been developed and market tested to signal that providers have adopted their standards and comply with their certification audits; these exist particularly in cloud markets (e.g., EuroCloud *'StarAudit'* and Cloud Security Alliance *'Security, Trust & Assurance Registry'*). Cloud service certifications typically consist of security, privacy and reliability requirements, and build on IT standards (e.g., ISO 27001, ISO 27017 and ITIL), and aim to ensure availability, integrity and confidentiality of cloud services for a validity period of one to three years [15].

2.2 The Need for Continuous Certification

Existing certifications represent only a retrospective look at the fulfillment of technical and organizational measures. Requirements of certifications may no longer be met throughout the validity period of the certification because cloud services are confronted with continuously emerging environmental dynamics. Especially, we refer to environmental dynamics that are difficult to predict, lead to an instability and create uncertainty for customers or providers [16]. The premise behind these assumptions is that external environments impact organizational performance, and organizations must take into account environmental characteristics and emerging dynamics when formulating strategies and structures as well as during daily operations. As such, inherent cloud computing characteristics, ongoing architectural changes, the emergence of environmental threats or changes in legal and regulatory landscape can be regarded as dynamics that might have an impact on actions taken by a provider. Certification reliability has to be re-evaluated over time if the assumptions under which a certification was awarded have changed. Consequently, we believe that CSC is required to assure continuously reliable and trustworthy certification and cloud services. CSC is a methodology that enables certification authorities to react and to adjust their certification reports simultaneously with the occurrence of events concerning the cloud service [6].

3 Research Approach

3.1 Literature Analysis

In this study, we focus on identifying factors that influence the adoption of CSC by certification authorities, and therefore conducted a thorough literature review. To find pertinent literature that deals with innovation adoption processes, we performed a search in the online database of EBSCOHost (Academic Search Complete and Business Source Complete). This search was executed on 15th March 2016 and was based on the following search string: *("Diffusion of Innovation*") AND (("Information System*") OR (IS))*, inspired by the Diffusion of Innovations theory [9]. The search was limited to title, abstract and keywords. Moreover, the results were reduced by applying the filters for only "peer-reviewed publications". This initial search revealed 81 potentially relevant articles, published from 1982 to 2015, which deal in different ways with the adoption or the diffusion of innovations. Some of these publications deal with innovations in general whereas others specifically refer to concrete innovations. By examining these articles, we determined 55 of them suggesting factors influencing the adoption of an innovation. Identified papers were read and factors impacting the adoption of an innovation were marked for further analysis, despite individual findings relating to the factors (i.e., regarding their empirical support) [17]; leading to 437 factors. As a lot of different factors were used in different articles, sometimes under different name, but we named them only once and noted their frequency of being mentioned, as this can be seen as an indicator of their importance. By this we reduced our list of factors to 258.

To further reduce this number of factors we carefully analyzed the used terms and their meaning. First, we identified synonyms, aggregated them into one factor and summed up the frequency of being mentioned for each of the synonymous terms. Second, we subsumed terms with similar meanings as for example *"competitors"*, *"competition"*, *"competitive advantage"*, and *"other industry players"* to *"competitive pressure"* and considered their total frequency of mention. Third, we excluded terms which, for example, refer to the adoption process itself rather than to factors influencing the adoption decision like *"earliness of adoption"*, and those terms which are referring to a concrete innovation, for example, *"website features"* and therefore cannot be transferred to CSC context. Finally, we carefully analyzed whether remaining factors are empirically supported and read research findings to ensure relevancy of factors. Based upon the remaining factors and on the frequency of being mentioned, we formed five groups of factors which have a major influence on the adoption of an innovation: *innovation's characteristics* (mentioned 124 times) including relative advantage, complexity, compatibility, observability and trialability; *organizational factors* (66) including organization, management and technology attributes; *individual factors* (49) including attitudes and skills; *environmental factors* (34) including the legal and regulatory landscape, market and competitive pressure; and finally *risks and costs* (16).

3.2 Theories of Factors Influencing the Adoption of Continuous Certification

The five groups of factors resulting from our literature analysis are in line with and can be assigned to two different theoretical models explaining the adoption of innovations: the Diffusion of Innovations theory (DOI) and the Technology-Organization-Environment (TOE) framework. The DOI theory was proposed by Everett M. Rogers [9] and focuses on why innovations – although having obvious advantages – are often very hesitantly adopted. A central concept of the DOI theory is the diffusion process, in which an innovation is communicated through certain channels, over time, among the members of a social system. Information about the innovation will be communicated during the diffusion process, which reduces uncertainty of potential adopters about the innovation itself, and finally leads to an adoption or rejection decision. An innovation is defined as an idea, practice or object that is perceived as new by an individual. The adoption rate is defined as the relative speed with which members of a social system adopt an innovation. While most research has concentrated on the adoption of innovations in regard to differences in their innovativeness, DOI theory examines the innovation itself, and how its characteristics affect its rate of adoption. DOI theory describes five main innovation characteristics: *relative advantage*, *compatibility*, *complexity*, *trialability* and *observability*. Literature shows that the DOI theory has a solid theoretical foundation and consistent empirical support (e.g., [18–20]). DOI theory focuses on the impact of innovation's characteristics, but acknowledges that the specific context, for example, the organization and her environment can influence the adoption rate as well [9, 21]. We integrate the TOE framework that serves as an important, additional theoretical perspective for studying such contextual factors [10, 11].

The TOE framework was developed by De Pietro, Wiarda and Fleischer [10], and is embedded into the research by Tornatzky and Fleischer [11] who describe the entire process of technological innovation, from the invention or development by engineers until the adoption and implementation by users within an organization. The TOE framework focuses on factors that influence the adoption and implementation of innovations in the context of an organization. It identifies three main contexts that influence the adoption of innovation: the technological, organizational and environmental context [10, 11]. The TOE framework has been used by researchers to examine the adoption of technological innovations, and has received ample empirical support (e.g., [20, 22, 23]).

To construct our theoretical model, we combined the DOI theory and the TOE framework by using the *innovation's characteristics* as representative factors for the *technological context.* In addition, we considered *organizational* factors, including both managerial and IT capabilities. We complemented them by *environmental factors* as well as the factor group '*risks and costs'* because they take a decisive influence with regard to the adoption of CSC (see Figure 1). We excluded the group of *'individual'* factors - although resulting from the literature research - because this study takes an organization level perspective. Finally, we excluded *trialability* as one of the innovation's characteristics because CSC cannot be tested easily beforehand as it affords high efforts and expenditures.

Figure 1. Factors influencing the adoption of CSC.

4 Theoretical Model of Factors and their Impact on the Adoption of Continuous Certification

In the following, we discuss identified factors in regard to the adoption of CSC by certification authorities, derive propositions about their impact and integrate them into a theoretical model.

Innovation's characteristics exert a great influence on the adoption of an innovation. Before an organization passes through the innovation-decision process, it seeks information in order to decrease uncertainty about the relative advantage of an innovation [9]. Such a *relative advantage,* which for example generates cost savings or offers the solution to an existing problem, can lead to the adoption of an innovation because it is perceived as better, more economic or expediently. Providing CSC services is beneficial for certification authorities because CSC increases their efficiency and reliability of issued certifications in particular.

In the context of traditional certification processes, adherence to certification requirements is observed by spot checks on a yearly basis only. Hence, certification deviations might be detected lately or hardly ever. In contrast, CSC allows the certification authority to actively detect critical defects as they occur. Hence, CSC can be considered as proactive and enables corrective actions as soon as a problem is detected. So CSC can improve reliability and trustworthiness of issued certifications. In addition, certification reports are more relevant to customer's decision makers. The change from yearly spot checks to CSC is often accompanied by the use of automated certification processes which enable certification authorities to test larger data samples and examine data in a faster and therefore more efficient way, compared to their manual predecessors. Finally, the certification authority might gain further benefits by offering innovative certification services for cloud customers and charging extra fees (e.g., enabling customers to validate requirement adherence on demand). While in traditional certification contexts a business relationship only exists between the cloud provider and the certification authority, CSC enables certification authorities to build up a direct relationship with cloud service customers, hence, creating new business models. Consequently, CSC provides significant relative advantages for certification authorities because it increases the efficiency and quality of certifications, enables new business models, and leads to continuously secure and reliable cloud services.

Proposition 1 (P1): Relative advantages foster the adoption of CSC by certification authorities.

The more *compatible* an innovation is perceived with sociocultural values and beliefs, the needs of potential adopters or with previous experiences the less uncertainty concerning the innovation is present; leading to a higher rate of adoption [9]. Certifications are well-recognized means for customers to assess goods and services [1]. Importance and number of independent third party product and service assessments steadily increase in recent years [3]. Yet, providers are threatened by a highly dynamic and ever-changing environment, and thus quickly respond to emerging environmental dynamics. With increasing reliance of customers on cloud services their demand for continuous, highly reliable and secure services gains importance. Consequently, it is necessary for the certification authority to continuously verify the conformity with certification requirements.

Previously introduced ideas and practices are a familiar standard against which the innovation can be interpreted [9]. Current certification practices are mostly based upon manual auditing operations, for example, performing interviews and manual security tests. The transition to CSC requires an automation of certification processes. The use of computer-based audit tools and technologies (CAATTs), which already aims at automating processes and facilitating the certification authority's work, could therefore promote this transition. Nonetheless, surveys reveal that CAATTs are not yet frequently and systematically used [24], although they are seen as useful and beneficial. We assume that CSC is compatible with the needs of relevant stakeholders and previously introduced ideas leading to a positive effect on the adoption.

P2: A high compatibility fosters the adoption of CSC by certification authorities.

The *complexity* of an innovation is measured by the degree to which the innovation is perceived as relatively difficult to understand and use [9]. The higher the complexity is, the greater is the uncertainty of potential adopters. Adopting CSC exhibits a high degree of complexity. Certification authorities must establish CSC and management systems to support the certification planning, management, operation and scheduling activities, develop new certification processes and train their employees. In order to reduce the complexity of the CSC, authorities can build on existing monitoring systems and processes of the provider to gather certification-relevant data [25]. For example, certification authorities might access an interface that enables the secure and reliable transmission of relevant data. Further on, the authority has not only to manage his own CSC operations, but also has to consider and align with providers' ongoing activities, which also increases the complexity of CSC. Consequently, the certification scope has to be adjusted individually for each cloud service, for example, in regard to available cloud systems, provider's organizational size, the number of employees as well as the level of technical knowledge and skills.

P3: A high complexity hampers the adoption of CSC by certification authorities.

The *observability* is the degree to which the innovation provides tangible results [9]. The higher the perceived observability of an innovation is, the more positively it affects the adoption rate. Performing CSC aims to increase transparency about cloud service operation and certification adherence. Results of CSC will be visible for the public, for example, by ongoing certification reports. In order to further increase the observability, CSC offers the means for a new generation of web assurance seals: dynamic, up-to-date, and accurate seals informing customers about the actual certification requirement adherence status. Creating a high transparency for cloud service customers promotes the observability of CSC and has a positive effect on its adoption rate. However, a high observability also places high burdens on the protection and anonymization of provided data to ensure data confidentiality, integrity and authenticity.

P4: A high observability fosters the adoption of CSC by certification authorities.

Organizational factors comprise features and characteristics of the organization, essential aspects of management as well as the extent and the level of use of technology; factors that influence the adoption of an innovation [10, 11]. An organization is characterized by its *age* and *size* among others. Since size represents several important aspects of an organization, such as slack resources, organizational structure and decision-making flexibility, it is a critical factor to influence innovation adoption [9]. In the IS literature different opinions exist regarding the role that size plays [20]. On the one hand, large and established authorities may be less flexible than smaller and younger organizations, might show less innovation readiness and rather insist on previously applied methods [20, 23]. But on the other hand, these authorities have access to profound experience and knowledge about certification processes and emerging innovations, and can build on more financial means and multifarious human and material resources in order to meet challenges posed by the adoption of innovations [9, 20]. We assume that certification authority's size and age will foster the adoption of the CSC because they generally possess slack resources and expertise to meet adoption challenges, including high initial investments and the redesign of certification business processes.

P5: The certification authority's size and age will foster the adoption of the CSC.

With respect to organization's *management*, its settings, policies and priorities in particular affect the adoption of innovations [10, 11]. Thus, for example, CSC adoption should be consistent with organizational objectives and strategy [21] and supported by the top management [26]. The top management should provide the vision, support and commitment around the innovation as well as commit resources and create the environment required for the adoption [27]. Thus, top management exerts a positive influence on the adoption of CSC.

P6: Management support fosters the adoption of CSC by certification authorities.

Further on, the certification authority's *technology competence* has an influence on the innovation adoption [10, 11, 20]. Technology competence refers to the technological characteristics available in the organization such as the IT infrastructure and IT professionals [23]. The IT infrastructure covers the installed technologies, systems and applications within the certification authority allowing an integration of CSC services and corresponding IT systems. IT professionals are the human resources with technical knowledge required to efficiently perform CSC. For example, if the existing IT infrastructure is highly developed and versatile, and supports the integration of new CSC components, adoption uncertainty is reduced and adoption rate increases.

P7: Technology competence fosters the adoption of CSC by certification authorities.

Environmental factors comprise environmental values and norms, customer and competitive pressures [10, 11]. The *environmental values and norms* can affect the adoption of CSC for example by changing or setting up new guidelines. If for example the validity period of cloud certificates is generally shortened, this prepares the transi-

tion to the CSC and could ultimately effect that certification authorities are only accredited when awarding their certificates based on CSC. Also the government can contribute to the adoption of CSC when well-reputed government institutions highlight the use of CSC as an effective way to increase the security and reliability of cloud services.
P8: The values and norms foster the adoption of CSC by certification authorities.

Cloud customer pressure can exert great influence on the adoption of CSC [9–11]. Certification authorities might start adopting CSC, for example, if an ever-increasing amount of (potential) cloud customers demands reliable certifications in modern, turbulent environments. In the future, customers might decide whether to use a cloud service or not, based on providers' willingness to be continuously certified. Consequently, customer pressure is assumed to be of great influence on the adoption of CSC.
P9: Customer pressure fosters adoption of CSC by certification authorities.

Certification authorities compete for certification requests. *Competitive pressure* also acts as a facilitator influencing the adoption of CSC. Either the incentive of first mover competitive advantages or the urgency to keep up with competitors will provide the focus and purpose to successfully overcome obstacles and resistance to innovation adoption within an organization [21, 28]. Likewise, innovation imposition strategies by providers and partners might foster adoption rate of CSC, for example, if cloud providers tend to engage only with certification authorities that apply CSC in order to fulfill the demands of their cloud customers. Subsequently, competitive pressure might force certification authorities to open up for CSC and to create necessary conditions for adoption.
P10: Competitive pressure fosters the adoption of CSC by certification authorities.

Risk and cost factors are referring to possible disadvantages or dangers, and to expenses, which may affect the adoption of an innovation. In general, risks and costs represent multi-dimensional constructs that need to be viewed from different angles and analyzed in detail. For example, various security and privacy risks might emerge that impact certification authorities' adoption intention differently. CSC implies the transmission and storage of data about the cloud service at the site of the certification authority. Subsequently, certification authorities are becoming a valuable target of attackers from the outside. Hence, this involves high risks of data theft, leads to significantly higher demands on data security and data protection, and may hamper the adoption.
P11: Risks hamper the adoption of CSC by certification authorities.

CSC of cloud services usually goes with automation of processes which on the one hand affords high expenditures for purchasing the technical equipment and a high amount of running costs for the operation and maintenance. On the other hand, an automation of processes might lead to (mid-term) cost savings.
P12: Costs influence the adoption of CSC by certification authorities.

Figure 2 depicts our theoretical model and summarizes identified factors and their impact on the adoption intention of CSC by certification authorities. Adoption intention refers to the probability that an organization will adopt CSC processes, set up required IT infrastructures, and provide CSC services for cloud providers.

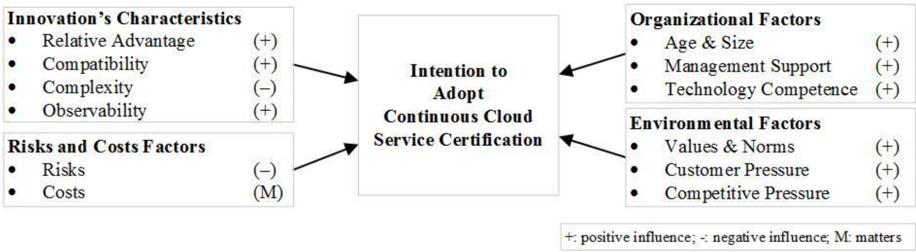

Figure 2. Theoretical model of CSC adoption by certification authorities.

5 Discussion and Conclusion

Based on a literature analysis, we developed a theoretical model by integrating the DOI theory and the TOE framework complemented by risk and cost factors to examine which factors influence the adoption of continuous cloud service certification. Thereby, we are able to analyze the adoption of an innovation from two different perspectives: the innovation itself with its characteristics and the surrounding organizational and environmental contexts. This study shows that many factors have an important impact on the adoption of CSC. We believe that the multifarious relative advantages of CSC and a high degree of observability will strongly motivate certification authorities to adopt CSC. On the other hand, a limited compatibility and a high complexity might hamper adoption. In regard to organizational factors, top management support and a high technical competence will positively influence the adoption of CSC. As environmental factors, customer and competitive pressures are of great importance when adopting CSC of cloud services. At last, risks and costs are relevant inhibitors for the adoption of CSC.

The identified and discussed factors have been considered separately, but some are closely related to each other, which might result in moderating effects on the adoption intention. First, relative advantages of CSC – due to a high observability of CSC results – are visible for both cloud customers and competitors, and thus they can lead to an increase of customer and competitive pressure as environmental factors. Second, a high technological competence, for example, due to the existence of a well-equipped IT department with well-trained specialists, reduces the complexity of CSC as well as increases innovation's compatibility. Finally, a close interrelationship between environmental pressures as well as perceived relative advantages, and top management support is apparent because they influence the strategy of an organization and actions that are preferred by the management.

With this study, we provide a two-fold contribution for research and practice. First, we advance the understanding of the CSC adoption process by providing a synthesis and discussion of relevant factors that influence adoption rate from a DOI and TOE perspective. Investigating how the attributes of an innovation affect its rate of adoption can be of great value to change agents seeking to predict the reactions to an innovation, and perhaps to modify certain of these reactions by the way they name and position an innovation [9]. Finally, we provide a theoretical model to be tested in future research to validate our assumptions, and to enhance the adoption process.

Nevertheless, this study has some limitations. Our discussion of the factors is based on literature analysis and theoretical reasoning research only since at the current diffusion state only a minority of certification authorities have started to deal with CSC adoption. However, we are currently working on a quantitative study to analyze to what extent the discussed factors influence CSC adoption. Within this study we focused on the adoption of CSC of cloud services by certification authorities, hence our theoretical model might be limited in regard to the context of cloud services as well as for the certification authorities as stakeholder. Finally, we neglected factors of individual adopters (i.e., managers) which might be of great importance in the actual adoption decision process.

"Last, […] an innovation's rate of adoption is affected by the extent of change agents' promotion efforts" [9]. On this account, we want to encourage researchers and practitioners with this study to participate in adopting and diffusing CSC.

Das Business Model House of Quality: Bewertung plattformbasierter Geschäftsmodelle mit Quality Function Deployment

Felix Schönhofen[1] and Sixten Schockert[1]

[1] University of Stuttgart, Chair of Information Systems II, Stuttgart, Germany
{schoenhofen,schockert}@wius.bwi.uni-stuttgart.de

Abstract. Companies in the IT industry are exposed to permanent change. These changes relate in particular to emerging markets and business models. To ensure the company's long-term success, their business models have to be evaluated continuously. Due to the high amount of different stakeholders in multisided markets, this challenge becomes even greater for companies which business models are based on multisided platforms. The following paper shows the possibility to evaluate business models in multisided markets using Quality Function Deployment (QFD). In cooperation with companies in the sharing economy QFD workshops were held to reach this goal and to evaluate the QFD approach to examine business models in multisided markets.

Keywords: Business Models, Platforms, Quality Function Deployment, Requirements, Multisided Markets

1 Motivation

Der fortschreitende Trend der Digitalisierung stellt einerseits große Herausforderungen an Unternehmen, verspricht andererseits aber auch Potenzial für die Entwicklung neuartiger Geschäftsmodelle [1]. Eine Reihe bekannter Neugründungen wie Uber, Car2go und Airbnb haben dies in den letzten Jahren erfolgreich ausnutzen können [2].

Diesen Unternehmen ist gemein, dass der Kern ihres Geschäftsmodells der Ausgangspunkt eines sogenannten Wertschöpfungsnetzwerks ist [3]. Ihr Produkt ist entsprechend eine Plattform, die einer größeren Bandbreite an Kundenanforderungen begegnen kann, als es dem Produkt eines einzelnen Anbieters möglich wäre [4].

Den genannten positiven Beispielen steht jedoch eine deutlich größere Anzahl gescheiterter Startups gegenüber [5]. Häufig sind eine fehlende Marktnachfrage und ein unvollständiges oder gar fehlendes Geschäftsmodell Grund für den Misserfolg [6]. Offensichtlich ist neben der richtigen Produktidee die Erarbeitung eines tragfähigen Geschäftsmodells eine wichtige Voraussetzung für einen erfolgreichen Markteintritt.

Die Auswirkungen des dynamischen Umfelds in dem die Unternehmen agieren, der hohe Grad an Unsicherheit aufgrund der Neuartigkeit der Produkte und Dienstleistungen sowie der Einfluss der Informations- und Kommunikationstechnik auf die Geschäftsmodelle erfordert von den Unternehmen darüber hinaus die Fähigkeit, sich

February 12-15, 2017, St. Gallen, Switzerland

Schönhofen, F.; Schockert, S. (2017): Das Business Model House of Quality: Bewertung plattformbasierter Geschäftsmodelle mit Quality Function Deployment, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1477-1488

schnell an ändernde Umgebungen anpassen zu können [7-8]. Hierfür ist allerdings eine Bewertung, ob und in welcher Ausprägung Änderungsbedarf besteht unerlässlich.

Im vorliegenden Beitrag soll ein Verfahren vorgeschlagen werden, wie plattformbasierte Geschäftsmodelle untersucht und hinsichtlich möglicher Schwachstellen bewertet werden können. Die Grundidee dabei ist, dass die konkreten Ausgestaltungen eines plattformbasierten Geschäftsmodells nicht zufällig gewählt werden, sondern begründet sind, d. h. die Ausprägungen der Merkmale eines plattformbasierten Geschäftsmodells beruhen auf möglichen Anforderungen an eben dieses Geschäftsmodell. Diese Zweck-Mittel-Beziehungen werden in diesem Beitrag mittels der ursprünglich für Produkt(weiter)entwicklungen verwendeten Methode Quality Function Deployment (QFD) dargestellt und ermittelt [17], [24]. QFD eignet sich dafür in besonderen Maße, da es zum einen mit seinen methodischen Merkmalen überall dort anwendbar ist, wo gemeinschaftlich in einem Team Lösungen zu bestimmten Problemen bzw. Antworten auf Anforderungen gesucht werden. Zum anderen trennt QFD analytisch konsequent zwischen Anforderungen und möglichen Lösungen und schafft so das Potential für die Gestaltung von alternativen, besseren Lösungen [17].

Entsprechend sollen die folgenden Fragen beantwortet werden:

Tabelle 1. Untersuchungsziele des Beitrags

Forschungsfragen
1. Welche Merkmale weisen plattformbasierte Geschäftsmodelle auf?
2. Was sind Anforderungen an plattformbasierte Geschäftsmodelle?
3. Wie kann ein Vorgehensmodell zur Bewertung plattformbasierter Geschäftsmodelle auf Basis von QFD gestaltet sein?

Zur Beantwortung dieser Fragen folgt dieser Beitrag grundsätzlich dem gestaltungsorientierten Forschungsansatz gemäß des Design Science Ansatzes [25]. Der Aufbau des Beitrags folgt entsprechend dem Publication Schema für Design Science Research von Gregor und Hevner [26].

2 Stand der Forschung

Seit den 1990er Jahren findet der Begriff Geschäftsmodell in der Öffentlichkeit zunehmend Beachtung und wird sowohl in Wissenschaft als auch Praxis häufig verwendet [9-10]. Trotz dieser Verbreitung existiert bis heute keine einheitliche bzw. allgemein akzeptierte Definition dieses Begriffes [11].

Eine häufig identifizierte Gemeinsamkeit der unterschiedlichen Definitionen ist die Position des Geschäftsmodells als Intermediär zwischen der Ebene der Geschäftsprozesse und der Unternehmensstrategie [1], [12-13]. Eine entsprechende Definition stammt von Al-Debei et al.: „A business model is a conceptual tool that contains a set of elements and their relationships and allows expressing a company's logic of earning money. It is a description of the value a company offers to one or several segments of customers and the architecture of the firm and its network of partners for creating, marketing and delivering this value and relationship capital, in order to generate profitable and sustainable revenue streams.“ [13].

In dem vorliegenden Beitrag sollen insbesondere solche Geschäftsmodelle betrachtet werden, die Ausgangspunkt eines Wertschöpfungsnetzwerkes sind. Solche Ausgangspunkte können sogenannte Plattformen gemäß der Definition von Branchenplattformen nach Gawer sein: Diese Plattformen umfassen alle Akteure, die innerhalb einer Branche zusammenarbeiten: Der Anbieter der Plattform muss zum Ziel haben nicht nur von den eigenen, sondern auch von komplementären Innovationen zu profitieren. Die Komplementoren selbst müssen versuchen von indirekten und direkten Netzeffekten zu profitieren [14]. Direkte Netzeffekte bezeichnen die positive Korrelation aus dem Nutzen den der einzelne Akteur aus dem Netzwerk zieht und der Gesamtzahl der Akteure. Die Indirekten werden durch die Größe der jeweilig anderen Marktseite bestimmt: Eine größere Anzahl an auf der Plattform versammelten Endkunden verspricht für die Komplementoren einen größeren Markt und vergrößert entsprechend den Anreiz Komplemente zu entwickeln. Umgekehrt bedeutet eine größere Zahl an Komplementen eine höhere Attraktivität der Plattform für die Endkunden [3], [8].

Aus diesen Zusammenhängen konstituiert sich die Grundherausforderung bei der Etablierung eines plattformbasierten Geschäftsmodells. Es muss eine Lösung für das sogenannte Henne-Ei-Problem gefunden werden: Ohne eine bedeutende Zahl an Endkunden, werden die Komplementoren der Plattform fernbleiben und umgekehrt [15]. Die Bedeutung dieses Kernproblems lässt sich an bekannten Beispielen wie BlackBerry beobachten.

Weitere Herausforderungen treten ein, wenn das Henne-Ei-Problem gelöst ist: Die eigentlich kooperierenden Akteure innerhalb des Netzwerkes können gleichzeitig in Konkurrenz zueinanderstehen. In der Literatur hat sich für diese Problematik der Begriff Koopkurrenz durchgesetzt [16]. Im Beispiel eines Vermittlers von Fahrgemeinschaften wird das Problem offensichtlich: Aufgrund der indirekten Netzeffekte profitiert der Anbieter einer Fahrt von einer hohen Zahl an anderen Fahrtanbietern und einem entsprechend hohen Angebot an Fahrten auf der Plattform. Allerdings erhöht eine hohe Zahl an Fahrtanbietern auch die Wahrscheinlichkeit, dass Fahrten angeboten werden, die in direkter Konkurrenz zu seinem eigenen Fahrtangebot stehen. Für den einzelnen Anbieter entsteht so die Konstellation, dass er gleichzeitig von den anderen Anbietern profitiert und mit ihnen konkurriert.

Beide Herausforderungen rechtfertigen so eine gezielte Betrachtung von diesen Geschäftsmodellen in mehrseitigen Märkten, die in diesem Beitrag mit plattformbasierten Geschäftsmodellen bezeichnet wird.

3 Untersuchungsdesign

Im folgenden Kapitel wird dargestellt, wie Anforderungen an plattformbasierte Geschäftsmodelle ausgehend von bestehenden Geschäftsmodellmerkmalen erarbeitet werden können. Hiermit sollen die Forschungsfragen 1 und 2 adressiert werden.

3.1 Quality Function Deployment

Im Rahmen der methodischen Produktentwicklung hat sich die Methode *Quality Function Deployment* (QFD) seit den 1960er Jahren bewährt [17], [24]. QFD wird definiert als „[....] method for structured product planning and development, that enables a development team to specify clearly the customer's wants and needs, and then to evaluate each proposed product or service capability systematically in terms of its impact on meeting those needs". Die zugrundeliegenden methodischen Merkmale von QFD lassen allerdings eine Anwendung auch auf andere Disziplinen zu [18]. Diese Vielseitigkeit ermöglicht es, QFD auch als Methode zur Bewertung plattformbasierter Geschäftsmodelle zu nutzen.

Als Vorteile wird von Herzwurm et al. unter anderem die Schaffung einer hohen Kundenzufriedenheit genannt, da sich die Entwicklungsvorgaben an den tatsächlichen Kundenbedürfnissen orientieren. Mit *Kunden* sind hierbei jedoch nicht (nur) die Kunden im Sinne möglichen Käufer eines Produktes gemeint, sondern alle Akteure (Stakeholder), die ein Interesse an dem zu entwickelnden Objekt haben [17]. In diesem Gedanken findet sich auch die Möglichkeit zur Anwendung von QFD für Geschäftsmodelle wieder: Auch wenn es sich bei einem Geschäftsmodell nicht um ein konkretes Produkt handelt, gibt es dennoch Stakeholder, die ein Interesse an einer möglichst erfolgsversprechenden Ausgestaltung haben.

Eines der charakteristischen Grundmerkmale von QFD ist die „explizite Trennung von Anforderungen und Lösungen", weiterhin sollen priorisierte Ziele formuliert und entlang des gesamten Entwicklungsprozesses verfolgt werden. Die genannten Anforderungen und Lösungen werden im sogenannten *House of Quality* (HoQ, siehe Abbildung 1) dargestellt. Neben den Anforderungen (*WAS*) und den Maßnahmen zur Anforderungserfüllung (*WIE*) enthält das HoQ die Korrelationen zwischen *WAS* und *WIE* [17]. Das grau hinterlegte „Dach" des HoQ wird in diesem Beitrag nicht betrachtet, bietet aber Anknüpfungspunkte für weitere Untersuchungen, siehe dazu Kapitel 5.

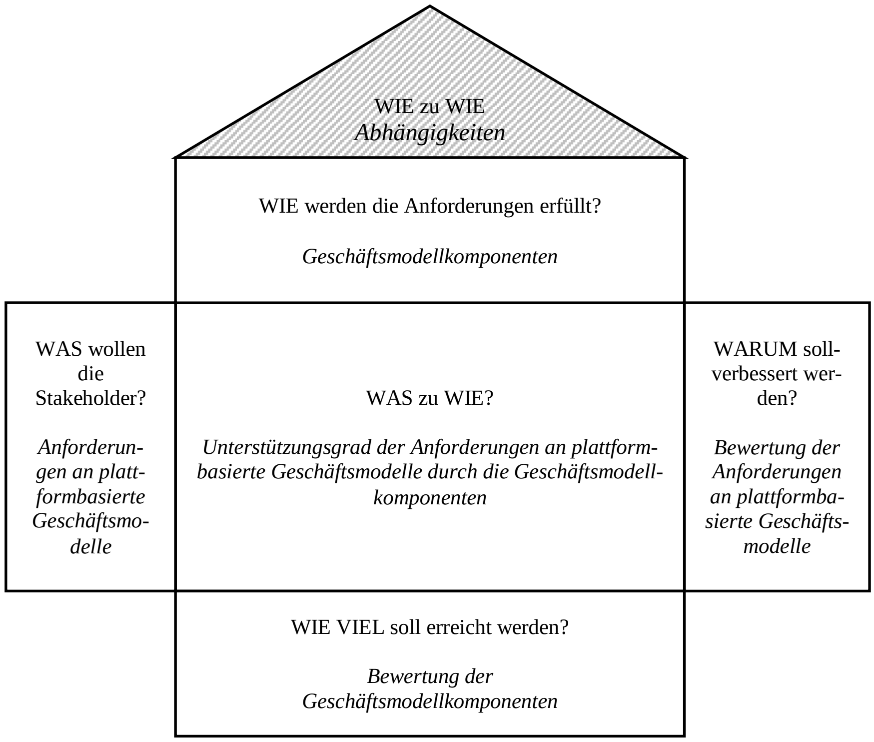

Abbildung 1. House of Quality plattformbasierter Geschäftsmodelle [17-18]

Grundidee ist, dass die Anforderungen mit den Lösungen auf eine bestimmte Art und Weise verknüpft sein müssen: Lösungen denen keine Anforderungen gegenüberstehen wären – eine korrekte und vollständige Exploration der Anforderungen vorausgesetzt – überflüssig oder würden zumindest keinen Beitrag zur Erhöhung der Kundenzufriedenheit beitragen. Umgekehrt und auf die Untersuchung von Geschäftsmodellen adaptiert bedeutet dies Folgendes: Weist ein Geschäftsmodell bestimmte Merkmale auf, muss es hierfür Gründe bzw. Anforderungen geben, die den das Geschäftsmodell erstellenden Akteur dazu veranlasst haben, dieses Merkmal zu berücksichtigen. Die Frage nach diesen Gründen könnte Hinweise auf die Anforderungen geben.

3.2 Vorgehen zur Identifikation der Anforderungen

Dieser Zusammenhang soll im Folgenden genutzt werden, um Anforderungen an plattformbasierte Geschäftsmodelle zu identifizieren. Die Erarbeitung dieser erfolgte in zwei Workshops in Zusammenarbeit mit Unternehmen aus dem Bereich der Sharing Economy, da hier die Vermittlungsleistung häufig im Vordergrund steht und entsprechende Plattformen häufig Kernbestandteil der Geschäftsmodelle von Unternehmen sind [19].

Mit Hilfe der sogenannten *Business Model Canvas* von Osterwalder und Pigneur [20] wurden während der Workshops Vertreter der Unternehmen nach der Ausgestaltung ihrer Geschäftsmodelle gefragt. Die Einteilung eines Geschäftsmodells in neun Kategorien wurde gewählt, da dieses Framework einen hohen Bekanntheitsgrad bei den untersuchten Unternehmen aufweist und entsprechend geringerer Erläuterungsbedarf bestanden hat [21]. Im Anschluss an diesen ersten Schritt wurden in einer moderierten Gruppendiskussion die Gründe für die jeweilige Ausgestaltung der Geschäftsmodellkomponenten erfragt und die Ergebnisse dokumentiert. Entsprechend der obigen Logik konnten dann in der Nachbereitung aus diesen Gründen Anforderungen an plattformbasierte Geschäftsmodelle extrahiert werden.

Mit diesem Schritt ist die erste Iteration des Vorgehens abgeschlossen. Die erarbeiteten Anforderungen dienen dann als Ausgangspunkt für die folgenden Workshopiterationen mit weiteren Unternehmen: Die Anforderungen werden gemäß Abbildung 1 als Anforderungen in das House of Quality eingetragen und können so den Geschäftsmodellmerkmalen der weiteren Workshoppartner gegenübergestellt werden. Der Unterstützungsgrad der Anforderungen durch die Geschäftsmodellkomponenten wird in der HoQ-Korrelationsmatrix folgendermaßen festgelegt [17-18]:

- 0: Geschäftsmodellmerkmal leistet keinen Beitrag zur Erfüllung der Anforderung
- 3: Geschäftsmodellmerkmal leistet schwachen Beitrag zur Erfüllung der Anforderung
- 9: Geschäftsmodellmerkmal leistet starken Beitrag zur Erfüllung der Anforderung

Ist dieser Vorgang abgeschlossen, kann die Korrelationsmatrix analysiert werden. Von Interesse ist hier insbesondere die Frage, ob sich sogenannte *schwache Zeilen* oder *Spalten* ergeben. Hiermit sind Zeilen/Spalten gemeint, die durchgängig niedrige Korrelationen aufweisen (also überwiegend den Wert 0 und nur wenige den Wert 3 enthalten). Eine solche schwache Zeile bedeutet, dass keines der Geschäftsmodellmerkmale (bzw. Ausprägungen von diesen) einen starken Beitrag zur Erfüllung der in dieser Zeile liegenden Anforderung leistet. Weiteren Aufschluss über die unterschiedliche Bewertung von Kundenanforderungen gibt das sogenannte *Kano-Modell zur Kundenzufriedenheitsmessung* [22]. Dementsprechend existieren Merkmale, die der Kunde nicht explizit verlangt, die bei Nichterfüllung allerdings Unzufriedenheit erzeugen (*Basismerkmale*). Merkmale, die der Kunde nicht verlangt, die allerdings bei Erfüllung die Zufriedenheit erhöhen und bei Nichterfüllung keine Unzufriedenheit auslösen, werden als *Begeisterungsmerkmale* bezeichnet. Merkmale, die bei Erfüllung Zufriedenheit und bei Nichterfüllung Unzufriedenheit auslösen, werden *Leistungsmerkmale* genannt. Diese Erkenntnis kann bei der Erarbeitung von Anforderungen über die Abfrage von Gründen für die Ausgestaltung des Geschäftsmodells von Bedeutung sein: Basis- und Begeisterungsmerkmale können Lösungen sein, zu denen (fehlerhafterweise) keine explizite Anforderung formuliert wurden [22].

Entsprechend diesem Modell können mögliche Gründe für eine solche schwache Zeile sein:

1. Die Anforderung ist von den Stakeholdern niedrig priorisiert und entsprechend werden keine Ressourcen für die Erfüllung dieser Anforderung verwendet.

2. Das verwendete Framework der Geschäftsmodelleinteilung weist eine Lücke auf.
3. Die Ausprägung der Geschäftsmodelle löst die Anforderung unzureichend.

Eine schwache Spalte bedeutet analog, dass das Geschäftsmodell Lösungsmerkmale aufweist, denen keine Anforderung gegenübersteht. Gründe hierfür können sein:

4. Es handelt sich um ein Begeisterungsmerkmal, nach dem die Stakeholder nicht explizit fragen.
5. Es handelt sich um ein Basismerkmal, nach dem die Stakeholder nicht explizit fragen.
6. Die vom betrachteten Lösungsmerkmal adressierte Anforderung wurde bisher noch nicht identifiziert.
7. Das Lösungsmerkmal ist überflüssig.

Hinweise auf den zutreffenden Grund kann die Priorisierung der Anforderungen und die Bewertung der Lösungsmerkmale bieten. Hierzu werden die bis zu diesem Zeitpunkt erarbeiteten Anforderungen und Geschäftsmodellmerkmale stakeholderspezifisch priorisiert. Dies kann über eine weitere Befragung der Workshopteilnehmer realisiert werden. Aufgrund der überschaubaren Anzahl an Anforderungen kann hier der paarweise Vergleich genutzt werden. Die Ergebnisse der Priorisierung werden im Anschluss in das HoQ eingetragen und können dann folgendermaßen zur Untersuchung genutzt werden [17]:

- Ist die Anforderung durch mindestens eine Stakeholdergruppe nicht niedrig priorisiert, kann 1. nicht zutreffen und 2. und 3. sind mögliche Gründe.
- Ist entsprechend ein Lösungsmerkmal nicht niedrig bewertet, aber trotzdem Ausgangspunkt einer schwachen Spalte, kann das ein Hinweis auf 6. sein, möglicherweise aufgrund von 4. oder 5.
- Entsprechend kann ein niedrig bewertetes Lösungsmerkmal in schwacher Spalte auf das Vorliegen von 7. hindeuten.

Sollten sich Hinweise auf 2., 3. oder 6. andeuten, wird damit die Notwendigkeit eines weiteren Workshops evident. Dieser verläuft analog mit dem ersten, wird allerdings am Ende um einen Vergleich der im letzten Workshop (oder im Falle mehrerer, aller bis dahin durchgeführten) erzielten Artefakte erweitert. Dieser Vergleich kann zu weiterem Informationsgewinn führen und bereits bei der Anforderungserhebung für die Experten zu einem Wissensgewinn führen.

Nach einer bestimmten Anzahl an Workshopiterationen wird die Untersuchung beendet. Der Zeitpunkt dieses Abbruchs bemisst sich am Grenzinformationsgewinn, der ein gewisses Limit unterschreitet (also keinem Vorliegen mehr der o.g. Punkte 2., 3. oder 6.).

3.3 Merkmale plattformbasierter Geschäftsmodelle

Die bereits erwähnte Business Model Canvas diente während der Workshops als Ausgangspunkt für die Erarbeitung der gesuchten Anforderungen. Im Vergleich zu den in diesem Framework vorgeschlagenen neun Komponenten umfasst der während der

Workshops erarbeitete Merkmalskatalog für plattformbasierte Geschäftsmodelle elf Komponenten. Die zusätzlichen Komponenten beziehen sich auf die Integration der komplementären Anbieter. Auf die Komponente *Kostenstruktur* wurde aufgrund der zu erwartenden tautologischen Zusammenhänge mit den Anforderungen verzichtet.

Tabelle 2: Merkmale plattformbasierter Geschäftsmodelle [20]

Nr.	*Merkmale plattformbasierter Geschäftsmodelle*
M1	Wertangebote
M2	Kundensegmente
M3	Kanäle zu Partnern
M4	Kanäle zu Kunden
M5	Kommunikation zu Stakeholdern
M6	Beziehung zu Kunden
M7	Beziehung zu Partnern
M8	Schlüsselaktivitäten
M9	Schlüsselressourcen
M10	Schlüsselpartner
M11	Einnahmequellen

3.4 Anforderungen an plattformbasierte Geschäftsmodelle

Die Ergebnisse der Anforderungsgenerierung auf Basis des vorgestellten Vorgehensmodells mit zwei Unternehmen aus dem Bereich der Sharing Economy ist in nachfolgender Tabelle 3 dargestellt. Die erarbeiteten Anforderungen werden mit A1-9 bezeichnet.

Tabelle 3. Anforderungen an plattformbasierte Geschäftsmodelle

Nr.	*Anforderung*
A1	Vertrauen in Problemlösungskompetenz schaffen
A2	Attraktivität für Multiplikatoren gewährleisten
A3	Vertrauen in andere Stakeholder schaffen
A4	Asymmetrische Marktentwicklung gewährleisten
A5	Schutz der Intermediärfunktion der Plattform gewährleisten
A6	Positive Wahrnehmung der Stakeholder durch Teilhabe am Plattformökosystem erzeugen
A7	Zuverlässigkeit gewährleisten
A8	Verfügbarkeit geeigneter personeller und materieller Ressourcen gewährleisten
A9	Potenzial zur Generierung regelmäßiger und planbarer Einnahmen gewährleisten

Dieser Anforderungskatalog dient als Ausgangspunkt für das im Folgenden vorgestellte Vorgehensmodell zur Bewertung plattformbasierter Geschäftsmodelle (Forschungsfrage 3).

4 Vorgehensmodell zur Bewertung von Geschäftsmodellen

Auf Basis der erarbeiteten Anforderungen an plattformbasierte Geschäftsmodelle sollen ebensolche Geschäftsmodelle künftig auf mögliches Verbesserungspotenzial hin untersucht werden können. Abbildung 2 stellt den Ablauf eines solchen Workshops graphisch dar. Das Modell entspricht im Wesentlichen einer Umkehrung des in Kapitel 3.2 erläuterten Modells zur Generierung von Anforderungen und folgt grob dem Aufbau eines klassischen QFD Workshops. Nachfolgend werden die einzelnen Schritte näher erläutert.

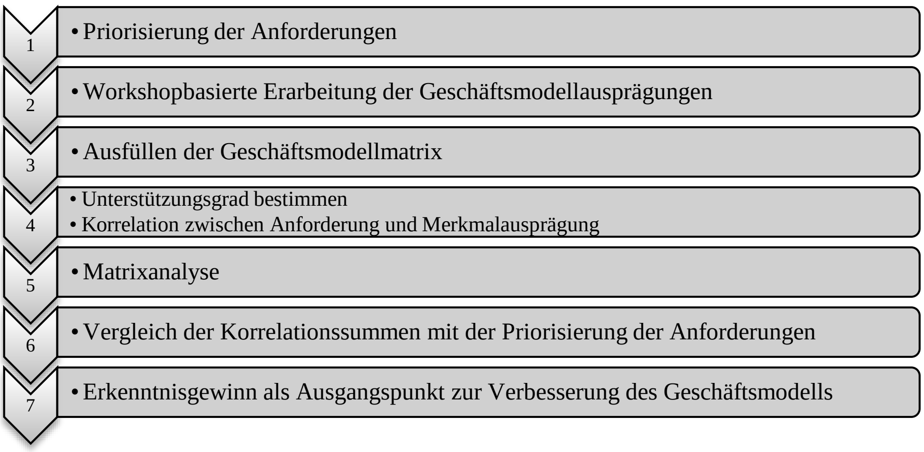

Abbildung 2. Vorgehensmodell zur Bewertung plattformbasierter Geschäftsmodelle

Da zu erwarten ist, dass sich die zu untersuchenden Geschäftsmodelle und das Unternehmensumfeld für das sie erarbeitet werden stark unterscheiden, ist entsprechend auch davon auszugehen, dass die Anforderungen an diese Geschäftsmodelle unterschiedlich bedeutend sein werden. Aus diesem Grund soll der Anforderungskatalog zunächst durch die Autoren des Geschäftsmodells priorisiert werden (Schritt 1). Dies kann einerseits dazu beitragen, dass sich die Workshopteilnehmer mit den Anforderungen auseinandersetzen, andererseits kann die Priorisierung in einem späteren Schritt zur Analyse der Geschäftsmodellmatrix genutzt werden. Im Anschluss sollen die Ausprägungen des Geschäftsmodells erarbeitet werden (Schritt 2). Dies kann workshopbasiert, beispielsweise mithilfe der Business Model Canvas oder den in Kapitel 3.3 vorgeschlagenen Geschäftsmodellmerkmalen geschehen. Die Ergebnisse sollen in Schritt 3 in die Geschäftsmodellmatrix eingetragen werden.

Nachfolgend soll der Unterstützungsgrad der Anforderungen durch die in Schritt 2 erarbeiteten Geschäftsmodellausprägungen diskutiert und mit den Werten 0, 3 und 9 bewertet werden (Schritt 4). In Schritt 5 soll die Matrix auf schwach gelöste Zeilen, also unzureichend gelöste Anforderungen, untersucht werden (siehe Kapitel 3.2). Mithilfe der in Schritt 1 erarbeiteten Priorisierungen der Anforderungen soll in Schritt 6 überprüft werden, ob die Merkmalsausprägungen des Geschäftsmodells dieser Priorisierung entsprechen. Dies kann Hinweise auf weiteren Änderungsbedarf aufzeigen. Im letzten Schritt (7) steht dann der Erkenntnisgewinn, der zur Überarbeitung und Verbesserung des Geschäftsmodells führen soll.

5 Kritische Würdigung

Mithilfe der vorliegenden Arbeit sollte eine Möglichkeit zur Bewertung plattformbasierter Geschäftsmodelle mit Quality Function Deployment erarbeitet werden. Hierzu wurden Mechanismen der Methode QFD genutzt, um Anforderungen an plattformbasierte Geschäftsmodelle zu erarbeiten, die künftig zu Bewertung solcher Geschäftsmodelle eingesetzt werden können. Diese Zielsetzung findet in der Formulierung der Forschungsfragen dieses Beitrags Niederschlag (Tabelle 1).

Bei der Beantwortung der ersten Forschungsfrage wurde evident, dass plattformbasierte Geschäftsmodelle alle Merkmale von klassischen Geschäftsmodellen aufweisen, jedoch darüber hinaus der großen Bedeutung der zusätzlichen Stakeholder Rechnung tragen müssen. Dies betrifft insbesondere das Management der Partner bzw. Komplementoren. Der Plattformanbieter sollte entsprechend nicht nur das eigene Geschäftsmodell im Blick haben, sondern auch sicherstellen, dass die auf seiner Plattform vertretenen Komplementoren selbst ein tragfähiges Geschäftsmodell betreiben können. Idealerweise enthält das Geschäftsmodell des Plattformanbieters bereits einen Blueprint für das Geschäftsmodell der Komplementoren.

Die identifizierten Geschäftsmodellmerkmale sind notwendig, um die spezifischen Anforderungen plattformbasierter Geschäftsmodelle lösen zu können. Diese Anforderungen betreffen insbesondere die Ausgestaltung der Beziehung zwischen den Stakeholdergruppen und die Attraktivität der dem Geschäftsmodell zugrundeliegenden Plattform für die relevanten Akteure.

Auf Basis dieser Ergebnisse konnte ein Vorgehensmodell für den Ablauf eines Bewertungsworkshops für plattformbasierte Geschäftsmodelle entwickelt werden.

Aufgrund von Restriktionen bezüglich der Bearbeitungszeit im Rahmen einer Abschlussarbeit sind Defizite bezüglich der Aussagekraft und Übertragbarkeit der erarbeiteten Ergebnisse zu erwarten. Eine erste Einschränkung ist der nicht beleuchtete Zusammenhang zwischen Geschäftsmodellmerkmalen. Dies kann die Analyse der Geschäftsmodellmatrix und damit die Formulierung genauerer Implikationen und Handlungsempfehlungen erschweren.

Weiterhin wurde bei der Wahl der verwendeten Geschäftsmodelleinteilung auf eine hohe praktische Durchführbarkeit Wert gelegt. Dies kann sich ebenfalls negativ auf den Detaillierungsgrad der erarbeiteten Ergebnisse auswirken. Weitere Defizite betreffen die Auswahl und Anzahl der teilnehmenden Unternehmen: Da es sich hierbei um Unternehmen in frühen Phasen ihrer Lebenszyklen handelt, ist der Erfahrungsschatz der am Workshop beteiligten Experten als eingeschränkt zu bewerten. Weiterhin war es aufgrund des hohen zeitlichen und personellen Aufwands der Anforderungsworkshops nicht möglich eine größere Anzahl an Unternehmen zu untersuchen. Entsprechend sind negative Auswirkungen auf die Allgemeingültigkeit der erarbeiteten Anforderungen zu erwarten. Ebenfalls aus Zeitgründen konnten die Korrelationen innerhalb der Matrix nicht in Zusammenarbeit mit den Experten erarbeitet werden, sondern wurden von den

Autoren dieser Arbeit auf Basis der Expertenaussagen vorgenommen. Die Beschränkung auf nur drei Korrelationswerte vereinfachte dies einerseits, führte aber ebenfalls zu Beeinträchtigungen hinsichtlich der Differenzierung der Ergebnisse.

Trotz dieser Defizite konnte die Eignung der Methode Quality Function Deployment für die Bewertung plattformbasierter Geschäftsmodelle gezeigt werden. Weiterhin betreffen die genannten Defizite hauptsächlich die operative Durchführung der Anforderungs- und Merkmalserhebung. Diese beeinträchtigen damit nicht die grundsätzliche Eignung des Verfahrens. Die positive Resonanz der teilnehmenden Experten lässt darüber hinaus auf das Potenzial dieses Verfahrens als Hilfestellung für junge Unternehmen schließen.

Die Ergebnisse der auf Basis des erarbeiteten Vorgehensmodells durchgeführten Workshops lassen auf sein Potenzial für weitere Untersuchungen schließen. Zur Minimierung der angesprochenen Defizite sollten weitere Workshops mit Unternehmen in reiferen Phasen durchgeführt werden. Die Ergebnisse können mit der Identifikation von möglichen Zusammenhängen der Geschäftsmodellkomponenten im *Dach* des House of Quality („WIE zu WIE“-Abhängigkeiten, vgl. Abbildung 1) weiter analysiert werden. Das Resultat sollte ein umfangreicherer und detaillierterer Anforderungskatalog sein. Zur Bildung eines solchen Kataloges können auch detailliertere Geschäftsmodellgliederungen wie bspw. die Service Business Model Canvas [23] genutzt werden.

Mithilfe dieser Anforderungen können Startups ihr Geschäftsmodell vor der Implementierung überprüfen. Die erarbeitete Bewertungsmethode kann somit potenziell einen Beitrag zur Vermeidung von gescheiterten Unternehmensgründungen leisten.

Das erarbeitete Verfahren bietet darüber hinaus auch Verwendungsmöglichkeiten über die betrachteten plattformbasierten Geschäftsmodelle hinaus: Unterstellt, dass diese eine spezifischere Teilmenge von Geschäftsmodellen insgesamt sind, könnten über die Anwendung des erwähnten Kano-Modells irrelevante Anforderungen identifiziert und aus der Betrachtung herausgenommen werden.

A Picture is Worth a Thousand Words: Visual Model Evaluation in Data Science Applications

Dennis Eilers[1], and Michael H. Breitner[1]

[1] Leibniz Universität Hannover, Information Systems Institute, Hannover, Germany
{eilers,breitner}@iwi.uni-hannover.de

Abstract. Besides programming and mathematical or statistical skills, domain knowledge about the investigated problem is an important factor in data science. In practical applications, however, there often exist a gap between data scientists who have the technical skills in advanced analytics methods and the domain experts like managers and decision makers with substantial knowledge in their field. Less participation of domain experts during the complex model building and evaluation process of the data science pipeline can lead to acceptance problems and prejudices against the results. Moreover, data scientists depend on the domain knowledge of experts when it comes to evaluation and problem identification of their models. In this paper we address this issue by introducing an easy-to-understand heat map visualization technique for model evaluation. It enables all parties to discuss the analysis on the same level of complexity. The benefits are demonstrated based on a real world business example.

Keywords: Data Science, Visualization, Machine Learning Model Evaluation, Heat Maps

1 Introduction and Motivation

Data science is often described as a combination of mathematics/statistics, programming and domain knowledge [1]. In a business context, data analysis is the task of specialized professionals who have substantial knowledge about the data bases, analysis tools and mathematical/statistical models. It is widely discussed in the literature how Decision Support Systems (DSS) based on data analytics can improve management performance [2-3]. From the opposite perspective, regarding the definition of data science, it is also an important question how to make use of managers' domain knowledge during the whole analysis process. Therefore, communication between the different expert groups is essential for team performance [4]. Data visualization can be a powerful tool for this purpose. There exist many studies about visualization for data exploration [5-6], result communication [7-8] and decision support [9-10]. Using visualization as a communication instrument between data scientists and domain experts during the actual model building and evaluation steps in the analysis pipeline is unexplored so far. The lack of participation in this technical and complex but crucial phase can lead to prejudices and acceptance problems on the part of managers about the final results. Especially the use of advanced analytics techniques

13th International Conference on Wirtschaftsinformatik,

Eilers, D.; Breitner, M.H. (2017): A Picture is Worth a Thousand Words: Visual Model Evaluation in Data Science Applications, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1489-1500

like Artificial Neural Networks (ANN) then often lead to the common “black-box” criticism. Using the experience of managers even with lesser technical skills can also help the data scientists during the model building and especially during the model evaluation phase. Problems with the model performance which are not attributable to the methods or algorithms (e.g. an omitted variable bias) can be identified much easier with the help of expert knowledge, which leads to better results in an iterative process of model building, evaluation and adjustment. Therefore, we are interested in the question of how visualization can help to integrate managers in the model building and evaluation process of the data science pipeline to generate acceptance, confidence and trust [11-12] and also to make better use of domain knowledge for model improvements.

This paper is motivated by a real world application in cooperation with a large German car manufacturer. The data analysis problem is about improving the residual value forecast for used cars to support the decision makers in the leasing business of the company. Based on discussions with the data scientists and domain experts (managers/decision makers) we propose a new visualization technique for machine learning model evaluation using the familiar idea of heat maps to address the aforementioned question. The contribution can be summarized as follows.

- From a manager perspective: The proposed heat map visualization for model evaluation provides a familiar and easy interpretable way to assess the performance of the analysis. Experience and domain knowledge can be incorporated during the discussions about the analysis with the data scientists. The participation in this phase can help to develop acceptance and trust in advanced analytics methods which lead to more confident decision making.
- From a data scientist perspective: The intuitive visualization helps to make better use of the domain knowledge from experts to identify the problems of the models. It also helps to identify the exact regions of bad performance in the data. The method is applicable for any model complexity and also possible to use with Big Data sets.

The next section provides an overview about the concrete problem statement in the real world business application. Section 3 describes the solution approach and the implementation of the proposed heat map model evaluation technique. In section 4, the results and limitations of this approach are discussed. Sections 5 concludes and provides an outlook for further research.

2 Set the Stage

This section describes the data analysis task in the real world business application and illustrates the problem statement. The general question of this analysis project is how residual values of used cars evolve over time [13-14]. This question is crucial in the leasing business, because the leasing rate (the amount of money a customer has to pay during the leasing period) is determined by the estimation of the future residual value of a car. The loss in value over time needs to be compensated by this rate. An overestimation of the residual value leads to a lower leasing rate (competitive advantage) but also generates a loss when reselling the car after the leasing period. A conservative underestimation leads to high leasing rates and therefore generates an avoidable competitive disadvantage. With more than 150.000 recorded leasing contracts and resales over four years (2011-2014) from a major German car manufacturer, this is a typical regression problem where machine learning models can be used to explain the residual values based on features of the car like the age, the mileage or the fuel type. The trained models can be used for future contracts to determine a more accurate estimation of the expected residual value. The results affect different stakeholders, namely the car manufacturer, the leasing bank, the authorized dealers and the customers.

In such a practical application the experience and domain knowledge from managers and decisions makers about the leasing market and its special characteristics are an important factor in the whole analysis process. The goal is to achieve a closer cooperation between the data science experts and the many different experts who have in depth knowledge and experience in the field of leasing contracts and the leasing market. For this forecasting application we use ANNs which are suitable for noisy and nonlinear data [15-16]. The common criticism of ANNs is their "black-box" characteristic. After training the ANNs with data from the past (not the focus of this paper) the models are able to produce a forecast of previously unseen data (new contracts). ANNs in general and the training process in particular are highly complex mathematical optimization problems which are difficult to understand for professionals with fewer technical skills. General rejection and prejudices can be the result. But in the end, the decisions are made by humans who have to accept and trust the forecasts. On the other hand, the data scientists face the problem of incorporating the domain experts during the analysis to get the necessary domain knowledge about the data and reveal possible problems with the models which can only be identified by experts who have probably less mathematical and statistical skills (e.g. identifying omitted variables).

The general idea is to use heat maps, a familiar tool for most business people [17], to incorporate all different kinds of experts in the evaluation phase of the initial analysis, which supports iterative adjustments and improvements. The goal is to provide a method where domain experts with less technical skills, managers and data scientists can discuss the performance of the current approach on the same level of complexity. Problems with the analysis like missing data, omitted input variables or nonlinearities can be identified together, whereby all participants are actively involved in the process of deriving new or improved models. The next section describes the implementation of the proposed heat map method for model evaluation and illustrates its functionality.

3 Visual Model Evaluation with Heat Maps

Heat maps are widely used in research fields like geology or meteorology [18] and play an increasingly important role in business applications. Buehler and Pritsch use heat maps to present results of risk management models in a more intuitive and comprehensible way [17]. By providing easy to understand heat map visualizations of different risk categories and business units they claim to make risk more transparent. Heatmaps could thus contribute to a dialogue between the board of directors, senior management and business unit leaders. Köpp et al. propose a heat map visualization technique for applications where forecast distributions of several future time steps are generated [19]. For an easier interpretation, forecast ensembles are often aggregated by the mean or median, which reduces the information to a single forecast line. The proposed heat map intuitively visualizes areas in the ensemble with high and low activity, which represents the uncertainty of the models and therefore facilitates decision making (for example the identification of the best point in time to buy a certain commodity). This is an example of how heat maps can be used to aggregate data without losing important information.

In this section, we propose a new technique for model evaluation using heat map visualizations of forecasting errors/residuals. In most data science oriented studies, model evaluation is based on some common performance measures like the Root Mean Square Error (RMSE) or the Mean Absolute Error (MAE) [20]. These performance measurements reduce the information about the model quality to a single number. These measures are usually used to compare different models or model specifications with each other in order to choose the best performing one. This common approach has the drawback that the information where exactly the model performs good or bad in the input and output space, cannot be observed. In addition, these rather technical evaluations of the analysis have no value for incorporating domain knowledge in the evaluation and are unable to generate trust in results of probably highly complex "black-box" methods.

Using heat maps for residual visualization is a new approach and has several advantages compared to conventional methods. With heat maps it is possible to incorporate a further dimension, because the information about the residuals can be visualized by a color scale. Therefore, it is possible to use a two-dimensional coordinate system with two variables of the input or output space on the axes. These "cuts" through the data enable the user to visualize the residuals in the same data space as a conventional scatterplot or density plot of the data points. This can help to detect hidden anomalies in the data/model when comparing the residual heat maps with scatterplots or density plots which are in the same range and size. These hidden anomalies can be, for example, a bad performance at the borders of the distribution or a special region like a data gap in the input space, which leads to bad performance in the results. This can give hints for an omitted variable bias or an insufficiently incorporated, nonlinear relationship between variables. The representation of the error terms in the form of a heat map remains clear and comprehensible even with a large number of data points, since the general appearance is independent of the number of data used to generate the visualization. Therefore, the method is also suitable for Big Data applications. However, in the case of large data sets, data aggregation takes place but without losing information about the performance in different regions of the data space, as is the case with single performance measures.

To illustrate the technique, let's consider 500 samples from a two-dimensional standard normal distribution. This stylized example serves as an artificial use case with known distribution and properties of the data points to validate the functionality of the method within a controlled environment. The two dimensions (x and y) represent two continuous input variables (features) of a machine learning regression model. This information can be used to generate a scatterplot of the data points to get an idea about the distribution and possible correlations. Figure 1 shows a smoothed scatterplot of this example.

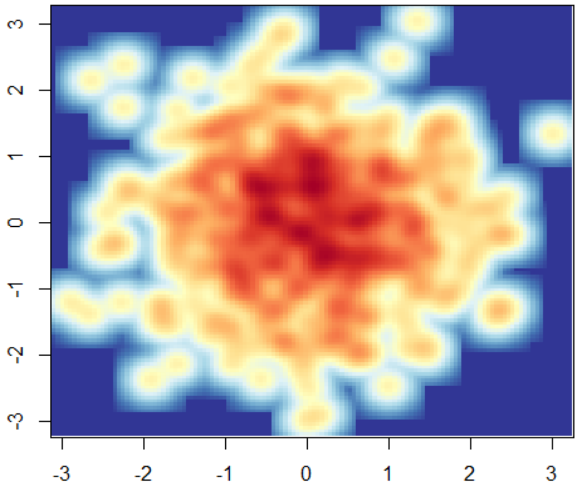

Figure 1. Smoothed scatterplot of 500 random samples of a two-dimensional standard normal distribution.

The residuals which correspond to these data points are now visualized in the exact same data space using a color scale. The assumption is, that each residual is representative for a specified region around its position. For example, it might be the case that a forecasting model predicts the realized values very well in one region of the data space (residuals in that area are rather low) and in another region the forecasting accuracy is less accurate (residuals in that area are rather high). Since the position of the data points are typically not on a regular grid, a method for weighting and smoothing is necessary. By using a kernel around the data points, each residual gets a specific range of influence. At the position of the data point, the influence of the residual should be high, while it decreases with increasing distance. The goal of using the kernel approach is to generate a regular grid with the weighted influence of the residuals on each grid point. A resulting discrete and regular grid is defined as a matrix of the dimension (m, n) within the same variable space. There are several other interpolation methods for irregular grids like kriging and inverse distance weighting [21], but in this use case, an actual weighting of the residuals has to be performed which must also work with data points at the exact same position (high density areas in the data). Each residual has a defined location in the variable space. In our approach, we use a two-dimensional Gaussian kernel with

$$\mu = \binom{\mu_A}{\mu_B} \text{ and } \Sigma = \begin{pmatrix} \sigma_A^2 & \rho\sigma_A\sigma_B \\ \rho\sigma_A\sigma_B & \sigma_B^2 \end{pmatrix} \quad (1)$$

where $\begin{pmatrix} \mu_A \\ \mu_B \end{pmatrix} := \begin{pmatrix} x_i \\ y_i \end{pmatrix}$ for each new residual i. The covariance matrix Σ can be set by the user but for the default value we specify equation 2 with size s = 1000 as control parameter for the expansion of the kernel and zero correlation

$$\Sigma_{default} = \begin{pmatrix} \frac{(\max(X)-\min(X))^2}{s} & 0 \\ 0 & \frac{(\max(Y)-\min(Y))^2}{s} \end{pmatrix} \tag{2}$$

The density function in the special two-dimensional case, for a specific residual i, at the grid points (m, n), can be defined as

$$f^i(m,n) = \frac{1}{2\pi\sigma_A\sigma_B\sqrt{1-\rho^2}} \exp\left(-\frac{1}{2(1-\rho^2)}\left(\frac{(n-\mu_A)^2}{\sigma_A^2} + \frac{(m-\mu_B)^2}{\sigma_B^2} - \frac{2\rho(n-\mu_A)(m-\mu_B)}{\sigma_A\sigma_B}\right)\right) \tag{3}$$

For each residual, the position (x_i, y_i) is defined as the mean of the density function and each grid point is inserted into the generated function 3. This results in a list of weights (according to the two-dimensional normal density) for each residual, for each grid point. The threshold parameter t can be set to specify the minimal value of a weight, otherwise this residual has no influence on this specific grid point. The weight $w_{m,n}^i$ for residual i at grid point (m, n) is defined by

$$w_{m,n}^i = \begin{cases} f^i(m,n), & \text{if } f^i(m,n) \geq t \\ 0, & otherwise \end{cases} \tag{4}$$

If the distance between the residual and the grid point is too high (grid point inserted into the normal density kernel, with mean equals the position of the residual, results in a value below the threshold) the influence for this specific value is set to zero. Figure 2 illustrates the weighting procedure.

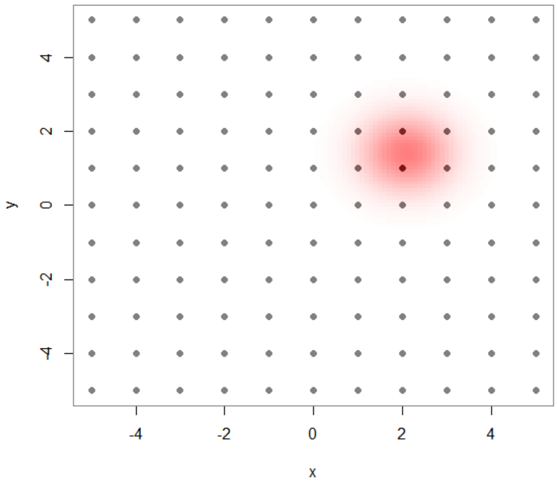

Figure 2. An example of one residual inserted into the regular grid of the heat map. The position of the residual in the data space is equal to the mean of the two-dimensional normal density.

The actual weighting for each residual r_i at each grid point is performed according to equation 5.

$$g_{m,n} = \begin{cases} \sum_{i=1} \left(r_i \frac{w_{m,n}^i}{\sum_{i=1} w_{m,n}^i} \right), & \text{if } \sum_{i=1} [w_{m,n}^i > 0] \geq c \\ NA, & \text{otherwise} \end{cases} \quad (5)$$

The cutting parameter c can be set to allow only those grid points to be colored that have at least a specified number of $w_{m,n}^i \geq c$ which means that more than one residual has an influence on that specific grid point. This can help to make the result more robust, because single value outliers are mitigated, but at the expense of greater information loss in low-density areas. After assigning a value $g_{m,n}$ to each point in the regular grid, the heat map can be produced. To illustrate the resulting heat maps, a third sample of 500 standard normal distributed values represents the artificial residuals corresponding to each (x, y) point in the data space. Figure 3 shows the result of this stylized example.

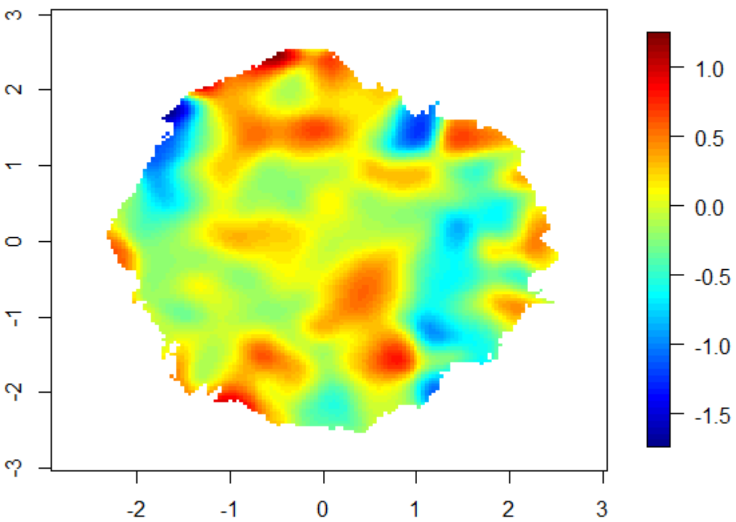

Figure 3. The figure shows a residual heat map which is generated according to the described procedure. In this case, the residuals are normally distributed which results in a heat map with no clear patters.

The red regions represent the high residual areas, while in the blue regions the residuals are rather small. In this example, there is no clear pattern apparent because the residuals are indeed normally distributed over the whole data space. This should be the case if the (forecasting) models work well in each area of the data space.

To illustrate a case when a specific region is biased, the residuals are now artificially manipulated by increasing the residuals located within the range of -0.1 and 0.1 on the x-axis according to equation 6.

$$r_i = \begin{cases} r_i + 2, & \text{if } -0.1 \le x_i \le 0.1 \\ r_i, & \text{otherwise} \end{cases} \quad (6)$$

Figure 4 shows the resulting heat map with the artificially biased region. A clear pattern is now visible, indicated by the red region. Such patterns would be expected if the model performs bad, especially in a particular region, for example because of an omitted variable or a nonlinearity which was not incorporated.

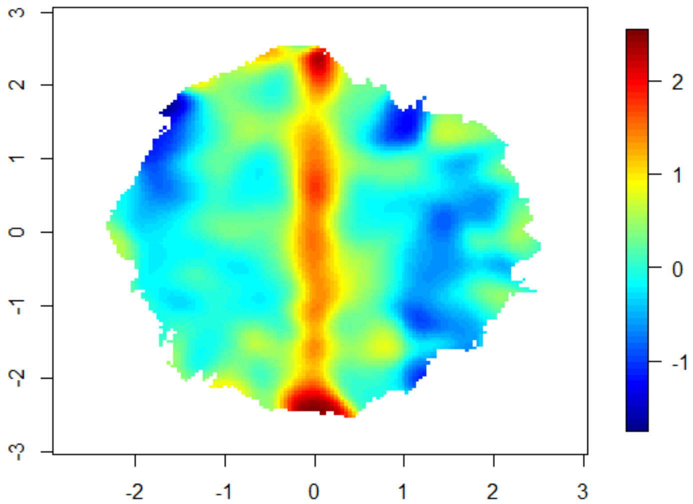

Figure 4. The residuals are now artificially manipulated by increasing the residuals located within the range of -0.1 and 0.1 on the x-axis. A clear pattern is visual now indicated by the red region. Such patterns would be expected if the model performs bad in a particular region for example because of an omitted variable or a nonlinearity which was not incorporated.

4 Discussion and Limitations

The method described in the previous section is now applied to the real world problem of forecasting the resale price of used cars. This example only serves as illustration purpose how visualization can be used in a business application and help to reveal previously unseen problems. After training the ANN models with the available input data, we visualize the resulting model errors on a validation dataset with 4500 hold out samples which were not represented in the training process. First, figure 5 presents a smoothed scatterplot of the observed residuals in the data space with the two variables “sale price” and “age” of the cars. The variable “age” is scaled and centered around zero (best practice for input variables of ANNs [22]), while the variable “sale price” is defined as the ratio of the initial list price and achieved market value. Figure 6 shows the resulting residual heat map (residuals as absolute values) of the same data set.

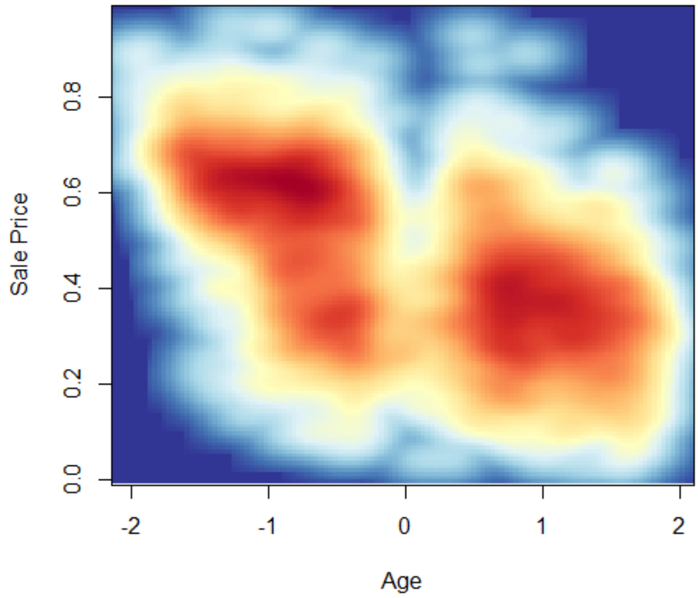

Figure 5. Smoothed scatterplot of the observed residuals in the data space with two variables: the sale price and age of the cars.

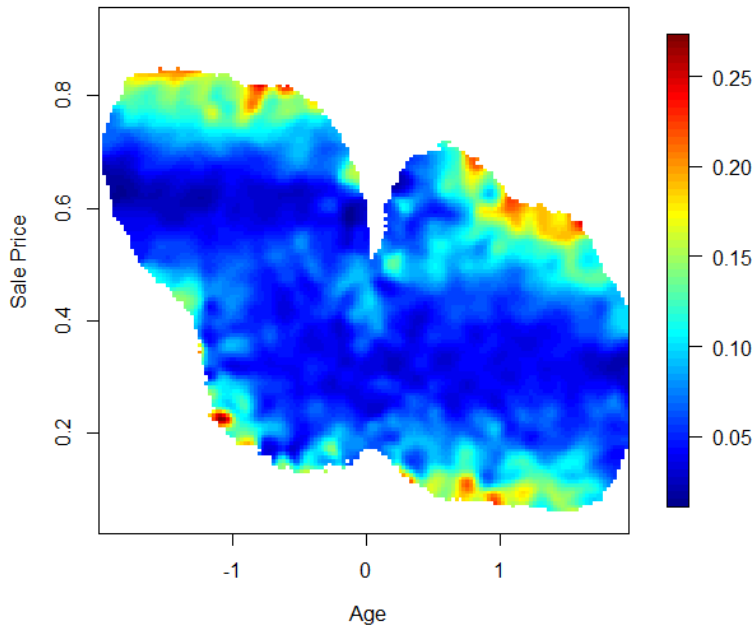

Figure 6. A systematic pattern in the residuals can be observed. In the upper and lower regions of the variable “sale price”, the residuals tend to be higher than in in the more centered parts.

A systematic pattern in the residuals of the ANN model can be observed. In the upper and lower regions of the variable “sale price” the residuals tend to be higher than in in the more centered parts. This can be a hint about information which are not incorporated in the model. Discussions with experts and managers about the observed results in this visualization reveal a plausible explanation at least for the upper regions of the sale price. In the data, no enhanced acquisition costs are reported. For example, a crane which was installed later on a used car increases the value of the whole car significantly, even if the residual value of the car decreases normally. When such cars are resold, no information about this extra equipment will be reported and the residual value of this car seems to be unusually high. The respective data points which would otherwise be marked as simple outliers can now be identified as patterns which are subject to a systematic bias induced by an omitted explanatory variable. Future data collection will incorporate information about enhanced acquisition costs.

From a manager perspective, this visualization technique enables the participation in the complex process of model building, evaluation and adjustment, even with lesser mathematical and statistical skills. They can assess the performance of the models within a familiar environment and actively discuss practice-oriented ideas about the problems of the advanced analytics models with the data science experts on the same complexity level. The participation in the “black-box” phase is also the basis for trust and acceptance of the results which can lead to more confident decision making.

From a data scientist perspective, this method can be used to uncover hidden problems in the data or algorithms based on the domain knowledge of experts in the field. This approach also offers a new way of visualizing the model error within the same data space as scatterplots or density plots. For example, comparing density plots and heat maps can provide a first insight about the performance in regions with less data or data gaps. This can give a hint if the problem is due to the data (possible omitted variables) or the used method (a nonlinearity which is not correctly incorporated). It provides much more valuable information than single performance measures like the RMSE. In contrast to conventional residual analytics methods like simple residual plots, the heat map can be used with an unlimited number of data points (applicable for Big Data machine learning models) in the evaluation. Residual plots are hardly interpretable if the number of data points increases. The color scale and the weighting function of the heat map allows to visualize many patterns without losing information about the model performance in different regions of the data space.

Like any approach, the heat map visualization faces some difficulties and drawbacks. Big Data machine learning applications often contain a large number of input factors, of which only two can be plotted simultaneously in one coordinate system. Scatterplot matrices can be used to represent all variables pairwise, but this also leads to a more complex visualization as the number of factors increases. In the described example, also only continuous variables are investigated within a regression problem. The information gain for one or even two discrete or binary variables on the axes is questionable. The method is also limited to regression problems. Classification problems can be incorporated by some adjustments on the heat map color scale (binary representation with two colors for true or false) for future tests. As mentioned in section 3, several parameters have to be set properly for achieving good results. These parameters could have a tremendous influence on the heat map appearance. It is not a plug and play solution and users need substantial knowledge about the backend of the system. It is therefore once again the responsibility of the data scientists to generate meaningful presentations which can also lead to skepticism. Wrong parameter settings could have tremendous negative effects regarding trust and decision making performance. The advantage that decisions can be made with more confidence using visualizations can also be a drawback if these approaches lead to overconfidence in the models. The principle "trust but verify" is important with any model, but the visualizations do not help to understand the mathematical structure or the training process in general. An important problem is how to measure the actual benefits and the role of trust, acceptance and confidence [11-12] when using such visualizations in the analysis process. In a real world application, hardly any quantifiable indicator exists for the performance improvements induced by this visualization except a qualitative argumentation.

5 Conclusion

In this paper, a heat map visualization for model evaluation is introduced. The overall goal is a better integration of managers and decision makers in the model building and evaluation process of the data science pipeline in order to generate trust and acceptance and furthermore, to make use of the experts' domain knowledge in this phase. Based on a real world business example, the benefits of this method were discussed. The visualization technique allows domain experts to actively participate in the technical and complex model building and evaluation process which helps to reveal a systematic bias induced by an omitted explanatory variable. Data scientists are equipped with a tool for visualizing model errors in the same data space as two dimensional scatterplots to identify the exact regions where the models perform good or bad. The method is applicable even for Big Data machine learning models.

In further research we are interested in better understanding the actual benefits of visualization for data science in general. One approach is the laboratory experiment, in order to measure the results of an analysis process in a controlled environment by providing different visualization tools for control and treatment groups. This also allows to measure the differences in trust, acceptance and confidence of the subjects. In general, this paper aims to encourage the use of visualization in data science and hopefully initiates more research in this important area.

Abstract:
In den letzten Jahren konnte sich Crowdlending als neuartige Form der Kreditvergabe zunehmend etablieren. Dabei hat es sich mit 11,2 Milliarden US-Dollar Kreditvolumen in 2014 zur bedeutendsten Form der Finanzierung innerhalb des Crowdfunding Paradigmas entwickelt und sammelt dabei mehr Investitionsmittel ein als alle anderen Formen des Crowdfundings zusammen. In zunehmendem Masse wird Schwarmfinanzierung damit relevant in Wirtschaft und Politik. Gleichzeitig hat sich Crowdfunding und Crowdlending als hochrelevantes Forschungsthema in der Wirtschaftsinformatik etabliert. Während sind die bisherige Forschung dabei weitestgehend auf den Einfluss sozialer Netzwerke, der Bedeutung von sozialem Kapital sowie subjektivem Risiko und Antiselektion konzentriert, ist der Einfluss von moralisch-ethischen Steuerungsmechanismen bisher noch nicht weiter untersucht. Anhand einer Mediationsanalyse der Daten einer Umfrage mit 118 Teilnehmern konnte explorativ-quantitativ bewiesen werden, dass Moral Disengagement Mechanismen die Tendenz, unmoralische Investitionsentscheidungen zu treffen, beeinflusst. Die Studie legt damit die Grundlagen für weitere Forschung im Bereich des Crowdlending, um besser zu verstehen, wie Crowdlending Plattformen gestaltet werden müssen, um unethische und unmoralische Investitionen zu verhindern.

Schwarz, D.; Haas, P. (2017): Die Rolle von Moral Disengagement in Crowdlending, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1501-1512

1 Einführung

In den letzten Jahren hat das Thema Crowdlending aufgrund hoher Wachstumsraten, neuen Erkenntnissen in der Forschung und zunehmender Berichterstattung in den Medien an Bedeutung gewonnen. Auf Crowdlending Plattformen können Kapitalnehmer ein Kreditgesuch einstellen, für die der potentielle Kreditgeber einen festgelegten Zinssatz als Risikoprämie erhält. So wurden über die weltweit führende Crowdlending Plattform *Lending Club* bereits Kredite mit einem Volumen von über 11,2 Milliarden US-Dollar vergeben mit stark steigender Tendenz [1]. Crowdlending gewinnt in der Wirtschaftsinformatik-Forschung immer mehr an Bedeutung, da erst das Internet und die Möglichkeiten des Web 2.0 den Erfolg der Crowdlending-Plattformen ermöglichen.

Kreditgeber bevorzugen im Crowdlending überwiegend Investitionen mit hohem Zinssatz und zeichnen sich durch überdurchschnittliche Risikobereitschaft aus [2]. Durch den einfachen Zugang zu Kapital auch für risikoreichere Zielgruppen und die attraktiven Renditen fördert Crowdlending zum einen die Gefahr der Überschuldung der Kreditsuchenden und zum anderen unmoralisches Investitionsverhaltens der Kapitalgeber [3]. Zum Beispiel werden im Crowdlending Kredite oft für die Rückzahlung von anderen Krediten wie beispielweise Kreditkartenschulden verwendet [4]. Unter unmoralischem Investitionsverhalten versteht man in diesem Kontext die Kreditvergabe auf Crowdlending Plattformen zum Nachteil des Kreditsuchenden. Dies kann sich in marktunüblichen und unvorteilhaften Kondition wie überzogenen Zinssätzen ausdrücken oder der Vergabe von Krediten trotz offensichtlich drohender Überschuldung. Hierbei umgeht der Kreditgeber die eigenen moralischen Selbstregulierungsmechanismen, was durch die subjektiv wahrgenommene Anonymität auf einer Internetplattform gefördert wird.

Aus diesem Grund wandelt sich die zuerst positive öffentliche Wahrnehmung von Crowdlending, was zu zunehmender regulatorischer Aufsicht führt. So limitiert beispielsweise das deutsche Bürgerliche Gesetzbuch den möglichen Zinssatz. Sittenwidrig ist dabei eine Kreditvergabe, wenn der effektive Jahreszins den Vergleichszins relativ um mehr als 91 Prozent überschreitet [5] und eine Notlage oder Unerfahrenheit des Darlehensnehmers ausgenutzt wird. Wenngleich die Gesetzgebung in Deutschland unethisches Investitionsverhalten vergleichsweise effektiv unterbinden kann, so ist die Regulierung in anderen Ländern nicht so streng.

Es ist somit von grosser Bedeutung zu verstehen, wie psychologische Mechanismen es ermöglichen, unmoralische Investitionen zu rechtfertigen. Zu diesem Zweck wird ein Strukturmodel anhand der Moral Disengagement Theorie nach Bandura et al. [6, 7] entwickelt, in dem Moral Disengagement als Mediator die Beziehung zwischen Moralischer Identität beziehungsweise Motive für finanziellen Gewinn und unmoralischem Investitionsverhalten moderiert. Zwar wurde in den letzten Jahren zum Thema Investorenverhalten bei Crowdlending geforscht und publiziert, allerdings konzertiert sich die Forschung dabei auf den Einfluss sozialer Netzwerke [8], subjektives Risiko (Moral Hazard) und Adverser Selektion [9]. Zur Frage des Einflusses moralischer Bedenken und der Überwindung derselben existiert bisher nur unzureichende Forschung.

Aus diesem Grund untersuchen wir in dieser Arbeit, wie Moral Disengagement im Crowdlending begründet wird und beschreiben, wie Individuen das persönliche moralische Selbstregulationssystem umgehen, welches unmoralisches Investitionsverhalten eigentlich reguliert. Dies öffnet eine neue Perspektive nicht nur in der Crowdlending Forschung, sondern lässt sich auch auf die Crowdfunding Forschung allgemein ausweiten. Hierfür wurde eine Befragung unter Kapitalgebern durchgeführt und mittels Mediationsanalyse ausgewertet. Die Ergebnisse zeigen, dass Investoren Moral Disengagement einsetzen, um das moralische Selbstregulationssystem zu überwinden und unmoralische Investition zum Ziele der Gewinnmaximierung zu tätigen.

Nach einem Überblick über die theoretischen Hintergründe zu Moral Disengagement und Crowdfunding stellen wir unser methodisches Vorgehen vor. Anschliessend werden die Ergebnisse der Mediationsanalyse analysiert und die Hypothesen ausgewertet. Schlussendlich werden theoretische und praktische Implikationen für Crowdlending Plattformen und Investoren diskutiert.

2 Theoretischer Hintergrund: Moral Disengagement

Zur Analyse des Einflusses von Moral auf die Investitionsentscheidung auf Crowdlending-Plattformen wurden zunächst die vier Dimensionen des Moral Disengagement Frameworks nach Bandura [6, 7] analysiert.

2.1 Kognitive Rekonstruktion der Handlung

Durch moralische Rechtfertigung, wohlwollende Sprache und vorteilhafte Vergleiche lassen sich soziale Handlungen kognitiv rekonstruieren. Werden Handlungen moralisch gerechtfertigt, dann werden sie damit erklärt, dass sie einem grösseren Zweck in der Gesellschaft dienen. Dies erlaubt es, ursprünglich als unmoralisch empfundene Handlungen moralisch akzeptabel zu gestalten, da Individuen normalerweise nicht dazu neigen, ohne Rechtfertigung unmoralisch zu handeln [6, 7]. Oftmals werden in diesem Zusammenhang unmoralische Handlungen zur Wahrung der Ehre und des Rufes ausgeführt [6, 10]. Die verwendete Sprache formt die Denkmuster als Basis der Handlung [7]. Dabei zeigt sich, dass Menschen auf grausamere Art und Weise handeln, wenn die Handlung selbst sprachlich von negativen Assoziationen befreit wird [11, 12]. Als weiteres Instrument der beschönigenden Sprache wird der passive Sprachstil verwendet, wodurch die Verantwortung für die Tat vom Individuum abgelenkt wird [13]. Die Methode der Marginalisierung durch wohlwollende Sprache und vorteilhafte Vergleiche nutzt bewusst das Prinzip der Kontrasterhöhung. Hierbei wird das eigene Verhalten einer moralisch besonders verwerflichen Handlung gegenübergestellt, wodurch es weniger gravierend erscheint [14].

2.2 Verleugnung und Minimierung der Verantwortung

Die Disengagement Mechanik wirkt als Modifikator auf die rationale Verbindung zwischen verwerflicher Handlung und schädlicher Auswirkung im moralischen Selbstregulationsprozesses [7]. Ein wichtiger Treiber von unmoralischen Handlungen ist deren Akzeptanz durch eine vom Individuum anerkannte Autorität, wodurch die Verantwortung verschoben wird. Dies erlaubt die Übertragung der persönlichen Verantwortung, wodurch der Selbstverurteilungsmechanismus umgangen wird. Dieser Effekt wird weiter verstärkt, wenn neben den befehlenden Personen auch die eigenen Bezugspersonen dem Befehl folgen [15, 16]. Durch Arbeitsteilung kann die Verantwortung verteilt werden, da jeder Arbeitsschritt die Verantwortung für das Endprodukt minimiert. Die Aufmerksamkeit des Individuums wird somit auf die eigene operationale Effizient gelenkt, wodurch die moralische Komponente der eigenen Arbeit in den Hintergrund rückt. Bei der Übertragung der Entscheidungsgewalt auf eine Gruppe fühlt sich Einzelne nicht mehr verantwortlich für das Gesamtergebnis [17].

2.3 Verzerrung der Konsequenzen

Die antizipierten Konsequenzen einer Tat sind ein starker Treiber der Selbstkontrolle des Individuums. Aus diesem Grund kann durch die Nichtbeachtung oder Minimierung der Konsequenzen für das Opfer das eigene moralische Selbstregulationssystem umgangen werden. Dieses tritt nicht in Kraft, wenn die schädlichen Folgen der eigenen Handlung verzerrt, minimiert beziehungsweise ignoriert oder nicht geglaubt werden. Wird ein Individuum mit den tatsächlichen Folgen konfrontiert, so diskreditiert es oftmals die Glaubwürdigkeit der Quelle. Aus diesem Grund ist dieser Mechanismus effektiver, je indirekter und damit unpersönlicher und weniger deutlich die Folgen wahrgenommen werden [6, 7].

2.4 Verantwortungsübertragung und Dehumanisierung des Opfers

Individuen neigen zur Selbstverurteilung, wenn sie schädliche Handlungen gegenüber Opfern durchführen, denen sie sich verbunden fühlen [6, 18]. Man unterscheidet dabei zwischen Schuldzuweisung und Entmenschlichung. Wird das Opfer oder die Umstände für die Handlung verantwortlich gemacht, kann sich der Handelnde auf das Recht zur Selbstverteidigung berufen. Durch Verdrehung der Kausalkette wird das Opfer für sein eigenes Leid selbst verantwortlich gemacht, was die Handlung entschuldbar macht und ein Gefühl der Selbstgerechtigkeit hervorruft [6, 7]. Ein wichtiger Treiber moralischen Verhaltens ist Gemeinschaftssinn. Die Vermenschlichung der Opfer führt zu einer deutlich reduzierten Aggressivität der Täter. Gleichzeitig hat die Entmenschlichung des Opfers eine entlastende Funktion für den Täter und reduziert die Wirkung des Selbstregulationsmechanismus [6, 7, 19].

3 Moral Disengagement in Crowdlending

Crowdfunding subsummiert verschiedene Formen der Finanzierung, die sich in ihrem Wertversprechen unterscheiden [20]: Belohnungs-basiertes Crowdfunding, Spenden-basiertes Crowdfunding, Eigenkapital-basiertes Crowdfunding sowie Kredit-basiertes Crowdfunding. In diesem Forschungsbeitrag wird das Kredit-basierte Crowdfunding untersucht, da es mit 11,08 Milliarden US-Dollar Kreditvolumen in 2014 eindeutig die finanziell relevanteste Form des Crowdfundings darstellt. Eigenkapitalbasierte Crowdfunding (USD 1,1 Mrd.) und hybrides Crowdfunding, eine Mischung verschiedener Modelle (USD 587 Mio.) folgen nur mit grossem Abstand [1].

Das gemeinsame Merkmal von Crowdfunding ist der öffentliche Aufruf im Internet an die „Crowd", die Summe der Nutzer der Crowdfunding Plattform. Eine Vielzahl an Investoren bringt dabei jeweils eine zumeist kleinere Summe ein, wodurch sich die Finanzierung auf eine grössere Anzahl an Investoren mit individuell kleineren Beiträgen verteilt.

Es konnte gezeigt werden, dass ein Zusammenhang zwischen Motivation und Wahrnehmung besteht, wobei Motive die Wahrnehmung gezielt lenken können um die gewünschte Handlung herbeizuführen. Dies wird durch eine gezielte Ausblendung von Informationen erreicht, welche der eigenen Motivation entgegenstehen. Gleichzeitig wird gezielt die Wahrnehmung auf Informationen gelenkt, welche die Motivation unterstützen [21].

Bezogen auf den Zusammenhang zwischen Motiven für finanziellen Gewinn und Moral Disengagement lässt sich dadurch ableiten, dass diese Steuerung der Wahrnehmung Einfluss auf das Moral Disengagement ausübt. Folglich bedeutet eine hohe Motivation zu finanziellem Gewinn, dass selektiv Informationen ausgeblendet werden, welche einer Optimierung der Rendite im Weg stehen. Dies können unter anderem Informationen zu moralisch bedeutsamen Themen sein, wie beispielsweise die negativen Auswirkungen für den Kreditnehmer [21]. Ebenso kann die gezielte Fokussierung auf finanziell relevante Informationen dazu führen, dass Investoren dazu neigen, das Verhalten ihrer Peers nachzuahmen. In diesem Fall wird die Verantwortung auf andere Investoren verteilt. Dabei wird die individuelle Verantwortung abgelehnt, da unterbewusst angenommen wird, dass Peers, die bereits in dem Projekt investiert sind, die Prüfung des Projekts zuvor schon vorgenommen haben. Durch diesen Mechanismus bleibt die eigene Unzulänglichkeit in der moralischen Prüfung unbewusst.

Hypothese 1a: *„Motive für finanziellen Gewinn begünstigen Moral Disengagement"*

Moralische Identität beschreibt das Eigenbild einer Person, welche ein relativ stabiles Selbstverständnis des Individuums ist, das sich aus spezifischen moralischen Charaktereigenschaften zusammensetzt. Diese formen hierarchisch geordnete Identitäten [22]. Eine Person, welche die eigene moralische Identität als sehr bedeutend wahrnimmt, fühlt stärkeres Mitgefühl für Mitmenschen auch ausserhalb der eigenen sozialen Gruppe. Aufgrund dieser Erkenntnis kann abgeleitet werden, dass Personen mit einer starken moralischen Identität weniger dazu neigen, unmoralische Investitionsentscheidungen zu treffen, indem sie Moral Disengagement Mechanismen aktivieren.

Hypothese 1b: *„Moralische Identität verringert den Einsatz von Moral Disengagement Mechanismen"*

Individuen treffen egoistische Entscheidung und können dabei gleichzeitig der Auffassung sein können, dass diese Handlungen korrekt sind [21]. Investoren stehen oftmals unter grossem Druck, eine Rendite zu erzielen. Aus diesem Grund ist anzunehmen, dass sich Investoren potentiell oftmals zwischen den Renditeansprüchen und den eigenen Moralvorstellungen entscheiden müssen. Dieses moralische Dilemma lässt sich kognitiv durch Moral Disengagement auflösen. Gleichzeitig rechtfertigt der Investor durch diesen Mechanismus unmoralische Entscheidungen, wodurch seine Prädisposition hierfür zunimmt.

Hypothese 2: *„Moral Disengagement der Crowdinvestoren ist positiv mit der Tendenz korreliert, unmoralische Investitionsentscheidungen zu treffen"*

Diese Arbeit argumentiert, dass verstärktes Moral Disengagement das vom Individuum empfundene Spannungsfeld zwischen eigener Erwartungshaltung an die Einhaltung moralischer Richtlinien und der tatsächlichen Handlung mindert.

Hypothese 3a: *„Moral Disengagement mediiert die positive Beziehung zwischen Motiven für finanziellen Gewinn und der Tendenz, unmoralische Investitionsentscheidungen zu treffen"*

Hypothese 3b: *„Moral Disengagement mediiert die positive Beziehung zwischen Moralischer Identität und der Tendenz, unmoralische Investitionsentscheidungen zu treffen"*

Folgende Darstellung illustriert das abgeleitete Mediationsmodell.

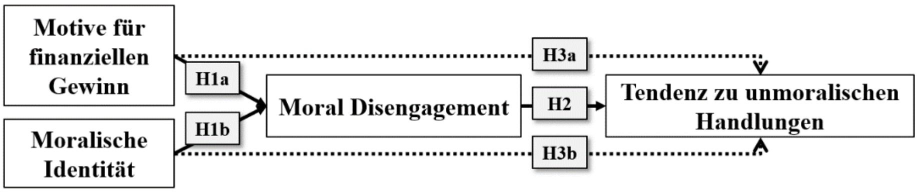

Abbildung 1: Darstellung des Mediationsmodells

4 Forschungsmethode

4.1 Datenerhebung

Um die Hypothesen zu testen wurde eine Online-Umfrage entwickelt, die sich an der Methodik von Baron et al. [21] orientiert und die Items bisheriger Moral Disengagement Studien adaptiert [21, 22]. Zur Messung der Tendenz zu unmoralischen Investitionsentscheidungen wurden ein Set aus vier Fallfragen (Vignetten) entwickelt, welche anhand einer kurzen Szenario-Beschreibung die Einstellung des Untersuchungsteilnehmers messen. Diese Szenarien im Rahmen der faktoriellen Umfragen erlauben es analog zu den Studien von Detert et al. [22] und Baron et al.[21], die Tendenz zu unmoralischen Handlungen zu messen. Dies erlaubt eine nuancierte Untersuchung der

Einstellung des Teilnehmers durch eine erweiterte Informationsdarstellung. Der Fragebogen wurde mit 10 Doktoranten vorgetestet, um sicherzustellen, dass die Fragen nicht zweideutig aufgefasst werden. Die gewählten Vignetten können online abgerufen werden[1], um das Untersuchungsdesign vollständig nachvollziehen zu können.

Die Umfrage richtete sich an Menschen mit Kenntnis oder persönlicher Erfahrung zum Thema Crowdfunding und wurde deshalb an Universitäten und in Crowdlending-fokussierten Foren verteilt. Total wurden 187 Antwortbögen des Onlineformulars eingereicht. Insgesamt 69 dieser Fragebögen wurden nur unvollständig beantwortet (mehr als 10% der Fragen wurden nicht beantwortet), wodurch sich die Zahl der Teilnehmer auf 118 reduziert. Die fehlenden Werte wurden mithilfe des Expectation-Maximization-Algorithmus (EM) vervollständigt, dessen Eignung mit dem Little MCAR Test festgestellt wurde. Die Umfrage wurde im Zeitraum Februar bis April 2016 durchgeführt. Die Teilnehmer sind mehrheitlich männlich (80; 67,8%). Der überwiegende Teil der Teilnehmer ist zwischen 18 und 24 Jahren (55,1%) beziehungsweise 25 und 29 Jahren (36,4%) alt. Dies erklärt sich aus der direkten Ansprache von Studenten, die meist in diese Altersgruppen fallen. 96% der Teilnehmer verfügen mindestens über die Hochschulreife, wobei 46,6% einen Bachelor und 11,9 einen Masterabschluss erreicht haben.

Die Aussagen wurden mithilfe einer 5-stufigen Likert-Skala abgefragt, wobei die Antwortmöglichkeit 1 „Stimme ganz und gar nicht zu“ und die Antwortmöglichkeit 5 „Stimme voll und ganz zu“ entsprechen.

4.2 Mediationsanalyse

Zur Untersuchung des Einflusses Moral Disengagement Mechanismen hat sich die Mediationsanalyse in der Forschung als robust herausgestellt [21, 22]. Die Mediationshypothesen werden anhand eines SPSS Makros [23, 24] geprüft.

Es lassen sich insgesamt drei Typen der Mediation unterscheiden: Komplementäre, Kompetitive und Nur-Indirekte Mediation [25]. Bei komplementärer Mediation und kompetitiver Mediation ist der direkte Effekt gegeben, allerdings deutet dies auf ein unvollständiges theoretisches Framework hin, da die Möglichkeit besteht, dass ein ausgelassener Mediator im direkten Pfad existiert. Ist der direkte Effekt allerdings nicht signifikant, so wird von nur-indirekter Mediation gesprochen. Hierbei ist der identifizierte Mediator konsistent mit dem theoretischen Framework und die Wahrscheinlichkeit, dass ein weiterer Mediator existiert, gering.

Preacher und Hayes [23] empfehlen den Bootstrapping Test des indirekten Effekts, um die Signifikanz des indirekten Pfades zu messen, da dieser im Gegensatz zum traditionell angewandten Sobel z-Test die Schiefverteilung der Stichprobe berücksichtigt [26]. Diese Arbeit folgt dieser Argumentation.

[1] Link: http://bit.ly/DS_MorDis_Fragenkatalog

5 Ergebnisse

Die Analyse mittels eines Mediations-spezifischen Makros [23, 24] wurde in SPSS durchgeführt und kann mit dem SAV-Datensatz[2] nachvollzogen werden. Die Variablen werden zuerst mit Hilfe des Cronbach Alpha Tests und der korrigierten Item-Skala-Korrelation bereinigt. Dabei zeigt sich, dass alle Variablen Alpha deutlich über den empfohlenen Grenzwerten von 0,6 und 0,7 für das Cronbach Alpha liegen [23, 24] und damit auch über vergleichbaren Werten von faktoriellen Umfragen im Bereich der Ethik und Moral [21, 22], was die Robustheit des Fragebogens bestätigt.

Die Analyse der zwei Mediationsmodelle bestätigen H1a, H2, H3a und H3b (siehe Abbildung 2).

H1a (angenommen): Die Analyse beweist, dass die Motivation zu finanziellem Gewinn die Neigung zu Moral Disengagement (Mediator) signifikant beeinflusst. Ebenso wirkt der Mediator signifikant auf die Tendenz, unmoralische Handlungen durchzuführen. Allerdings kann kein direkter Effekt nachgewiesen werden. Aus diesem Grund kann angenommen werden, dass eine nur-indirekte Mediation vorliegt. Der Bootstrapping Test ergibt ein BootLLCI von 0,009 (untere Grenze) und ein BootULCI von 0,124 (obere Grenze). Da dies nicht die Zahl 0 einschliesst, kann die indirekte Mediation bestätigt werden.

H1b (angenommen): Auch hier kann nachgewiesen werden, dass die Antezedens Variable (hier: Moralische Identität) einen signifikanten Einfluss auf den Mediator hat. Ebenso kann gezeigt werden, dass der Mediator signifikant auf die Neigung zu unmoralische Handlungen wirkt. Gleichzeitig liegt kein signifikanter direkter Effekt vor.

Der Bootstrapping Test ergibt ein BootLLCI von 0,024 (untere Grenze) und ein BootULCI von 0,213 (obere Grenze) und schliesst damit nicht die Zahl 0 ein, womit eine indirekte Mediation vorliegt.

Die Erkenntnis, dass eine starke moralische Identität ebenfalls Moral Disengagement begünstigt widerspricht bisherigen Erkenntnissen [22, 27] und zeigt auf, dass Individuen mit höheren moralischen Standards eher auf Moral Disengagement Mechanismen angewiesen sind, um unmoralische Handlungen zu begehen.

H2 (angenommen): Es konnte aufgezeigt werden, dass Moral Disengagement positiv mit unmoralischen Investitionsentscheidungen korreliert ist. Investoren stehen meist unter grossem Druck, eine grösstmögliche Rendite erzielen zu können. Dies kann dazu führen, dass eigene Moralvorstellungen übergangen werden müssen. Die Ergebnisse deuten darauf hin, dass sich dieses moralische Dilemma kognitiv durch Moral Disengagement auflösen lässt.

H3a (angenommen): Eine zentrale Annahme ist, dass Moral Disengagement als Mediator wirkt zwischen Motive für finanziellen Gewinn und der Tendenz, unmoralische Investitionsentscheidungen zu treffen. Dies konnte in der Mediationsanalyse bestätigt werden. Es handelt sich hierbei um indirekte Mediation nach Zhao et al. [26].

[2] Link: http://bit.ly/Dataset_DSchwarz

Damit ist der identifizierte Mediator konsistent mit dem vermuteten theoretischen Framework, Moral Disengagement kann somit als Mediator bestätigt werden.

H3b (angenommen): Die zweite entscheidende Hypothese besagt, dass Moralische Identität und die Tendenz, unmoralische Investitionsentscheidungen zu treffen, durch Moral Disengagement mediiert wird. Die Mediationsanalyse zeigt, dass eine indirekte Mediation vorliegt, welche den vermuteten Mediator bestätigt. Damit kann Moral Disengagement als Mediator im verwendeten Framework bewiesen werden.

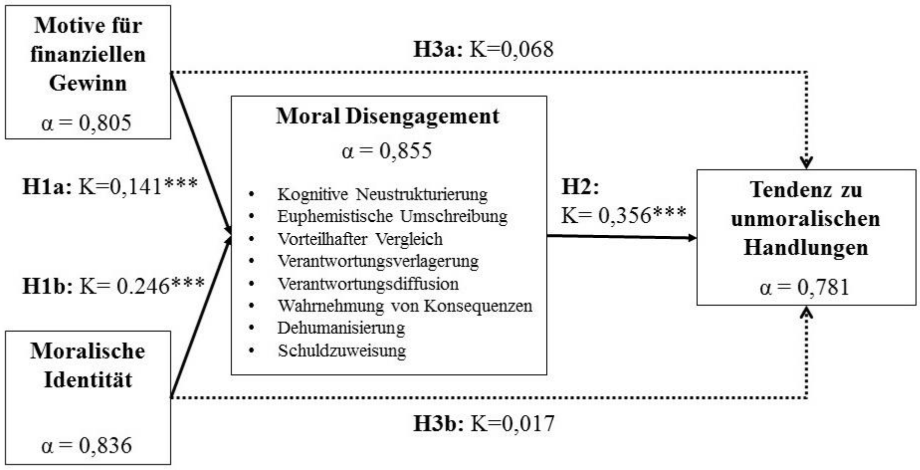

Abbildung 2: Ergebnisse des Mediationsmodells[3]

6 Diskussion & Implikationen

Crowdlending ist in den letzten Jahren eine ernstzunehmende Säule der privaten und geschäftlichen Kreditvergabe geworden. Durch die zunehmende Marktreife und die Rolle der Plattformen als vertrauenswürdige Intermediäre werden mittlerweile auch neue Investorengruppen erschlossen. Je relevanter für das Kreditgeschäft an sich und je gesellschaftlich akzeptierter Crowdlending wird, desto wichtiger wird es von akademischer Seite, die psychologischen Mechanismen zu verstehen, welche die Investitionsentscheidungen beeinflussen. Es konnte eine Forschungslücke im Bereich des Moral Disengagements identifiziert werden, die in dieser Arbeit anhand einer Mediationsanalyse untersucht wurde.

Die Arbeit präsentiert zwei massgebende theoretische Beiträge. Erstens, das in der Arbeit präsentierte Mediationsmodell fördert die Erkenntnisgewinnung zu moralischem Verhalten und Entscheidungsfindung im Crowdfunding. Dabei wurde der Fokus auf Moral Disengagement als holistischer Mediator gelegt. Diese Betrachtungsweise folgt dabei den Erkenntnissen von [6, 22]. Moral Disengagement und die Frage nach

[3] **Legende:** K = Koeffizient; α = Cronbach's Alpha; *** = p<0,01 | ** = p<0,05 | * = p<0.1

moralischem Verhalten wurde bislang in der Forschung zum Thema Crowdfunding weitestgehend vernachlässigt. Der Druck zu schnellen Investitionsentscheidungen mit limitierten Informationen und der Ausblick auf attraktive Renditen fördert beim Kapitalgeber die Tendenz zu unmoralischem Investitionsverhalten und somit das Umgehen des Selbstregulierungsmechanismus. Zweitens, stellt die Anwendung von Moral Disengagement auf die Crowdfunding Domäne eine Erweiterung der Forschung zum Moral Disengagement dar. Während Moral Disengagement in zahlreichen anderen Kontexten untersucht wurde, ist die Übertragung auf den Kontext Crowdlending neu. Dies dient als Ausgangslage für die weitere Untersuchung des Phänomens auch in anderen Crowdfunding-Arten dar.

Ausserdem präsentiert die Arbeit interessante Erkenntnisse für Praktiker. Das Verständnis über die Profitorientierung von Kapitalgebern und ihrer Tendenz zum Umgehen der moralischen Selbstregulierung ist sowohl für existierende als auch künftige Betreiber von Crowdlending-Plattformen von grossen Nutzen. Die Ergebnisse der Arbeit ermöglichen es Ihnen, Strategien und Mechanismen zur Vermeidung von unmoralischem Verhaltens von Kapitalgebern zu entwickeln. Diese sind notwendig um künftige Reputationsschäden zu vermeiden und damit zu verhindern, dass Kapitalgeber und Kapitalnehmer Crowdlending den Rücken zukehren oder womöglich eine härtere Regulierung des Marktes für Crowdlending ausgelöst wird.

Im Gegensatz zu Detert et al. [22] konnte nicht nachgewiesen werden, dass Individuen mit einer ausgeprägten moralischen Identität grundsätzlich weniger anfällig für Moral Disengagement Mechanismen sind. In dieser Studie wurde eine positive Korrelation zwischen Moralischer Identität und Moral Disengagement nachgewiesen. Dies könnte darauf schliessen, dass Individuen, denen moralisches Handeln besonders wichtig ist, zwangsläufig stärker auf Moral Disengagement Mechanismen zurückgreifen müssen um unmoralische Handlungen überhaupt erst zu ermöglichen. Umgekehrt kann argumentiert werden, dass Personen mit geringeren Ansprüchen an sich selbst hinsichtlich moralischer Standards auch nicht auf Moral Disengagement Mechanismen angewiesen sind, da sie eventuell die Handlung aus ihrer subjektiven Sicht nicht als unmoralisch empfinden. Diese Erkenntnis schafft die Grundlage für weitere Forschung hinsichtlich des Zusammenhangs von Moralischer Identität und Moral Disengagements.

Die Ergebnisse der Studie legen nahe, dass aufgrund der signifikanten Tendenz zu Moral Disengagement die Gestaltung des Kreditgesuchs einen entscheidenden Einfluss auf die Investitionsentscheidungen der Investoren hat. Für diese haben die Erkenntnisse dieser Studie insofern Einfluss, als dass sie Bewusstsein für das Thema und die Problematik von Moral Disengagement Mechanismen schafft. Hier gilt es zu überprüfen, welche Möglichkeiten bestehen, den Fokus der Investoren von Gewinnorientierung hin zu moralisch vertretbarem Investitionsverhalten zu lenken. So könnte untersucht werden, ob die Anzeige der anderen Investoren des Kreditgesuchs (oftmals mitsamt Profilbild) zu einer Minimierung der Verantwortung führt, da der Investor argumentieren kann, dass bereits andere das Angebot moralisch geprüft und als akzeptabel empfunden haben. Ebenso liegt eine Untersuchung darüber nahe, welche spezifischen Informationen über den Kreditsuchenden (z.B. Alter, Geschlecht, Kredithistorie, Verwendungszweck des Kredits, etc.) das Moral Disengagement beeinflussen. Auch von Relevanz ist die Darstellung der Kreditkonditionen. Hier kann vermutet werden, dass beispielsweise eine vergleichende Darstellung mit marktüblichen Konditionen das Risiko senken kann, dass Investoren Unwissenheit über die unvorteilhaften Konditionen eines spezifischen Kredits für Moral Disengagement einsetzen. Aufgrund der Neuartigkeit des Themas existiert noch keine weitere Forschung zu Moral Disengagement bei Crowdlending.

Ein wichtiger Beitrag dieser Forschungsarbeit ist folglich, implizit wirkende Mechanismen explizit zu machen. Es kann vermutet werden, dass das Wissen um die eigene Anfälligkeit für Moral Disengagement die Investitionsentscheidungen beeinflussen kann. Moralische Kontrollmechanismen müssen deshalb eine zentrale Rolle in der Entwicklung einer Crowdlending Plattform spielen.

Abstract. Managing IT employees' commitment in and after mergers and acquisitions (M&A) in the software industry is a key reason for success and failure of these initiatives. Thus, the purpose of this research is to identify influencing factors for IT employees' organizational commitment level during this process. Based on the case of a German software company that has been involved in several M&A over the last couple of years, qualitative data was gathered via personal semi-structured interviews with acquired employees, managers, and employees concerned with the mergers. All interviews are conducted and evaluated as well as presented using a narrative case approach. Results of the interviews suggest an overview on fields of action and processes in the field of organizational culture. Findings show that those IT employees, who're feeling being part of the new organization are more likely to stay motivated and committed while creating something new. In contrast, a strong culture at the prior employer lowers the feeling of being part of the new software company. As main contribution, this research discloses the two-sided coin of communication leading both to enhanced commitment due to increased transparency as well as to information overload decreasing employees' commitment during an M&A.

Ilgili, A.; Eckhardt, A. (2017): Examining the role of changing organizational culture on IT employees' commitment in M&A – Insights of a case study with a German software company, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1513-1525

1 Introduction

Researchers believe that companies engage with mergers and acquisitions (M&A) in order to increase profitability. But many other reasons, such as operating and financial synergies, contribute to an increasing activity of M&A as well [1]. Especially in the software industry, the progressive level of competition linked to M&A is remarkable. M&A trail organizational changes, which lead to different feelings, such as frustration, insecurity, stress, or non-appreciation among employees. These reactions can have a huge impact and cause the employees to rethink their commitment level to the organization. Although M&A might have many gains, such as increased turnover or profit, some companies look good on paper in the beginning, but hick-ups will confront both sides. M&A, especially in the IT industry, are very trendy and much sought-after since 2005, because these unions increase sales performance, grow assets, and develop networks.

While M&A are in great demand, companies have different processes, approaches or methods regarding the management of their employees during M&A, and this is an often critically discussed and considerably researched topic [1-3]. Within the Information Systems (IS) field, studies on IT workers' commitment have a long tradition, but to date there is no work examining their commitment during an M&A initiative [4-7]. Prior research only emphasizes that IS managers need to focus on the effect of motivating potential, group cohesiveness, and stress level during change initiatives [4]. According to Klaus et al., these aspects contribute to greater IT worker commitment, minimize turnover, increase their retention, which, especially in the IS industry, contributes to the company's profitability and long-term survival during larger organizational changes [4-5]. While employee commitment is considered being very important and the core variable in several research approaches is IT workers' turnover [6-7], there is still a research gap when it comes to the role of employee commitment during different stages of organizational development, such as after a merger or an organizational acquisition.

Therefore, this research aims to answer the following research questions:

RQ1: What are drivers and consequences for the commitment of acquired IT workers during an M&A initiative?

RQ2: What is the role of the changing organizational culture before, during, and after the M&A initiative?

In order to answer these research questions, this paper applies a qualitative research approach and introduces cases of several M&A processes involving a major German software corporation and acquired firms. In order to gather useful information, semi-structured personal interviews with managers, and employees affected by M&A were conducted. The respective data was evaluated and presented, using a narrative case approach [8]. Before we represent our case study results, we review prior literature for factors and concepts influencing employee commitment during M&A initiatives in the following section.

2 Research Background

This section will share theories and concepts as well as categorize topics on the role of organizational culture possibly affecting employee commitment during M&A. These aspects show the cause behind the proposition formed at the end of this section, which state the relevance of this study.

2.1 Influence of Old and New Organizational Culture during M&A

Cartwright and Cooper compare M&A with a civil marriage of two people and explain that they disturb the cultural peace, because when two different cultures come together, it might clash [9]. The bigger the difference, the bigger is the clash. Robinson indicates that start-up companies shoot from the hip while large concerns have their established processes [10]. Both have their advantages, but this can cause an organizational culture collision very often and lead to blurry working environments, conflicts among the employees and stress. Thus, less employee commitment is given and consequently the organizational performance is affected by job dissatisfaction [9].

Although most organizations agree on the fact that culture creates value to an organization, they have not found a successful recipe, because there is no 'right' or 'perfect' culture. It only depends on how two cultures get along with each other, just like in a marriage [9].

Cultural Orientation and Types

Previous literature on organizational behavior provides the foundation for Cameron's "Competing Values Framework" consisting of four quadrants – collaborate, control, create and compete [11]. Each one stands for a particular type of culture. The create-oriented culture has its focus on the products and future innovations, constantly developing new ideas based on technology and processes. Employee development, involvement and satisfaction are the characteristics of a collaborate-oriented culture with the aim to build skills and employee commitment. The control-oriented culture concentrates on transferring better processes to improve the efficiency. Whereas the compete-oriented culture strictly follows and observes the external competitiveness, which is determined by shareholder value, customer satisfaction, market shares, and so on [11]. An organization might have dominating aspects in its culture, but usually a little bit of every quadrant is present, because of differing forms of value creation. This might influence the merger type, because in an M&A the cultures can differ dramatically due to two different cultural approaches. This can result in frustrated employees leaving the organization or not performing efficiently in all merger phases.

Communication Culture

Regardless which cultural orientation or type companies have, employees are involved and will behave accordingly to the alignment of two organizational cultures. Larsen explains that in order to have a good relationship with employees and establish trust in general, a transparent communication is needed [12]. Furthermore, Larsen suggests supporting the communication strategy with managerial listening sessions [12]. Listening people evokes a feeling of appreciation and values opinion among the employees. This triggers loyal behavior towards the organization, lowers fear and increases satisfaction. Watson emphasizes that fear, doubt, and uncertainties are steady companions of M&A, because people will always have the question of what will happen next [13]. Furthermore, Watson stresses that an honest, informing, engaging and balanced communication will not result in a high level of fear [13]. Adding to this, Nahass et al. point out that communication has to be present at all stages – from the beginning to the end and long after the integration – because this transparency takes away fear, builds trust and therefore increases employees' commitment [14]. On this basis, Schwaab et al. illustrate that adequate information for employees' motivation is necessary, but not enough [14]. The top management has to show also persuasiveness, assertiveness, credibility and even more. Therefore, people who are part of the M&A should receive and give enough information at each stage at the integration via communication. Every concern needs attention, in order to build trust, increase the bond strength, lower uncertainty and grow employee commitment.

Cultural Working Environment

Organizations have different working environments, which are an important part of the culture. During an M&A, employees are in an identifying mode if they are compatible with the new organizations' work environment. For example, many companies have dress codes, core times or modern and colorful offices as well as room for creativity and new ideas. Mitchell et al. stress that employees seeing themselves suited to the organizational culture, are more attached to the organization in a professional and personal way [16]. Hom and Griffeth and Kane-Urrabazo suggest that the strongest indicator for employee retention is the creation of a positive working place and the linkage to job satisfaction [17-18].

Cultural Awareness

Schwaab et al. explain that M&A cause stress and fear for the individuals, because they are personally affected [15]. Whether it is the loss of workplace, the new technology, a change in the team, the long sought for career step, or the new organizational culture with a possible new name of the company. Schwaab et al. stress that M&A will always trigger fear, because each individual has different experiences, personalities and emotions [15]. It is more important to figure out how to deal with this fear and stress level employees have. Hereby, the organizational environment and the culture have a major role. The culture can lower the fear or stress level of employees by seeing it as a chance for the new or creating diversity [15]. In order to understand this, organizations have to achieve this cultural awareness and spread it.

Organizational Development & Diversity

The organizational development is a major factor in a human resources structure and adds to the company's' culture. According to Groysberg and Fernandez-Araoz, an organization needs to follow three steps, in order to find and develop their rising stars.

First, create a clear structure for the organizational priorities. Second, know how to select the right high-potential employees and third, have a plan on how to develop and reward these high-potentials. These steps can also be applied during an integration, in order to keep the acquired employees on board and increase their commitment level [19].

2.2 Research Proposition

After discussing the issues of M&A and examining a part of the existing literature regarding managers, work task, organizational culture and individual differences in general and in M&A, the focus is now shifting to the aim of this case study. It is based on a qualitative data gathered in semi-structured interviews. As mentioned before, there is still a research gap when it comes to the role of employee commitment during different stages of organizational development. It appears that although many companies have a theoretical construct with an overall picture of influencing factors of present or future employee commitment, still M&A fail or the aftermath endures too long. Therefore, within this case we observe the following proposition.
Proposition: Cultural integration at the software company is not always successful, because communication and information can lead to confusion and consequently exclusion.

3 Methodology

The subsequent sections describe the methodology including the applied research approach, case description, and data collection instruments as well as data analytics instrumentation.

3.1 Research Approach

The methodology of this case study follows a concept named "*a linear but iterative process*". Yin outlines that a case study is *"a contemporary phenomenon (the "case") in its real-world context, especially when the boundaries between a phenomenon and context may not be clearly evident"*, whereof the researcher has little control over the phenomenon or its behavior as well as a contemporary focus [8]. This case study consists of Yin's five features. The interviews allowed the participants to share what they want and feel and were not limited to questionnaire procedures (people's performance under real life conditions). Additionally, the three different groups gather different participant views, which emphasize the feelings and values of people who actually lived the incident. The contextual conditions, such as the social and external environment, have a strong effect on these incidents that people lived. Furthermore, the company employees bring in new perspectives and exclude the branding experiences from the past (preexisting and originating concepts). In addition, the three different groups base its conclusions on various sources. These five features lead to a mosaic of methodological and philosophical views, which contribute to different interpretations of people of the same event [8]. The multiplicity in interpretations gives the opportunity to present how opinions differ, because every individual interprets and feels experiences – the same reality – in a different way [11]. Furthermore, the different perspectives show where the company has faulty processes and what leaves room for improvement in order to reach a high level of employees' commitment during and after M&A.

3.2 Case Description

The company in our case has about 78.000 employees in 130 different countries and acquires companies since 2007. To observe the effect of old and new organizational culture, the interviewers selected a total number of 20 individuals from the software company in Germany, which represent the larger group of employees regarding the M&A topic. These interviews demonstrate three expert groups, whereof eight interviewees were acquired employees from different acquisitions during the past thirteen years (AcqEmpl= 8), seven current employees concerned with M&A and HR processes (Empl= 7), and five employees holding management positions (Mgmt= 5). The acquired employees shared their views in regards to contextual environment such as communication, technology, security, manager's role, trust, pace, information flow, being a part of the old and new organization, as well as their commitment level during the integration. The current employees contributed by explaining the effect on their internal daily working tasks in regards to feedback of acquired employees. The management group accompanied integrations from different departments, such as labor relations, M&A, board office, as well as HR and shared their so-to-say external perspectives on integrations. Each member of every group was part of M&A directly or indirectly of approximately seven different acquisitions in the last thirteen years. This contributed to multiple perspectives and sources of evidence (triangulation) in regards to integrations. The length of each interview was between 20–45 minutes and had the format of an open and virtual conversation. In order to gather the data and record the interviews in mp4 format, quiet rooms at the workplace were provided. The interviewer recorded the sessions and transcribed them subsequently. The interviews were conducted in a rough time span of one month, absolute anonymous and on a voluntary basis. In total, there are eleven female and nine male interviewees.

3.3 Data Collection Instrument

The different interview groups as well as acquisitions of this case study reason a multiple case design categorization. It explores a unique case as a unit with multiple acquisitions and data including documents, interviews and physical artifacts in form of company servers and former M&A information as sources of evidence [20].
This case study leans on a descriptive and explanatory approach that pumps as much information as possible [20]. Therefore, the interviewer used semi-structured narrative interviews. The interviewer asked the participants consistently for precise emotional states during the integration in order to overcome the past time frame of 13 years and filter the experienced feelings. Thus, the interviewer was able to support the

participants' deviation or asked further questions in case of insufficient answers. This structure of interview is also called in-depth inquiry and was supported by "how", "why" and/or "please describe" questions as well as matters with scalable answer possibilities following the request to describe their decision [8]. Besides the interviews, notes, tables, and narratives created the case study database.

3.4 Data Analytics Instruments

In a qualitative research, the focus is on the relevance of reviewed subjects concerning content representativeness. This means, the individual aspects play a major role. For this, Yin explains that generalization, validity and reliability have to be considered entirely [8]. In this connection, several steps were listed – paraphrasing, thematic order and comparison, conceptualization and generalization. First, paraphrasing implies that the content of the interviews are reflected and statements to a certain subject are highlighted, following the main themes from the interviews were assigned and compared (thematic order). In the conceptualization phase, commonalities and differences considering the theoretical body of knowledge of this study are expressed. The final phase of the analysis is the analytical generalization aspect, which compares the previous theoretical propositions to the results of this study. This study includes interviewees with acquired employees, managers as well as current employees of the company comprising M&A of the last thirteen years and is exploring an empiric subject by following Yin's iterative procedures [8].

4 Results

This section delivers categorized insight into the different perspectives and aspects of cultural change before and after the integration. For this, the resulting data is described by examining and categorizing the feedback of 20 semi-structured interviews and the above mentioned literature regarding influencing factors for employees' commitment. The following themes originated from this procedure.

Old Culture

All of the acquired employees mentioned how comfortable and fully committed they felt with their old employer. Additionally, the start-up or hands-on mentality was emphasized. Due to several factors, their commitment changed once the integration to the software company took place.

"It was a great place to work. We had something called "Hybris Spirit", which kind of described our way of work…"It's a life style, not just a work place"… It was a culture open for mistakes. We had quite a hands-on mentality, because we did everything for the first time. It was quite a family feeling." (Interviewee1, AcqEmpl)

One pointed out that the average age in their former team was younger, which contributed to a more dynamic working environment and behavior. Interestingly,

some mentioned their loyalty towards their old employer, because the relationship with the organization was not only on a professional, but also on a personal level.
"…the things they've done for me - both professionally and personally - have been pretty great; so I feel a great deal of loyalty there." (Interviewee4, AcqEmpl)

Also, almost all of the acquired employees pointed out that their colleagues and 'creating something new together' contributed to a great deal of loyalty and a feeling of 'being an important part' of the company (Interviewee5, AcqEmpl, p. XXI). Interestingly, one explained that a start-up company has only a few employees who might have to do more than they had to. This includes the willingness to dedicate more time and effort to the organization on a voluntarily basis.
"Culture - especially - was a big, big topic… when you are kind of small, you need people to play many roles, and people that are willing to not simply do their stuff, but take on things that need to be done." (Interviewee6, AcqEmpl)

These aspects all led to high levels of commitment with the prior employer and prevented the development of commitment with the new employer.

Organizational Culture
Many of the interviewees highlighted that the company has a lot of diversity in terms of people, culture, and languages and is a very open-minded organization with room for new ideas.
"I am not native German… culture means that everyone is welcome. They don't expect me to speak German… to understand their culture, at least in a professional environment. Everything is diverse and respectful." (Interviewee11, Empl)

Furthermore, the culture of networking in terms of coffee appointments was mentioned in a very positive way. The coffee corners mentality offers the face-to-face meetings, which give employees a personal note to their work. Nevertheless, employees note the lack of understanding relating to processes and procedures among the acquired employees during the organizational change. It was mentioned that there was no room for flexibility to approach processes differently. Everyone had to follow the established process steps, which were time consuming and partly confusing. *"Since the company is such a big company all processes take rather long. Everything is kind of linked to a formal procedure. And employees from acquired companies, which are usually much smaller than this software company, are not used to all this formality which at times can lead to frustration." (Interviewee14, Empl)*

The Giant
Many interviewees mentioned that the size of the organization and the volume of the change matters when two cultures come together. Instruments such as buddies, coffee corner sessions or organizational tools provide an additional insight into both organizations. However it was largely expressed by acquired employees that the software company was perceived as the 'Giant'. The primary reason for that was the imposition of working behavior and neglecting their culture.

"It was more of 'Wow. We bought you. We're a huge company. We know what we are doing. Here's what you're going to do.' And for some things they're probably right to do that. In other case… the things they were trying to tell us… simply wouldn't work for us. We understand that the software company bought us and therefore they have the right to make certain decisions. But at the same time we're trying to tell them what made us successful…" (Interviewee4, AcqEmpl)

Interestingly, one interviewee explained that employees' commitment level decreases automatically in an integration with two companies differing this much in their sizes. In a start-up organization, this combination was seen as a given fact. Due to the size of the company, it was rather perceived as impossible to establish this kind of combination and therefore a high level of commitment in the company.
"I'm not working for and with, at least, 75 thousand people - I will never meet them, I will never talk to them. I have no idea what they are doing. And it's likewise. So I rely on a lot of things that happen without having the tiniest chance of influencing anything. By way of not being ... the 1/75000th part of a company, my potential influence on anything, of course, has diminished as well. And in that sense, of course, it's harder to build up that relationship and that amount of trust and commitment to a company that you had before." (Interviewee6, AcqEmpl)

Respect
Showing mutual respect when two organizations come together was found to be a fundamental element of culture. The managerial interviewees are aware of the fact that people at the company tend to think their working behavior is more structured compared to the small-acquired company. The correlation of the 'behemoth' and the 'small, innovative and shooting from the hip' company causes disturbance, because the basic behavior among individuals have to be given, in order to create something new together. Employees believed that respect needs to be given first and it is in everybody's own hands. Therefore, a respectful treatment and showing interest in the counterpart is a crucial aspect.
"There is also a cultural aspect, which is respecting the culture that they come from and respecting the success that they had as a company… When they come in, there is this tendency to want to impose the same structures on them as we have... I think, sometimes some of that is necessary… And if you do need to impose certain rules, than we need to do it in a more sensitive way. And I think the other cultural aspect is just valuing what they do well. Making sure that this is being recognized and appreciated." (Interviewee19, Mgmt)

Having a Voice
Current employees assumed that the new acquired employees don't have a voice although many instruments are offered. In particular, the coffee corner session was described slightly underemphasized that it might not be the best instrument, because not every person is comfortable with speaking out concerns in front of others. *"Sometimes they get a voice… I don't have the impression that the exchange is going on very well… Yes, they have some options to express their selves in coffee corner*

sessions. If they dare to, but I think not everyone likes to speak up in a coffee corner session and to express his/her concern. This depends on your character...” (Interviewee12, Empl)

Interviewees found that being a part of this company have a great influence on the colleagues, the emotions and the organization. The cultural integration is at an acceptable level, but still has room for improvement. In order to make everyone a part of the organization and avoid ‘us vs. them’ attitude, listening and responding to the employees is one starting measure in cultural workshops, considering that finding the balance in cultural differences varies case by case. Therefore, approaches have to constantly be customized.
“That's another one of those things that you need to figure out in the cultural assessment upfront. Is this the kind of company that would like that and wants to feel as a part of the software company? Or do they want to be left alone a little bit more. Often, they do want to be left alone. But then the question is, we don't want to leave them alone too much, because than they won’t feel like a part of the family. So, you always have to come up with that balance.” (Interviewee19, Mgmt)

5 Discussion

We started our qualitative investigation with the proposition that cultural integration in M&A is in the software industry is not always successful, because communication and information can lead to confusion and exclusion. We outline the major implications of our research on drivers and consequences of IT workers’ organizational commitment in M&A initiatives in this section. Therewith we emphasize how IS research on managing the workforce can benefit by our approach [4-7].

5.1 Implications for Research

In integrations, culture is multifaceted. One important aspect is the cultural orientation. Following Cameron’s explanation about cultural orientation, the software company belongs to the create-oriented section, since it has its focus on the products and future innovations, constantly developing new ideas based on technology and processes [11]. Relating to M&A and according to the theory by Cartwright and Cooper [9], the company follows the approach of a redesign merger during an integration, which includes creating win-lose situations. This means, the dominant acquiring company forces its culture onto the acquired company. According to many statements from interviewees, the software giant’s cultural dominance during an integration applies completely. One reason is the difference in the size of the companies. Most of the acquired organizations are significantly smaller than the software company. Another point is the lack of flexibility from the company’s side when it comes to processes and procedures. On the one hand, these established and structured activities are needed. On the other hand, acquired employees see the

company as a behemoth forcing their cultural aspects onto others. The expectations are rather different and asking for the acquired company's 'recipe' for success is missed.
Secondly, communication is essential for employees going through a complex organizational change. The interview results are the basis for dividing the negatively perceived communication and information in three categories. First, interviewees pointed out that lack of communication leads to uncertainty among the employees and consequently results in dissatisfaction. Second, the wrong communication/information leads to distrust, because too optimistic communicated aspects cannot be fulfilled later on. Whereas too much communication/information is very overwhelming and end up e.g. in deleting mails.
"Yes, the software company sends out tons of emails…, but there is always a delete button if you are not interested." (Interviewee1, AcqEmpl)

All three categories result in confusion, frustration, lack of trust and dissatisfaction, which are influencing factors for commitment. Although the software company tries to include the employees during an integration via their numerous communication instruments, employees are totally confused or overwhelmed at some point, which leads to exclusion. These aspects negatively affect employees' commitment level. Based on the mentioned literature, this could have a negative effect on employees' productivity and therefore the company's success. Moreover, this could be a reason why some employees are still rebuilding their relationship with the new employer, although the integration was several years ago.

5.2 Implications for Organizational Practice

The company observed in this case studies is known as a very attractive and reliable employer that puts a huge focus on their organizational culture and employees. The happier the employees, the better the performance. Moreover, the company values employee satisfaction and therefore puts their focus on motivation with various programs or methods. One program is called the Fellowship program, which is designed to engage employees in strategic projects and to grow strengths in different business areas. It can range from 4 weeks to 6 months in length and includes a possible relocation. The main purpose of this program is that employees accelerate readiness for broader responsibilities and collaborate on strategic projects to support execution of the company's strategy. One interviewee mentioned that there was an employee, who took part at this fellowship program, mainly to support them in their integration phase. His responsibility was to onboard his future colleagues in company systems and tools including its forecasting, budgeting and Q&A sessions. This helped to shorten the learning curve. Moreover, they felt appreciated and addressed all the concerns or issues in that area. The fellow on the other hand, was able to dive into a different department in another country. Therefore, this program is an ideal option to expand in the pre-merger phase of M&A in the future. This could help to reduce the frustration level among the employees regarding the technological area and provide a confident and positively emotional stage during the integration among the employees.

Furthermore, it would suit the acquired employees, because they often mentioned in the interviews that they prefer the face-to-face contact in such organizational changes.
A second point, which was mentioned by some interviewees, was related to the cultural workshops. Here, it was a group of employees, who visited the acquired companies to approach possible issues, offer transparency, discuss strategy, set up cultural scans, ask for feedback etc. As far as it was explained, this only happened one time during an M&A, although it received only positive feedback to this procedure. This might be another option to tackle and implement the cultural workshops as inherent part in the M&A processes in the pre-merger phase for future integrations.
There is a lot of energy in the beginning of an M&A and the organizational change will carry many emotional stages. It will start with excitement and continue with doubt and discomfort. At this turning point, difficulties with various aspects will rise. The importance is to use the right measures at this explicit turning point to reduce the negativity and increase motivation and commitment. Moreover, it is important to understand that acquisitions are a good thing and help to secure a company's success. As one manager explained:
"…these acquired companies, they help us and they secure our revenue stream, our success and with that we have the workplaces we have right now. For every acquired workplace, we secure another year or something like that and to me it's clear that it's that way, but maybe that should be clearer to everyone, or should be made clearer to everyone here." (Interviewee20, Mgmt)

5.3 Limitations and Interesting Avenues for Further Research

Nonetheless, the study has limitations. The study was conducted with 20 employees and based on qualitative data. Meaning, although the theory proves that lack of trust, communication etc. leads to frustration and therefore to low commitment level, the values from the interviews are not analog to the statements received from the interviewees. While acquired employees are very frustrated in many aspects, their commitment level is only minimally lower, which is a compliment for the new employer. Surprisingly, current employees and managers estimated the commitment level of acquired employees extremely lower. The same findings were examined with the overall expectations in relation to commitment level. We assumed that the company must have other positively influencing factors for commitment, which convince the employees and avoid the extreme decrease of commitment, e.g. the IT industry, size of the company, numerous opportunities. However, in order to find out the reasons for the nearly non-changing commitment level among employees during an integration, large-scale interviews in the IT industry might be an idea. Hereby, it is suggested to put the focus on qualitative data again, since it offered a good platform with much information.
Secondly, interviewing drop-offs of former M&A can support creating a wider understanding of this matter. This could give further insights to commitment, turnover, and other predictors that could add value to the organization and research.

The Core Capabilities of Green Business Process Management – A Literature Review

João Carlos Maciel

University of Liechtenstein, Institute of Information Systems, Vaduz, Liechtenstein
joao.maciel@uni.li

Abstract. Environmental sustainability has become a key concern of contemporary organizations, due to the impact of their operations on the environment. Organizations can be seen as sets of business processes that aim to generate business value, and business process management can play a significant role in designing and implementing more environmentally sustainable processes. Green BPM is the discipline that integrates sustainability-related thinking into business process management. In this paper, we present the results from a literature review on Green Business Process Management. Using the six core elements of BPM – Strategic Alignment, Governance, Methods, Information Technology, People, and Culture – as an analytical lens, we identify key capabilities required in Green BPM. Based on our analysis, we derive a Green BPM lifecycle to identify relevant methods, techniques, and approaches that can be applied to help organizations design improved business processes that exert a minimal impact on the natural environment.

Keywords: Green BPM, Environmental Sustainability, Core Elements of BPM, Green BPM Lifecycle, Literature Review.

1 Introduction

Environmental Sustainability is one of the various concerns of contemporary organizations, and sustainability is now often seen as an explicit performance dimension, in addition to traditional ones such as cost, time, and quality [1]. Sustainability has become increasingly important as organizations need to comply with rules and policies with regards to their operations and their consequences on the natural environment [2].

Organizations can be seen as sets of business processes operating to generate business value. The enterprise's business processes play an important role in contributing to the carbon footprint an organization emits [3]. Therefore, as BPM focuses on the understanding and improvement of an enterprise's business processes [4], it can be a significant enabler towards more environmentally sustainable organizations. Furthermore, Green BPM is the discipline that integrates sustainability-related thinking into business process management.

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Maciel, J.C. (2017): The Core Capabilities of Green Business Process Management - A Literature Review, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1526-1537

In this paper, we present the results from a literature review on Green Business Process Management. Prior literature reviews on the topic can be found [5], [6], [7]. However, this study takes into account a different approach to analyze the current state of Green BPM research. Using the six core elements of BPM [8] – Strategic Alignment, Governance, Methods, Information Technology, People, and Culture – as an analytical lens, we identify key capabilities required in Green BPM. This study also differs from previous literature reviews as it depicts a Green BPM lifecycle, which encompasses diverse methods and techniques derived from the literature. Our essential research question is:

What is the current state of Green BPM research?

The remainder of this paper is structured as follows. Section 2 provides an overview on the concepts of Green BPM and green business process, as well as on the six core elements of BPM. Section 3 describes the methodology used for the literature review. Section 4 presents the main findings from the analysis of the literature. Section 5 presents the Green BPM lifecycle derived from literature. Potentials for future research are disclosed in Section 6. Finally, Section 7 concludes with a summary of the results.

2 Research Background

2.1 What is Green BPM?

We firstly present the concepts of sustainability and BPM, which are followed by a definition of Green Business Process Management. Sustainability is commonly defined as the "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" [9]. Business process management can be defined as the discipline that provides appropriate concepts, methods, and tools to model, implement, operate, and monitor business processes [10]. Different yet similar definitions of Green BPM can be found. They commonly build on the business process lifecycle from "classical" BPM, and add the ecological factor. Examples are the "dedicated consideration paid to the environmental consequences of these business processes" [11], the optimization of business processes considering the ecological dimension [12], and the aim to support environmental objectives [13].

Thus, one can understand Green BPM as the discipline that provides appropriate concepts, methods, and tools to support business process modeling, implementation, execution, monitoring, and continuous change with dedicated consideration of the environmental impact of these business processes.

2.2 What is a Green Business Process?

The execution of a business process has always a certain impact on the environment [12]. Business processes play thus an important role in contributing to the carbon footprint of an organization [3]. As a business process transforms inputs into outputs, the renewable and non-renewable inputs as well as the type and environmental quality of the outputs determine the sustainability of a business process [14]. In this line of thought, the extent of renewable inputs as well as the extent of emissions (outputs) that can be kept within the assimilative capacity of the environment should be maximized, while the extent of non-renewable inputs and the extent of emissions (outputs) that exceed the assimilative capacity of the environment should be minimized [14].

Therefore, a green business process is an environmentally conscious business process that is necessary, efficient, effective, agile, and measurable in the context of an organization [3] and delivers organizational value with a minimal impact on the natural environment [14]. Additionally, from a more technological perspective, an energy-aware business process is a service-based business process that considers functional and non-functional requirements, as well as specific annotations for guiding energy assessment [15].

In summary, one can understand that an environmentally sustainable (green) business process is a business process that generates business value with minimal impact on the environment, thus without compromising the environmental resource availability for future generations.

2.3 The Six Core Elements of Business Process Management

In this study, we consider the model of BPM capabilities [8] (Table 1) to analyze the literature on Green BPM in terms of its contributions related to the six core elements of BPM: strategic alignment, governance, methods, information technology, people, and culture. This model seems very appropriate for this study as all these elements represent critical success factors for BPM in an organization [8]. Therefore, each element should be considered by organizations seeking success with BPM [8]. For each element, distinct capability areas were identified, as shown in Table 1. The six core elements can be described as follows [8]:

- **Strategic Alignment**: The complete cycle of BPM needs to be tightly linked with the overall strategy of the organization, enabling continuous improvement and achievement of business goals.
- **Governance**: BPM Governance establishes pertinent and straightforward accountability for different levels of BPM. In addition, it provides support to the design of decision-making and compensation processes to manage process-related actions in business process management.
- **Methods**: Set of instruments and techniques that enable and support consistent actions along the BPM lifecycle.

- **Information Technology**: IT-based solutions are the software, hardware, and information systems that enable and support BPM activities.
- **People**: Individuals and groups who continuously develop and apply their BPM-related skills and knowledge in order to enhance business performance.
- **Culture**: Culture is the collective beliefs and values that define BPM-related attitude and behavior in order to enhance business performance.

Table 1. The six core elements of BPM [8]

Strategic Alignment	*Governance*	*Methods*	*Information Technology*	*People*	*Culture*
Process Improvement Planning	Process Management Decision Making	Process Design & Modeling	Process Design & Modeling	Process Skills & Expertise	Responsiveness to Process Change
Strategy & Process Capability Linkage	Process Roles and Responsibilities	Process Implementation & Execution	Process Implementation & Execution	Process Management Knowledge	Process Values & Beliefs
Enterprise Process Architecture	Process Metrics & Performance Linkage	Process Monitoring & Control	Process Monitoring & Control	Process Education	Process Attitudes & Behaviors
Process Measures	Process-Related Standards	Process Improvement & Innovation	Process Improvement & Innovation	Process Collaboration	Leadership Attention to Process
Process Customers & Stakeholders	Process Management Compliance	Process Program & Project Management	Process Program & Project Management	Process Management Leaders	Process Management Social Networks

3 Methodology

We conducted a structured literature review [16] to answer our research question presented in Section 1. The subject of this literature review is environmentally sustainable business process management. Therefore, the search terms were “Green”, “Sustain*”, “BPM”, “Business Process Management”, “Business Process”, and “Process”. *Google Scholar* was the main search engine used for the literature search, but *ScienceDirect* and *ABI/INFORM Complete* were also considered to corroborate the search process. The terms *Green IT* and *Green IS* were excluded from the search, since we aimed to find BPM-related papers exclusively. Initially, we retrieved 52 papers that we considered relevant for this study based on their title and abstract. However, we did not have access to full-text of ten papers, thus these ones were excluded for further analysis. The final set contained 42 articles selected for deeper analysis, as they were identified to be relevant to our study, and we had access to their full content.

Based on the framework described on the previous section, we classified the literature according to its main coverage content. For each source, the categorization took into account frameworks, models, and propositions related to Green BPM. A paper that, for instance, simply mentions that strategic alignment is important in BPM, or that Information Technology plays a critical role in delivering process innovation, would *not* be categorized in the Strategic Alignment and Information Technology capability areas, respectively.

4 Findings

The analysis of the literature led us to two main categories of papers: (i) papers that provide a more general view on Green Business Process Management (10), such as literature reviews, or papers presenting holistic approaches covering many aspects of business process management; and (ii) papers with a focus on one or more specific areas of interest for Green BPM (32). Additionally, 67% of the papers analyzed were conceptual in nature.

The papers classified as *General* present: (i) differences and commonalities between green and conventional business process management [2]; (ii) a literature review on Green BPM [5]; (iii) a literature review and research framework for Green BPM [6]; (iv) a literature review on Green BPM [7]; (v) an introduction to and a framework for Green BPM research and practice [11]; (vi) an approach that utilizes a BPM framework in order to transform and manage business processes for a Green Telecommunications company [17]; (vii) ways to manage sustainability in the face of unordered business processes [18]; (viii) opportunities and challenges of Green BPM based on conceptual considerations [19]; (ix) a Green BPM readiness model [20]; and (x) the role of business process management in green initiatives [21].

With regards to the core elements of BPM, this study shows that most of the papers (54%) are focused on *Methods* (See figure 1). *Methods* and *Information Technology* together represent more than 80% of the literature. Our analysis thus shows that Green BPM research has been mainly focusing on the process lifecycle, aiming to find answers related to issues in the design, measurement, and improvement of processes in terms of environmental sustainability.

5 Green BPM and the Process Lifecycle

Based on the literature review, we derived a **Green BPM lifecycle** (Figure 2 - adapted from [47]), which considers the methods, techniques, and approaches yielded through our literature analysis. The model represents a non-exhaustive rack of items found in the literature. This lifecycle model thus identifies which methods, techniques, and approaches might be selected and combined according to the specific business context, and under consideration of the environmental, process-related goals of an organization. Some of the methods present in the lifecycle (e.g. Process Viewing Patterns, process automation) are not exclusively designed for Green BPM. Nonetheless, we assume that, whether combined with other techniques or not, they might support the overall enterprise-wide process management framework, thus being able to contribute to making business processes more environmentally sustainable. We believe that the Green BPM lifecycle can serve as a framework for future studies in this field, and we thus encourage its empirical application and evaluation.

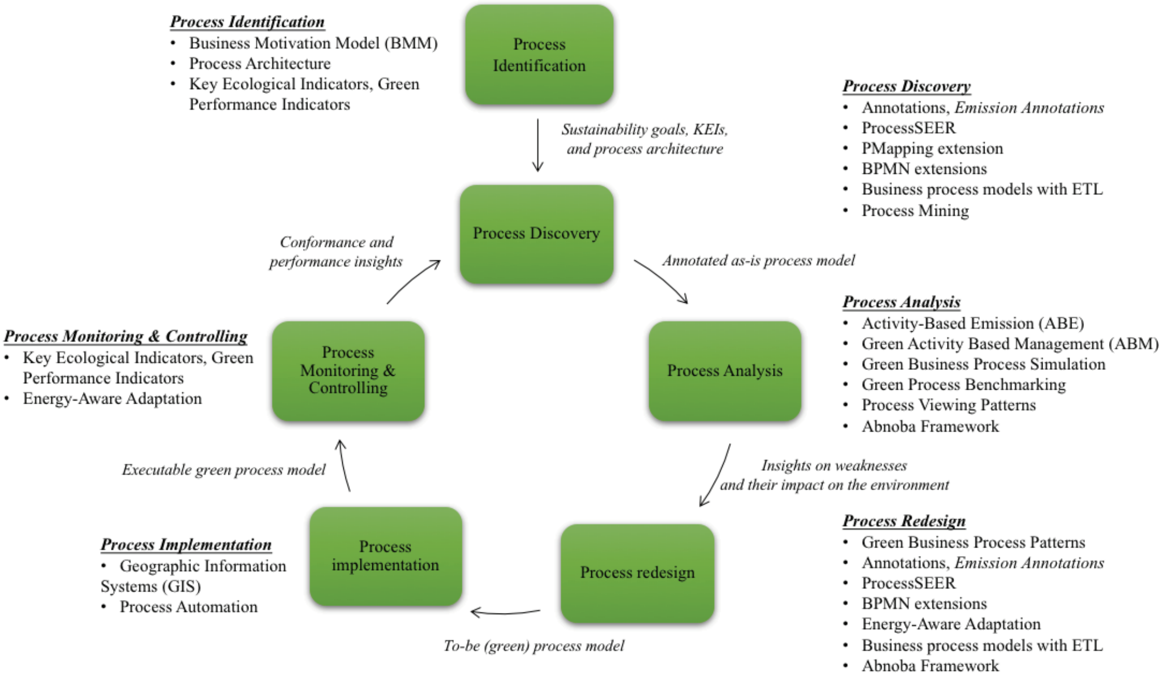

Figure 2. Green BPM lifecycle (Adapted from [47])

6 Research Agenda

From the literature analysis, we found several approaches that integrate sustainability-related thinking into business process management. Since most of the papers are conceptual, we believe that future research should focus on empirical studies that propose and evaluate methods, techniques, and initiatives that can be applied to all six core areas of BPM, and that can support organizations in the execution of business processes leading to as little impact as possible on the natural environment.

Strategic Alignment is mostly considered in terms of *Process Measures*, with environmentally sustainable performance indicators [2], [15], [23], [24], [25], [26], [27]. However, little or no attention has been paid to the other capability areas within this core component of BPM (e.g., process improvement planning, etc. – see Table 1). Future studies might focus on the alignment of Green BPM with the overall strategy of an organization. So, how could organizations address the trade-off between economic and environmental goals in their strategy? How to consider environmental characteristics of processes in the *Enterprise Process Architecture*? Which sustainability factors should be acknowledged in a *Process Improvement Plan*?

We found several **Methods** that can support the adoption of Green BPM and help organizations reduce the negative impact of their business processes. Nevertheless, there was no paper classified in the *Process Program & Project Management* capability area, and little attention has been paid to *Process Implementation & Execution*. So, how can sustainability factors be embedded into executable business process specifications? Which methods and approaches should be used for the management of green BPM projects?

Even though some relevant research on **Information Technology** as an enabler of Green BPM exists, there is still a lack of explicit focus on the process lifecycle. This is the case, for example, of process modeling tools that incorporate green process modeling notation extensions (e.g. BPMN, EPC) or BPM systems that consider ecological characteristics. How should these extensions be described in order to facilitate their implementation by BPM software vendors? Which tools could facilitate the management of green initiatives? We strongly encourage more in-depth research on solutions that support the mining, modeling, analysis, simulation, implementation, and monitoring of green business processes, thus providing means of integration and incorporation of sustainability factors within those information systems.

Our analysis indicates that research has paid little attention to **Governance, People,** and **Culture** in green business process management. We thus argue that there is still a need for studies on Green BPM that address these areas in more detail. In the context of *Governance,* what would be appropriate methods to measure an organization's Green BPM maturity? How to design structured and consistent decision-making processes to guide sustainability-related actions? When considering *People*, what are the *Process Skills and expertise* necessary in a sustainable BPM approach? For *Process Education* initiatives, what needs to be considered in a Green BPM education curriculum? In terms of *Culture* in Green BPM, what are the essential values and attitudes for meeting Green BPM objectives? What is the role of social networks in Green BPM?

7 Conclusion

This study aimed to analyze the current state of research on Green BPM. To that end, we conducted a literature review, which comprised several studies on Green Business Process Management that were categorized according to the six core elements of BPM. We found that most of the contributions were presented as conceptual studies and that the majority of papers were focused on methods and techniques that consider sustainability factors in business process management. We contributed with the description of the Green BPM lifecycle based on the methods, techniques, and approaches derived from the analysis of the literature. We argued that the Green BPM lifecycle can serve as a framework for future studies that aim to apply, combine, and compare methods that can be utilized in each phase of the business process management lifecycle to help organizations become more environmentally sustainable, thus reducing their impact on the environment. We discussed key gaps regarding Green BPM that emerged from our analysis, and suggested avenues for future research for each core element. We argued that future research should consider all six elements of BPM, and should evaluate and propose means to address the environmental impact of business processes. Furthermore, this study is not without limitations. First, we did not have access to full-text versions of all papers, so some relevant contributions might not have been included in this study. Having access to full-text papers for all literature found could have disclosed additional Green BPM approaches. Second, the paper coding was conducted by only one person, which might have led to biased paper classification. It might have been better if two researchers had been involved working on a pair coding mode. Still, by using the criteria provided by the BPM maturity model [8] the author took care to base the coding on formal concepts derived from the literature.

Acknowledgments

This paper has been written in the context of the Student Research Fellowship at the Institute of Information Systems at the University of Liechtenstein. The author is pleased to acknowledge Prof. Dr. Stefan Seidel for his support in the entire process. The author thanks the anonymous reviewers for their very constructive remarks.

Abstract. The present paper is concerned with the automation of the process of conducting literature reviews. Manual reviews are getting more and more difficult as the number of publications increases steeply. Against this backdrop, we investigate the application of deep learning techniques for the automation of the time consuming step of comparing and categorizing large sets of scientific literature. In contrast to prior research, we leverage the potential of the word2vec algorithm that provides a more semantic focus of analysis than common text mining approaches. We evaluate our artifact considering an exemplary document collection comprising 906 articles on Radio Frequency Identification. Our results indicate that our word2vec-based system provides better results than a system based on traditional text mining approaches.

Keywords: Text Mining, Literature Review, Word2vec, Design Science, RFID

1 Introduction

Free text is the most natural form of storing information. Nair and Narayanan [1, 2] show that up to 80% of the world's data is stored in the form of unstructured data such as text documents and that such data is growing at 15 times the rate of structured data. In times of proceeding digitalization, capturing the content of this growing data pool becomes increasingly difficult. As a result, the means to structure and understand unstructured data become more and more important.

This problem is particularly evident in the process of creating literature reviews, which summarize the current state of research in a scientific field and are thus a fundamental component in the process of knowledge creation. The Thomson Reuter's Web of Science, for example, contains about 58 million articles. This large number is clearly illustrated by Van Noorden et al. [3] who outline that printing just one page of every item would lead to a stack of papers that would reach almost to the top of Mt. Kilimanjaro. Moreover, Bornmann and Mutz [4] show that the number of publications doubles approximately every 24 years. Obviously, the large number of articles make it difficult to identify relevant information [5]. We conclude that there is a need for improving the process of conducting literature reviews in order to successfully process this increasing number of articles.

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Dann, D.; Hauser, M.; Hanke, J. (2017): Reconstructing the Giant: Automating the Categorization of Scientific Articles with Deep Learning Techniques, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1538-1549

To address this information overload problem, firstly, the literature review process should be structured and follow well established frameworks (e.g., [6–8]). This helps the creation of consistent and comparable reviews and allows researchers to extend easily the work of others and so keep the research community up to date [6]. Secondly, techniques for partial automation of the process should be investigated in order to keep up with the ever growing acceleration of article publications [5].

To facilitate the automation of reviews, a structured review process is a necessary prerequisite. In our research, we consider the structured process for conducting literature reviews described by vom Brocke et al. [6] and investigate the automation of the most labor-intensive process step. Their framework encompasses five phases. In the first phase, the focus of the review is defined. In the next step, one has to gain a broad conception of the selected research topic which covers, for example, the understanding of key concepts and the uncovering of relevant search terms. Afterwards, relevant articles for the review are identified based on these search terms. In the fourth step, the literature is analyzed and synthesized. Here, vom Brocke et al. [6] suggest using a concept matrix to categorize the literature. These matrices were adapted for literature reviews by Webster and Watson [7] and map individual articles to the concepts they belong to. In the last step of the framework, a research agenda is created based on the results from previous phases.

In our research, we aim at automating the fourth phase of the considered framework which is especially complex and time-consuming. To this end, we apply data mining techniques to compare and categorize semantic contents of large amounts of scientific articles. To approach this task, the text documents must first be transformed into a structured data form. For this step, systems described in literature mostly rely on the commonly known bag-of-words model (e.g., [5, 9–11]). This model, however, has several drawbacks and is less suited for categorizing literature owing to loss of word order and the linguistic phenomena of ambiguity and synonymy which are not well handled by the model [5]. In contrast, we develop a system based on the word2vec model introduced by Mikolov et al. [12]. This model uses high quality vector representations of words to express their semantic information value and therefore should be more suitable for comparing and categorizing literature.

2 Related Work

Algorithm-based comparisons of scientific documents and their potentials have been of great interest to researchers (e.g., [5, 9–11, 14–16]). These approaches can be roughly categorized by the way they transform unstructured data into structured data. We differentiate between (i) text-based, (ii) citation-based, and (iii) hybrid approaches. Text-based approaches compare the textual content of articles (e.g., [9–11]), link-based approaches the citation links of articles (e.g., [14, 16]), and finally, hybrid approaches build on both approaches (e.g., [5, 15]).

The text-based approaches we found in literature use the bag-of-words model for the data transformation step but consider different text sections (e.g., keywords, titles, abstracts, full texts) and pursue different objectives (e.g., categorization of documents or development of recommendation systems). Gulo et al. [10] analyze abstracts of articles and use machine learning techniques and Bayesian classifiers for categorizing these articles. In contrast, Wang and Blei [11] develop a recommendation system for scientific literature. To this end, they process abstracts and titles of scientific articles with topic modelling and collaborative filtering techniques. The document collection of Afonso and Duque [9] contains titles of articles, abstracts, keywords and the first page or column of the introductions. They again aim at categorizing scientific literature and therefore compare different automated text-based clustering approaches.

Carpenter and Narin [14] use citation-based approaches for the data transformation step. For this purpose, they assume that journals in the same scientific domain have similar reference patterns and thus refer primarily to each other. As a result, they base their clustering process on cross-citation links of articles. Chen [16] uses this assumption and develops a citation-based system for analyzing and structuring literature. Deploying principal component analysis, he generates a correlation value which serves as a measurement for the relatedness between scientific papers.

Hybrid approaches were proposed by Bolelli et al. [15] and Aljaber et al. [5]. As with the purely text based approaches, both author groups use the bag-of-words model for the data transformation step. However, in contrast to these approaches they also consider the citations of articles. The first group considers complete article texts and the citation graph spanned by the articles for the categorization of documents.[1] In contrast, the second group considers citation contexts which are sequences of words surrounding citation markers within the full texts of the documents. They argue that including the citation contexts addresses the issue of synonymy, one of the drawbacks of the bag-of-words model. This is because, according to the authors, these contexts provide "relevant synonymous and related vocabulary which will help increase the effectiveness of the bag-of-words representation". The authors furthermore benchmark their model against a purely citation-based and a text-based model that considers the full texts of documents. Their results indicate that citation-based approaches are inferior to text-based approaches for document categorizations.

Counter to Bolelli et al. [15] and Aljaber et al. [5], we choose a purely text-based approach. We do, however, not rely on the bag-of-words model for building word representations. Instead, we use the word2vec model introduced by Mikolov et al. [12], that is able to express the semantic information value of big amounts of data in a way the bag-of-words model is not. In contrast to the hybrid approach developed by Aljaber et al. [5], the word2vec model addresses not only the synonymy issue of the bag-of-words model but also the issue of ambiguity and considers the information value of the word order. This makes a combination of link-based and text-based approaches unnecessary and justifies our purely text-based approach.

[1] A citation graph is a graph with papers as vertices and citations as directed edges between citing and cited documents.

3 Design-oriented Research

We pursue a design-oriented research approach to develop an artifact that automatically compares and categorizes scientific literature. The artifact design process follows the guidelines put forward by Hevner et al. [13]:

- **Problem Relevance:** Conducting a structured literature review is a complex and time-consuming endeavor and is getting more and more difficult as the number of publications increases every day [4]. To cope with this trend, it is essential to examine whether available text and data mining techniques are suitable for automating the process of structuring scientific articles.
- **Research Rigor:** In our research, we utilize deep learning and established data mining techniques. The proposed artifact is based on the word2vec model introduced by Mikolov et al. [12] that is capable of processing large amounts of textual data.
- **Design as a Search Process:** The idea of conducting an automated literature review is not completely new, but has been a field of research for several years [9]. Our paper examines in particular whether the word2vec model is suited to automate the fourth phase of vom Brocke et al.'s [6] literature review framework.
- **Design as an Artifact:** We design an IT artifact consisting of three components to provide an automated categorization of scientific literature. The artifact is implemented using the Python programming language.
- **Design Evaluation:** We evaluate the artifact considering an exemplary document collection comprising 906 articles on Radio Frequency Identification. We benchmark the artifact against a system based on the bag-of-words model.
- **Research Contribution:** We propose an artifact that is able to process large numbers of scientific articles and conceptualize them. Therefore, we apply novel deep learning methods that provide a more semantically focus of analysis than ordinary text processing models.
- **Research Communication:** A system that allows to capture large amounts of scientific literature quickly and effectively is an enrichment for scientists from all research disciplines. In addition, our paper addresses an audience with a more technical focus by explaining in detail the design of the proposed artifact.

4 Artifact Description

The artifact architecture is depicted in Figure 1 and consists of three components. The first component generates a word vector model based on the user-generated document collection (Subsection 4.1). This model allows the representation of each document in a vector space. Subsequently, comparing these vectors enables determining the similarity of documents. The output of the first component is a matrix containing all the similarity values among the documents in the collection and is input to the artifact's second component. This component groups the documents based on this matrix with a hierarchical clustering algorithm (Subsection 3.2). Finally, in the third component each cluster is automatically labelled with meaningful keywords through the application of a keyword extraction algorithm (Subsection 4.3). The keywords describe the clusters and thus inform users about the predominant topics within the individual clusters.

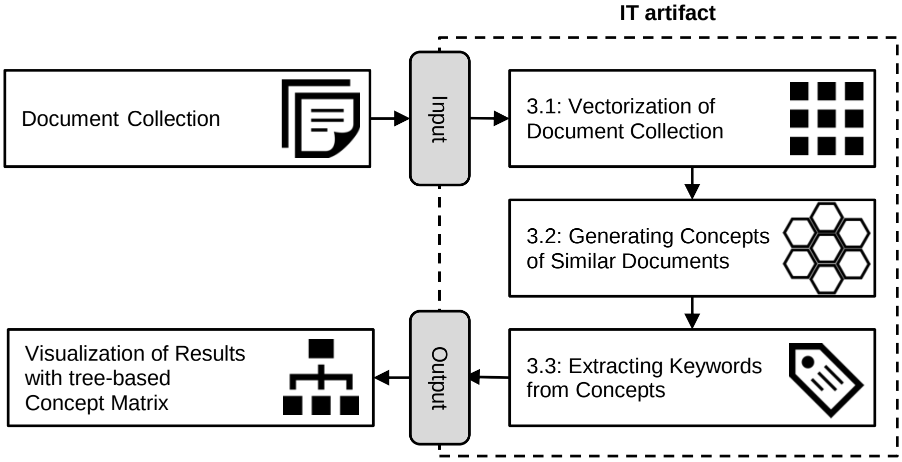

Figure 1. Architecture of the IT artifact

4.1 Vectorization of Document Collection

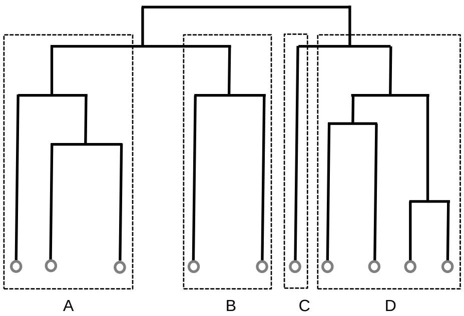
A user-generated collection of text documents serves as input for the proposed artifact. To represent the single documents as vectors, we train a data model using the Paragraph Vector algorithm introduced by Le and Mikolov [17] which is an extension of Mikolov et al.'s word2vec model [12].

Word2vec aims at training a word vector for each word occurring in the document collection using artificial neural networks. Using this deep learning technique enables us to prevent the drawbacks of the commonly used bag-of-words model. On the one hand, the bag-of-words model does not make use of the information value of the word order which may lead to errors because the model provides identical representations of semantically different sentences in case the same words are used [17]. On the other hand, the model cannot capture the linguistic phenomena of ambiguity and synonymy. The first phenomenon denotes lexically similar but semantically distinct words, the second semantically different but lexically similar words. These weaknesses lead to a more syntactic than semantic focus of the analysis, which makes the bag-of-words model less suitable for comparing and categorizing literature. In contrast, the word2vec model considers the context of words and thus eliminates the problems of traditional text processing models. Mikolov et al. [18] defines the word context as the words that surround a particular word. Leveraging these word contexts allows taking the word order into account. In addition, considering all individual word contexts in the entire document collection results in a high dimensional vector space in which vectors of semantically related words are located in close proximity to each another.

In order to make documents comparable, the Paragraph Vector algorithm builds on the word2vec model to represent each document as a concatenation of its word vectors in structured form. This vector representation of entire documents allows content-based similarity calculations using traditional distance measures. We apply the cosine distance, which is widely used in text mining applications to quantify the semantic relatedness of documents. We construct a document×document similarity matrix containing similarity values ranging from 0 to 1 with high values indicating similar contents and vice versa. The matrix is input to the artifact's second component.

4.2 Generating Concepts of Similar Documents

The second component automatically groups content-related documents based on the generated similarity matrix. We apply an agglomerative hierarchical clustering approach because it does not require an explicit specification of the number of clusters.[2] We employ the Unweighted Pair Group Method with Arithmetic Mean (UPGMA) algorithm introduced by Sokal and Michener [19]. This algorithm iteratively compares all pairs of the assembled clusters based on the average distance of all elements within them. This allows the construction of a representation of all the documents in the collection in the form of a dendrogram (i.e., a tree-based diagram used for the visualization of clustering results). To receive homogeneous clusters, we automatically merge different branches of the generated dendrogram using the elbow-method introduced by Thorndike [20].[3] Each of the remaining clusters can be considered as columns in Webster and Watson's [7] concept matrix and thus be seen as a distinct concept (see Figure 2). Subsequently, to define the concepts, the artifact's third component applies keyword extraction techniques.



Articles	Concepts			
	A	B	C	D
1	✓			
2			✓	
3				✓
4	✓			
5		✓		
…				

Figure 2. Visualization of clustering results with dendrogram (left) and concept matrix (right)

[2] This approach builds clusters by initially treating each data point as its own cluster. The most similar clusters are then recursively merged until all data points form one single cluster.

[3] The elbow-method aims at finding the optimal number of clusters. The method, therefore, determines the clustering step in which merging two clusters leads to the maximum of variance between all clusters' centroids (which is equal to the maximum value of the second derivative of the average within-cluster distance values function).

4.3 Extracting Keywords from Concepts

The artifact's third component labels each concept with a predefined number of keywords that provide an impression of the documents' content. These keywords are directly drawn from the words occurring in the concept's original texts. To this end, we use the Rapid Automatic Keyword Extraction (RAKE) method developed by Rose et al. [21], which is an unsupervised, domain- and language-independent method for extracting keywords from text collections.[4] RAKE is particularly suited for our system due to its ability to pick highly specific terminology. As a result, our artifact generates meaningful concepts containing content-related scientific documents. As called for by vom Brocke et al. [6], the artifact thus provides a synthesis of scientific documents which facilitates working on the fifth phase of the framework – the generation of a research agenda.

5 Preliminary Evaluation

For evaluation, we instantiate our artifact based on an exemplary collection of scientific articles on Radio Frequency Identification. We consider articles containing the search term "RFID" in title, abstract or the full text.[5] The resulting document collection comprises 906 articles from 39 different journals and conference proceedings.

We benchmark our artifact against a system based on the bag-of-words model.[6] Before feeding the articles into the two systems, the titles, abstracts, keywords and reference sections were removed leaving only the articles' full texts. Based on the previously mentioned elbow-method, each of the systems identified 24 different concepts.

Figure 3 visualizes the systems' results. While the circular dendrogram generated with the bag-of-words-based system (left dendrogram) depicts one very large concept covering almost two thirds of the documents, the dendrogram generated with the word2vec-based system (right dendrogram) shows a more even distribution of concepts.

Figure 3 also zooms into the dendrogram generated with the word2vec model and lists the document titles of two exemplary concepts. Reading the titles of the documents in the concept displayed above the dendrograms suggests that all listed articles are

[4] The algorithm finds representative keywords by first splitting the text into text sequences using delimiters like punctuation or stop words. Then, for individual words in these sequences, word scores are calculated based on word frequency and word degree (i.e., the sum of the length of all sequences the particular word occurs in). The RAKE method then selects the top-scoring words as keywords.

[5] Following suggestions in literature (e.g., [6, 7]) we only consider high-quality articles. Therefore, we relied on the VHB-JOURQUAL 3 ranking [22] and examined articles in the sub-ratings "Operations Research" and "Wirtschaftsinformatik" that were at least B-ranked.

[6] We trained the word2vec model using the genism toolkit (http://radimrehurek.com/gensim/) and the bag-of-words model with the common term-frequency inverse document-frequency weighting using the scikit-learn library (http://scikit-learn.org/). In both cases we relied on the suggested default parameters.

healthcare-related. The titles listed below the dendrograms indicate articles about logistics and supply chain management. Given that the titles of the articles were not part of artifact's input, the results seem promising and indicate a comprehensible conceptualization.

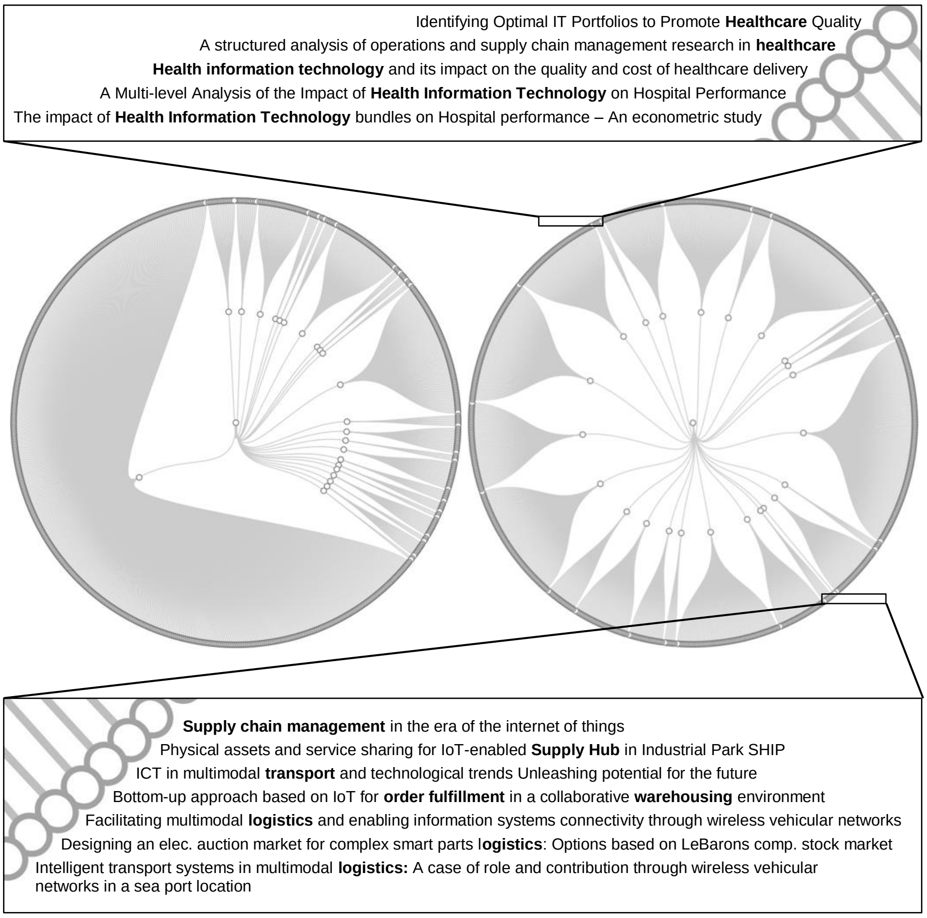


Figure 3. Circular dendrograms generated with bag-of-words-based system (left dendrogram) as well as word2vec-based system (right dendrogram) and two highlighted exemplary concepts

We consider two measures that allow a first quantitative assessment of the two systems' results. Our measures are based on assumptions similar to those introduced by Carpenter and Narin [14] who postulate that "journals which deal with the same subject area will have similar journal referencing patterns" and "journals which deal with the same subject area will refer to each other". Our underlying assumptions are:

1. The content of articles in a specific research domain (e.g., Operations Research) is more likely to be semantically related than content of articles in different research domains.
2. The content of articles in a specific journal (e.g., JAIS, EJOR) is more likely to be semantically related than content of articles in different journals.

We deduce from the first assumption that articles of a specific research domain should be more likely to get grouped into the same concept (research domain score). Second, we conclude from assumption 2 that articles of a specific journal should be more likely to get grouped into the same concept (journal score).

Therefore, we calculate the journal score by

$$\text{journal score} = \sqrt{\sum_{i}^{I}\sum_{j}^{J}(\frac{N_j}{N} - \frac{N_{ij}}{N_i})^2 \cdot N_j} \ ,$$

where I is the number of concepts, J the number of journals and conference proceedings, N_j the number of articles in j, N_i the number of articles in i, and N_{ij} the number of j's articles in i. The journal score compares the distribution of journals in individual concepts with the distribution of journals in the entire document collection.[7] An accumulation of one journal's articles within one concept thus leads to a high score.

In analogy, the research domain score is given by

$$\text{research domain score} = \sqrt{\sum_{i}^{I}\sum_{d}^{D}(\frac{N_d}{N} - \frac{N_{id}}{N_i})^2 \cdot N_d} \ ,$$

where D is the number of research domains. The research domain score can be considered as a generalization of the journal score. The higher the values of the score, the higher the accumulation of one domain's articles within one concept.

Table 1 summarizes the results for both systems. These preliminary results indicate that the bag-of-words-based system is inferior compared to the word2vec-based system. Although the results are very promising, further evaluations are necessary to fully evaluate the quality of the artifact.

Table 1. Evaluation Results

System	*Concepts*	*Journal score*	*Research domain score*
Bag-of-words-based	24	6.32	13.84
Word2vec-based	24	8.23	20.00

[7] Similar to the statistical measure standard deviation, which considers deviations of single observations, the journal score considers deviations of distributions within concepts. As the individual concepts differ in size, we normalize their squared deviations with their size.

6 Expected Contribution and Future Work

The understanding of an ever-growing number of scientific articles is an increasing challenge for any research domain. Literature reviews are an important instrument for structuring this information. They inform a research community about new findings and enable them to stay up-to-date. However, the number of available publications doubles approximately every 24 years [4]. This can make the process of structuring current research within a research domain very time-consuming, if not impossible. To cope with this trend, the present paper presents an IT artifact that leverages the potential of deep learning techniques to automate the time-consuming fourth phase of the literature framework proposed by vom Brocke et al. [6]. This phase comprises comparing and categorizing large amounts of potentially relevant literature.

Our research has a number of implications for both theory and practice. Regarding theory, we show that text- and data- mining techniques can be applied for this automation step and present an IT artifact capable of automatically categorizing large collections of scientific papers. Furthermore, our preliminary evaluation indicates that the clustering results benefit from the utilization of novel deep learning techniques. Due to the capabilities of Mikolov et al.'s [12] word2vec model to represent linguistic phenomena like ambiguity, synonyms or the information value of word order, it is better suited in the task of processing textual data than the common known bag-of-words model.

For practitioners (in this case scientific researchers), the study provides insights into the capabilities of an automated analysis of scientific document collections of arbitrary size. Implementations of automated literature categorization systems can (i) enable categorizing an amount of scientific literature which is impossible to handle manually, (ii) reduce the time needed to perform the complex but not complicated phase four of document analysis and synthesis and thereby (iii) improve both the researcher's productivity and the quality of the conducted literature review.

We consider the present paper as research in progress. As the evaluation of the artifact is a central activity in conducting rigorous Design Science Research [13], we are currently working on additional possibilities to demonstrate the artifact's capability. Firstly, we are working on including another score for assessing the quality of the results. To this end, we are implementing a measure considering citation patterns of scientific articles based on the assumptions proposed by Carpenter and Narin [14]. These authors identified related articles using a cross-citing matrix and a correlation measure to form article clusters referencing each other. Based on their assumption that articles with similar topics have a higher proportion of citations among themselves, these clusters will allow a direct comparison with the clusters generated by our proposed artifact. In addition, we aim at gathering empirical evidence for the validation of our system leveraging the focus group approach adapted for design science by Tremblay et al. [23]. This quantitative evaluation approach seems especially suitable because it enables direct interactions with domain experts and potential users of our artifact.

Abstract. Die vorliegende Arbeit befasst sich mit der Entwicklung von Designanforderungen und Designprinzipien und Gestaltungsrichtlinien für die audiovisuelle Kommunikation auf Crowdsourcing-Plattformen. Zur Identifizierung bestehender Probleme in der Praxis, wurde eine Prozessanalyse der Kommunikation auf einer Crowdsourcing-Plattformen analysiert, sowie durch Nutzer-Interviews Probleme bei der Kommunikation ermittelt. Um das identifizierte Problem zu verstehen, wurden mit Hilfe der Cognitive Load Theory drei Designanforderungen ermittelt. Daraufhin wurden nach den Prinzipien der Cognitive Theory of Multimedia Learning die Design Prinzipien und die Gestaltungsrichtlinien zur audiovisuellen Kommunikation entwickelt. Basierend auf den Erkenntnissen dieser Arbeit, kann eine weitere wissenschaftliche Beschäftigung mit computervermittelter Kommunikation, speziell auf Crowdsourcing Plattformen, und der Evaluation der vorliegenden Ergebnisse erfolgen.

Kogga, D.; Krawietz, N.; Cevik, F.; Brandau, S.; Li, M.M. (2017): Design Prinzipien für Microlearning Crowdsourcing-Systeme - Konzept für audiovisuelle Mediengestaltung, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1550-1561

im Unternehmen können Wettbewerbsvorteile generiert werden [2]. Eine Art IT-gestützter Problemlösungsplattformen sind Crowdsourcing-Plattformen. Diese bieten Platz, auftretende Probleme mit anderen Nutzern zu teilen und Hilfestellungen von diesen zu erhalten. Online existieren bereits seit längerer Zeit allgemeine Plattformen wie Quora oder programmierspezifische Plattformen wie Stackoverflow.com. Diese existieren ebenfalls im unternehmensinternen Rahmen und sind in der Lösungsfindung für die Mitarbeiter sowie für das Unternehmen von Vorteil [3]. Für das Lösen von Problemen ist es von Bedeutung, die Mitarbeiter zur aktiven Mitarbeit zu motivieren und ihnen eine Plattform und Werkzeuge zur Hand zu geben, um möglichst gute Lösungsvorschläge zu erbringen. Aktuell beschränkt sich die Kommunikation von Microlearning Crowdsourcing-Plattformen, auf das Medium von Freitexten. Um eine weitere Möglichkeit zum Kommunizieren auf Crowdsourcing-Plattformen anzubieten, wird die Kommunikation per Videobotschaften eingeführt.

Etablierte Plattformen, wie z.B. Youtube oder Snapchat, bieten die Option der Kommunikation per Videos bereits mit großem Erfolg an. Durch dieses Alleinstellungsmerkmal grenzen sich diese Plattformen von der Konkurrenz ab und bieten ihren Nutzern einen Mehrwert. Dieser Mehrwert soll auf Crowdsourcing-Plattformen transferiert werden, was ein stärkeres sozio-emotionales Erleben ermöglicht und somit die Mitarbeiter zur Kommunikation auf Crowdsourcing-Plattformen motiviert [4]. Eine effiziente Videobotschaft zu erstellen und an andere weiterzugeben, ist für viele Mitarbeiter mit hohem Aufwand verbunden. Wichtige Anforderungen, wie eine angemessene kognitive Belastung, sollten bei dem Erstellen eines Videos beachtet werden. Durch Gestaltungsrichtlinien für die Videokommunikation können Mitarbeiter an die effiziente Erstellung eines Videos herangeführt und dabei unterstützt werden.

Dieses Paper beschäftigt sich gezielt mit der Frage, wie eine Richtlinie zum Generieren von Videos erstellt werden kann, um die Kommunikation auf Crowdsourcing-Plattformen effektiver zu gestalten. Dazu wurde in einem ersten Schritt der Kommunikationsprozess einer Crowdsourcing-Plattform näher betrachtet, um die Ist-Situation zu analysieren. Anschließend wurden anhand von semistrukturieren Interviews mit potentiellen Nutzern Probleme ermittelt, die bei der Kommunikation auf einer Crowdsourcing-Plattform auftreten. Basierend auf den neuen Kenntnissen wurden im letzten Schritt Design Anforderungen und Design Prinzipien aus der Cognitive Load Theory sowie der Cognitive Theory of Multimedia abgeleitet, welche für die Richtlinien zur Erstellung von Videos definiert wurden.

2 Methode

Der gestaltungsorientierte Forschungsansatz, auch bekannt als „Design Science Research" (DSR), wird als eine angewandte Form der Wissenschaft bezeichnet. Orientiert man sich an dem DSR Cycle von Vaishnavi und Kuechler [2004], so erhält man eine konkrete Vorgehensweise zur Durchführung eines gestaltungsorientierten Forschungsvorhabens [5]. Dieser idealtypische Forschungsprozess gestaltet sich als ein iteratives Modell, bestehend aus mehreren Phasen: Awareness of Problem, Suggestion, Development, Evaluation und Conclusion. Die vorliegende Arbeit orientiert sich partiell an Meth et al. [2015], indem die Herleitung von Design Anforderungen sowohl aus der Praxis, als auch theoriebasiert stattfindet und die Design Prinzipien (Solution Space) aus weiterer Literatur abgeleitet werden [6].

Da sich diese Arbeit mit dem Nutzungsverhalten auf Crowdsourcing-Plattformen beschäftigt, wurde in einem ersten Schritt der Nutzungsprozess auf einer Plattform betrachtet. Hierfür wurde auf eine Plattform eines führenden deutschen Crowdsourcingsanbieters zugegriffen. Der Prozess wurde anschließend in bestehende Erkenntnisse zu Crowdsourcing-Prozessen eingebettet und als Gesprächsgrundlage für die semistrukturierten Interviews herangezogen. Die Interviews wurden mit 12 potentiellen Nutzern im Alter von 24-52 Jahren durchgeführt. Die zentrale Frage bestand darin zu verstehen, wie man die Effizienz der Plattform steigern könnte. Die Untersuchungen zeigten, dass die Nutzer die Kommunikation als wenig ansprechend und, aufgrund des hohen Leseaufwands, teilweise auch anstrengend, empfanden. Nach dem Identifizieren der Probleme folgte eine Recherche der bestehenden Literatur [7], durch welche die Probleme mit Hilfe bestehender Theorien eingeordnet werden konnten. Dabei haben sich die Cognitive Load Theory nach Sweller [2011] sowie die Cognitive Theory of Multimedia Learning nach Mayer [2008] als geeignete Herangehensweisen für die Entwicklung von Richtlinien als Vorschlag zur Reduzierung der Probleme herausgestellt. Ziel war es, den Nutzern eine Lösung anzubieten, welche die von ihnen geäußerten Probleme adressiert und gleichzeitig die Potentiale in der Kommunikation ausschöpft. Die Basis der Herangehensweise bilden die drei Arten der kognitiven Belastung nach Sweller und seiner Annahme von den begrenzten Kapazitäten des Arbeitsgedächtnisses [8]. Diese wurden den Prinzipien nach Mayer [2008] zugeordnet.

3 Grundlagen

3.1 Crowdsourcing

Der Begriff des Crowdsourcing ist auf Howe [2010] zurückzuführen. Er beschreibt die Thematik als die Auslagerung von unternehmensinternen Aufgaben per offenen Aufruf an eine Gruppe von Menschen, der sogenannten Crowd [9]. Crowdsourcing lässt sich in zwei verschiedene Typen unterscheiden, dem internen und externen Crowdsourcing [10]. Da diese Arbeit sich mit Crowdsourcing-Nutzungsprozessen innerhalb von Unternehmen beschäftigt, wird sich ausschließlich auf das interne Crowdsourcing fokussiert. Als interne Crowd werden hier ausschließlich die Mitarbeiter eines Unternehmens verstanden, welche IT-gestützt miteinander kommunizieren [11]. Wir betrachten das Crowsourcingsystem, welches sich aus den Akteuren Crowdsourcers, Crowdsourcees und der Plattform zusammenstellt. Es verfolgt das Ziel der Selbsthilfe durch Microlearning.

3.2 Microlearning

Unter Microlearning versteht man eine Form des Lernprozesses, welche sich durch spezifische Eigenschaften auszeichnet. Das Besondere hierbei ist, dass das Lernen durch zeitliche kurze Lerneinheiten (auch als Learn Nuggets bekannt) definiert ist. Des Weiteren spielt bei dem Lernprozess die Komplexität des Inhalts eine elementare Rolle. Die Inhalte innerhalb der einzelnen Einheiten sollten einfach und leicht verständlich sein. Die einzelnen Schritte des Microlearnings sollten in ein umfassendes Gesamtkonzept eingebunden und durch ein passendes Medium vermittelt werden. Hierbei ist die Form des Mediums, wie beispielsweise über die Crowdsourcing-Plattform (Technologie), von besonderer Bedeutung [12]. Der Lernprozess des Microlearnings, der sich aus dem Microcontents zusammensetzt, kann von wenigen Sekunden bis zu 15 Minuten dauern [13]. An das Microlearning werden besondere didaktische Anforderungen, wie z.B. ein motivierend gestaltetes Feedback, gestellt [14].

4 Awareness of Problem

4.1 Ist-Zustand und Einbettung

Um auftretende Probleme bei der Nutzung von Crowdsourcing-Plattformen zu identifizieren, ist es zunächst wichtig, den Ist-Zustand zu analysieren. Dies geschah in Kooperation mit einem realen Crowdsourcing-Plattformanbieter. Dabei wurde der Prozess aus Abbildung 1 identifiziert.

Crowdsourcing-Plattformen zielen darauf ab, reale Probleme von Nutzern zu lösen [15]. Der gesamte Nutzungsprozess des Crowdsourcingsystems (CSS) teilt sich in drei Pools auf, in Crowdsourcers (Nutzer, die ein Problem haben und dieses als Frage formulieren) und Crowdsourcees (eine Gruppe von Nutzern, die auf Problemanfragen antworten) [16]. Bestimmte Crowdsourcees haben zudem eine besondere Moderatorenrolle, da diese aus der Masse an Lösungsvorschlägen durch Selektion eine Endlösung formulieren können. Der Prozess läuft wie folgt ab: Bei einem auftretenden Problem wird dieses im ersten Schritt vom Crowdsourcer auf einer Plattform gepostet. Anschließend wird die Problemstellung für alle Crowdsourcees sichtbar. Einzelne Nutzer haben dann die Möglichkeit, Antworten oder Lösungsvorschläge für die Problemstellung zu erstellen und zu veröffentlichen. Diese einzelnen Lösungsmöglichkeiten werden wiederum durch die Plattform für alle Crowdsourcess bereitgestellt und eine gemeinsame Diskussion bis zur endgültigen Lösungsfindung durch den Moderator erfolgt. Diese wird in einem letzten Schritt veröffentlicht und der Crowdsourcer erhält somit eine Antwort auf seiner Frage. Damit ist der Prozess beendet.

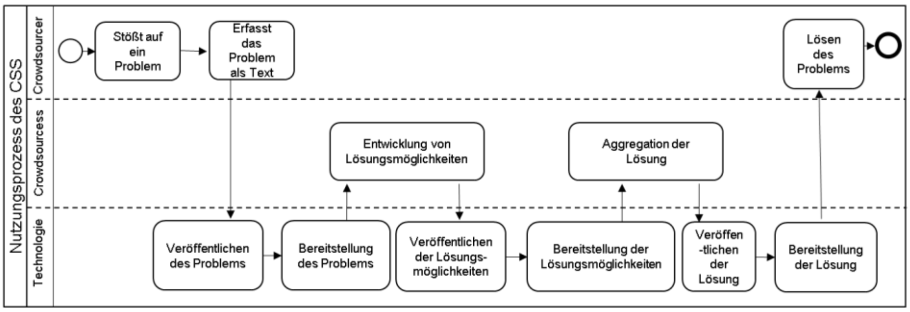

Abbildung 1: Nutzungsprozess einer internen Crowdsourcing Plattform *(Eigene Darstellung)*

Geiger et al. [2011] charakterisieren den Crowdsourcing-Prozess anhand von vier Phasen: 1. Preselection of contributors, 2. Accessibility of peer contributions, 3. Aggregation of contributions und 4. Remuneration for contributions [17]. In Phase 1 werden die Crowdmitglieder ausgewählt und in Phase 2 werden die jeweiligen Inhalte, die ein Crowdmitglied von einem anderen Crowdmitglied sehen kann, bestimmt. Phase 3 stellt das Zusammentragen von Lösungen dar. Phase 4 definiert, wie die Crowd für ihre Leistung entlohnt wird. Da in dieser Arbeit ausschließlich eine Betrachtung des internen Crowdsourcing im Unternehmen stattfindet, umfasst die Crowd alle Mitarbeiter des Unternehmens. Für diese sind alle Problemfragen offen sichtbar, sodass Phase 1, 2 und 4 ausgeklammert werden können. In Phase 3 findet die Kommunikation der Crowd durch das Teilen von erstellten Lösungsvorschlägen statt. Somit ist der Prozess aus Abbildung 1 primär in dieser Phase anzusiedeln und geht darüber hinaus, indem er sich explizit mit der Erstellung einzelner Beiträge beschäftigt.

4.2 Ergebnisse aus den Interviews

Die Aussagen der Befragten in den Interviews zeigten diverse Problembereiche auf. Diese lassen sich im Wesentlichen vier Kategorien zuordnen: Kommunikation, Motivationsbereitschaft zur Nutzung, Nutzerfreundlichkeit sowie allgemeine Bekanntheit der Plattform/des Plattformanbieters. Im Rahmen dieser Untersuchung erfolgt eine Fokussierung auf den Bereich der Kommunikation. Die Ergebnisse zeigten auf, dass acht der befragten Nutzer unzufrieden mit den bereitgestellten Kommunikationswerkzeugen sind und zudem fünf Nutzer den Wunsch nach visueller Kommunikation äußerten. Acht Befragte gaben an, dass sie die Kommunikation in alleiniger Textform als „zeitaufwändig" und zu „überwältigend" empfanden und es wurde fünf Mal der Wunsch nach Vereinfachung der Kommunikationsmöglichkeiten geäußert. Die Befragten empfanden das Verfassen in Textform als „langweilig und mühselig". Außerdem wurde die Annahme der audiovisuellen Videolösung als Darstellungsmedium durch den Vergleich mit Youtube-Tutorials durch die Befragten bestätigt. Folglich zeigen die Ergebnisse der Befragung den Wunsch nach der Erweiterung des Nutzungsprozesses in den Schritten „Erfasst das Problem als Text" und „Lösen des Problems" durch eine audiovisuelle Komponente.

4.3 Herleitung der Design Anforderungen

Zum besseren Verständnis und zur Diagnose der Gründe des Problems erfolgt auf Basis des „Activity Framework for Design Science Research", eine Auseinandersetzung mit dem Problemraum [18]. Zuerst erfolgt eine Ableitung von Design Anforderungen, sodass im nächsten Schritt die Problematik der Kommunikation effektiver gestaltet werden kann. Auf Basis dessen, sollen dann Design Prinzipien abgeleitet werden, welche die Nutzer der Crowdsourcing-Plattformen bei der Erstellung von Videobotschaften unterstützen. Es wird ein Augenmerk auf die didaktischen Anforderungen aus dem Bereich des Microlearnings gelegt. Die Lerninhalte, welche durch Videos kommuniziert werden, sollen möglichst verständlich, klar, kurz und effizient sein, um die Kommunikation und den Lernerfolg des Crowdsourcingsystems zu fördern [12, 13, 14]. Um dies zu gewährleisten werden Erkenntnisse aus der Cognitive Load Theorie herangezogen [8, 19, 20, 21]. Bei der Cognitive Load Theory nach Sweller [1988], werden zwei Annahmen getroffen: die Begrenztheit des Arbeitsgedächtnisses, was die These des Microlearnings unterstützt und dass das Arbeitsgedächtnis ein auditives und ein visuelles Zentrum für die Verarbeitung von Informationen besitzt. Um den Kommunikationsprozess effizient zu gestalten, ist es daher notwendig, die Informationen sowohl bildhaft als auch verbal zu übermitteln. Dieser Effekt wird auch als „Modality Effect" bezeichnet [8, 22]. Um die Anforderungen an die Design Prinzipien zu gestalten, werden im Folgenden die Arten der extrinsischen Belastung definiert und den in den Interviews identifizierten Problemen zugeordnet.

Festgestellt von den Nutzern wurde ebenfalls das Problem „Große Textmengen". Diese gehören nach Sweller der Art der extrinsisch kognitiven Belastung an [22, 23]. Viel Text führt dazu, dass die Nutzer konzentrierter arbeiten müssen und Ressourcen des Arbeitsgedächtnisses zusätzlich beansprucht werden. Da durch den Text nur das visuelle und nicht das auditive Zentrum angesprochen wird, findet ebenfalls eine Überlastung des visuellen Kanals statt [22, 23]. Als zweites Problem wurden die „schwierig zu verstehende Inhalte" genannt. Der Lerninhalt lässt sich der intrinsischen kognitiven Belastung zuordnen. Abhängig von der Komplexität des Lern/-Informationsinhaltes variiert der Belastungsgrad beim Nutzer [22, 24]. Als drittes Problem wurden die „schwierig zu vermittelnden Inhalte" genannt. Das dritte Problem kann teilweise der extrinsischen Belastung zuordnet werden, weil die schwierige Vermittlung des Inhaltes von der Gestaltung des Lernmaterials abhängig ist. Jedoch ist der schwierig zu vermittelnde Inhalt primär mit der lernbezogenen kognitiven Belastung erklärbar. Diese wird als der Aufwand verstanden, den Nutzer erbringen müssen, um das Lernmaterial zu begreifen [22]. Diese lernbezogene Belastung muss gefördert werden, um einen effizienten Informationstransfer zu gewährleisten. Die Bildung und anschließende Nutzung von Schemata hält die extrinsische kognitive Belastung gering und unterstützt bei der Aufnahme neuer Informationen [22].

Ziel der Cognitive Load Theory und somit eine wichtige Anforderung an die Design Prinzipien ist es, die kognitive Belastung möglichst gering zu halten, um effektiv Informationen aufnehmen bzw. kommunizieren zu können [8]. In Wissensübergabe umformuliert, wurden anhand der identifizierten Probleme folgende drei Design Anforderungen formuliert:

- *DR1. Für eine effektive Wissensübergabe durch Crowdsourcing-System entwickelten Lösungen, soll die extrinsische Belastung möglichst reduzieren.*
- *DR2. Für eine effektive Wissensübergabe durch Crowdsourcing-System entwickelten Lösungen, soll die intrinsische Belastung möglichst reduzieren.*
- *DR3. Für eine effektive Wissensübergabe durch Crowdsourcing-System entwickelten Lösungen, soll die lernbezogene Belastung möglichst erhöht werden.*

Um die in der qualitativen Befragung identifizierten Probleme zu verstehen, wurde in diesem Abschnitt die Cognitive Load Theory als theoretische Linse herangezogen. Daraus wurden die Design Anforderungen 1 – 3 abgeleitet, welche sich auf die Reduktion der kognitiven Belastung und somit die Entlastung des Arbeitsgedächtnisses beziehen.

5 Suggestion und Development

In diesem Schritt gilt es die Design Prinzipien zu entwickeln, welche einen effektiven Informationstransfer auf Crowdsourced-Microlearning-Plattformen ermöglichen. Hierfür werden die Arten kognitiver Belastung [8] und die bei den Interviews identifizierten Probleme den Prinzipien zugeordnet [18]. Ziel ist es, die Arten der kognitiven Belastung zu reduzieren, um das Arbeitsgedächtnis zu entlasten und einen effizienten Wissenstransfer zu ermöglichen. Auf dieser Basis werden Handlungsempfehlungen entwickelt, die die Nutzer bei der audiovisuellen Kommunikation unterstützen [20].

5.1 Herleitung der Design Prinzipien

Dass audiovisuelle Mitteilungen eine geeignete Maßnahme sind, die Kommunikation effektiv zu gestalten, wurde bereits von Paivio in seiner dual codingtheory festgestellt. Diese Theorie unterstützt Swellers und Mayers Annahme vom „Modality Effekt“ und besagt, dass das menschliche Gedächtnis unterschiedliche Repräsentationen besitzt, die von visueller sowie verbaler Natur sind [21, 22].

Auf diesen Erkenntnissen beruhend, entwickelt Mayer ein duales Model, welches sich auf die visuelle und auditive Informationsverarbeitung fokussiert und leitet daraus unterschiedliche Prinzipien ab [18]. Diese wirken sich förderlich auf den Wissenstransfer im multimedialen Lernen aus. Da die Erstellung von Microcontents als Lösungsvorschläge auch als Wissenstransfer betrachtet werden kann, wurden die als passend für den vorliegenden Betrachtungsgegenstand anerkannt. Die ersten fünf dieser Prinzipien beschäftigen sich mit der Reduktion extrinsisch kognitiver Belastung, die durch eine optimierte Verarbeitung relevanter Informationen stattfindet [19, 22].

Diese Prinzipien sind die Kohärenz (Reduktion von irrelevanten Informationen), die Signalisierung (Hervorhebung relevanter Informationen), die Redundanz (Vermeidung von Text bei Audioanimationen), die räumliche Kontiguität (Platzierung von Textzeilen neben der zugehörigen Grafik) und die temporale Kontiguität (Parallele Präsentation von visuellen und den dazugehörigen auditiven Inhalten) [8, 19]. Des Weiteren stellt Mayer Handlungsempfehlungen vor, die einen Umgang mit komplexen Sachverhalten ermöglichen. Diese sind die Segmentierung (das Aufteilen von Animationen in kleinere Segmente), das Pretraining (Trainings/ Schulungen über den zu behandelten Sachverlauf zum Beispiel Fachwörter), sowie die Modalität (Kombination visueller und auditiver Komponenten). Das Pretraining und die Modalität werden beim weiteren Vorgehen nicht berücksichtigt, da das Pretraining nicht vom Nutzer des CSS durchgeführt wird. Die Modalität wird ebenfalls nicht weiter beachtet, da dieses Prinzip bereits durch die Anwendung der Plattform auf Basis audiovisueller Kommunikation erfüllt wird [19].

Die letzten zwei Prinzipien wecken das Interesse des Nutzers an den zu vermittelnden Informationen. Dazu gehören Multimedia (Parallele Präsentation von Wörtern und Bildern ist besser als nur von Wörtern) sowie die Personalisierung (Informelle Informationsvermittlung wirkt sich positiver auf den Wissenstransfer als formelle aus). Da multimediale Quellen allein durch die Anwendung der Plattform erfüllt werden, werden diese ausgeklammert [19]. Die identifizierten Prinzipien liefern mögliche Lösungsansätze, um das Microlearning auf Crowdsourcing-Plattformen und somit die Kommunikation zu optimieren. Da der Wissenstransfer Microlearning CSS auf das multimediale Lernen abzielt, bilden die Prinzipien nach Mayer eine gute Basis für das weitere Vorgehen [8, 19, 20].

5.2 Aggregation von Design Anforderungen und Design Prinzipien

Wie das Zusammenspiel der aus der Theorie hergeleiteten Design Anforderungen, Design Prinzipien und konkreten Gestaltungsrichtlinien auf die aus der Praxis identifizierten Probleme ausüben, wird anhand Tabelle 1 erläutert:

Zu Beginn wurde das Problem „Große Textmenge“ durch die Interviews identifiziert. Dabei handelt es sich um eine extrinsische Belastung (DR1). Viel Text führt dazu, dass die Nutzer konzentrierter arbeiten müssen und Ressourcen des Arbeitsgedächtnisses zusätzlich beansprucht werden [8]. Um die kognitive Belastung zu reduzieren, sollte hier das Kohärenz Prinzip herangezogen werden. Irrelevante Informationen führen zu einer Erhöhung der Textmenge. Diese erhöht die extrinsische Belastung [8, 19]. Der „Expertise Reversal Effect“ sollte beim Video ebenfalls eine wesentliche Rolle spielen. Die Videos sollten zielgruppenspezifisch adressiert werden, um unnötige Informationen zu vermeiden [24]. Um DR1 zu adressieren ziehen wir das Signalisierungsprinzip heran. Informationen, die innerhalb des Videos besonders relevant sind, müssen hervorgehoben werden, um die Aufmerksamkeit des Nutzers zu wecken. Dadurch wird auch die Verarbeitung von weniger relevanten Informationen vermieden. Bei der Erstellung sollte ebenfalls das Redundanzprinzip berücksichtigt werden. Exakt die gleichen Informationen, die von den auditiven und visuellen Zentren empfangen werden, führen zu einer doppelten Beanspruchung. Informationen sollen sich ergänzen und nicht identisch sein. Des Weiteren sollte darauf geachtet werden, dass Abbildungen, zusammen mit der dazugehörigen Beschriftung präsentiert werden und somit das Prinzip der räumlichen Kontiguität eingehalten wird. Das Prinzip der temporalen Kontiguität sollte ebenfalls Beachtung finden. Zusammenhängende

Informationen sollten parallel bzw. nacheinander kommuniziert werden, um die kognitive Belastung bei der Verarbeitung zu reduzieren [8, 19, 22].

Awareness of Problem		Suggestion & Development	
Problem	**Design Anforderungen**	**Design Prinzipien**	**Gestaltungsrichtlinien an audiovisuelle Kommunikation**
Große Textmengen	DR1. Reduzierung der extrinsischen Belastung	1. Kohärenz Prinzip: Nicht relevante Information reduzieren 2. Signalisierung Prinzip: Relevante Informationen hervorheben 3. Redundanz Prinzip: Text bei Audioanimationen vermeiden 4. Räumliche Kontiguität Prinzip: Textzeilen neben der zugehörigen Grafik platzieren 5. Temporale Kontiguität Prinzip: Präsentation von visuellen und den dazugehörigen auditiven Inhalten parallel vorstellen	1. Gestalten Sie das Video möglichst simpel. Bei der Erstellung sollte der Fokus auf das Wesentliche gelenkt werden. 2. Wichtige Sachverhalte sollen klar identifizierbar und erkennbar sein. Hierfür ist es möglich Signalfarben zu wählen. Auf diese Weise wird die Aufmerksamkeit in die gewünschte Richtung gelenkt und das Arbeitsgedächtnis nicht unnötig belastet. 3. Vermeiden Sie die doppelte Darstellung identischer Informationen. Diese lenken ab und haben einen negativen Effekt auf das Arbeitsgedächtnis. Sich ergänzende Informationen oder Hervorhebungen sind jedoch förderlich für den Wissenstransfer. 4. Stellen Sie Inhalte übersichtlich im Video dar. Platzieren Sie hierfür die Beschriftung neben der zugehörigen Grafik. Auf diese Weise setzten sie die Kapazitäten des Arbeitsgedächtnisses beim Nutzer optimal ein. Die Informationen ergänzen sich. 5. Zeigen Sie zusammenhängende Inhalte parallel in Videos. Audiokommentare und die dazugehörenden Animationen müssen parallel im Video erscheinen, um im Arbeitsgedächtnis auf möglichst simple Weise zusammengefügt zu werden.
Schwierig zu verstehende Inhalte	DR2. Reduzierung der intrinsischen Belastung	6. Segmentierungsprinzip: Informationen in kleinere Segmente aufteilen	6. Teilen Sie die Informationen in kleinere Segmente auf. Komplizierte Sachverhalte, die aus diversen abhängigen Elementen bestehen, lassen sich so simpler kommunizieren. Ebenfalls wird das Arbeitsgedächtnis nicht überlastet.
Schwierig zu vermittelnde Inhalte	DR3. Erhöhung der lernbezogenen Belastung*	7. Personalisierungsprinzip: Informelle Informationsvermittlung wirkt sich positiver auf den Wissenstransfer aus als formelle	7. Kommunizieren Sie im Gesprächsstil. Durch die Nutzung einer einfachen informellen Sprache, hat die Zielgruppe das Gefühl an einem Gespräch teilzuhaben. Dies ist für die Motivation der Nutzer förderlich. Aus diesem Grund sollte die im Video verwendete Sprache nicht informell und distanziert sein. Dadurch lassen sich komplizierte Sachverhalte simpler darstellen. **insb. durch Schemata, da hierdurch das Arbeitsgedächtnis entlastet wird: Es müssen keine neuen Systematiken oder Raster gelernt werden.*

Tabelle 1.Design Prinzipien für die Reduzierung der kognitiven Belastung für die Steigerung der Kommunikation. Eigene Darstellung anhand [8, 19, 24, 25]

Als zweiten Punkt wird das Problem der „Schwierig zu verstehende Inhalte" adressiert. Dabei handelt es sich um eine intrinsische Belastung (DR2). Um dem Problem effektiv vorzubeugen, sollte das Segmentierungsprinzip herangezogen werden. Es beschreibt die Aufteilung von Informationen in kleinere Segmente. Das Arbeitsgedächtnis ist begrenzt, werden zu viele komplexe Informationen über einen längeren Zeitraum vermittelt, geht viel Informationsgehalt verloren. Daher ist es ratsam, mehrere Videos zu komplexen Sachverhalten zu erstellen[19, 22].

Als letztes Problem wurden „schwierig zu vermittelnden Inhalte" von den befragten Nutzern identifiziert. Das Problem lässt sich mit Hilfe der lernbezogenen kognitiven Belastung erklären (DR3). Diese sollte nach Möglichkeit gefördert werden, indem das Personalisierungsprinzip angewandt wird. Durch die Nutzung einer einfachen informellen Sprache, hat die Zielgruppe das Gefühl an einem Gespräch teilzuhaben. Dies ist für die Motivation der Nutzer förderlich. Aus diesem Grund sollte die im Video verwendete Sprache nicht informell und distanziert sein. Abgesehen davon lassen sich dadurch komplizierte Sachverhalte [8, 19, 20].

Zusammenfassend sollte festgehalten werden, dass die kognitive Belastung reduziert werden sollte und die lernbezogene Belastung zu fördern ist. Dies wird erreicht, indem die aufgestellten Design Prinzipien befolgt werden und der Lernende neue Schemata im Arbeitsgedächtnis aufbaut oder bereits vorhandene Schemata nutzt. Dies kann durch eine bessere Gestaltung des Lernmaterials geschehen. Die Benutzung und Förderung von Schemata wird als optimaler Weg beim Verständnislernen angesehen [22]. Die Gestaltung von interaktiven Videos umfasst neben kognitiven Aspekten ebenfalls visuelle Punkte. Bei der Erstellung von den Videos bildet das Raster eine gute Vorgehensweise, um diese zu strukturieren und zu standardisieren. Durch die Anordnung der Nutzungsfläche entsprechend der Rastervorgaben (Gestaltungslayout) wird eine Ordnung geschaffen, die dem Nutzer hilft vorhandene Schemata zu aktivieren[8, 24, 25]. Die Gestaltungsrichtlinien an audiovisuelle Kommunikation aus Tabelle 1 fassen nochmals die instanziierten Prinzipien zusammen. Somit wurden drei Mengen an problemspezifischen Designprinzipen identifiziert, die alle im Einzelnen auf jeweilige Richtlinien gemapped sind (siehe Nummerierung).

6 Diskussion und Ausblick

Die vorliegende Arbeit trägt zur Verbesserung der Kommunikation auf internen Crowdsourcing-Plattformen bei. In der bestehenden Literatur wurden Crowdsourcing und die Verbindung zur Unternehmensführung [26], unterschiedliche Arten von Crowdsourcing-Communities [27] oder Potentiale von Crowdsourcing [28] bereits betrachtet, nicht jedoch für Microlearning-Aufgaben. Es ist auffällig, dass verbal übermittelte Informationen innerhalb der Cognitive Load Theory eine besondere Bedeutung besitzen [24]. Erste Ansätze, die sich mit dem Thema eines effektiven Wissenstransfers auseinandersetzen, findet man in den von Mayer [2008] aufgestellten für die Wissensweitergabe aus kognitiver Sicht stärkenden Prinzipien, die für das Microlearning CSS herangezogen wurden [19]. Die Theorie der reduzierten sozialen Hinweisreize (Reduced-Social-Cues-Approach) vertritt die These, dass bei einer Reduzierung der Kommunikationskanäle ein Informationsverlust erfolgt, sodass bei reinen Textnachrichten im Unterschied zur sog. Face-to-Face-Kommunikation ein Teil der Sinneskanäle nicht genutzt werden. Dieser Umstand wird durch die Einführung der audiovisuellen Kommunikationsmöglichkeit erheblich optimiert. Die Kommunikation wurde als essentieller Bestandteil auf internen Crowdsourcing-Plattformen für die Erstellung von Microlearning-Lösungen identifiziert. Sie dient der Lösung von Problemen innerhalb eines Unternehmens, die durch Microlearninginhalte gelöst werden. Jedoch kann dies nur durch einen aktiven Austausch im CSS stattfinden. Die vorliegende Arbeit knüpft an den identifizierten Kommunikationsschwächen an. Diese wurden anhand von semistrukturierten Befragungen und mithilfe von CSS-Prozessen auf einer internen Crowdsourcing-Plattform erfasst. Anschließend erfolgte die Einbettung der Probleme in bestehende Theorien. Hieraus ergab sich eine Ableitung möglicher Herangehensweisen, die den Nutzer bei der Erstellung von Videos unterstützen.

Der theoretische Beitrag beschränkt sich auf ein noch nicht demonstriertes und evaluiertes, aber hierfür theoriegeleitetes Konzept zur Verbesserung des Crowdsourcing-Prozesses durch die Erstellung von Microlerninhalten. Dies geschieht in Form von Design Anforderungen und Design Prinzipien. Um die aus der Praxis identifizierten Probleme zu verstehen und einen ersten Schritt in eine Klasse von ungelösten Problemen [29] zu abstrahieren, wurden drei Design Anforderungen formuliert. Zum Adressieren dieser, wurden drei Mengen an zusammengehörenden

Design Prinzipien aus den 7 identifizierten Prinzipien nach Mayer [2008] entwickelt. Diese sollten übertragbar auf ähnliche Problemklassen (DR) sein. Der praktische Beitrag besteht darin, dass Plattformentwicklern, die sich darauf spezialisieren Probleme mit Microlerninhalten zu lösen, Prinzipien zur Gestaltung von Werkzeugen, die es ermöglichen diese konsumfreundlicher zu gestalten, zur Verfügung gestellt werden. Die konkreten Richtlinien sollen sowohl den Betreibern, als auch den Erstellern von Microlerninhalten auf Crowdsourcing-Systemen als Referenz dienen.

Um die erarbeiteten Prinzipien zu demonstrieren, muss im nächsten Schritt eine Anpassung der beobachteten Plattform an die Prinzipien geplant werden. Zur Evaluation kann ein Expertenworkshop mit Mitarbeitern des CSS-Anbieters, bei dem die erstellte Herangehensweise an die Nutzer weitergegeben wird, dienen. Die Entwicklung von Design Anforderungen und Design Prinzipien stellt zukünftiges Bestreben nach einer Designtheorie dar. Das Forschungsvorhaben der Autoren ist daher diesem zukünftigen Bestreben durch die Ergründung von Problemtheorien und Entwicklung des Problemraums zuzuordnen [18].
