Towards Thought Leadership in Digital Transformation

13. Internationale Tagung Wirtschaftsinformatik (WI 2017)

Tagungsband

Wirtschaftsinformatik 2017

Institut für Wirtschaftsinformatik

Universität St.Gallen

Vorwort der Tagungsleitung

Die Internationale Tagung Wirtschaftsinformatik ist die Hauptkonferenz der deutschsprachigen Wirtschaftsinformatik Community und war mit der 13. Ausgabe unter dem Konferenzmotto „Towards Thought Leadership in Digital Transformation“ in St. Gallen ein ganz besonderes Austauschforum zwischen Wissenschaft und Praxis für innovative und relevante Themen der Wirtschaftsinformatik und richtete sich an Wissenschaftler und Studierende mit Interesse an der Forschung und insbesondere Praktiker mit Bezug zur Wirtschaftsinformatik.

Es war uns als Gastgeber des Instituts für Wirtschaftsinformatik (IWI-HSG) der Universität St.Gallen und den Lehrstühlen von Prof. Dr. Jan Marco Leimeister und Prof. Dr. Walter Brenner eine Ehre die WI 2017 in St.Gallen ausrichten zu dürfen.

Es war uns zudem eine grosse Freude mit über 750 Teilnehmenden aus Wissenschaft und Praxis und der deutschsprachigen Wirtschaftsinformatik-Community die WI 2017 zu bestreiten. Wir hoffen die Tage in St. Gallen werden allen Teilnehmenden und Mitwirkenden in guter und bleibender Erinnerung bleiben.

In 14 wissenschaftlichen Tracks, einem Start-Up Track und dem Student Track bot die Konferenz vielfältige Möglichkeiten für einen intensiven Austausch zwischen Wissenschaft und Praxis. Besonders hervorheben möchten wir die interessanten Präsentationen im Rahmen des CIO Dialogs, das Doctoral und Junior Faculty Consortium sowie die Prototype & Experiment Session. Zusätzlich bot das Format des Prototype & Experiment Tracks mit einem neuen Einreichungsformat die Möglichkeit, innovative und gestaltungsorientierte Forschung im Rahmen der Konferenz interaktiv vor einem grossen Publikum zu präsentieren.

Weiterhin haben wir vor der Konferenz bei der WI 2017 einen neuartigen und innovativen Review-Prozess eingeführt, um die Geschwindigkeit und auch Qualität der Reviews für Autoren deutlich zu erhöhen. Hierzu haben, unter Leitung der Conference Chairs und des Reviewmanagements, die Track Chairs mit Hilfe Ihrer Associate Editor einen bisher einzigartigen Double-blind Peer Review Prozess durchgeführt. Dieser neuartige Prozess hat dabei den über 200 Associate Editors, welche sich im Vorfeld für die Tracks als Editors bewerben konnten, eine besonders wichtige Rolle zugestanden. Im Rahmen des „Fast and Constructive Associate Editor Rejects“ wurde die Geschwindigkeit des Review-Prozesses stark erhöht und Last von den Schultern der über 600 Reviewer genommen. Die Associate Editors und Reviewer haben dann dafür Sorge getragen, dass Beiträge mindestens dreimal begutachtet wurden und Autoren ein reichhaltiges und konstruktives Feedback auf die Forschungsarbeiten erhalten haben. Damit möchten wir den Track Chairs, Associate Editors als auch Reviewern für die Unterstützung im ganzen Prozess unseren herzlichen Dank ausdrücken und die extrem wertvolle Arbeit der Wirtschaftsinformatik-Community hervorheben.

Insgesamt wurden auf der Konferenz 119 Beiträge präsentiert und in diesem Tagungsband abgedruckt, wobei die Annahmequote der wissenschaftlichen Vollbeiträge bei 32,3% liegt. Wissenschaftliche Beiträge konnten bei der WI 2017 zudem auch als Extended Abstract veröffentlicht werden, insbesondere um den Autoren die Möglichkeit zu geben, Forschungsarbeiten für die Publikation in Journals weiter aufzubereiten. In diesem Kontext möchten wir hier nochmals hervorheben, dass Autoren im Zuge der WI 2017 die Chance hatten, im Review-Prozess für eine Fast-Track Publikation in renommierte Journals (BISE, EM, EMISA, HMD, i-com, ISeB) der Wirtschaftsinformatik eingeladen zu werden.

Der vorliegende Tagungsband der WI 2017 liefert auf dieser Basis einen Überblick über innovative und relevante Themen sowie Herausforderungen der Wirtschaftsinformatik, welche unter dem Konferenzmotto „Towards Thought Leadership in Digital Transformation“ standen.

Unser Dank gilt dabei den zahlreichen Sponsoren, Partnern und Förderern, welche durch die substanzielle Unterstützung diesen Event in dieser Form erst möglich gemacht haben. Weiterhin möchten wir dem ganzen Organisationsteam sowie Dr. Christoph Peters als Projektleiter herzlich danken.

Abschliessend danken wir allen Teilnehmenden, dass Sie den Weg in die Schweiz nach St. Gallen gefunden haben und hoffen, dass Sie ein attraktives Programm mit zahlreichen Forschungsbeiträgen, Keynotes, Panels, Workshops aber auch Rahmenprogramm wahrnehmen konnten.

Track 13: Prototype & Experiment

Autonomie im Internet der Dinge: Anforderungen an die Gestaltung autonomer Agenten in Cyber-physischen Systemen

Christian Janiesch[1] und Valentin Nentwich[2]

[1] Julius-Maximilians-Universität Würzburg, Würzburg, Germany
christian.janiesch@uni-wuerzburg.de
[2] Audi Planung GmbH, Neckarsulm, Germany
valentin.nentwich@audi-planung.de

Abstract. Durch die Digitalisierung in Gesellschaft und Industrie findet eine wachsende Autonomisierung bzw. Automatisierung der Wertschöpfungssysteme über Sensoren und Effektoren, sogenannte Cyber-physische Systeme, statt. Diese Automatisierung erlaubt eine schnellere und häufig auch fehlerfreiere Arbeit in vernetzten Systemen, bspw. im Bereich Industrie 4.0. Es ist derzeit allerdings weder möglich noch sinnvoll jedweder Maschine volle Autonomie zu gewähren, so dass es nötig ist, genau zu definieren, in welchem Rahmen und mit welchen Zielen eine Maschine selbstbestimmt handeln darf. Allerdings gibt es für die Gestaltung von autonomen Maschinen im CPS derzeit keinen allgemein anerkannten Ansatz oder Methodik, wie solch ein Autonomie-Konzept umgesetzt werden könnte. Basierend auf einer Literaturanalyse der IT-Autonomie-Forschung werden 12 Anforderungen für die Umsetzung von autonomen Agenten in CPS erarbeitet. Es werden die Eigenschaften eines Agenten sowie dessen Interaktion mit dem Menschen über Autonomiestufen detailliert aufgearbeitet. Das resultierende Meta-Modell kann als Basis für die Gestaltung von Agenten, bspw. über eine Modellierungssprache, dienen.

Keywords: *Internet der Dinge, Cyber-physische Systeme, IT-Autonomie, Modellierung, Agent*

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Janiesch, C.; Nentwich, V. (2017): Autonomie im Internet der Dinge: Anforderungen an die Gestaltung autonomer Agenten in Cyber-physischen Systemen, in: Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 1-15

1 Einleitung

Digitalisierung ist ein Leittrend in Gesellschaft und Industrie, der eine Kernherausforderung für die Wirtschaftsinformatik darstellt. In der Produktion wird in diesem Zusammenhang von Industrie 4.0 als dem Organisationsprinzip der Zukunft gesprochen. Allgemeiner spricht man von selbststeuernden Objekten, die Internet-ähnliche, vernetzte Strukturen zur Kommunikation nutzen, dem sogenannten Internet der Dinge [1]. So soll letztendlich eine wachsende Autonomisierung bzw. auch Automatisierung der Wertschöpfungssysteme über Sensoren und Effektoren, in sogenannten Cyber-physischen Systemen (CPS), stattfinden.

Das starke Wachstum an Sensoren und deren Vernetzung fördert dabei die Erzeugung und Verbreitung von Daten und wird folglich aufgrund der Menge und der Geschwindigkeit, in der Daten heute entstehen, zu einer großen Herausforderung für Entscheidungsträger. Diese sind letztendlich durch die Vielzahl an Informationen und die Beschränktheit ihrer kognitiven Fähigkeiten nicht in der Lage, adäquate und zeitnahe Entscheidungen für alle durchgeführten Analysen zu treffen, ohne dabei Optimierungspotentiale zu verschenken und ohne Fehler zu machen [2].

Ein möglicher Lösungsansatz besteht darin, den Grad der Autonomie von Maschinen zu erhöhen. Mit anderen Worten ausgedrückt bedeutet dies, eine Maschine zu befähigen Entscheidungen als selbstständiger Agent zu treffen und dadurch die Kontrolle über Situationen und Handlungen zu übernehmen. Allerdings gibt es für die Gestaltung von autonomen Maschinen im CPS derzeit keinen allgemein anerkannten Ansatz oder keine Methodik, wie ein Autonomie-Konzept umgesetzt werden könnte.

Der Schwerpunkt dieses Artikels liegt auf der Systematisierung von Forschungsansätzen der IT-Autonomie. Basierend auf einer Literaturanalyse wird ein Konzept für die Umsetzung von Autonomiestufen und autonomen Agenten in CPS erarbeitet und die Basis für deren Spezifikation, bspw. über eine grafische Modellierungssprache, vorbereitet, welche die Modellierung von Autonomie ermöglichen würde. Das bereitgestellte Konzept schließt die Lücke zwischen der abstrakten Idee von autonomen CPS und der praktischen Gestaltung solcher Systeme in der Realität.

Im Folgenden werden zunächst Grundlagen zum Internet der Dinge und CPS vorgestellt. Darauffolgend werden die Kernaspekte hinsichtlich IT-Autonomie aufgezeigt. Diese allgemeingültigen Erkenntnisse bilden das Fundament der abschließend vorgestellten Grundlagen für eine Spezifikation des autonomen Verhaltens von Agenten. Sie gliedern sich zunächst in mehrere Anforderungen und werden anschließend in einem Meta-Modell umgesetzt und diskutiert. Das Papier schließt mit einem Ausblick auf weitere notwendige Arbeiten zur Gestaltung der Autonomie in CPS.

2 Grundlagen

2.1 Cyber-physische Systeme und Internet der Dinge

In der Literatur finden sich zahlreiche Erläuterungen des Begriffs Cyber-physisches System, eine anerkannte Definition liefern diese jedoch nicht. [3, 4] prägten zuerst den

Begriff des Internet der Dinge für Computer, die nicht nur eigenständig Informationen sammeln, sondern dazu befähigt werden, aus den gesammelten Informationen zu lernen und die Welt durch ihr stetig kumuliertes Wissen selbst wahrzunehmen und über ein Netzwerk, bspw. das Internet, kommunizieren zu können.

[5] differenziert darauf aufbauend CPS als physische, biologische und/ oder bautechnische Systeme, die über eine Recheneinheit integriert, überwacht oder gesteuert werden. Die Recheneinheit ist dabei ein verteiltes, eingebettetes System. [6] hebt zudem die Interdependenzen von Recheneinheiten und physischen Prozessen in Feedbackschleifen hervor. [7] ergänzen die Notwendigkeit einer oder mehrerer multi-modaler Mensch-Maschine-Schnittstellen zur Kommunikation und Steuerung von CPS und die weltweite Nutzbarkeit von Daten und Diensten für lokale Operationen.

Zusammenfassend bezeichnen CPS also die Kopplung von informations- und softwaretechnischen Komponenten mit mechanischen bzw. elektronischen Komponenten, die über eine Kommunikationsinfrastruktur, wie zum Beispiel das Internet, in Echtzeit miteinander kommunizieren. Diese Komponenten können in unterschiedlichem Grade automatisiert und autonom handeln, woraus Konsequenzen für die Mensch-Maschine-Interaktion entstehen [2].

2.2 (IT-)Autonomie

Der Begriff Autonomie besitzt im Allgemeinen die zwei Bedeutungen Unabhängigkeit und Selbstständigkeit. Selbstständigkeit beschreibt die Fähigkeit einer Entität, bzw. eines Agenten, für sich selbst zu sorgen, während Unabhängigkeit für die Freiheit einer Entität vor der Kontrolle einer von außen einwirkenden Instanz steht [8].

Im Kontext der IT kann Autonomie als eine nichtfunktionale Systemeigenschaft gesehen werden, die sich auf einzelne Funktionen übertragen lässt. Autonomie wird hierbei als Spezialisierung der Adaptivität betrachtet, der Fähigkeit zu verstehen, eine Zielstellung in Bezug auf eine Eingabemenge zu erfüllen und dabei die eigenen Strukturen an die Änderungen in der Umwelt anzupassen. Es wird eine Bindung von Autonomie an eine Funktion erreicht, indem die autonome Funktionserfüllung als Basiseigenschaft aufgefasst wird, mehrere Systeme miteinander in Bezug zu setzen [9].

Autonomie steht in einem engen Zusammenhang mit Automatisierung, welche eine maschinelle Handlung ohne menschliche Unterstützung darstellt. Es ist demnach ein Mittel für die Ablösung von Aufgaben eines Menschen [10]. Durch Automatisierung kann eine höhere Geschwindigkeit sowie eine bessere Effizienz bei der Aufgabenbewältigung erreicht werden. Weiterhin kann der physische und geistige Aufwand für einen Menschen reduziert werden.

IT-Autonomie kann den Menschen insbesondere bei Koordinationsaufgaben entlasten und so die Geschwindigkeit oder Sicherheit erhöhen. Sie lässt sich nicht nur gänzlich auf einzelne funktionale Aspekte eines Agenten übertragen, sondern durch eine graduelle Abstufung unterschiedlicher Ebenen der Interaktion zwischen Menschen und Maschinen kennzeichnen [11]. Diese Abstufung kann als Kontinuum zwischen der vollständigen Autonomie, bei der Maschinen Entscheidungen selbstständig gemäß ihrer eigenen Zielstellungen treffen, und dem größten kognitiven sowie physischen, menschlichen Einsatz auf der anderen Seite verstanden werden [2].

Wir verstehen unter Autonomie keine reine Systemeigenschaft, welche sich anhand des Informationsgradienten und des emergenten Verhaltens feststellen lässt [9]. Vielmehr rücken Aspekte der Interaktion zwischen einem Menschen und einer Maschine sowie der dadurch festgelegte Grad vorhandener Autonomie in einem System in den Vordergrund (siehe Kapitel 3.3). Abgedeckt wird hierbei das Spektrum vollständiger Kontrolle der Zielerreichung durch sowohl den Menschen als auch der Maschinen sowie das Kontinuum an Möglichkeiten, welches zwischen beiden Extremen liegt.

3 Autonomie in Cyber-physischen Systemen

3.1 Eigenschaften autonomer Agenten

Agenten sind eine Entität, wie bspw. Maschinen aber auch der Mensch, die ihre Umwelt über Sensoren wahrnehmen und mittels Effektoren auf diese Umwelt einwirken können [12]. Autonome Agenten handeln dabei entsprechend ihrer eigenen Agenda [13]. Die wichtigsten Bestandteile eines Agenten sind folglich Sensoren für die Sinneswahrnehmung und Effektoren für das Ausführen von Aktionen auf eine Umwelt. Eine Umwelt bezeichnet dabei den Wirkungskreis eines Agenten. Nach dem Verständnis von [14] stellt eine Umwelt ein System dar, welches aus einer Vielzahl von Agenten besteht. Hierbei kann ein System selbst wiederum ein Agent sein, welcher ein Teil eines größeren Systems respektive Agenten ist.

Beispiele für Sensoren menschlicher Agenten sind deren Augen und Ohren. Als ihre Effektoren werden häufig Hände und Mund genannt. Für künstliche Agenten zählen bspw. Kameras, Temperaturfühler oder digitale Schnittstellen zu Sensoren. Effektoren können Teile der Robotik aber, auch akustische Signale oder elektronisch übertragene Nachrichten sein.

Die Implementierung der Logik, Zielstellung und Wertvorstellung in Bezug auf die Informationsverarbeitung eines Agenten lassen [12] offen. Sie unterscheiden für die konkrete Definition genannter Eigenschaften folgende vier Typen von Agenten:

- **Agent mit Reflexen:** Agiert entsprechend einer vorgegebenen Menge von Regeln. Befindet sich die wahrgenommene Welt in einem definierten Zustand, wird die dem Zustand zugeordnete Aktion ausgeführt.
- **Agent mit internen Zuständen:** Erweitert einen einfachen Agenten mit Reflexen, so dass nicht nur der aktuelle Umweltzustand, sondern auch die Vergangenheit und die verfolgte Entwicklung des Umweltzustandes relevant für die auszuwählende Aktion des Agenten sind.
- **Agent mit Zielen:** Erweitert einen Agenten mit internen Zuständen um die Fähigkeit anhand von Zielstellungen den Einfluss von Aktionen auf seine Umwelt abzuwägen. Eine Zielvorgabe beschreibt den Zustand der Umwelt, der durch einen Agenten erreicht werden soll. Hierbei wird nicht genauer spezifiziert, wie der Zielzustand erreicht werden kann [15].
- **Agent mit Nutzenfunktion:** Erweitert einen Agenten mit Zielen um die Fähigkeit, den Nutzen für seine möglichen Handlungsalternativen festzustellen und die entsprechend der Nutzenfunktion beste Alternative zu wählen.

Durch das Hinzufügen des Aspektes der Autonomie erhalten Agenten die Fähigkeit, selbstständig zu entscheiden, wann sie welche Aufgaben wie ausführen und wann sie mit wem, auf welche Art und Weise, zu diesem Zweck kommunizieren. Hierdurch sind Agenten fähig, auf vorhergesehene und unvorhergesehene Ereignisse aus ihrer Umwelt zu reagieren, erwartete und unerwartete Probleme zu lösen und Teil einer Organisation mit dynamischen Strukturen zu sein [15, 16]. [13] geben eine Übersicht von Eigenschaften, welche für die Klassifizierung von Agenten (siehe Tabelle 1) herangezogen werden kann. Ihrer Auffassung zufolge erfüllen autonome Agenten zumindest die ersten vier Eigenschaften dieser Übersicht: Reaktivität, Autonomie, Ziel-Orientierung und Kontinuität. Reaktivität in Form einer zeitnahen Reaktion auf asynchrone, externe Reize ist eine Schlüsseleigenschaft eines autonomen Agenten. Deshalb sollte die Informationsverarbeitung in Echtzeit erfolgen [17].

Tabelle 1. Eigenschaften zur Klassifizierung von Agenten (in Anlehnung an [13])

Eigenschaft	*Beschreibung*
Reaktiv	Reagiert zeitnahe auf Veränderungen in der Umwelt
Autonom	Übt Kontrolle über seine eigenen Aktivitäten aus
Ziel-orientiert	Keine einfache Reaktion auf die Umwelt
Temporär	Kontinuierlich laufender Prozess
Kommunikativ	Kommuniziert mit anderen Agenten, eventuell Menschen eingeschlossen
Lernend	Verändert sein Verhalten basierend auf Erfahrungen
Mobil	Fähigkeit, sich selbstständig auf eine andere Maschine zu transportieren
Flexibel	Aktionen folgen keinem Skript
Charakter	Glaubhafte „Persönlichkeit“ und emotionaler Zustand

[18] heben ergänzend die sozialen Fähigkeiten insbesondere die Kommunikation mit anderen künstlichen oder menschlichen Agenten, als zentrale Eigenschaft hervor. [19] untersuchen soziale Interessen von Agenten in Bezug auf die Entscheidungsfindung. Sie unterscheiden zwischen folgenden drei Formen sozialer Kompetenzen:

- **Eigennutz:** Ein Agent stellt die eigene Zielstellung respektive seine eigenen Vorteile über den globalen Nutzen der Gruppe.
- **Hilfsbereitschaft:** Ein Agent wählt Alternativen, welche aus Sicht der Gruppe vorteilhaft sind. Hierbei sind auch Alternativen möglich, die keinen individuellen Vorteil für den einzelnen Agenten bringen.
- **Kooperation:** Agenten wählen Alternativen, welche einen positiven Nutzen für die Gruppe kooperierender Agenten bringen. Zwar ist eine Wahl von Alternativen möglich, die einen individuellen Nachteil des Agenten nach sich ziehen, allerdings wird dieser Nachteil von einem Vorteil übertroffen, der durch eine in einem Team ausgeführte Aktion erzielt wird.

Vorangehende Ausführungen bezüglich der Konzepte zu Autonomie und zu autonomen Agenten zeigen, dass Informationsverarbeitung auf der einen Seite und Interaktivität auf der anderen Seite ausschlaggebend für die Bestimmung des Autonomielevels von Maschinen sind. Vergleicht man die Menge der innerhalb der Grenzen eines Systems verarbeiteten Informationen mit der über die Systemgrenzen hinweg ausgetauschten Informationsmenge, lässt sich der Informationsgradient als Indikator des Autonomiegrades eines Systems bestimmen [9].

Bezüglich der Informationsverarbeitung stützen sich [20, 21] auf die vier Funktionen Überwachung, Erzeugung, Auswahl und Implementierung. Diese können wie folgt auf den Prozess der Informationsverarbeitung übertragen werden: Systemstatus wahrnehmen, mögliche Reaktionen ableiten, Aktionen auswählen und Aktionen umsetzen. Während [20] den Grad der Autonomie über die Zuordnung der Grundfunktionen zu Menschen und Maschinen festlegen, beschreiben [21] eine Divergenz des Autonomiegrades innerhalb der einzelnen Funktionen selbst.

[22] liefern eine Taxonomie acht möglicher Kommunikationsmuster zwischen Menschen und Maschinen, im Speziellen Robotern.

- **1 → 1:** Der Mensch nimmt eine steuernde Rolle ein, während die Maschine einerseits Informationen aus der Umwelt wahrnimmt und an den Menschen weiterleitet und andererseits die durch den Menschen vorgegebenen Aktionen ausführt.
- **1 → 1+1+…:** Zwei oder mehr Maschinen werden von einem Menschen gesteuert. Der Mensch ist für die Aufteilung der Aufgabe und die Koordination der Ausführung zuständig. Die Maschinen arbeiten unabhängig voneinander ihre Teilaufgaben ab.
- **1 → n:** Zwei oder mehr Maschinen werden von einem Menschen gesteuert. Die Maschinen nehmen die Anweisung durch den Menschen als Gruppe wahr und koordinieren die Unterteilung der Aufgabe sowie deren Ausführung selbst.
- **n → 1:** Zwei oder mehr Menschen erarbeiten in einem Team Aktionen für eine Maschine und übermitteln diese nach gemeinsamer Abstimmung an eine Maschine zur Ausführung.
- **n → 1+1+…:** Zwei oder mehr Menschen erarbeiten in einem Team Aktionen für zwei oder mehr Maschinen. Die Menschen sind für die Aufteilung der Aufgabe und die Koordination der Ausführung zuständig. Die Maschinen arbeiten dann unabhängig voneinander ihre Teilaufgaben ab.
- **n → n:** Zwei oder mehr Menschen erarbeiten in einem Team Aktionen für zwei oder mehr Maschinen und übermitteln diese nach gemeinsamer Abstimmung an die Maschinen zur Ausführung. Die Maschinen nehmen die Anweisung durch den Menschen als Gruppe wahr und koordinieren die Unterteilung der Aufgabe sowie deren Ausführung selbst.
- **1+1+… → 1:** Zwei oder mehr Menschen übermitteln unabhängig voneinander Aktionen an eine Maschine. Die Maschine übernimmt die Koordination eingehender Aufgaben.
- **1+1+… → n:** Zwei oder mehr Menschen übermitteln unabhängig voneinander Aktionen an eine Gruppe von Maschinen. Die Maschinen entscheiden innerhalb ihrer Gruppe über die Zuweisung der Aufgaben an einzelne Gruppenmitglieder sowie über die Prioritäten bei der Aufgabenbearbeitung.

Die Fähigkeit der Gruppenbildung weist Parallelen zu komplexen adaptiven Systemen auf [23], in denen Agenten miteinander interagieren, aber auch lernen und sich anpassen. Eine weitere sich daraus ergebende Eigenschaft ist die Selbstähnlichkeit.

Zur Übertragung von Informationen ist ein Kommunikationsmedium erforderlich. [24] beschreibt Varianten der Kommunikation eines Menschen mit einer Maschine und vice versa. Diese orientieren sich an den klassischen fünf Sinnen Sehen, Hören, Riechen, Fühlen und Schmecken.

[25] bezeichnen Vertrauen als Basis der Verlässlichkeit bei der Kommunikation. Vertrauen ist immer dann ein notwendiger Faktor, wenn eine Bewertung von Handlungsalternativen aufgrund von Unsicherheiten und hoher Komplexität nicht möglich ist. Der Grad des Vertrauens dient dann als ein Indikator dafür, ob eine Entscheidung akzeptiert oder selbst getroffen wird. Attribute für die Vertrauenswürdigkeit von Kommunikation sind bspw. Aufmerksamkeit, Verlässlichkeit, Konformität und Sicherheit.

3.2 Anforderungen an autonome Agenten

Agenten agieren in einer Umwelt. Sie müssen Reize mittels Sensoren wahrnehmen, Aktionen wählen und diese Aktionen durch den Einsatz eigener Effektoren an ihre Umwelt zurückgeben. Die Umwelt kann dabei als holonisches Multi-Agenten-System betrachtet werden. Das bedeutet, dass ein Agent aus der Vogelperspektive beobachtet wie ein einzelnes Teil mit sichtbaren Sensoren und Effektoren wirkt. Im Querschnitt dieses Agenten wird deutlich, dass sich der Aufbau des Hauptagenten aus einer Vielzahl von Subagenten zusammensetzt. Es besteht eine rekursive Beziehung zwischen Agenten, die eine beliebige Granularität zulässt.

Anforderung 1: Die Spezifikation muss hierarchische Anordnungen von autonomen Agenten abbilden.

Ein Agent besitzt beliebig viele Sensoren und beliebig viele Effektoren. Mit Effektoren gibt ein Agent Informationen eines bestimmten Typs ab. Der Agent selbst oder andere Agenten in seiner Reichweite nehmen diese Informationen mit den jeweils entsprechenden Sensoren wahr.

Anforderung 2: Die Spezifikation muss abbilden, welche Arten von Sensoren und Effektoren von Agenten unterstützt werden und welche Sensoren die Datenobjekte welcher Effektoren wahrnehmen können.

Die Richtung einer Interaktion bestimmt den Datenfluss zwischen den Teilnehmern an einer Interaktion. Hierdurch wird auch die Abhängigkeit zwischen Agenten sowie die Gesamtstruktur eines Netzwerkes aus Agenten ausgedrückt.

Anforderung 3: Die Spezifikation muss die Richtungsdefinition einer Interaktion abbilden, so dass deren kommunikatives Verhalten sichtbar gemacht wird.

Ein Agent ist genau dann autonom, wenn dieser Aufgaben selbstständig ausführen kann. Hierzu zählt das Treffen relevanter Entscheidungen bzgl. Ressourcen und Ausführungszeitpunkten.

Anforderung 4: Die Spezifikation muss einfache und komplexe Regeln, welche das Handeln eines Agenten beschreiben, abbilden.

Ergänzend müssen die Entscheidungen auf Basis des internen und externen Zustandes getroffen werden.

Anforderung 5: Die Spezifikation muss verschiedene Zielstellungen, Nutzenfunktionen und Zustände abbilden.

Die Anforderung, in Echtzeit auf Stimuli zu reagieren, zeigt insbesondere bei Menschen, dass die Auswertung von Sensordaten nur in einem beschränkten Maße möglich ist. Die als Aufmerksamkeitskapazität bezeichnete Fähigkeit beschreibt sowohl eine Beschränkung des Kurzzeitgedächtnisses als auch der Phasen Wahrnehmung, Entscheidungs- und Aktionsauswahl sowie Aktionsdurchführung. Aus ökonomischen oder technologischen Gründen kann eine vergleichbare Beschränkung auch auf Maschinen zutreffen.

Anforderung 6: Die Spezifikation muss eine kapazitive Beschränkung von Funktionalitäten durch ein Konstrukt ähnlich der Aufmerksamkeit abbilden.

Unter dem Aspekt der Gruppierung respektive der Teambildung lassen sich mehrere Agenten zu einer Gruppe zusammenfassen. Beispielsweise übergibt ein Mensch eine Aufgabe an eine Gruppe von Maschinen, welche die Arbeitsaufteilung und Aufgabenbewältigung selbst koordiniert. Wie beschrieben können Agenten auch aus beliebig vielen Subagenten aufgebaut und durch Zielstellungen, Nutzenfunktionen, Regeln und Zustände spezifiziert werden. Diese müssen nicht konfliktfrei sein.

Anforderung 7: Die Spezifikation muss den Aspekt der sog. sozialen Rationalität abbilden und Formen sozialer Kompetenzen darstellen sowie eine Möglichkeit abbilden, Agenten unterschiedlichen Typs zu Gruppen zusammenzufassen. Das gilt auch für Agenten desselben Typs, wenn deren Kommunikationsverhalten eindeutig bestimmt ist. Dies erfordert die Bildung von Agentenklassen, bei denen die Anzahl möglicher, konkreter Instanzen individuell festgelegt werden kann.

Sicherheit ist einerseits ein Mechanismus, der Korruption bei der Nachrichtenübertragung verhindert und somit bewusste Manipulationen und Angriffe von Dritten auf Datenströme erschwert. Andererseits wird dem Sicherheitsaspekt die Eigenschaft der Zuverlässigkeit bei der Nachrichtenübermittlung zugeordnet.

Anforderung 8: Die Spezifikation muss Vertrauens-Parameter einer Beziehung respektive eines Datenübertragungskanals, wie Aufmerksamkeit, Verlässlichkeit, Konformität und Sicherheit, abbilden.

Die Beispiele zu den allgemeinen Koordinationsprotokollen sowie die Ansätze aus dem Bereich des Spezialfalls der Supervisory Control [26] zeigen, dass strukturelle Vorgaben für die Koordination von Agenten über deren Zustände und Regeln abgebildet werden können. Folglich entstehen aus dem Bereich der Koordination keine gesonderten Anforderungen.

3.3 Anforderungen an die Interaktion autonomer Agenten

Es gibt mehrere Konzepte die sich mit der Einteilung von Autonomie in unterschiedliche Stufen bei der Interaktion zwischen Mensch und Maschine beschäftigen [2, 20, 21, 26-30]. Tabelle 2 fasst die verschiedenen Konzepte zusammen und bildet die entsprechenden Stufen ab. Eine detaillierte Besprechung der verwandten Arbeiten findet sich in Kapitel 5. Eine eindeutige stufenartige Staffelung, welche sich zwischen den beiden Extremen der vollständigen Autonomie einer Maschine S (Stufe 1) oder eines Menschen M (Stufe 19) bewegt, ist nicht möglich.

Die beiden Extremfälle auf Stufe 1 und 19 beschreiben jeweils Situationen, in denen entweder ein Mensch oder eine Maschine die vollständige Kontrolle über die Entscheidungsfindung und die Aktionsdurchführung besitzen. Die bereits für autonome Agenten identifizierten Anforderungen genügen, um beide Sachverhalte adäquat abzubilden. Folglich entstehen aus den Randbereichen keine gesonderten Anforderungen.

Tabelle 2. Übersicht der Autonomiestufen

Nr	*Beschreibung*	*Quelle*
1	S trifft Entscheidung komplett und führt Aktionen autonom aus, keine Funktion durch M	[2, 20, 21, 26, 27, 30]
2	S trifft Entscheidung komplett und führt Aktionen autonom aus, M überwacht S und greift ggf. steuernd ein	[20, 27, 28]
3	S trifft Entscheidung komplett und führt Aktionen autonom aus, M überwacht bestimmte Bereiche von S und greift ggf. steuernd ein	[29]
4	M trifft Entscheidung und führt Aktion autonom aus bis zur Übergabe an S, dann führt S Aktionen autonom aus	[20, 26]
5	M trifft Entscheidung und übergibt Aktion zur Ausführung an S	[20]
6	S trifft Entscheidung und führt Aktion solange aus bis M ein Veto einlegt	[2]
7	S wählt Aktion und gibt M beschränkte Zeit für Veto	[21, 26, 30]
8	S wählt Aktion und führt nur auf Zustimmung von M aus	[20, 21, 26, 27, 30]
9	S bietet M alle Alternativen zur Auswahl an	[21]
10	S bietet M vorausgewählte Alternativen zur Auswahl an	[2, 21, 26, 27, 30]
11	S bietet M genau eine Alternative an, M kann dennoch ablehnen	[2, 21, 26, 27, 30]
12	S und M schlagen Alternativen vor, M wählt beste Alternative aus	[20]
13	M schlägt S Alternativen vor, S wählt die beste Alternative aus und führt diese aus	[20]
14	S führt Aktion aus und benachrichtigt M nach eigenem Ermessen	[21, 26]
15	S führt Aktion aus und benachrichtigt M auf Nachfrage von M	[21, 26, 30]
16	S führt Aktion aus und benachrichtigt M immer	[21, 30]
17	M trifft Entscheidungen und steuert S	[28]
18	M trifft Entscheidungen und steuert, aber S übernimmt Teile der Steuerung und führt diese autonom aus	[28]
19	M trifft Entscheidung komplett und führt Aktionen autonom aus, keine Funktion durch S	[20, 21, 27, 30]

Stufe 2 und 3 beschreiben eine Situation, in der einer der beiden Interaktionspartner Aktionen auswählt und ausführt, während der andere Partner die Rolle einer überwachenden Instanz einnimmt und in kritischen Situationen steuernden Einfluss auf die Ausführung nimmt. Die beiden Stufen unterscheiden sich im Grad der Überwachung, welcher sich über die Menge der überwachten Funktionen festlegen lässt. Beide Stufen entsprechen dem Konzept der Supervisory Control und den Anforderungen, die mit diesem Konzept verknüpft sind (siehe oben).

Eine weitere Gruppe bilden die 4. und 5. Stufe. Bei beiden liegt die Autorität einer Entscheidung bei einem Menschen. Beide Stufen unterschieden sich durch den Grad der Aufteilung einer Aufgabe bei deren Ausführung. Durch das Konzept der autonomen Agenten wurde bereits eine Anforderung definiert, welche Datenobjekte als Teil des hier auszuarbeitenden Meta-Modells beschreibt, die zwischen zwei oder mehreren Agenten ausgetauscht werden. Der Fokus dieser beiden Gruppen liegt auf dem Austausch von Aufgaben und Teilaufgaben.

Anforderung 9: Die Spezifikation muss Aufgabenlisten als speziellen Typ eines Datenobjektes abbilden.

Ein ähnlicher Fall ergibt sich aus den Stufen 9 bis 11, welche unterschiedliche Mengen an Alternativen, die einem Agenten von einem anderen Agenten vorgeschlagen werden, beschreiben: (1) alle Alternativen, (2) eine Auswahl an Alternativen sowie (3) genau eine Alternative. Stufe 12 und 13 beschreiben das gleiche Verhalten aus gegensätzlicher Perspektive.

Anforderung 10: Die Spezifikation muss Datenobjekte des Typs Aufgabenlisten entsprechend der beschriebenen Abstufung abbilden.

Stufe 6 bis 8 beschreiben die Situation, in der eine Maschine selbstständig Aktionen auswählen und ausführen kann. Die Stufen unterscheiden sich darin, dass ein Mensch unterschiedliche Möglichkeiten besitzt, durch sein Veto die Ausführung einer Aktion zu unterbrechen oder gar zu verhindern.

Anforderung 11: Die Spezifikation muss Datenobjekte zur Zustimmung und Ablehnung von Aufgaben abbilden.

Eine weitere Kategorie kann aus den Stufen 14 bis 16 abgeleitet werden. Diese beschreiben die Situation, dass ein Agent eine Aktion ausführt und dabei einen weiteren Agenten auf unterschiedliche Art über seinen aktuellen Zustand benachrichtigt: (1) nach eigenem Ermessen benachrichtigen, (2) immer benachrichtigen und (3) auf Anfrage benachrichtigen.

Anforderung 12: Die Spezifikation muss den Typ der Benachrichtigung abbilden.

Die verbleibenden Stufen 17 und 18 zeigen starke Ähnlichkeit zu den Stufen 2 und 3. Der Unterschied zwischen beiden Gruppen liegt in der aktiven beziehungsweise in der passiven Haltung des menschlichen Agenten. Auf der einen Seite nimmt dieser eine passive, beobachtende Rolle ein und wird nur in kritischen Situationen steuernd aktiv. Auf der anderen Seite ist der menschliche Agent durchgehend aktiv, trifft zu einem gewissen Grad Entscheidungen und steuert den zweiten Agenten. Auf abstrakter Ebene betrachtet, macht die Frequenz der Eingriffe den Unterschied zwischen den Stufen aus, welche sich über die Komplexität der zu steuernden Aufgaben ergibt. Folglich kann dieser Sachverhalt über das Formulieren von Regeln für die beteiligten Agenten abgebildet werden und stellt keine weiteren Anforderungen.

4 Meta-Modell zur Spezifikation autonomer Agenten

Der folgende Abschnitt definiert die abstrakten Bestandteile einer Sprache, ein Meta-Modell, das die Spezifikation von Autonomie erlauben soll. Abbildung 1 stellt den Aufbau eines Agenten in drei Kategorien dar: Bestandteile, kennzeichnende Elemente und beschreibende Elemente. Diese modellierten Informationen könnten dann für die Charakterisierung der Autonomie in CPS, bspw. von (Sub-)Prozessen im Bereich Business Process Management oder von Event Processing Agents bzw. Networks im Bereich

Complex Event Processing, verwendet werden, um zu signalisieren, wie autonom sich diese Prozesse bzw. Analyse-Netzwerke in Bezug auf ihre Umwelt verhalten sollen.

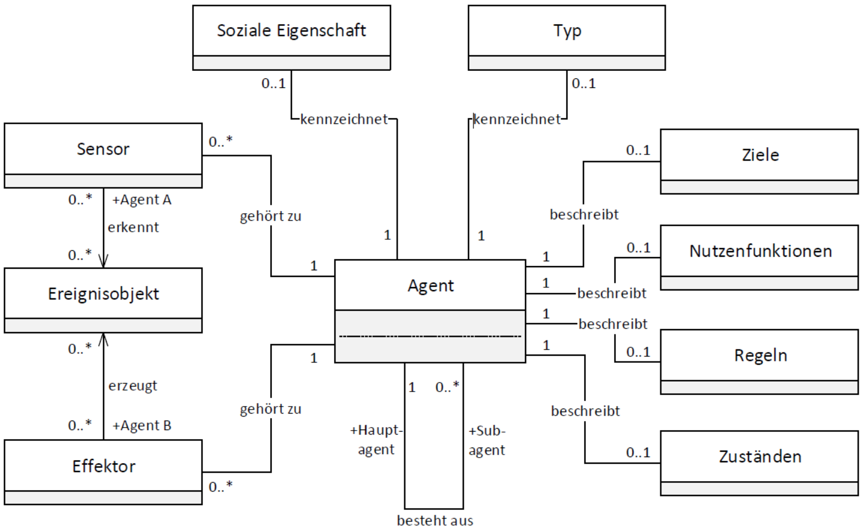

Abbildung 1. Übersicht Meta-Modell

Die Kategorie Bestandteile umfasst die Sensoren und Effektoren eines Agenten. Im traditionellen Sinne ist ein Sensor immer genau einem Agenten zugeordnet. Maschinen sind jedoch grundsätzlich in der Lage gemeinsam auf Sensoren und Effektoren zuzugreifen. Weiterhin kann ein Agent beliebig viele Sensoren zugeordnet bekommen. In der gleichen Beziehung steht ein Agent zu seinen Effektoren. In beiden Fällen sind auch die Extreme möglich, dass einem Agenten keine Sensoren oder keine Effektoren zugeordnet werden. Im Meta-Modell ist dies implizit über die Hierarchisierung von Agenten abgebildet.

Es gibt grundsätzlich sechs Kanäle über die Effektoren und Sensoren kommunizieren: visuell, auditiv, olfaktorisch, taktil, gustatorisch und generisch. Die Einteilung der ersten fünf Kanäle orientiert sich hierbei an den von Schmauk als klassische Modalitäten eingeordneten fünf Sinnen. Der generische Sensor dient als offener Typ, der über zusätzliche Parameter näher bestimmt werden kann und somit alle diejenigen Kanäle abbilden kann, welche nicht durch eine der anderen fünf Klassen spezifiziert werden können. Hierzu zählen bspw. elektronische Kommunikation von Maschinen oder Hirnströme bei Menschen.

Zwei oder mehrere Agenten können in einer Beziehung stehen, wenn sie Sensoren und Effektoren besitzen, die kompatibel zueinander sind, d. h. wenn Ereignisobjekte erzeugt werden, die von einem der Sensoren des anderen Agenten erkannt werden können. Eine Beziehung zwischen zwei Agenten kann durch optionale Parameter beschrieben werden. Diese beschreibenden Parameter können von Agenten bei deren Entscheidungsfindung herangezogen werden und können somit Einfluss auf die Entscheidung selbst haben. Ein Beziehungsparameter offenbart grundlegende Eigenschaften, die das

Verhältnis zwischen zwei Agenten betreffen. Beziehungsparameter spezialisieren sich zu Aufmerksamkeit, Verlässlichkeit, Konformität und Sicherheit.

Die Aufmerksamkeit bezeichnet wie oben eingeführt eine kapazitive Obergrenze an Informationen, die in den verschiedenen Stufen der Verarbeitung wahrgenommen werden kann. Wir nutzen dieses Konzept, um den von einem Effektor erzeugten Anteil der Ereignisobjekte einer Beziehung zu beschreiben, der von einem Sensor erkannt wird, oder um technische Limitationen bei der Auswertung zum Ausdruck zu bringen. Verlässlichkeit und Konformität leiten sich aus den Konzepten bezüglich des Vertrauens bei der Interaktion zwischen Mensch und Maschine ab. Der Unterschied zwischen den beiden Parametern liegt in ihrer Wirkungsrichtung. Verlässlichkeit beschreibt das Vertrauen eines wahrnehmenden Agenten gegenüber dem sendenden Agenten. Es ist also ein Indikator dafür, zu welchem Grad die Signale zur Entscheidungsfindung von einem wahrnehmenden Agenten herangezogen werden. Die Konformität wirkt entgegengesetzt zu der Verlässlichkeit und beschreibt somit das Vertrauen eines sendenden Agenten gegenüber dem empfangenden Agenten. Sicherheit beschreibt als letzter Aspekt die Vertrauenswürdigkeit des Kommunikationskanals.

Die zweite Kategorie enthält die kennzeichnenden Elemente eines Agenten. Hierzu zählen einerseits die sozialen Eigenschaften und andererseits die unterschiedlichen Typenausprägungen eines Agenten. Eine gesonderte Betrachtung der sozialen Eigenschaften zu den unterschiedlichen Agententypen ist notwendig, um soziale Eigenschaften als Indikator für das Auflösen von Konflikten zwischen den Zielen, Nutzenfunktionen, Regeln und Zuständen eines Hauptagenten zu seinen Subagenten bzw. Konflikten zwischen Agenten in einem Netzwerk zu nutzen und somit das spezifische, autonome Verhalten eines Agenten zu zeigen. Die Kennzeichnung durch den Typ eines Agenten gibt Aufschluss über das allgemeine Verhalten bei der Ereignisverarbeitung. Einem Agenten kann maximal eine soziale Eigenschaft zugeordnet werden. Die Assoziation zwischen einem Agenten und seinem Typ folgt der gleichen Kardinalität wie bei den sozialen Eigenschaften.

Eine dritte Kategorie bilden die vier beschreibenden Elemente Ziele, Nutzenfunktionen, Regeln und Zustände. Die Summe der Elemente respektive deren Zusammenspiel beschreiben das autonome Verhalten eines Agenten. Die Kardinalitäten der Assoziation eines Agenten mit den jeweiligen Elementen dieser Kategorie entspricht den bereits beschriebenen Kardinalitäten der kennzeichnenden Merkmale. Folglich sind auch diese Elemente für die Spezifikation optional und zeigen primär an, ob ein Agent durch eine Menge von Zielen, Nutzenfunktionen, Regeln und Zuständen beschrieben wird oder nicht.

Eine weitere Eigenschaft eines Agenten, die durch Abbildung 1 dargestellt ist, ist eine Assoziation zu sich selbst. Diese reflexive Assoziation zeigt an, dass sich ein Hauptagent in beliebig viele Subagenten zerlegen lässt.

5 Verwandte Arbeiten

[26] stellen eine zehnstufige Skala für die Unterscheidung verschiedener Grade der Automatisierung bei der Entscheidungsfindung vor. Zwischen den beiden Extremen der

vollständigen Entscheidungskompetenz liegen Stufen, welche durch das Bilden von Interaktionsmustern zwischen Mensch und Maschine differenziert werden.

Auch [21] beschreiben eine graduelle Abstufung von Autonomie in zehn Stufen. Jede dieser Stufen ist hierbei auf die einzelnen Phasen der menschlichen Informationsverarbeitung anwendbar. Neben der Stufe der vollständigen Autonomie werden die Stufen nach den drei Kategorien Art der Information, Vetorechte und Anzahl der angebotenen Handlungsalternativen differenziert. [30] reduzieren diese Skala auf acht Stufen. Die Autoren gehen hierbei speziell auf den Fall einer durch den Computer ausgewählten Handlungsalternative ein.

[31] beschreibt ein Modell, welches die grundlegenden Eigenschaften aus dem Konzept der Supervisory Control abbildet. Er beschreibt eine fünfstufige Skala für die Bestimmung des Automatisierungsgrades in Bezug auf den Prozess der Informationsverarbeitung. [29] identifiziert sieben Arten der Beeinflussung gegenseitiger Autonomie durch Veränderung von Systemparametern. Bisherige Ansätze werden dahingehend erweitert, dass autonomes Verhalten nicht nur von der eigenen Autorität über das Treffen von Entscheidungen abhängt, sondern auch von weiteren Entitäten im System beeinflusst und geprägt wird.

[32] schlägt 13 Eigenschaften eines Agenten vor, anhand derer die autonome Abhängigkeit zu seiner Umwelt festgestellt werden kann. [14] bauen auf diesen Eigenschaften der Dimensionierung von Autonomie auf und zeigen in ihren Untersuchungen Autonomie in Bezug auf Multi-Agenten-Organisationen.

[27] zeigt vier unterschiedliche Grade von Autonomie auf. [33] greifen diese Skala auf und vergeben für die autonome Abstufung die folgenden Bezeichnungen: keine Systemunterstützung, Entscheidungsunterstützung, konsensuelle und überwachte, künstliche Intelligenz sowie vollständige Autonomie. [20] erweitern die Skala zu einer Taxonomie mit zehn Stufen. Diese reichen von manueller Kontrolle bis zu vollständiger Autonomie.

[28] klassifiziert unterschiedliche Grade von Autonomie: Überwachung und logisches Denken, Planung des Fahrwegs, Kollisionsverhinderung und einfache Steuerung. Auch diese Abstufung reicht von der vollständigen Kontrolle des Menschen bis zur Überwachung von Zielvorgaben durch den Menschen.

[19] beschreiben in ihrem Ansatz das Verhalten von Agenten in Gruppen. Sie knüpfen Autonomie an die soziale Bereitschaft eines Agenten, welche über die Zielstellung eines Agenten an die Maximierung eines individuellen oder gesellschaftlichen Nutzens gebunden ist. [8] wählen ebenfalls einen Ansatz, welcher Autonomie unterschiedliche Dimensionen zuordnet. Sie beschreiben die Anpassung von Autonomie entlang gewählter Dimensionen durch das Einschränken oder das Erweitern von Berechtigungen, Fähigkeiten, Möglichkeiten und Verpflichtungen eines Partners, welcher sich in einer Beziehung zur Erfüllung gemeinsamer Aufgaben befindet.

[2] untersuchen wie sich die automatisierungsbedingte Leistungsfähigkeit von Menschen bei unterschiedlichen Automatisierungsstufen verändert. Die Autoren weisen auf einen Kosten-Nutzen-Kompromiss hin, der sich daraus ergibt, dass zwar Routine-Aufgaben bei korrekter Arbeitsweise auch bei veränderlicher Arbeitsbelastung schneller erledigt werden können, aber die Performance und das Situationsbewusstsein deutlich sinkt, wenn das Entscheidungsunterstützungssystem fehlerhaft arbeitet.

6 Zusammenfassung und Ausblick

Aufbauend auf einer umfangreichen Literaturstudie zur IT-Autonomie wurden 12 Anforderungen für die Spezifikation autonomer Agenten in CPS-Systemen bestimmt. Diese wurden übersichtlich in einem abstrakten Meta-Modell zusammengefasst, welches die Möglichkeit eröffnet, die Autonomie von Agenten eindeutig zu beschreiben. Es ist zunächst bewusst abstrakt gehalten und kann für verschiedene Komponten eines Mensch-Maschine-Systems verwendet werden, wie bspw. ein CPS-System, das Menschen sowie Maschinen mit oder ohne physischer Präsenz (bspw. virtualisierte Prozess- oder Analyse-Systeme) enthält.

Die nächsten Schritte werden sich mit der Umsetzung des abstrakten Modells in eine konkrete Notation und die Verknüpfung derer mit existierenden Modellierungssprachen beschäftigen. Außerdem werden wir Entwurfsmuster für die Mensch-Maschinen-Kommunikation basierend auf den vorgestellten Autonomie-Leveln entwickeln, um die Implikationen für den Kommunikationsablauf besser darstellen zu können.

Do We Really Want Blockchain-Based Accounting? Decentralized Consensus as Enabler of Management Override of Internal Controls

Nadine Rückeshäuser

nadine.rueckeshaeuser@iig.uni-freiburg.de

Abstract. Research proposing the application of blockchain technology in accounting assumes the utilization of decentralized consensus mechanisms based on the exertion of scarce resources (Proof-of-Work; PoW), leading to the validation of transactions without the need of any third party. Together with the blockchain, a shared database, PoW is expected to lead to nearly immutable and, therefore, fraud-resistant, real-time financial registers. This conclusion must be reconsidered, taking into account recurrent top-management involvement in accounting scandals, often conducted through deliberate exposures of internal and external control systems. This paper asserts that blockchain-based accounting using PoW-based consensus paves the way for the suspension of controls by the management, since exerting the majority of computer power is easier than circumventing internal and external control systems in conventional accounting systems. Alternatives to PoW must be considered for blockchain-based accounting that prevents the management from conducting fraud and, thereby, qualifies the blockchain for its application in accounting.

Keywords: *Decentralized Consensus, Blockchain Customization, Blockchain-Based Accounting, Accounting, Management Override of Controls*

1 The Blockchain: The New Cure All?

Today, blockchain technology in combination with decentralized consensus mechanisms (DCMs) and its application in various business sectors is on everyone's lips. Blockchains are shared databases that are maintained and verified amongst actors that participate in a network, ensuring digital transparency and confidence of records of information without a trusted third party [26]. Whereas the financial sector was an early adopter, the demand for the technology has increased over the past years and comes from diverse industries, such as health care or logistics. This demand is not surprising, given the blockchain's ability to enable decentralized autonomous business models, defined by self-governed programs through decentralized governance and collective consensus [27]. In particular, this allows the execution of

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Rückeshäuser, N. (2017): Do We Really Want Blockchain-Based Accounting? Decentralized Consensus as Enabler of Management Override of Internal Controls, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 16-30

Turing-complete codes for so-called smart-contracts, leading to self-executing programs that automatically enforce properties of digital contracts [35].

One major business sector expected to benefit from the features of the blockchain is accounting. In particular, blockchains may facilitate the maintenance of permanent and timely records of financial transactions [36]. Its decentralized and transparent nature further implies potential immutability, meaning that financial records cannot be altered ex post and, if so, the probability of detection will be very high [2]. Thus, blockchain-based accounting could possibly rule out the conduction and concealment of improper accounting methods, illicit structuring of transactions and financial database manipulations [16]. The possibility of blockchain-based accounting, therefore, has recently become an intensively discussed issue, not only in an industrial [2, 34] but also in an academic context [8, 25, 36]. The growing interest in this topic is also reflected by the formation of several start-ups offering blockchain-based services for decentralized bookkeeping, such as *Factom* [37] or *Scorechain* [38]. Overall, the application of blockchain technology in the context of accounting could be conducive to the industry, which is still mainly based on standardized technology such as computer assisted audit techniques [2]. As the digitization of accounting is still in its infancy, the application of blockchain technology may leads to the technological progress needed.

However, industrial and academic advocates of blockchain-based accounting seem to neglect the still present and well-known challenges of proper accounting that is top-management involvement in accounting fraud [17, 32]. The severity of this topic gets obvious when looking, for instance, at fraud incidents in the United States, where accounting fraud conducted by the management amounts to 89 percent of all financial statement fraud cases of public companies [3]. The following paper investigates whether the blockchain is qualified for an application in accounting. To this end, it is investigated how the management is able to conduct fraud and whether the proposed intra-corporate blockchain application is able to decrease the opportunities to commit fraud. Accordingly, it is assumed that there exist incentives for the management to commit fraud, however, there might be technical mechanisms for its actual prevention. Most of all, this implies an investigation of DCMs regarding their ability to impede the management from conducting accounting fraud.

The paper is structured as follows: The next section provides a case study of the Comroad accounting scandal and investigates the used manipulation and concealment techniques. Based on this case study, a generalization of the fraud pattern and the relationships between internal and external control systems is deducted, using additional scientific literature to support the identified relationship in the case of Comroad. Section 3 subsequently presents a layer model for blockchain customization, on which basis a scenario for blockchain-based accounting systems is developed. Using the scenario as well as the general fraud pattern and opportunities to commit fraud, identified in section 1, various DCMs are investigated concerning their ability to serve as technical mechanism for fraud prevention.

2 How to Conduct Accounting Fraud: A Case Study & Analysis

Accounting fraud is the deliberatively attempt to prepare and disseminate material that misstates a company's financial situation [32]. Involvement of the top management, such as Chief Executive Officers (CEOs) and/or Chief Financial Officers (CFOs), in accounting fraud (hereafter: management accounting fraud, MAF) is frequently observed [3]. Thereby, MAF includes either direct involvement of top-management in conducting accounting fraud or indirect involvement by convincing or enforcing the provision of fraud by other parties. To identify the requirements on blockchains in respect to MAF prevention, a case study of the Comroad accounting fraud scandal and a generalization of this case for a further analysis are provided.

2.1 The Comroad Accounting Scandal

Comroad was a German telematics service provider, who developed worldwide applicable, server-based traffic systems. These systems were sold to trading partners, whereas retailers offered the systems as well as complementary services to end-costumers [15]. Comroad entered the international trading floor in the beginning of 1999, whereas it sales quadrupled at the end of this year, compared to its prior year's level of DM4.6 million. Afterwards, the company exhibited exorbitant growth perspectives, despite overall negative trends in the industry. In particular, Comroad forecasted an increase of sales to DM250 million in 2002 [15].

Comroad's success story, however, turned out to be one of the major accounting scandals of publicly traded firms in Germany. Sales developments were the result of numerous fictitious transactions, for which Comroad invented commercial relationships with non-existing trading partners, amounting to €19.9 million as declared in Comroad's financial annual report [11]. One of those trading partners was a company named *VT Electronics*, which was allegedly in charge of the production and deliver of board computers on behalf of Comroad. However, *VT Electronics* was only collecting money from likewise fictitious end-customers. For the purpose of concealment, payment from end-customers was cleared with the production costs of equipment of *VT Electronics* and by down payment for further hardware and possible retained surpluses. The only task of Comroad was to prepare invoices and to pretend that invoices were send to end-customers. Comroad stated additional transactions with various other Asian trading partners following a similar fraud pattern [15]. Surprisingly, the illicit practices of Comroad were not detected over a period of three years and despite of various controls in accordance to national and international legal requirements (e.g. the Germany Stock Corporation Act (AktG), Euro-Bilanzgesetz (EuroBilG)) as well as standards for accounting (e.g. IFRS). Thus, in the following the manipulation and concealment techniques of Comroad will be discussed.

2.2 The Manipulation and Concealment Techniques of Comroad

Dorin [15] describes several incidents of MAF and also the previously presented case study of Comroad by using the so-called *swiss cheese* model. The model shows, how systems may breakdown due to human intended or unintended as well as technical failures [28]. Accordingly, MAF may be conducted despite the existence of several legally required and/or voluntarily implemented firewalls, i.e. internal and external control systems as well as technical precautions. Perpetrators of fraud are able to circumvent those controls and security measures by using the system's deficiencies (loopholes) for their own benefit [15].

According to German regulations, the publicly traded company Comroad was managed by a two-tier board structure consisting of the management, responsible for the oversight of day-to-day business operations, and the board of directors, responsible for oversight of the management and acting as final authority with respect to decision making [1]. Despite this top-down approach of control, additional internal controls are legally required, for example, according to the AktG [13], the Act for Control and Transparency in the Corporate Sector (KonTraG) [7], as well as auditing standards such as IDW PS 261 [18]. Internal controls are measures and methods adapted to safeguard assets of a company as well as to check the accuracy of bookkeeping [7]. However, there exist no specified requirements for the corporate-specific design of internal control systems in the German legislation. In general, the board of directors is under legal obligation to monitor the implementation and development of an adequate internal control system, which may includes internal auditors and/or an audit committee [7].

In the case of Comroad, it seems obvious that neither the board of directors nor the internal control system was sufficient to prevent the deduction of accounting fraud. Particularly, the CEO of Comroad was able to bypass and to suspend the internal control system – a practice called management override of internal controls [9] – by staffing the board of directors with his wife, who was involved in the fraudulent activities, thereby undermining the board's independence. As a consequence, the board tolerated the illicit practices [15] as well as the internal auditor, who received monetary remuneration for the maintained silence [10]. Despite the arrangements within the company, the establishment of a close relationship to the external auditor KPMG, by which both parties received mutual advantages, offset external controls. Lastly, financial statement users such as investors, the stock market as well as supervisory authorities, were misled and deceived, as they relied to a great extend on the audited and certified financial statements attested by KPMG [11, 15].

2.3 Generalization: Dependencies in Control Systems and Accounting Fraud

The described hierarchy of the company, the external and internal control system as well as the associated relationships between the control systems and organs in the context of the Comroad scandal are transferred to an arbitrarily chosen stock company i, to which the German Stock Corporation Act applies. The identified loopholes in the control systems of Comroad are generalized and crosschecked by the economic literature, among others [1, 3, 6, 15] as well as [32], and combined in Figure 1. For example, existing theoretical or empirical work about the management's influence on the board of director's independence [1] and other relationships [4, 9] were reviewed, by which the management is able to exert control over the board. Solid lines indicate that there is a broad consensus about the indicated relationship in the examined literature, whereas dashed lines emphasize controversies. The influence of the management on the board of directors is determined by a variety of factors, such as the geographically disparity or career perspectives of board members. However, the strong influence of the management on the board of directors in the case of Comroad can be substantiated by a large part of the literature and is, therefore, assumed within Figure 1. It should be noted that the emphasized relationships are not generally true, but may be part of the problem when considering the emergence of MAF.

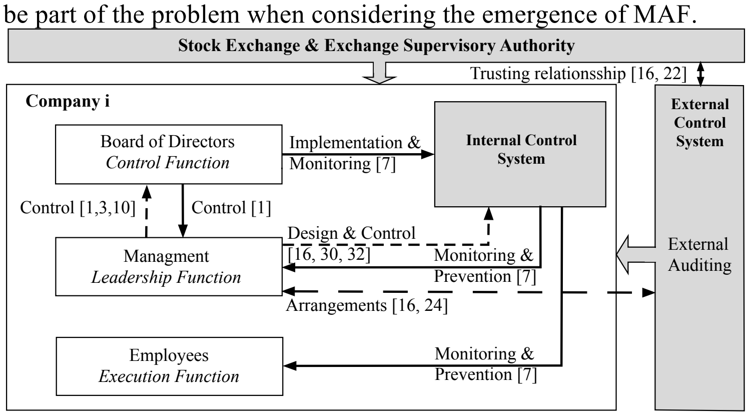

Figure 1. Stylized illustration of a company's control system and dependencies

Analyzing Figure 1, the existence of circular references between the management, the board of directors and the internal control system get apparent. In particular, if the board of directors depends partly or completely on the management and if the internal control system is determined by the management, than there exist no internal mechanism that might prevent the management from conducting accounting fraud by the exertion of effective controls. This observation is supported by the findings of Sawyer [30] as well as Caplan [9], noticing that the management will always be able to override internal controls, especially because they are able to choose the strength of these systems through its influence on the board. Moreover, if management override of controls happens, there is no obvious reason for external auditors to revise their evaluation of management integrity [9, 22], leading to additional negative effects for the effectiveness of controls. Despite the effects of external auditors are controversial discussed, the observations of [9, 22] coincide with those in the case of Comroad, where the assurance service of external auditor seems to have deteriorated and, therefore, was not able to deter management fraud [15]. Moreover, these inefficiencies are expected to exert further negative effects on the external control system, that is, first of all, external auditors, as well as the market, which typically trust (at least to a great extend) third-party financial audit [22].

Overall, this leads to the conclusion that the core of the management's ability to conduct and conceal accounting fraud is an inefficient internal control system resulting from a dependent board of directors, which is strongly influenced by the management. Based on this observation, a first step towards the prevention of MAF seems to be the strengthening of the independence of both mechanisms. This can be done in terms of impeding the management's influence on the internal control system and the board of directors as well as by the avoidance of interdependencies between those entities and control systems. Second, MAF can also be prevented by decreasing the probability of successful concealment of fraud through the covering up of tracks, i.e through database manipulations and the circumvention of technical precautions. Consequently, an effective strategy for the prevention of MAF must take into account an organizational as well as a technical perspective.

2.4 Could Blockchains Prevent Accounting Fraud?

In view of the above considerations, the suitability of the blockchain for accounting must be discussed, as several academic and industrial research papers propose this, e.g. [2, 8, 36]. Certainly, the blockchain in combination with decentralized consensus induces organizational transformation through the decentralization of single business processes and by the potential increased involvement of employees because of high transparency. For instance, decentralized consensus could potentially raise employee involvement in accounting issues and the validation of business transactions, leading to more diversified controls through the transparency induced by the blockchain. Financial transparency is a major issue in accounting and for the internal control system, which is concerned about the openness and availability of information [20] that could potentially be moderated by the blockchain. Moreover, facilitating the involvement of employees could solve a frequently mentioned problem in internal control systems, which are claimed to be design, using an excessive agency view that promotes a strong adversarial relationship between the management and shareholders, but leaves out the relationship of the management and employees [32]. Summarized, given the potential organizational changes induced be the blockchain, it can be concluded that it is worthwhile to have a closer look on the technology and the impact of organizational restructuring. From a technical view, the blockchain is expected to introduce immutability of data stored on the blockchain, a feature that is frequently mentioned not only in the context of its possible application in accounting, e.g. [2, 8, 25]. This argument is based on the assumption to apply a proof-of-work (PoW) based DCM, which is a cryptographic puzzle, consisting of solving a mathematical problem by the exertion of computer power. In particular, PoW is a mechanism to ration resource access in client-server relationships and consist in finding a byte string combined with a block header, which results in a cryptographic hash that can only be done by the exertion of computer power [12]. Given this assumption, the suitability of an application of the blockchain for accounting will be analyzed not only with respect to the organizational transformations but also concerning the applied DCM.

3 Blockchain Customization and Organizational Restructuring

In this section, the structure and possible customization of the blockchain will be discussed in the context of a business environment. Based on the blockchain design decisions, a scenario for blockchain-based accounting will be presented.

3.1 The Blockchain in a Business Environment: Structure and Customization

Using a very basic definition, a blockchain is a synchronized global log of events between nodes in a peer-to-peer network. Particularly, a blockchain is replicated at every node and assists nodes in reaching consensus on the state of all accounts [26]. Blockchains can be customized for special use cases and adjusted to business environments, which is illustrated by a layer model presented in Figure 3. It is assumed that the layers overlap and are partially interconnected. The layer model provides an overview on how blockchains may fit in and support a company by providing deployment choices and by enabling flexibility.

At the lowest layer the blockchain provides a **digital infrastructure**, called distributed ledger. This basic infrastructure consists of three elements: The peer-to-peer network consists of homogenous nodes and is characterized by the ability to exist without a central node, responsible for network control. In the context of the blockchain, each node keeps a complete replica of all data needed to independently verify the validity of any data that should be incorporated into the distributed ledger. Before data are incorporated they must be broadcasted through the network. After broadcasting, a common order over data has to be agreed among the nodes, which is a non-trivial problem in a distributed network, known as the Byzantines generals problem [21]. This problem is solved by a cryptographically puzzle and the exertion of computer power by which a particular target value must be found (PoW; note that this mechanism will be explained in greater detail later). After reaching consensus, data are logged and permanently stored in the distributed ledger. At this level the customization of the blockchain for a business environment and/or application may happens by the choice of general rules according to which consensus is found.

The second layer is characterized by the choice of different **deployment modes** that depend on the desired openness of the peer-to-peer network and the type of data validation. Blockchains can either feature permission-less access or permissioned access. In the former case, everyone is able to participate as node and no prior authorization is needed [25]. Contrarily, blockchains that are characterized by permissioned access pre-select their participating nodes, e.g. through white- or blacklisting and some type of gatekeeping mechanism [31]. Irrespective of the access type, the validation of the blockchain can be either performed in a decentralized way or by one particular or several nodes, i.e. centralized validation. Despite this sounds counterintuitive using a DCMs, centralization may stems from the fact that the validation is transmitted to a set of changing nodes (e.g. delegated proof-of-work) that are responsible for the validation, for instance, to avoid too much overhead and to allow for low latency. Contrarily, decentralized validation is characterized by the fact that all nodes in the network are able to validate data that should be incorporated into the blockchain. Typically, permission-less decentralized ledgers are featured by decentralized validation (e.g. Bitcoin) whereas permissioned ledgers use centralized validation. However, every other combination or hybrid form are conceivable [31]. This definition excludes unintended centralization, for instance, through the undesired accumulation of the majority of computer power in the case of PoW.

On the third level, the blockchain is shaped by system design decisions in regard to the **foundation and integration** of the envisaged application. This includes that rules within the application must be designed in accordance to the particular business process or compliance requirements. In contrast to the general rules mentioned in the first layer that, these *specific* rules state additional, technical feasible requirements. For example, these rules may obey requirements referring to a specific section of the AktG. Moreover, a service-oriented architecture (SOA) might be taken into accounting, if a blockchain application must be integrated within an existing enterprise systems [33]. However, most likely not only the interaction of the blockchain and decentralized consensus with other information systems must be considered, but also user interaction. Nevertheless these system design decisions are only exemplary and customization may include numerous other aspects.

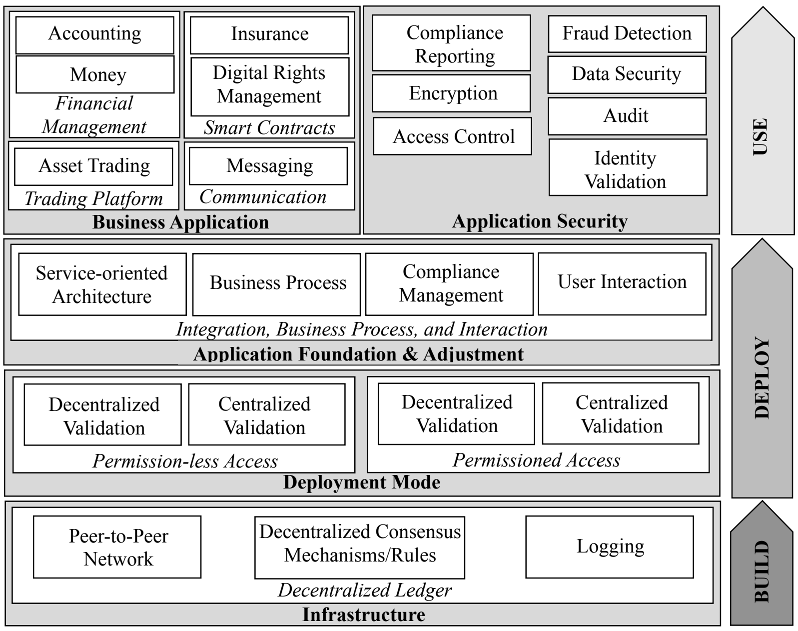

Figure 2. Blockchain layer model and customization in a business environment

Lastly, on the top layer particular **applications** are built on the basis of the preceding layer decisions. For example, smart contracts can be implemented for insurance services or digital rights management. However, as depicted in Figure 3, applications of the blockchain can relate to various business sectors, whereas this list is not exhaustive. Lastly, apart from the fact that the blockchain itself offers particular **security features** through cryptography, additional security mechanisms might be implemented on the upper layer. Depending on the concrete application, these mechanisms may range from additional data securing mechanism and fraud detection to audit, whereas, again, this list is not exhaustive.

3.2 Scenario: Blockchain-Based Accounting and Organizational Changes

Proposed applications of the blockchain for accounting vary significantly from joint registers [2] to intra-firm blockchain-based record keeping [8, 34, 36]. However, industrial and academic literature lack a description on the concrete implementation of the blockchain as well as application scenarios, on which basis the blockchain and the proposed DCM can be evaluated. Contrarily, this paper develops a scenario for a blockchain-based accounting system using the layer model for customization.

As depicted in Figure 3, the basic infrastructure of the proposed accounting system is the distributed ledger, where business transactions are referenced on as monetary value and not as tokens. The deployment model of the blockchain is a private blockchain maintained by a network of individuals within the company that validate transactions, here called intra-corporate blockchain. Particularly, intra-corporate blockchains are chosen in this paper, since full transparency of sensitive financial data to particular companies or - in an extreme scenario - to the general public could lead to severe losses in competitive advantages for an individual company. For example, lawfully discretionary accounting practices would be no longer feasible, which could be exploited by competitors, whose financial data are not completely transparent. Thus, the following scenario is inspired by the facts from the Comroad study and the obligation of German stock companies for publishing annual accounts (AktG), which not implies full and real-time transparency. A comparison of intra- and inter-corporate ledgers is purposely excluded by referring to the associated strong focus of this study.

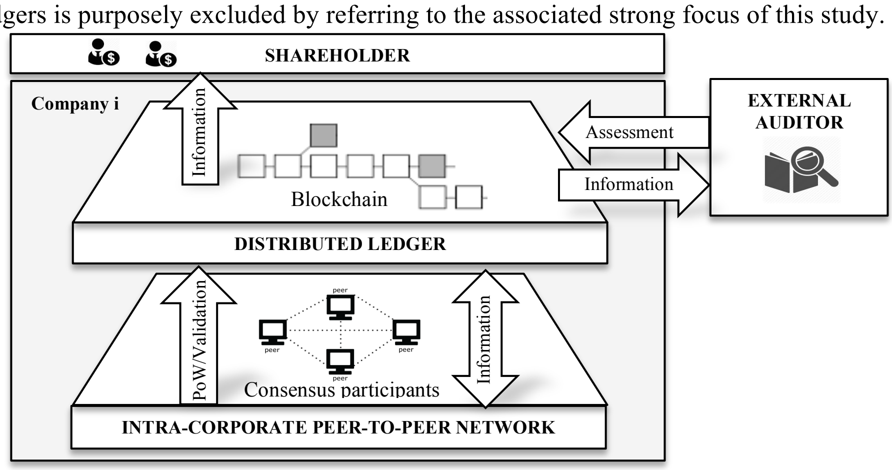

Figure 3. Scenario of a blockchain-based accounting

The network is assumed to consist of employees, especially, the accounting department, the management, and associated control entities that are the board of directors and an optional internal auditor or an audit committee, which together build the pool of consensus participants. Employees are likely to be enforced to participate on the consensus, as part of their work assignment. In contrast, executives and shareholders are assumed to act in their own interest and participate either because they want to influence the consensus protocol in a negative way, e.g. to conduct fraud, or in a positive way, as shareholder are likely to be concerned about the accuracy of the financial situation. Consensus is found in accordance to the PoW mechanism, which is assumed as DCM in all identified papers that propose an application of blockchain technology for accounting, e.g. [2, 8, 36]. In this system, consensus will only be found if transactions are in accordance to the pre-specified rules. Consensus participants will reject transactions that are not compliant. Valid transactions are subsequently logged and serve as publicly available source of information within the company and to particular outsiders (e.g. external auditors). Simultaneously, consensus participants are the source of information by conducting transactions via the accounting system and broadcasting it to the rest of the network for validation.

4 Can We Prevent Management Accounting Fraud?

In the following, PoW as well as alternative DCMs will be investigated and assessed concerning their ability to prevent MAF. According to the previously presented scenario the decentralized consensus cannot be separated from the peer-to-peer network. Thus, it is acknowledged that there exist threats that result from the peer-to-peer network. Related attacker scenarios are, among others, Sybil attacks, Eclipse attacks, Byzantines Joint attacks as well as Churn attacks [14]. Secure blockchain-based accounting system must account for those attacks. However, given numerous works dealing with the security of peer-to-peer networks, it is assumed that there exist mechanisms to provide a considerable security level for the network. Thus, in the following the focus lies on DCMs and their ability to prevent MAF.

4.1 Management Override of Controls and Proof-of-Work Based Consensus

PoW is a mechanism to rationing resource access in client-server relationships, consisting of solving a mathematical puzzle, using computer power [5]. Particularly, PoW consists in finding a byte string, called nonce that combined with the block header, results in a cryptographic hash with a given number of leading zero bits. A block contains all transactions, which have been committed on the previous block. Finding a nonce, can only be done by calculating the hash of the block for all possible nonces [12]. In addition, each block references to the preceding block, which hash has to be known, meaning that blockchains represent consensus over the history of data stored on the blockchain. The history is considered as true, when it deploys the longest chains, conforming to the exertion of the most power exertion. Thus, if someone wants to revert the history, an alternative reality must be created (blockchain fork), which occurs if not all nodes agree on the same blockchain header [12]. The blockchain fork will only be accepted if it becomes longer than the already existing blockchain, which implies the exertion of a huge amount of computer power, starting from the point that should to be altered (51% attack). This requires not only computational power but also faster data processing than the rest of the network [26].

While PoW seems to provide a reasonable level of security in large networks, small-scale networks have been proofed to remain vulnerable of 51% attacks [5]. In particular, this holds for intra-corporate blockchain-based accounting systems, where the management is potentially able to deliberately reach the majority of computer power. Without convincing, enforcing or circumventing exiting internal and external control systems as well as technical barriers, the management could simply use computers or a single server, which have more computing power than the remaining participants of the network for the effortless override of internal controls. Moreover, if logged transaction can be altered or possible deleted ex post, transparency of financial information is useless. This leads to the aforementioned negative effects on the external control system, as retrospective fraud detection mechanisms that may be conducted through external auditors are getting ineffective and subsequently also large parts of investors or exchange market participants, which rely on disclosed and allegedly external audited financial information. Consequently, using PoW as DCM for blockchain-based accounting, MAF will not be impeded, neither from an organizational perspective by decentralization nor through immutability of data, i.e. the technical perspective. Notably, PoW would even ease the override of controls, as the management does not need to convince others to support and conceal the fraud such as in the case of Comroad. This especially holds in the absence of direct monetary incentives that encourage honest behavior such as in the case of Bitcoin.

4.2 Alternative Decentralized Consensus Mechanisms

Table 1 provides an overview over DCMs developed after the emergence of PoW. For the sake of completeness PoW-based consensus is also included. A differentiation of the DCMs is conducted according to their ability to allow for permission-less or permissioned access of nodes as well as whether the mechanisms facilitate decentralized validation or not. This differentiation is done in accordance to the second layer of the model presented in Figure 3.

Table 1. Overview of decentralized consensus mechanisms after the emergence of PoW

	Permission-less Access	Permissioned Access
Decentralized Validation	• Proof-of-Work • Proof-of-Stake • Proof-of-Work based derivatives • Federated Byzantines Agreement	• Proof-of-Work • Proof-of-Stake • Proof-of-Work based derivatives • Federated Byzantines Agreement
Centralized Validation	• Delegated Proof-of-Stake	• Redundant Byzantines Fault Tolerance • Ripple consensus • Bilateral node-to-node (N2N) • RAFT and derivatives • Delegated Proof-of-Stake

Certain DCMs enable both, permissioned as well as permission-less access (although they might designed to be used in a permission-less system at first). Contrarily, it is assumed that a mechanism, by intention, will not feature decentralized validation and centralized validation at the same time. However, it is acknowledged that in practice decentralized validation may exhibit centrality tendencies. In the following, DCMs will be analyzed, if they feature permissioned access as well as decentralized validation and are, therefore, suited for an application according to the preciously presented scenario of blockchain-based accounting.

Proof-of-Stake

Proof-of-Stake (PoS) is based on the assumption that PoW's dependence on energy consumption creates unnecessary cost overhead in networks. PoS is a form of proof of ownership of the currency in the network [19]. Instead of using relative hash rates of miners for network stability, the protocol splits blocks and the according transactions proportionally to the current wealth of miners [26]. In a blockchain-based accounting system stakes will most likely be stocks. As the management will probably have the majority of stocks (this was also observed in the case of the Comroad scandal [15]), the management would be enabled to change financial transaction registers at their will, without having to respect any control system. Thus, despite the Proof-of-Stake is initially designed to promote decentralized validation, in practice the validation of transaction using this mechanism will be centralized and most likely led by the management. Moreover the protocol exhibits other general security issued, such as the so-called "nothing at stake" attack, where attackers can commit collateral as they can go back and rewrite history from a point where they still had stake [19].

Proof-of-Work Based Derivatives

Proof-of-Activity (PoA) is a combination of PoW and the PoS and described as one example of different PoW derivatives. Finding consensus by using PoA consists of the transformation of a pseudorandom value into a satoshi, which is the smallest unit of the cryptocurrency Bitcoin. According to [6], this is done by selecting a pseudorandom index between zero and the total number of satoshis in existence up to the last block, inspecting the block in which this satoshi was minted and following each transaction that subsequently transferred this satoshi to an address until reaching the address that currently controls this satoshi. Only active stakeholders, who maintain a node, get rewarded in exchange for the service they provide for the network. Despite PoA induces less overhead in terms of communication, it does not prevents "nothing-at-stake"-attacks [6] and therefore, does not guarantee for the fraud resistance of data on the blockchain. For the sake of completeness it should be mentioned that there exist further DCMs such as proof-of-capacity or proof-of-burn that are based on or are related to PoW. However, they are rather used for distributed payment systems and rarely discussed for other appliances in a scientific context.

Federated Byzantines Agreement

Federated Byzantines Agreement (FBA) allows each node to select a set of other trusted nodes, which induces so-called flexible trust, meaning that all users have the freedom to trust any combination of parties. Nodes may select those participants based on arbitrarily criteria such as repudiation. To find consensus, a node waits for the vast majority of trusted nodes (quorum slice set) to agree on a transaction before considering the transaction settled. In turn, those nodes do not agree to the transaction until the participants they consider as important agree to the transaction as well, and so on. The key distinction between the FBA and prior Byzantines Agreements is the individual and decentralized trust decisions. If enough network nodes accept a transaction, it becomes infeasible for an attacker to roll it back [23, 29]. Moreover, security rest on digital signatures and hash families whose parameters can realistically be tuned to protect against adversaries with unimaginably vase computing power [23].

Notably, the FBA is a majority voting system, related to the decisions of selected trusted nodes. As in every voting system and, especially, if voting nodes are known to each other in a closed system, strategic voting cannot be excluded. Thus, it may be easy for the management to couple votes of particular nodes and their influence on other nodes to career perspectives and/or monetary or non-monetary incentives, leading to a strong influence of the management on the voting outcome and data that will be incorporated on the blockchain. Moreover, the management may also be able to influence the majority of nodes to subsequently alter data on the blockchain to cover up traces. Consequently, FBA is not able to prevent the occurrence of MAF.

5 Conclusion and Outlook

Academic and industrial work proposing the application of blockchain technology for accounting emphasize the immutability of financial recording based on a proof-of-work based decentralized consensus, probably leading to fraud-resistance. After identifying one of today's core problems of proper accounting, i.e. MAF, and proposing a scenario for blockchain-based accounting within a public company, this paper asserts that PoW is not effective in terms of preventing MAF. This conclusion is based on the assumption that there exist no incentive that prevents the management from committing fraud in accordance to [9, 16, 32], rather it is the mechanism, here distributed consensus that probably could prevent the commitment of MAF. Moreover, proof-of-work is even expected to ease the conduction and concealment of MAF, owing to the prevailing centrality tendencies within the system. Alternative decentralized consensus protocols were examined in accordance to the presented scenario of blockchain-based accounting. This paper concludes that currently, there exist no DCMs that promote permissioned systems, featuring decentralized validation and simultaneously preventing MAF. Overall, the ability of the blockchain and DCMs in the proposed scenario might be overestimated or even overhyped, even if a certain general potential of the technology in accounting could be attested owing to its decentralized and transparent nature. However, proposals for concrete applications must be strongly oriented on the de facto problems such as in the case of accounting and MAF. Accordingly, further research should focus on the development of advanced consensus mechanisms that take into account the above-discussed issues, and especially, the ability of management override of controls. Variations in the proposed scenario are also conceivable. Overall, a special emphasis should lie on the cost-efficiency of such systems as well as security as basic requirements. Without these two prerequisites it is hard to imagine that any such system will be implemented in the future. Moreover, a comparison of intra- and inter-corporate solution as well as other possible scenarios should be pursued, in order to receive a more compressive evaluation of the potential of blockchain-based accounting.

Abstract. In the manufacturing industry the provision of smart services is an opportunity to gain a competitive advantage. As there are high demands on machine availability, smart services in the field of installed base management are important. Through integrating condition monitoring data with installed base data a digital twin of the installed base can be created. This enables comprehensive analyses and the provision of individualized smart services. But this requires to structure and standardize the data. Following the action design research (ADR) approach, in this article design principles of an information architecture are developed. The architecture is evaluated and improved in the context of an international engineering and manufacturing company. A test run with real machine data shows the applicability in practice.

Keywords: Digital twin, information architecture, installed base management, smart services, product-service system

1 Introduction

In manufacturing industry, machinery and equipment are subject to high demands on availability and productivity [1], [2]. To meet these requirements, original equipment manufacturers (OEMs) as well as machine component suppliers shift in emphasis from selling only technical products to offering additional individualized smart services [3], comprising e. g. maintenance, repair, spare parts delivery, process consulting. Services are an economic guiding force for OEMs and machine component suppliers [4] because the supply of services in addition to products leads to new sales opportunities and to greater customer loyalty [5-7].

When considering individualized smart services, a major challenge for OEMs and machine component suppliers is that they often lack knowledge about the state of the machinery and equipment during the use phase [1]. Therefore, the collection and processing of condition monitoring data (field data) has been discussed within academic literature as inevitable for offering guaranteed machinery and equipment availability and productivity [8], [9]. However, the integration of condition monitoring

Dreyer, S.; Olivotti, D.; Lebek, B.; Breitner, M.H. (2017): Towards a Smart Services Enabling Information Architecture for Installed Base Management in Manufacturing, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 31-45

data with installed base data (i.e. product master data, service data and contractual data [10]) is a necessary precondition for the provision of individualized smart services that has been rarely recognized by researchers. Organizations in value networks (i.e. OEMs, machine component suppliers and machine owners/operators) face the problem of how to use existing data from IT systems (e. g. ERP, MES, CRM) to depict machines with the respective installed components, locations, maintenance protocols etc. and how to enrich them with real-time data. Creating a digital twin based on these data provides the basis for rendering individualized smart services in value networks. Digital twins are realistic models representing machines with all their components, their current state as well as their interaction with the environment [11], [12]. Therefore, a digital twin is not static but dynamic which is why a standardized and consistent data and information management is necessary [13]. Although researchers began to work out information sources for installed base characterization [14], a generalized information architecture for installed base management that aims to enable smart services is still missing. An information architecture enables to store and process data, to analyze and evaluate them and to use them to offer services. Therefore we proposed the following research question:

> *RQ: What are general design principles of an information architecture for installed base management that enables smart services?*

To answer this research question and to build a bridge between academic rigor and practical relevance, we adapted the action design research (ADR) approach [15] in the context of an international engineering and manufacturing company. With the use of different cycles, ADR allows continuous interaction between researchers and practitioners in early stages.

The remainder of this article is structured as follows: Section 2 introduces the action design research approach and its application. The information architecture is designed in section 3, including a literature review in the field of installed base management. General design principles are carried out and results are discussed in chapter 4. The article ends with limitations and conclusions in sections 5 and 6.

2 Research Design

Starting from existing work in the research field of installed base management, the aim of this study was to develop an information architecture for practitioners to enable individualized smart services. Additionally, design principles of an information architecture for installed base management that can be applied within multiple companies were developed as theoretical contribution. For this purpose, the action design research (ADR) approach by Sein et al. [15] was selected as the underlying research methodology. Motivated by an increasing debate about the gap between organizational relevance and methodological rigor [16], [17] in IS research, ADR was developed in order to close this gap by presenting an integrative research approach of action research and design research [15]. ADR is well suited for deriving generally applicable knowledge while incorporating two main challenges. First, in order to generate practically relevant outcomes, ADR aims to solve a problem in an organizational setting by facilitating ongoing interaction of researchers and practitioners. Second, in order to account for academic rigor, ADR develops generalized design principles that address a class of problems through formalized learning from organizational intervention (Figure 1).

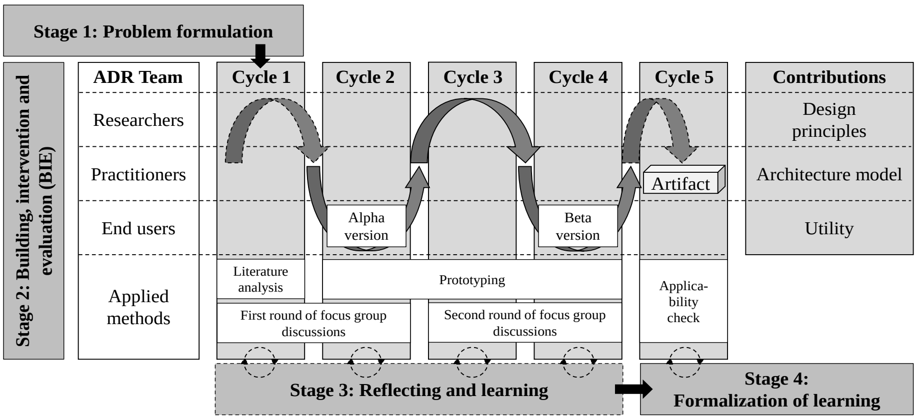

Figure 1. Research design based on the ADR approach from Sein et al. [15]

In the context of this study, the first stage was driven by a problem perceived at an international engineering and manufacturing company. In order to offer individual smart services in the area of installed base management, the target company required an information architecture to be able to organize and analyze machine owner's installed base data. In stage one the specific practical problem was formulated as an instance of a broader class of problems. An ADR team was formed, made up of researchers from a German university, practitioners from the target company's IT department and product service account management as well as end users from customer service department. The shared competencies facilitated the problem definition and formulation. In the building, intervention and evaluation (BIE) stage, five iterative cycles were carried out in order to build and continuously evaluate a prototype for an information architecture for installed base management. In the first cycle of the BIE stage, an initial prototype ('Alpha version') was derived from requirements analysis that was conducted during the problem formulation stage, as well as analysis of existing literature and a series of focus group discussions involving practitioners and end users. Subsequently, the alpha version was presented to practitioners and end users for evaluation by conducting a second series of focus group discussions in cycle two. Each focus group discussion was documented and qualitatively evaluated afterwards [18]. Based on the feedback gathered in the previous cycle, the prototype was further improved and specified ('Beta version') in cycle three. The applicability of the proposed information architecture was assessed during a test run with real data from a customer organization in cycle four. For the purpose of evaluation, next to end users, members of the target company's service product management, service account management, IT application development and IT strategy departments were involved. Feedback was used for incremental reshaping of the prototype in cycle five until the final version was reached. For continuous evaluation of each development step of the proposed information architecture, stage three (reflection and learning) was carried out simultaneously to the BIE stage. This procedure allowed a better understanding of the problem from different points of view. In stage four, learning from the specific solution was generalized in order to address a broader class of problems. Hence, the developed information architecture aims for general applicability for various companies and is not limited to the use case of the target organization. The development of design principles contributes to this.

3 Information Architecture Development

3.1 Problem Formulation

The presented information architecture emerged from a project of an international engineering and manufacturing company for storing and structuring machine owner's installed base data. Agile project management was used to realize the project what is appropriate to the ADR approach. The executing company operates in 60 countries and has the headquarters in Germany. The project concerned a service where machine and component data of a customer's machine are collected and structured subsequently. A detailed overview of the built-in components and its condition is given through creating a digital twin. This provides the basis to offer individualized smart services.

A use case was defined as an example for smart services in the manufacturing industry which are basing on installed base management. The examples arose from focus group discussions with employees of a large German automotive manufacturer, a machine owner. The participants of the focus group discussion came from the departments of maintenance processes, systems technology and automation technology. Additionally, practitioners from the engineering and manufacturing company, a component supplier, formed part of the group. They mainly came from the IT and the services department. The discussion dealt with services that would help to simplify tasks related to asset management. Mainly, there were six key questions the participants of the focus group discussion have which are not answered until now.

Table 1. Key questions of a machine owner regarding installed base management

Key question
How can installation errors be avoided?
How can error causes be identified immediately and reliably?
How can maintenance efforts be minimized?
How can maintenance schedules be planned optimally?
How can we learn from experiences?
How can knowledge be provided at the right time and at the right place?

All the questions, shown in Table 1, were answered within a use case for smart services. The use case as an example for smart services contributes to specify the information architecture for installed base management. The idea of the use case was to use sensor data and to connect them with further installed base data to identify the current state of the machine as well as of the integrated components. When knowing exactly for what kind of task the components are used analyses enable to identify error causes immediately and reliably. During the production, it does not only have to be looked at a single machine but the context of all machines in a production line is important. For example, on the basis of digital twins maintenance schedules can be optimized. This includes systematic maintenance as well as predictive maintenance depending on the analyses results of the data. Such a smart service would help the maintenance department to ensure a high availability of the machines. Additionally, an integrated visualization cockpit enables to support the machine operator. In case of an error the machine operator receives concrete instructions what has to be done to solve the problem. This requires that a history of former errors, the respective error code and solutions exist. In a first step, an information architecture was necessary to be able to structure, standardize and analyze installed base data. Requirements for the architecture were determined in several focus group discussions as well as from existing literature.

3.2 Related Literature

According to the first cycle of ADR, a comprehensive literature review was conducted [19] to identify and analyze the current state of research in the area of installed base management and digital twins. A list of search terms was predefined and it was mainly searched through seven databases: AISeL, IEEExplore, JSTOR, ResearchGate, Science Direct, SpringerLink, Taylor & Francis.

Table 2. Number of hits for different search terms

Search term	*Hits*	*Temporal and thematic restriction*	*Relevant title and abstract*	*Strong relation to research topic*
“installed base management“	84	22	92	26
“asset management”	20389	1042		
“inventory management”	4090	706		
“inventory data”	14957	382		
“asset data”	1715	585		
“machine data”	3645	711		
“installed base data”	25	24		
“digital twin”	53	53		
“digital shadow”	71	71		

As there were many hits due to the search terms (Table 2), the hits were temporally restricted. Publications older than 1995 were excluded. Furthermore thematically restrictions were made and only publications in journals and proceedings in fields related to information systems were included. The identified articles were checked for general relevance for the research topic by title and abstract. Afterwards the remaining publications were examined regarding their contribution to at least one of six categories developed (Table 3) by considering the whole article. The term installed base management is rarely discussed in academic literature. Asset management has a close relation to installed base management which is why this is also part of the literature review. According to Lin et al. [8] the objective of asset management is to support and optimize the lifecycle of physical assets. As an extension to asset management, in installed base management the individual components of the machines and their interplay within the machine and across them are also in focus. Installed base management goes deeper into the machines to ensure a high machine availability. But in contrast to installed base management asset management has found plenty of recognition by researchers.

● Considered topic ○ Partially considered topic

Borchers et al. [14] outlined that the sources of installed base data are manifold. Sales and enterprise resource planning (ERP) systems, production databases and service information systems are the sources mentioned by the authors. Turunen et al. [20] supplemented this list and indicated that field technicians and other operational staff are an important channel for additional information. Louto [21] agreed and noted that manually collected data plays a decisive role when executing services. Sarfi et al. [22] consider data quality as an important aspect in the field of asset management. Cai et al. [23] looked more closely at the completeness of the data as part of data quality and proposed a method for evaluating it. Because a huge amount of data is required to maintain a good record, Power [24] described how to use semi-structured and unstructured large datasets for analytics. Although the author emphasized machine data as a main contributor to adding value, the article gives a more general overview of the topic of large datasets. Bahga et al. [25] looked especially at machine data and how to analyze it. But in their article, machine data is put on a level with sensor data. The concentration on sensor technology is pursued by Furtak et al. [26]. Creating a digital twin, also named as digital shadow, is rarely considered in academic literature. Abramovici et al. 2016 [27] define digital twins as virtual smart products. Gabor et al. [12] see digital twins as the basis for further applications. Rosen et al. 2015 [11] agree to that and discuss the importance of digital twins for autonomous systems in manufacturing. They summarized that digital twins are important in the whole lifecycle of a product [11]. As there is no additional value unless the data is used to generate new services, the service aspect is subject of discussion in several publications. Services based on remote technology is covered by Zolnowski et al. [28]. Neely [29] agreed that collecting data and analyzing it forms the basis for implementing new services in the area of asset management. Not only do business models have to be created, the implementation of an IT solution becomes necessary for using a data management platform for services. Mohseni et al. [30] stated that a management tool that integrates different aspects is necessary to manage an asset successfully. Müller et al. [32] explained how to realize access to field device information by means of an information server. A reference architecture for condition monitoring was presented by Wollschlaeger et al. [33]. Zampou et al. [34] deduced an architectural framework for environmental performance monitoring of machines.

Results indicated that many publications emphasize the importance of generating services out of installed base management (see Table 3). The existence of different data sources are also part of many publications, in contrast to the topic of creating a digital twin. Information architectures for asset management were also a research topic. But researchers are mainly focusing on condition monitoring data to offer services. Using existing data to describe components, machines and whole plants and enriching them with real-time data is not the focus of research. Therefore, to the best of our knowledge, there is no information architecture existing which is meeting the requirements resulting from the project goal. An information architecture for installed base management to enable smart services is still missing.

3.3 Requirements on an Information Architecture

A series of focus group discussions with different employees from an international engineering and manufacturing company was conducted to ensure creating an information architecture for installed base management that is relevant in practice. The participants came from the fields of business process consulting, application development, product management, service account management, and technical customer service. For a better structure, the discussion was divided into three parts: objective of the information architecture, general structure, and information architecture design.

The focus group stated that the objective is to be able to structure and standardize installed base data. Organizing the data into structures is important to simplify its further use [33]. Aggregating data from different sources should be enabled to create a basis for installed base management because using existing data prevents duplication of data. This means that existing data should be used and imported as required. Existing data, manually captured data and sensor data should be brought together in order to create a digital twin. To simplify subsequent analyses a uniform structure of components and machines should be ensured. The focus group recommended referring to the superior object of a component by creating a hierarchical structure. A structure from general to specific is named as suitable to represent a machine and its components.

Data quality is an important factor in installed base management [22]. The quality of data has to be ensured for successful asset management and therefore for installed base management [8]. It is mentioned by the focus group that the applicability of the information architecture should not be limited to the German-speaking area. General formats should be found because engineering and manufacturing companies often operate worldwide. The possibility of using a single information architecture for installed base management to enable smart services contributes to avoid isolated solutions. Regarding analyses of the data participants of the focus group mentioned that it should be possible to analyze structured as well as unstructured data like free texts. It is stated that sometimes it is not possible to find a uniform format, e. g. to describe the current condition of a machine. Analyses across machines and plants should also be possible. Diverse access rights for different persons would contribute to transparency.

3.4 Information Architecture Design

With focus on the requirements determined a conceptual model of the information architecture was designed (Figure 2). The first layer describes the data storage and processing. Many different types of data have to be considered to be able to reach the objective of a digital twin. For example, data generated during the production phase of a component is important. Another data pool that was discussed by the focus group was the topic of successor data. The requirement is guaranteeing that only current products can be sold. The orientation on the product lifecycle helps to meet this requirement. Another source of data considered is the installed base itself. This data is mainly collected on-site by service technicians and includes the installed base structure, a condition description of the whole machine and a description of the individual components. As required by the focus group condition monitoring data such as sensor data were also considered. The data is stored in different systems, depicted due to a systems sub-layer. All data saved in different systems is transferred to a database management system to relate the data for a component or machine. The second layer concerns services. They are necessary to generate value based on the digital twins created. On the one hand the data of components, machines and plants have to be analyzed. It is also possible to compare the data across components, machines, or even plants. On the other hand a knowledge management is necessary to turn data into information. E. g. when sensor data indicated an anomaly, knowledge is necessary to interpret the data and to give advices to the machine operator. Tools such as mathematical models may also help evaluate the analysis results. The third layer concerns the presentation and is the interface for the participants of the value network. Role-based user interfaces enable to individually define read and write permissions.

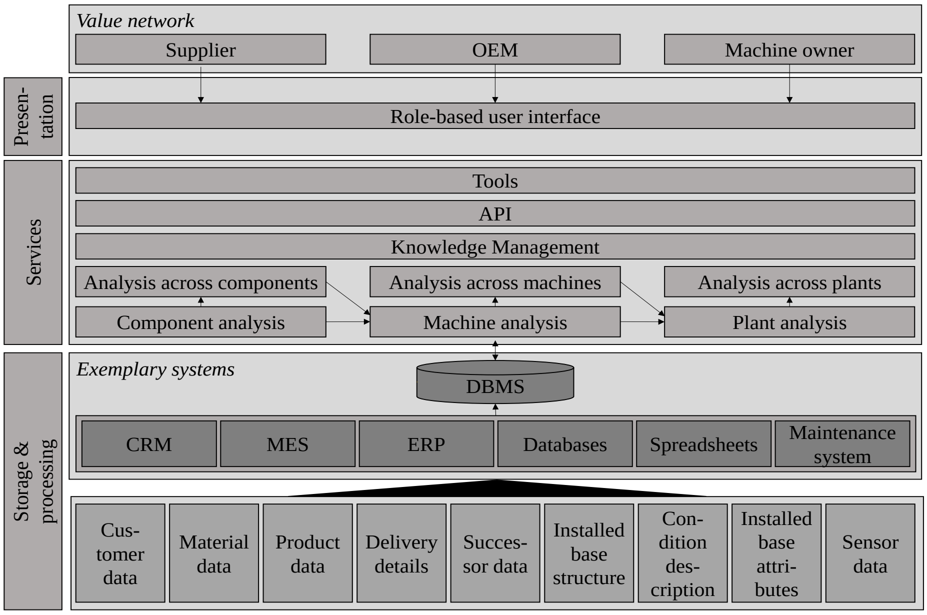

Figure 2. Conceptual model of the information architecture

3.5 Evaluation and Optimization

The implemented information architecture was evaluated in a test run. Real installed base data collected in a production site was organized through the architecture to identify optimization possibilities. Proving a conceptual model in practice leads to great improvements [36]. With the test run, it was ensured that the platform is applicable in practice as an applicability check is an essential part of a research process [41]. Additionally, focus group sessions as part of the evaluation helped to further improve the information architecture [16]. Therefore, a series of focus group discussions with participants from the application development, product management, service account management, and technical customer service of an engineering and manufacturing company were conducted to find further points for improvement.

With basis on the information architecture it is possible to create a digital twin of the machine. The focus group appreciated the fact that existing data from other databases can be added to the respective component. For example, information on production already stored in a system can be assigned to the respective component. But it has to be ensured that the information imported is also understandable for external groups. The use case that was worked out as an example for smart services included the visualization of analyses results and further information about the machine, its current state and its environment. It is also possible to partially import data and to complement it with manually entered data. All predefined installed base data could be implemented and standardized. Documents and photos could also be attached to components. It is mentioned that it should be easy to integrate new databases or spreadsheets. When using the serial number to insert existing data, it should be ensured that this data is reliable and kept up to date. Furthermore, it should be ensured that the data storage and structure is consistent for the different components and machines. This is necessary to automatically analyze the data for offering smart services subsequently.

In accordance with the fifth cycle of ADR, the points of criticism were taken up to optimize the information architecture and to create the final artifact. The valuable recommendations led to improvements of the information architecture. Thus, the evaluation helped to further simplify the creation of a digital twin of machines and whole plants with the objective to offer smart services for machine owners.

4 Formalization of Learning and Discussion of Results

Following the ADR approach, an information architecture to manage installed base data was developed. The five cycles presented in this research method were used to create an artifact that is relevant in practice. Several focus group discussions and a test run were conducted to ensure practical relevance. Through formalization, the learning was converted into general design principles to contribute academic knowledge to the research field (Table 4). At the beginning of the project, transparency was named as a challenge to create a digital twin of a machine. This means that it has to be clear how the structure of the digital twin is designed. It ensures that the structure is understood by different persons and also facilitates analyses. As it should be possible to identify the components, they have to be named uniformly. Nevertheless, an unequivocal number for each component should exist to enable locating a specific component. In the presented project, each component had a serial number for clear identification. For example, this is important when a component has to be replaced because it is affected by a production error. Standardized data is a precondition for further analyses and evaluation. For the same information it should always be used the same data format. The structure as well as information does not only have to be understood by employees of only one apartment or a single plant but in the whole company what requires international valid regulations to avoid misunderstanding. The participants of the focus group discussions that were asked regarding their requirements towards an information architecture worked at a component supplier. But as there are several participants in the value network apart from component suppliers, different perspectives on the digital twin are necessary. For example, machine owners are primarily interested in analyses concerning their own machines and plants. A role-based authentication is the tool to realize this. All named design principles contribute to an easy analysis and evaluation of the collected data across components, machines and plants. It is depicted in the services layer in the developed information architecture. As it is not possible to structure all data, for example because of free texts from employees in the field, semantic analyses should also be enabled. A service orientation of the information architecture ensures that tools such as mathematical models can be integrated. Real-time data handling is inevitable to be able to store and process sensor data.

Table 4. Set of design principles

Design principle	*Description*	*Examples*	*Standards/ best practices*
Transparency - Consistent vocabulary - Clear allocation of components - Clear identification of products	It is necessary to have a clear hierarchical structure of the data. The naming should be consistent and generally comprehensible. An unequivocal identification of the products contributes to the clear structure and the creation of a digital twin.	Uniformly named components, serial numbers for unequivocal identification of components	Extensible Markup Language (XML), International Standard Serial Number (ISSN)
Standardization - Uniform data format - Machine readability of the data	A uniform format of the data is necessary for further analyzing. It ensures both that the data is understandable for different target groups and readable by machines.	Uniform sensor data format, enabling exchangeability between companies	eCl@ss
Internationality - International data format - Transferability to other languages	As organizations in the manufacturing industry often operate worldwide, it is of importance that the data has an internationally understandable format. The transferability to other languages should be given.	Uniform date format, multiple language data maintenance	ISO (e. g. date/time ISO 8601)
Perspectives - Adaptable structure depth - Adaptable access rights	The data is used by different participants and by users of smart services. Therefore, a role-based authentication with different read and write permissions is required.	User-dependent view, selective transaction authorization	One-time passwords (OTP), Certified-based Authentication (CBA)
Analysis - Across components, machines, plants - Unstructured data	It should be possible to analyze the data, independent on whether they are structured or not.	Comparing the state of different machines, analyzing unstructured comments in text boxes	Apache Hadoop
Service orientation - Tool integration - (near) Real-time data handling	Tools enable individualized smart services. The use of condition monitoring data for smart services requires real-time data handling.	Visualization tools, automated reports, real-time sensor data processing	

The information architecture enables to offer smart services through analyzing and evaluating installed base data. From a supplier's or an OEM's perspective it becomes possible to see the machine owner's needs in the short and medium term. Building on this, further services can be offered. The chance of participating in future projects is higher because of the direct contact with the machine owner. As a consequence, sales and customer satisfaction as well as loyalty are increasing. The consequence is a necessary service orientation because it is only possible to generate value out of the analysis results when offering services. For example, in the described use case visualizing data and information was important. In the information architecture this is represented due to the presentation layer. Tools may be necessary to realize individualized smart services that are carried out automatically. As results from condition monitoring data such as sensor data are an important part of the digital twin, real-time data handling is necessary. In the information architecture the data storage and processing layer represents this.

5 Limitations and Further Research

The created information architecture provides the opportunity to manage installed base data efficiently. However, certain limitations have to be considered. The information architecture was designed in a project of an engineering and manufacturing company. Installed base data collected by service technicians and existing data of the company were used as basis for defining the necessary data types. This was supplemented by requirements stated during a series of focus group discussions in the same company. When talking about an installed base management different participants of the value network have to be taken into account. In the presented project it is focused on a component supplier and its requirements. Therefore, it cannot be excluded that the architecture has to be adapted for other participants. In future research the requirements of other participants of the value network will be focused. Real-time data was no part of the test run. The company did not provide real-time condition monitoring data, thus it was not possible to perform a test run for this kind of data. Therefore, it cannot be said whether adjustments are necessary to be able to handle this high amount of data.

As the architecture was developed and tested in the headquarters in Germany, it is not sure whether the transfer to other languages is possible without much effort. The data were mainly stored and structured in German and a transfer to other languages was not necessary in the test run. The information architecture provides the opportunity to unite different data types and to standardize them. Smart services based on installed base management can be provided. Depending on the offered service, it could be necessary to expand the architecture. Using the information architecture for other smart services apart from the proposed use case will be tested in the future. Evaluating the information architecture flexibility and extensibility is another interesting approach for future research. Similar restrictions regarding the adaptability apply to the installed base data. It is not certain whether it is possible to standardize all data types in the future because future requirements are not yet known. Restrictions also apply to the evaluation of the information architecture. The information architecture was evaluated in a test run and not over a longer period in practice. Therefore, the information architecture was not checked under real conditions. The evaluation with other data may also lead to further enhancements and optimizations. Furthermore, it would be interesting to evaluate the information architecture and the developed design principles in focus group discussions with employees from different participants of the value network.

6 Conclusions

In this article, an information architecture to offer smart services based on installed base management in the engineering and manufacturing industry was worked out. Following the ADR approach, requirements on an information architecture for an engineering and manufacturing company were developed in a series of focus group discussions and due to a literature review. Structuring and standardizing installed base data to be able to analyze and evaluate them afterwards is inevitable to provide smart services. As an example a use case for a smart service was worked out. Based on this, the information architecture was created and refined. This was also done through several focus group discussions. Considering the discussion and limitations, the information architecture contributes to theoretical and practical knowledge. From an organization’s perspective, the information architecture enables to create a digital twin to offer individualized smart services. Answering the research question, formalization of learning led to design principles which contribute to academic knowledge in this area. Both the developed information architecture and design principles for creating an information architecture provide the basis for future research and expanding and optimizing the digital twin of machine owner’s installed base.

{prifti,marlene.knigge,harald.kienegger,krcmar}@in.tum.de

Abstract. This paper analyzes employee competencies for employees with higher education in Industry 4.0. An Industry 4.0 competency model based on a behavioral oriented approach concerning three variants, namely Information Systems, Information Technology and Engineering is developed by extending the SHL Universal Competency Framework through a structured literature review and focus groups with academic staff. The presented study contributes to research by providing a starting-point for further research regarding employee competencies for Industry 4.0. It contributes to practice as the provided competency model can be applied to Industry 4.0 job descriptions.

Keywords: Digital Transformation, Industry 4.0, Internet of Things, Competency, Competency Model.

1 Introduction

Recent technological developments, such as sensors, cyber-physical systems, the Internet of Things (IoT), or smart networks will influence each area of our life. This development is referred to as the fourth industrial revolution, also known as "Industrie 4.0" or "Industry 4.0" (I4.0). I4.0 is widely used in the international context, however we focus on the German concept of I4.0. In this context it approaches some of the challenges the world is facing today including the rise of resource and energy efficiency, production, demographic change etc. [1]. Further, it offers a huge potential especially for Germany as a global leader in the manufacturing industry [1]. Germany also possesses significant information technology (IT) know-how and competencies in automation, embedded systems or smart networks [1]. This offers the perfect prerequisites for Germany to become a leader in I4.0. "In essence, I4.0 will involve the technical integration of cyber-physical systems into manufacturing and logistics and the use of the Internet of Things and Services in industrial processes." [1]

I4.0 will influence our working environments significantly. E.g., it will change processes in purchase, production, manufacturing, sales or maintenance by including concepts as smart manufacturing, smart maintenance as well as a high degree of automation and integration in all enterprise processes [2]. It will have far-reaching implications on business value creation, business models, downstream services, and work organization [1]. As a consequence, employees will be confronted with transformed work processes and business models as well as with new technologies [2]. The model of work organization will transform due to the disruptive nature of emerging

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Prifti, L.; Knigge, M.; Kienegger, H.; Krcmar, H. (2017): A Competency Model for "Industrie 4.0" Employees, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 46-60

technologies and modified structures for communication and collaboration [3]. Processes will become interconnected and more complex. The technical, organizational and social spheres of work activities will overlap. The way we work will be one of the most affected changes in I4.0 [4]. I4.0 will not only affect technology and production, but the way we will work in all its dimensions [5].

This transformation of the work environment will change the job profiles and therefore requires employees to be outfitted with a wide range of competencies [1, 2, 6]. In I4.0, work profiles that require a higher education will gain increasing significance, while labour workforce will be mostly replaced by automated processes [1]. As a consequence, various practitioners and researchers agree that the competency development for students and employees applying for jobs that require higher education, is one of the key challenges to adapt I4.0 [3, 7-12]. To address this challenge, Erol, Jäger, Hold and Sihn [9] propose competencies derived from the literature by offering a scenario-based learning concept for students. acatech, Fraunhofer Institut für Materialfluss und Logistik and equeo GmbH [2] analyzed German companies by following a holistic approach and propose a set of competencies divided in two areas: competencies that the companies should master and competencies that the employees should adapt. Other authors also analyze working in I4.0 by specifying competencies that will become important [4, 7, 13-15].

In order to successfully get through the transformation towards I4.0, a clear definition of the competencies for I4.0 is needed [7, 8, 16]. Furthermore, a clear description of the relationship and connection between these competencies can provide the foundation for competency development in the future [2]. The best way to address this point would be a structured competency model, which addresses I4.0 competencies for graduates. I4.0 is accompanied by the enhancement of production machines, which requires adjusted competency profiles for engineers. IT assumes the role of programming these machines and designing adjusted IT architectures, which requires new competencies for IT professionals. These changes in production, the transformation of business processes as well as new ways of communication and collaboration will lead to adjusted or even new IT processes and structures, but also to a different way of managing people, which requires customized competency profiles for Information System (IS) professionals. Job profiles for engineering, IT, and IS employees need to be adjusted and include new competencies in order to cope with I4.0.

Therefore, we address this research gap by identifying competencies for I4.0. We focus on three areas that require higher education and will be of high relevance in I4.0: IS, IT, and Engineering. Our research addressed the following research question:

RQ: What competencies are critical for job positions that require higher education for effectively and efficiently performing in I4.0?

We offer a competency model with three different variants for these three areas by combining two research methods: a literature review and focus groups.

In the next section of this paper we describe the main concepts used throughout this research: “Competency”, “Competency Model” and “Industry 4.0”. Afterwards we explain the applied methodology by describing in detail each of the applied research methods namely the literature review and the focus groups. In the following section we present the result of the research by describing the results delivered by each of the methods and the delivered competency model. We conclude the paper with a discussion of our findings.

2 Background

2.1 Competencies

Many disciplines of research, such as Psychology, Education, Organizational Management, Human Resources or Information Systems have studied the concept of competencies. Various researchers provided different definitions over the years and caused a debate that is still ongoing [17]. The first definition of competencies was delivered by McClelland [18], who defined a competency as “a personal trait or set of habits that leads to more effective or superior job performance”. On later years further definitions can be found in research, e.g., Klemp [19] defined a competency as “an underlying characteristic of a person, which results in effective and/or superior performance on the job”. With regards to Spencer and Spencer [20], “competencies are skills and abilities; things you can do; acquired through work experience, life experience, study or training”. Bartram, Robertson and Callinan [21] state that competencies are “sets of behaviors that are instrumental in the delivery of desired results or outcomes”.

Research on competencies has mainly followed three approaches that were developed independently [17]. The behavioral approach, focuses on attributes which go beyond the cognitive ability, like self-awareness, self-regulation and social skills [18, 22]. This approach argues that competencies are fundamentally behavioral unlike personality or intelligence and can be taught through learning and development. The functional approach focuses on competencies as requirements for successfully fulfilling a task by restricting the term of competencies to the skills and know-how required for conducting a task [23, 24]. The holistic/multi-dimensional approach describes competencies as a collection of individual competencies required from an individual – and organizational competencies required on the organization level to achieve the desired results [25].

In this study we focus on the individual as a key factor in I4.0, by analyzing the broad spectrum of competencies for individuals not only on functional but also on behavioral level. We do not define a list of skills for fulfilling a certain task and also do not address organizational competencies. Moreover we want to offer an overview of the competencies that should be taught to individuals for successfully working in I4.0. Therefore we apply the behavioral-based approach since it offers the best fit for our purpose, by giving also the possibility to describe the relationship between competencies as constructs on the one hand, and psychological constructs such as motives and personality traits on the other [26].

For the purpose of this study we use the definition of Bartram, who defines competencies as: “sets of behaviors that are instrumental in the delivery of desired results or outcomes” [21]. In this sense “a competency is not the behavior or performance itself but the repertoire of capabilities, activities, processes and responses available that enable a range of work demands to be met more effectively by some people than by others” [27].

2.2 Competency Models

A competency model consists of desired competencies for a certain task and may also include a description of single competencies [28-30] as well as indicators to measure performance and outcome. This lists may include different detail levels and also describe relationships between the competencies.

Many competency models have been developed over the years. E.g., Erpenbeck and Rosenstiel [31] offer a model by separating the competencies into four categories: personal, social/interpersonal, action-related and domain-related competencies. Egeling and Nippa [32] use another classification by separating competencies in meta, domain, method and social competencies. Other authors offer competency models for leadership and management [22, 24, 33]. There are also competency models for certain tasks or job profiles [26, 32].

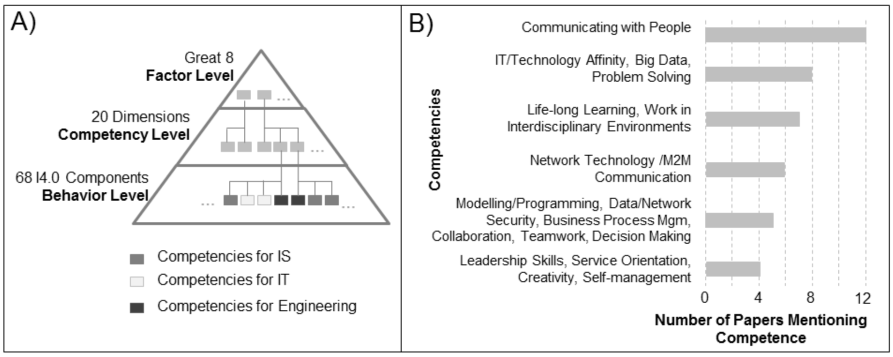

Fig 1. **A)** Industry 4.0 Competency Model Structure (Source: Own representation with regards to [37]); **B)** Most Mentioned Competencies in the Literature (Source: Own representation)

CEB Inc. [34][1] offers the SHL Universal Competency Framework (UCF)[2] [35] as a generic foundation for building competency models. This behavioral-based framework was derived by analyzing practitioners and academic approaches. It consists of three hierarchical levels, with the first level called “Great Eight”. It describes the eight core factors that underpin job performance. All competencies can be clustered in these eight groups of competencies, followed by 20 competency dimensions that divide these eight groups in further categories, which are separated into 112 component competencies. At this level all available competencies are described and each competency can be matched

1 CEB Inc. is a global best practice and insights technology company providing services to businesses worldwide [34].

2 SHL Universal Competency Framework (UCF) presents a state-of-the-art perspective on competencies and is used worldwide from well-known companies as e.g. Coca Cola [36]. It is offered by CEB Inc (see above) [35].

at one of the 112 elements (Fig. 1A). Moreover, it offers a deep level of detail. This framework offers a general perspective on competencies, within which competency models for concrete topics can be developed. For our model we adapted the competency framework (see Fig. 1A) by using the "Great Eight" as the first level and the 20 competency dimensions as the second level. We adapted the needed competencies of the behavior level as third level based on our results from the literature and focus groups. This way we based our model on a well-known framework from practice and research and adapt this framework for the I4.0 needs.

Choosing this existing framework offers many advantages. It offers a state of the art structure for competency modeling by not only listing the competencies but also showing the relationships between them. The framework is used both in research and practice, so our work makes a two-fold contribution. Since many companies apply it to build their competency profile, it offers the potential to compare our results with industry profiles in practice.

2.3 Industry 4.0

I4.0, also known as the fourth revolution, is one of the ten future projects of the High-Tech-Strategy 2020 action plan that was announced the first time by the Federal Government at the „Hannover-Messe" in 2011[1]. Its aim is a more efficient, flexible and individual production, achieved through decentralized controls of production and completely digitally controlled or even self-organized value chains [4], and where automation, real-time and sensor technologies play a crucial role [1]. "Plattform Industrie 4.0"[38] defines I4.0 as:

„[...] the fourth industrial revolution, the next stage in the organization and control of the entire value stream along the life cycle of a product. [...] based on increasingly individualized customer wishes and ranges from the idea, the order, development, production, and delivery to the end customer through to recycling and related services. [...] availability of all relevant information in real-time through the networking of all instances involved in value creation as well as the ability to derive the best possible value stream from data at all times. Connecting people, objects and systems leads to the creation of dynamic, self-organized, cross-organizational, real-time optimized value networks, which can be optimized according to a range of criteria such as costs, availability and consumption of resources."

It should be noted that the term I4.0 is widespread in German speaking countries. However, similar concepts and visions are often used under another term in the international context. For instance, I4.0 is known by the term „industrie du futur" in France, or the „Industrial Internet"[39] as well as further similar concepts as „Internet of Things", „Internet of Everything" „Smart Factory" or "Digital Transformation" in the international context [40, 41]. All this concepts include the use of automation, real-time, sensors and further modern technologies to transform business processes and therefore achieve a business value, however they slightly differ from one another in various aspects. For the purpose of this study we refer to I4.0 as a German concept with regards to the definition presented above.

3 Methodology

3.1 Literature Review

To define competencies for I4.0 we conducted a systematic literature review, which offers a rigorous view of research results [42]. We chose a concept-centric approach by following the recommendations of Webster and Watson [43]. The main objective of the literature review was to identify, classify and summarize competencies about I4.0 that were defined in the literature.

Following the guidelines of Webster and Watson [43] we searched by using the keywords: “Industrie 4.0”; “Industry 4.0”; “Digital Transformation”; “Internet of Things”; “IoT”; “Cyber Physical Systems”; “CPS” and combined each of them with the keywords: “competence”, “competency”; “skill”; “knowledge”; “attitude”; “ability”; “value”; “education”. Our goal was to conduct an exhaustive literature search and cover the state-of-the art literature about I4.0 competencies. The chosen databases were ACM Digital Library, IEEE, Springer and EbscoHost[3] because they cover publications from the IS, Economics, IT and Engineering discipline, as well as many Education outlets including conferences like EDUCON, REV, ICL, and Frontiers in Education that are often target outlets for publishing competency studies regarding actual topics like I4.0. The search included all articles that were published until August 2016. All the hits were first screened based on the title and abstract. In a second phase, the whole articles were screened. Additionally, a Google Scholar search was conducted in order to discover relevant articles from conferences and journals that were not included in the databases mentioned above. Here, the articles were sorted by relevance and the first 30 hits for each search string were screened. By following the recommendations of Webster and Watson [43], a backward and forward search was also conducted from the analyzed articles. Articles that did not include concrete competencies were excluded from our analysis. We had a total of 3363 hits in the database search, after the first screening 26 articles from the databases remained for further analyzes. Only articles where explicit competencies are mentioned were chosen. At the end a total of 17 that mention competencies for I4.0 or similar concepts such as IoT, were selected for further analysis. One of the articles was from the backward search.

Since the topic is new, only little research exists. However we conducted a literature review to summarize the state of the art before gathering any further data. The topic is of high practical relevance and broadly discussed in practitioners’ texts. Therefore by following the recommendations of Levy and Ellis [44], we also considered practical articles, white papers and reports that propose competencies for I4.0. These were determined through Google search and delivered a total of 10 practical articles included in our analysis. Finally, 27 articles including research and practitioners’ publications were considered and analyzed.

[3] The used EbscoHost Databases are: Business Source Premier, EconLit, Information Science & Technology Abstracts, Education Source, ERIC, Business Source Complete

From each article we extracted the mentioned competencies and built a concept matrix as proposed by Webster and Watson [43]. If the same competency was covered as a synonym in different papers e.g. “smart data” and “big data” we considered this as one competency and used the more popular term.

3.2 Focus Groups

For evaluating and extending the literature review, we conducted focus group interviews as recommended by Krueger and Casey [45]. A total of four focus groups with 18 - 25 participants each were conducted. The focus groups lasted 45 minutes on average. The participants in the focus groups were lecturers with previous experience in companies or various years of experience in university teaching and education in the areas of IT, IS, Economics and Engineering. This target group was addressed since lecturers have a general understanding of competencies and apply competency targeted teaching. Most of them also are involved in research and therefore are aware of I4.0, its relevance and the importance of building up competencies for the future employees. Three of the focus groups included lecturers from different countries in the EMEA region e.g. Germany, Austria, Netherlands and Egypt. They were conducted at the Technical University of Munich during training workshops for lecturers, who are interested in modern technologies that can be applied for teaching purposes, including topics of digital transformation, IoT and I4.0. The last focus group included professors and lecturers from Germany, Austria and Switzerland. It was conducted during a workshop at a German software company that aimed, among other topics, in discussing challenges and technologies that should be applied in today’s education. Using the setting of a workshop was helpful since each group had already known each other during the workshop and built a certain group dynamic that positively influenced the discussion. The participants also had time to discuss and think about I4.0 related topics during the workshops, so they were in the right mindset for the discussion and for building up ideas. Due to the given group dynamic and workshop setting we decided to limit the focus groups to the given lecturers and professors, since most of them had also practical insights from their previous jobs.

All focus groups have been moderated by the same person, a co-author of the paper. We used the same semi-structured guidelines in each of the focus groups to ensure that the findings are comparable. We applied the Critical Incident Technique [46, 47] for the focus group guidelines in order to derive the competencies for I4.0. The participants were presented with typical work scenarios and products of I4.0. Then questions were asked about the competencies that employees should bring in Engineering, IT and IS to efficiently work in this scenario.

The focus groups were recorded and transcribed. We coded the transcripts using the software MAXQA and combined an inductive with a deductive coding approach. This means we took the competencies from the literature as codes and started coding the transcripts. If a new competency was mentioned in a focus group that was not part of the codes, we used this as a new code meaning a new competency in our list. The coding was conducted twice from two different researchers. The codes were lastly compared and the differences were discussed until a common decision on the code was achieved.

4 Results

4.1 Results from Literature

Based on the literature, a total of 64 competencies could be derived. Most of them were behavioral ones and underline the importance of behavioral competencies for I4.0. It cannot be expected that a single person possesses all the mentioned competencies. So different combinations of the competencies represent specific job profiles for I4.0. The most mentioned competencies and their occurrence in the analyzed literature are presented in Fig. 1B.

Various authors underline that communication is one of the key competencies required from graduates [1, 2, 6, 7, 9, 13, 48-53]. Others go further by putting the communication competency in relation with other competencies like literacy [50] and technical communication [9, 50], intercultural competency [9, 13, 50], or presentation ability [54]. Social skills like collaboration [2, 7, 49, 54, 55], compromising [9], and negotiating [55] combined with emotional intelligence [55] will play a key role in I4.0 since they also play an important aspect in teamwork [7, 9, 48, 49, 51], project management [52, 53], and management ability [6], customer orientation [2, 13], maintaining customer relationships [2, 56], and creating business networks [2, 56]. Work and collaboration will become more complex, therefore I4.0 requires graduates with analyzing competencies like problem solving [2, 4, 6, 7, 9, 15, 49, 55], optimization [2, 4], analytical skills [9, 12, 57], and cognitive abilities [55]. To be able to coordinate these competencies, being able to manage complexity [2, 9] and abstraction ability [6, 9, 15] are crucial. Graduates in I4.0 should bring leading and deciding competencies like decision making [1, 2, 6, 55, 58], taking responsibility [6] and leadership skills [2, 6, 12, 55], which should be combined with a set of principles and values with competencies like respecting ethics [51], environmental awareness [52, 53], and awareness for ergonomics [48].

I4.0 will lead to a dynamic, international and interdisciplinary work environments, therefore competencies such as working in interdisciplinary environments [2, 4, 7, 12, 48, 51, 54], flexibility [9], adaptability [48, 49] as well as innovating [2, 14], creativity [7, 9, 14, 49], critical thinking [49], and change management [56] gain a new importance. For being able to always adapt the latest technologies and make the most out of them, graduates should apply life-long learning [4, 9, 12, 49, 50, 51, 54] and knowledge management [48, 49] while being focused on business strategy [3], always changing business models [3, 54] and entrepreneurship [49]. The work environment will become very demanding, so a graduate will need to find work-life balance [9] and needs to have the competency of self-management and organization [1, 6, 48, 49] as well as of planning and organizing work [13, 49, 57]. Nevertheless he should bring legislation [48, 52, 53] and safety awareness [51, 57] as well as individual responsibility [6].

Apart from all the behavioral competencies mentioned above, graduates must also bring domain related competencies as well as the ability to apply expertise and use technology. In this area all graduates need to bring IT and technology affinity [2, 4, 9, 12, 13, 48, 56, 57], economics knowledge [52, 53], and be able to extract business value from the use of social media [9, 56]. IS graduates should have knowledge in service orientation and product service offerings [2, 3, 56, 59], business process [2, 3, 9, 48, 54], and change management [56]. IT graduates should have knowledge of digital security, including data and network [2, 3, 51, 56, 59], and while working with engineers both groups should bring the competency of integrating heterogeneous technologies [51-53], knowledge about mobile technologies [56] and embedded systems and sensors [51], knowing network technology and M2M communication [2-4, 9, 54, 59] as well as possess knowledge of robotics and artificial intelligence [2, 12, 57]. On the other hand, IT and IS graduates should both bring modelling and programming knowledge [9, 12, 48, 58, 60], knowledge about cloud computing and cloud architectures [2, 56, 59], in-memory DB knowledge [56] and statistics [48]. For both groups, big data and data analysis and interpretation [2, 3, 9, 12, 48, 54, 56, 61] will be of big importance.

4.2 Focus Group Results

The most mentioned competency in the focus groups was big data/data analytics competency. "*I think it is about all different kind of data, also geo data but also video data, images, all ERP data, structured data and unstructured data like Facebook etc." "So to use anonymized big data and volume data and data traffic to predict macro business events rather than micro."* The participants see this as the next big thing and believe that for succeeding in I4.0, a combination of big data competency with sensors and mobile technology as well as predictive maintenance and machine learning will be very important.

The next most mentioned competency is process know-how and process management competency. De facto, processes are in the focus of I4.0, with automation playing an important role. The participants also underlined that business model understanding and entrepreneurship will play a special role in I4.0 since this will transform business models. The employees of tomorrow should be prepared to use the technological advances as an advantage and adapt in a fast changing world. "*The question is: Which potential does the digitalization bring and which new services can be offered based on that?*"

The participants also stressed that interdisciplinary competency will play a new role in I4.0. An engineer will have to collaborate with the IS and IT specialists in order to achieve results in the interconnected environment that we will face.

The domain or analytical oriented competencies like IT and technology affinity, network administration, data security cloud architectures, programming, in-memory DBs were also important in the discussion. *"Just to have the picture. You run through the world and Industry 4.0, you know there are so much sensors." "The more technical people they should know afterwards how to create systems."*

Lastly the participants also mentioned further behavioral competencies like customer orientation, decision making, communication, innovating, legal, ethics, and teamwork. *"I do not need to understand the whole technical background, but I need to be able to make decisions." "...we should offer group work, so that the participants learn to communicate and work in teams".*

Compared to the literature we could add four new competencies that were mentioned in the focus groups but have not been found in literature, as customer relationship management, IT architectures, machine learning, and predictive maintenance. Competencies in the dimension of leading, like leadership skills, or persuading and influencing like negotiating and emotional intelligence that were often mentioned and analyzed in the literature have not been mentioned at all during the focus groups. The mentioned competencies were generally more abstract, lacking high detail compared to the literature.

4.3 Developing the Model

The SHL UCF[2] developed by CEB Inc.[1] is based on different competency approaches from research and practice [35]. It offers a behavioral approach for competency modeling by focusing on the individual and considering competencies of behavioral nature, meaning an individual can learn and adopt them unlike, e.g., personality. As a framework it offers a structure and overview of the competencies, by fitting them into descriptive categories [62]. This framework can be used to develop competency models, which represent a descriptive and simplified view of the competencies as a specific phenomenon to be analyzed [62]. The SHL UCF is widely used in practice and many companies use it to describe their competency models for specific job positions [26].

As described earlier, the SHL UCF is composed of three hierarchical levels: the "Great Eight", the competency dimensions and the competency components. We kept the structure and the relationship between the elements and adapted the third level competencies based on the results of our research. The framework delivers 112 single competencies. For I4.0, we considered 68 competencies (Fig. 1A) as relevant. Based on the results of the literature review and focus groups we expanded some of the single competencies or adapted their formulation to serve our purpose. For each of the competencies we did a clustering whether it is relevant for IS, IT or Engineering graduates or whether it can be considered as an interdisciplinary competence for two of the mentioned areas or all three of them. The process of clustering was conducted separately from two researchers and then compared to each other. In case of disagreement the clustering was discussed until achieving a consensus.

The results show that most of the behavioral competencies should be adapted by all three groups of graduates. These competencies are marked in light grey color eg. *Decision Making* or *Teamwork*. It means that the employees of the future, independently from their position should bring a high level of behavioral competencies to successfully work in I4.0. Only competencies under the dimension "Applying Expertize and Technology" have three variants. This dimension of competencies represents domain knowledge, therefore depending on the domain the employees should bring different competencies. Some competencies in this dimension are also categorized to two or more groups of graduates. E.g., *Predictive Maintenance* will be a competency for IT as well as for Engineering graduates, whereas *Big Data* will be a needed competency not only for IS but also for IT graduates. Economics graduates, who follow a technical oriented carrier path, will adapt similar competencies as the IS

Fig 2: "Industrie 4.0" Competency Model (Source: Own representation with regards to [35])

graduates, since these disciplines have similarities. This shows again that the work in I4.0 will be interconnected. Therefore, competencies such as interdisciplinary working, collaboration, communication or teamwork will have a special role.

Our model is presented in Fig. 2. For each of the employee groups you can follow the path and gather all the competencies that should be fulfilled by this group. It cannot be expected that one employee of a certain group masters all the competencies. Therefore, a combination of the competencies, depending on the position will deliver different job profiles for I4.0. E.g. a competency profile for a data scientist responsible for extracting, modeling and visualizing the data produced by a certain sensor in I4.0 can be defined by extracting concrete competencies from the area of IS such as *Taking Responsibility*, *Big Data Analytics and Interpretation*, *Analytical Skills*, *Cognitive Ability*, *Creativity*, and *Critical Thinking*. By following this schema different profiles for different jobs could be defined.

5 Discussion and Limitations

In our research we used the SHL UCF [35] to develop an I4.0 competency model. Most of the defined competencies are not new, however the presented specific combination of competencies for I4.0 is new and makes a contribution to research. Overall, our research emphasizes the importance of employee competencies to successfully get through the transformation towards I4.0. The results of the literature review and the focus group discussions delivered mostly behavioral competencies and only a small part of the competencies represented domain related knowledge. This is also a new aspect with regards to competency building and underlines the changes that I4.0 will bring to the way we work. Job vacancies in today's economy often focus on a list of domain knowledge and comprise only some very generic behavioral competencies, like teamwork or independently working. The same situation is presented if we analyze university lectures and curricula. Their focus often is on teaching the students' domain knowledge. The training of further competencies still often is limited to teamwork situations or presentations to be held. These examples show that domain knowledge are the focus of today's economy, while I4.0 will turn around the work environment. Behavioral competencies will be the most important competencies that employees should bring. Therefore, research should focus on analyzing how the competency profile of today's employees as well as of students could be adapted for I4.0. This could include the definition of requirements for curricula and training programs for I4.0. Conceptualizing and defining learning strategies and curricula for I4.0 might be another interesting topic for research.

If we consider today's economy and disciplines, there is a clear separation between the competencies that employees from different disciplines should bring. If, for instance, we mention IT, everyone recalls a certain job profile and competency set in their mind that is completely different from the profile that one would recall if we mentioned IS or Engineering. Our study reveals that in the future the competency sets that different disciplines should bring will be very similar and will differentiate only in some aspects of domain knowledge. This would be a further point where research could offer teaching methods for interdisciplinary teaching.

Our literature review also showed that research on I4.0 competencies is rather scarce. The analyzed works mostly underline that the work environment will change, however no concrete vision or competency models were proposed. With our work we make an initial contribution that could be further expanded for other professions that require higher education.

This work has practical implications as well. The proposed competency model could be used in practice by companies and universities. Companies could use the model to define job profiles for I4.0 vacancies. It cannot be expected that one employee will bring all the competencies included in the model, however by combining some of them depending on the position, different profiles can be described. The results can also be used in competency-based curricula designing.

Although there are limitations to our study, we believe that it can serve as a foundation for further research. Our analysis was based on a literature review as well as four focus groups with academic staff. The literature search was limited to the databases, where access by our university, is provided. To complete the results further literature, especially conference proceedings as well as empirical data e.g. focus groups or expert interviews from practitioners would be helpful. We acknowledge that further research in the area of I4.0 competencies is required to study further aspects of competencies as well as define how the model could be applied in practice. Especially a definition of a competency profile for a certain job description, e.g. which competencies of the model should a programmer bring, could be a further interesting point for research and practice.

Abstract. Product information sharing, i.e., inter-organizational transfer of master data relating to products, is a problematic, error-prone, labor-intensive, and costly process in many companies. This paper presents findings of a focus group interview and case studies at three wholesale trading companies that share product information with hundreds of suppliers. We identify and assess coordination mechanisms and tools used to facilitate product information sharing. Spreadsheet files, e-mail messages, telephone calls, and personal meetings are predominant coordination tools. EDI connections, product identification and classification standards, online product catalogs, and data pools are not widely adopted in the trading organizations covered by our study. Reasons for the low adoption rate are that employees responsible for master data quality are either unaware of these resources or that they are convinced that the tools are too cost-intensive or not flexible enough.

1 Introduction

Interoperability is a major prerequisite for the digitization of value chains. Legner and Wende [1] define business interoperability as „the organisational and operational ability of an enterprise to cooperate with its business partners and to efficiently establish, conduct and develop IT-supported business relationships with the objective to create value." [1]. Legner and Wende emphasize, that "being 'interoperable' refers to being able to share information between business partners, understand and process exchanged data, [and] seamlessly integrate it into internal ICT systems." [1] Achieving and maintaining an adequate level of quality of master data is a crucial precondition for business interoperability [2–5].

Intra-organizational issues of ensuring and maintaining quality of master data have gained extensive attention in the literature [6, 7]. However, achieving an adequate level of master data quality in inter-organizational business processes – particularly in product information sharing – has had much less attention [2, 5, 8, 9].

Product information can be defined as a set of data, e.g., identification number, weight, size, etc., that represents the product [2, 5, 9]. Product information sharing denotes the inter-organizational transfer of product information, a concept labeled "product information supply chain" by Legner and Schemm [8]. The term master data refers to critical business objects of an organization [3]. It describes products, suppliers, customers, employees, and similar objects that rarely undergo changes [10].

Data quality denotes the extent to which data meet specified requirements. Data quality is "a measure of the adequacy of the data for specific requirements [...] Data quality is a multidimensional, contextual concept, as it cannot be described with a single feature, but on the basis of different data quality dimensions and measures" [7]. A key quality characteristic is "fitness for use" [2, 6]. In a study of product information sharing de Corbière [2] identified four major data quality dimensions, namely, accuracy, completeness, timeliness and security.

The objective of our study is to identify and to assess mechanisms and tools for coordinating quality of master data in inter-organizational product information sharing. We aim to answer two research questions:

- R1: What mechanisms and tools do trade companies apply to coordinate master data quality in product information sharing with suppliers?
- R32: What strengths and weaknesses of coordination mechanisms and tools do experts perceive?

This paper is organized as follows. The next section presents findings of our literature survey. Section 3 explains the research methodology. In section 4 we describe findings of three case studies: processes, mechanisms and tools for coordinating quality of product information exchanged between wholesale trading companies and their suppliers. Section 5 presents and discusses key findings of our study. Finally, we conclude by summarizing implications for practitioners and by pointing out research opportunities.

2 Prior Research

We conducted a literature survey to identify prior research into arranging for quality of master data in inter-organizational product information sharing and to describe the state of the art in this field. In contrast to a literature review, a literature survey gives an overview of the relevant literature but does not provide a detailed analysis. Due to space limitations we cannot describe the method and our findings in full detail. Therefore, we shall limit the description to some key features here. We followed the guidelines provided by Webster and Watson [11] and vom Brocke et al. [12] to identify relevant publications. As a first step, we examined IS journals and IS conference proceedings using the AIS Electronic Library, ScienceDirect, Google Scholar, and SpringerLink. We conducted electronic searches in titles and abstracts on the following search term: [("data" AND "quality") AND (("inter-organizational" OR "business-to-business" OR "supply chain") OR ("product" AND "information" AND "sharing") OR ("data exchange"))]. These searches identified a total of 175 publications. After analyzing each article's abstract, keywords, or the full article when necessary, we excluded 144 articles that were duplicates or did not appear to be concerned with or relevant to our research focus. As a third step, we performed a forward and backward search in relevant articles to identify further sources that had not been identified by the previous step. A total of 39 publications was read in full and coded. We excluded all publications that only stated the keywords mentioned in the search term without elaborating on these concepts. Out of the 39 coded articles, 12 include passages of interest. The following statements present key findings of our survey.

- Data quality is a critical success factor for efficient cross-company collaboration [5, 13–16]. This is particularly the case for product information sharing in supply chains [2, 8, 15].
- Various studies have found that manufacturers, wholesale trading companies, and retailers are concerned about the quality of product information shared between trading partners [2, 8].
- Several surveys have shown that poor quality of product data exchanged between cooperation partners may lead to substantial cost increases or loss of sales [8, 13].
- The attempt to improve product data quality is a key driving force for using electronic exchanges of product information, e.g., the Global Data Synchronization Network (GDSN) data pool [2, 9]. Nakatani et al. [13] define a data pool as a repository that supports trading partners in obtaining, maintaining, and exchanging information on trade items in a standard format through electronic means.
- Using inter-organizational information systems for synchronizing data, e.g., data pools, electronic catalogs or marketplaces, often does not lead to the promised benefits. Trading partners also need to take steps to improve data quality internally [2, 5, 13]. Several companies are still in the process of setting up appropriate coordination mechanisms for managing their internal product information supply chain [8]. Dalmolen et al. [5], for example, found that IT personnel in large(r) organizations often have little awareness of the product information sharing

process in their own organizations. Likewise, business units lack sufficient IT knowledge to initiate potential improvements.

- Several authors [5, 9, 17, 18] found that standards for product identification and classification, e.g., the Global Trade Item Number (GTIN) and the United Nations Standard Product and Services Code (UNSPSC), and data pools, e.g., the GDSN data pool, have not gained wide acceptance in many industries because they do not meet key requirements of trading companies.
- The exchange of product information between trading partners is often supported by telephone calls, fax or e-mail exchanges. These processes are problematic, error-prone, labor-intensive, and costly [2, 8, 9, 13, 19]. Legner and Schemm [8] cite various studies that report significant direct labor costs due to the manual transfer of product information and its administrative processing as well as indirect effects of poor data quality on the supply and demand chain. Falge et al. [16] suggest that trading partners should establish a process for agreeing on common standards and systems and for defining service level agreements for data quality.
- Several scholars [2, 5, 14, 16, 19] encourage further research into data quality in the inter-organizational exchange of product information. Legner and Schemm [8] suggest qualitative and quantitative studies into sharing of product information between suppliers and retailers of goods. They also ask for more extensive investigations of interdependencies and coordination mechanisms in the inter-organizational product information supply chain.
- In our literature survey we have identified only few studies [8] that have attempted to assess mechanisms and tools for coordinating quality of master data in inter-organizational product information sharing. Most of these studies focus on only one or on a limited set of coordination mechanisms and tools. To the best of our knowledge, no author has yet attempted to assess a broad range of tools for coordinating quality of master data in inter-organizational product information sharing.
- Most of the papers included in our survey do not explicitly build on a theory. In the rare cases, when a theory for analyzing master data quality management in inter-organizational product information sharing is used [8, 14], the authors build on coordination theory.

3 Research Methodology

Our research combines a focus group interview and case study-based research. A focus group interview is an advanced form of an expert interview. Researchers interview a group of experts and document the findings for later evaluation [20–22]. Focus group interviews are well suited for acquiring new insights and ideas, and for structuring research questions into manageable chunks. In section 2 we have shown that arranging for adequate quality of master data in inter-organizational product information sharing is a research domain that has gained only little attention from scholars. Focus group interviews are especially suited for obtaining several perspectives about a complex topic. They help to structure the research domain and to identify research questions for further investigation.

In March 2016 we conducted a focus group interview with 14 master data experts from 12 enterprises. Five are trading companies, four manufacturers, and three IT service providers. All companies are dependent on high quality master data provided by hundreds of business partners. Each company has established a team or a project with the objective to improve inter-organizational product information sharing. The focus group deals with the exchange of product master data between manufacturers and retailers. The interview helped us to identify practically relevant research fields. The interview revealed that the process of setting up products in trading companies' product databases frequently leads to severe problems due to inadequate quality of master data provided by suppliers. Therefore, ensuring an appropriate level of quality of master data is of key importance for maintaining efficient supply chains among suppliers and wholesale trading companies. This finding is consistent with the research results described in section 2 of this paper. For this reason, we focused on this field in the subsequent case study research.

Case study research examines complex and ill-structured phenomena in a practical environment [23, 24]. Our research follows a single case study approach in order to extend our knowledge of the inter-organizational exchange of product master data. This approach was chosen due to little empirical research in the domain of inter-organizational master data quality as mentioned in section 2. The case study research was structured as follows: Similar to the research approach by Legner and Schemm [8], the selection of case study organizations was mainly driven by purposeful sampling, availability of multiple sources of information, and the willingness of experts to cooperate. We decided to focus on wholesale companies as these entities act as intermediaries between suppliers and retailers of goods. Thus, wholesale companies are particularly dependent on the quality of master data relating to trade items.

We conducted semi-structured expert interviews and analyzed documents and IT artifacts provided by three case study organizations. Interview guidelines were created based on the results of a pretest with several business experts. The guidelines comprise 22 questions. The interview questions were sent by e-mail to the experts one week before interviews took place. The interviews were held between June and August 2016. We talked to a total of 10 experts in three retail companies: master data experts, procurement staff and IT personnel. The interviews lasted between 4 and 6.5 hours. All interviews were recorded. Immediately after completing the interviews, the experts' answers were documented and coded. We then analyzed all findings following the recommendations of Mayring and Fenzl [25]. Subsequently, the interview documents were provided to the experts asking them to verify the findings and to resolve potential misunderstandings. The experts also provided us with internal documents, master data descriptions and spreadsheet files used to transfer product information among trading partners. These artifacts helped us to better understand specific details, processes, mechanisms, and tools for the inter-organizational coordination of master data quality in product information sharing.

4 Processes, Mechanisms and Tools for Coordinating Master Data Quality in Product Information Sharing

In the next paragraphs we describe processes, mechanisms and tools for coordinating quality of product information exchanged between wholesale trading organizations and their suppliers.

4.1 Case 1: Wholesale Trading Company in the Retail Market

The first study was carried out in a wholesale trading company in the retail market, hereafter referred to as C1. This company employs more than 5000 people and generates an annual turnover exceeding one billion Euros. C1 procures goods from more than 2000 suppliers and sells products to about 2000 customers worldwide, mostly retail stores. C1's product database consists of more than 300,000 items. Product master data sets include 109 attributes. About 120,000 master data sets are modified per year.

The organizational unit responsible for managing product master data, labeled MDM for short, is part of C1's fulfillment department. MDM consists of 18 staff members who are in charge of master data administration related to fulfillment tasks. At C1, fulfillment is defined as order handling process spanning from responding to sales inquiries over procurement to delivery of products to the retail sector.

The process of coordinating and agreeing on an appropriate level of master data quality with suppliers consists of several steps: (1) MDM creates an Excel file that serves as a container for product master data that C1 requests from suppliers. The file specifies about 100 attributes for each product. (2) C1's procurement department sends the file to suppliers by e-mail requesting to complete 20 to 30 attributes for each product. The exact number of required attributes depends on the product category. (3) 45 percent of all suppliers fill in the relevant data and return the completed file via e-mail. Approx. 55 percent of the suppliers do not fill in the Excel file. They provide the data in other formats, e.g., CSV or XML files, or on paper. Suppliers that do not provide data in Excel files cause substantial overhead for data import and/or data entry at C1. A limited set of suppliers run a customer portal. They provide master data for wholesale customers via the portal. In these cases, C1's MDM staff import data from the portal into the Excel file. (4) When master data provided by a supplier is received, C1's procurement department checks the data entries. About half of all files provided by suppliers are appropriate and correct. The other half is incomplete or defective. Inappropriate files lead to further inquiries via telephone or e-mail when C1's employees attempt to adjust and to complete product data. (5) Frequently, the Excel file needs to be returned to suppliers requesting to rectify master data sets. (6) In the next step, procurement staff members complement the data sets with about 30 further attributes. Characteristic examples are attributes that identify or categorize products, i.e., product identification numbers. (7) The Excel file is then forwarded to MDM. This unit carries out more quality checks. (8) In case of incomplete or false data entries MDM consults the procurement department or the supplier. During this step, the Excel file often has to be returned to the sender again with the request to complete or to amend master data sets. (9) When MDM employees consider the file appropriate they add another set of approx. 10 attributes, e.g., country-specific information needed for exporting products to international markets. (10) MDM than creates an upload file and loads the data into the database of the ERP system.

Figure 1 illustrates the process of inter-organizational product information sharing in UML notation as an activity chart.

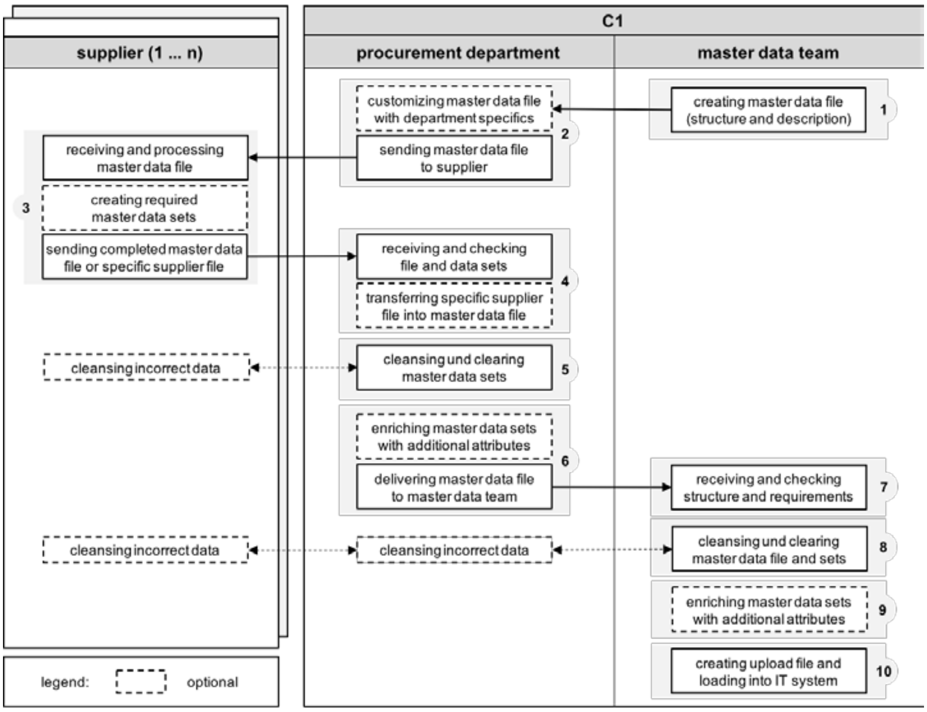

Figure 1: Overview of the process of product information sharing

4.2 Case 2: Wholesale Trading Company in the Automotive Aftermarket

The second case study was conducted in a wholesale trading company in the automotive aftermarket, hereafter called C2. The company has more than 5000 employees and generates approx. 1.6 billion Euros turnover per year. C2 purchases parts from more than 2000 suppliers and sells products to approx. 30,000 customers, mostly garages in five European countries. The stock of articles comprises 1.5 million items. Product master data sets consist of 92 attributes. 50,000 to 120,000 master data sets need to be modified per day.

The organizational unit responsible for managing master data is part of the procurement department and employs 8 people. They are in charge of master data administration related to all procurement tasks. However, master data team members usually do not directly communicate with suppliers. This is one of the duties of procurement staff.

Basically, C2's process of coordinating master data quality is similar to C1's process. In order to avoid repetitions, we refrain from describing the entire process again. We only mention specific features of C2's process in this section.

- C2's framework contracts with suppliers comprise a clause that mutually obligates trading partners to supply master data in adequate quality. However, this clause does not specify any details.
- C2's Excel file sent to suppliers consists of 92 attributes. 20 attributes are mandatory fields that must be filled in by suppliers.
- C2 utilizes the TecDoc catalog [26], a standardized electronic parts catalog that contains data sets for more than 5,400,000 products in the automotive aftermarket. Missing, incomplete or inaccurate data sets are complemented by C2's staff with data obtained from this catalog.
- Unlike C1, C2 utilizes several automatic routines to check quality of master data provided by suppliers before uploading master data sets into the product data base.
- Similar to the process at C1, C2's procurement staff members communicate with suppliers, request product master data and provide suppliers with Excel files to fill in the master data. Procurement employees frequently modify spreadsheet files sent to suppliers in order to better adapt to the specific requirements. This leads to an ambivalent situation: On the one hand the Excel files are tailored to the specific requirements of procurement units and to certain product categories. On the other hand, procurement staff members do not communicate these modifications to personnel in the master data unit. This leads to inconsistencies in master data sets, to frequent check backs, and to substantial rework.

4.3 Case 3: Purchasing Association in the Furniture Industry

Case 3 describes coordinating quality of product master data in a purchasing association in the furniture industry, hereafter referred to as C3. The association serves as a mediator between furniture manufacturers and retailers. C3 draws up and makes framework contracts between producers and vendors, and provides procurement, marketing, financing, and IT services. C3 supports, for example, the exchange of master data between furniture suppliers and retailers. C3 employs more than 50 people and generates an annual turnover of about 50 million Euros. 700 furniture producers and dealers are members of C3.

C3's product data base contains about 100,000 master data sets. More than 1000 new master data files are imported and approx. 30,000 master data sets need to be modified per year. The organizational unit responsible for managing master data directly reports to C3's executive board. The master data team consists of 5 employees. C3's process of arranging for and agreeing on an appropriate level of master data quality is similar to the processes at C1 and C2.

- C3 sends Excel files to furniture manufacturers requesting to provide master data in a form that meets requirements of furniture retailers. About 50 percent of the suppliers fill in the templates and provide master data in Excel files. The other half provides master data sets in proprietary formats, in PDF files, or on paper.
- Similar to the situation at C1 and C2, a high percentage of all files provided by suppliers are incomplete or incorrect. This gives rise to frequent check backs. The process is labor intensive and causes high personnel cost. However, our interview partners were not able to quantify efforts needed to complete or to amend master data sets.
- C3's procurement team regularly communicates with suppliers. They attempt to clarify any inconsistencies. However, arranging for and ensuring an appropriate level of master data quality is not a top priority for procurement personnel. Master data experts are not involved in talks and negotiations with furniture manufacturers. Similarly, C3's IT department does not actively support the process of exchanging master data with suppliers.
- Unlike C1 and C2, C3 does not complement master data sets with additional attributes. C3 serves as a data broker only.
- C3 does not apply any product identification or classification standard. They neither use EDI messages for transferring master data nor data pools for enriching and amending incomplete or incorrect data sets.
- C3 does not use any automatic routines to check the quality of master data provided by suppliers before transferring master data sets to furniture retailers. Once C3's master data team considers the data sets appropriate, they transfer the data into a product data base. Product information is then made available for furniture retailers via C3's extranet, a controlled private network allowing members to gain proprietary information.

5 Findings and Discussion

In this section, we answer the research questions and discuss findings of our study. We first present the assessment of coordination tools used by the trading companies included in our case studies. We then analyze our findings using the lens of coordination theory.

5.1 Assessment of Coordination Tools used by Trading Companies

During the case study interviews, we identified a set of eight coordination tools that are applied to define and to check quality of product master data exchanged between suppliers and wholesale companies. However, as already mentioned in section 4, not each company included in our study makes use of all of these tools.

As part of the case study interviews, we asked participants to assess the tools. We invited the experts to qualitatively evaluate strengths and weaknesses of the tools. Table 1 shows the results of the assessment.

Table 1. Assessment of coordination tools for ensuring quality of product master data

Coordination Tools	*Strengths*	*Weaknesses*
Framework contract	- provides legal basis for data exchange including confidentiality agreements	- does not specify requirements for master data quality
MS Excel file	- ease of use - high adoption rate - simple editing - no IT expertise required - low set up cost	- most suppliers do not document modifications in files - complex rework required - automated validation of master data sets not feasible - files are not self-descriptive
EDI message	- standardized, tested and reliable technology - reliable data sets	- low adoption rate - EDI messages cannot easily be tailored to specific requirements - high implementation cost
Customer portal	- automatic syntax check - documentation of all operations in log files	- specific "look and feel" of each portal - insufficient ease of use - data sets are not tailored to specific needs of trading partners
Online product catalog	- all products can be mapped and made available	- trading partners must be persuaded to use product catalogs
Identification and Classification standard	- high data quality - high adoption rate - full documentation and good support	- cannot be tailored to specific requirements - low adoption rate
Data pool	- covers a wide range of products - focus on specific industries - high data quality - unified communication platform - communication processes are logged	- limited number of attributes - specific "look and feel" of each data pool - high access and usage fees - not all business partners have access
Mutual adjustment (e-mail messages, telephone calls, personal meetings)	- ease of use - flexibility	- error prone - labor-intensive - costly

5.2 Analyzing the Cases Using the Lens of Coordination Theory

We build on coordination theory to structure our findings and to reflect the insights we gained in our case studies. Malone and Crowston [27] define coordination as "the act of managing dependencies between entities and the joint effort of entities working together towards mutually defined goals". Coordination theory is the "body of principles about how activities can be coordinated, that is, about how actors can work together harmoniously" [28]. Thus, coordination theory focuses on essential questions of inter-organizational product information sharing, namely, how trading partners can work together harmoniously in order to ensure smooth and cost-efficient supply processes and how they can manage interdependencies resulting from the need to operate on high quality product master data. Another reason for selecting coordination theory as a theoretical basis is that it matches well with our research questions. Coordination theory explores which types of coordination mechanisms have which strengths and shortcomings under which conditions [27, 29, 30]. Moreover, it has been successfully applied by prior research into inter-organizational product information sharing [8, 14].

Inter-organizational coordination of master data quality is a highly complex, yet hardly systematized or automated process in the companies covered by our study. The process of check backs and providing previously missing or defective data is not standardized or automated. Procurement employees and master data staff perform these tasks on an ad hoc basis. Most subtasks are performed manually. Apparently, many suppliers and their customers make considerable efforts to achieve and to maintain an adequate level of master data quality. However, options for standardization, rationalization, and automation have not yet been fully used by the companies included in our study. These findings confirm the research results of Legner and Schemm and Otto et al. [4, 8].

Several authors [27–31] have suggested frameworks that describe basic concepts of inter-organizational coordination.

Actors denote individuals and organizational units responsible for coordination [28]. Entities responsible for the quality of product master data are centralized in all companies covered by our study. However, the process of coordinating master data quality with suppliers is decentralized. Procurement personnel and staff members of master data teams are involved. Both entities adjust incorrect data and complement incomplete data sets. This requires additional intra-organizational coordination effort. We had expected that IT departments play a crucial role in the exchange of master data sets and in ensuring and improving master data quality. However, IT departments do not actively participate in this process. IT staff run the IT infrastructure and they assist in uploading master data files into ERP systems. Yet, they are not consulted when it comes to technical solutions for improving inter-organizational coordination of master data quality.

Interdependencies are “goal-relevant relationships between the activities” [28].. According to Malone and Crowston [28] interdependencies can be analyzed in terms of common objects. Common objects in a trading relationship are trade items and product master data sets that are transferred between trading partners. However, master data are not of key importance for all actors participating in the trading process. Procurement personnel rather focus on trade items, prices, and terms and conditions. Improving quality of master data is seen as an annoying and bothersome technical task. Thus improving quality of master data does not receive the necessary attention. As mentioned before, IT personnel – who would be able to adequately assess the importance of the task – usually are not involved in inter-organizational product information sharing.

Romano [32] differentiates between several types or configurations of inter-organizational relationships. A dyadic network involves the interaction between two firms (1:1), a multiple dyadic network involves the interaction of one firm with several other firms (1:n or n:1). A many-to-many network is one where several firms interact with several other firms (m:n). The types or configurations analyzed in our study are multiple dyadic networks. This corresponds to the results of Le Dû and de Corbière [19] who found that synchronization of product information is mainly performed on a dyadic basis. Each of the three wholesale organizations has trade relations to several hundred suppliers. Quality of master data needs to be arranged, agreed on, and checked on a one-to-one level between trading partners. Obviously, the extent and complexity of this task makes it impossible to ensure an adequate quality of product information exchanged with all trading partners.

Xu and Beamon [29] define coordination mechanisms as a set of methods used to manage interdependencies between organizations. Coordination tools are specific elements of organizational action, interaction or behavior that enable inter-organizational coordination [31]. Arshinder et al. [30] suggest identifying whether a single or a combination of mechanisms are required to tackle complexities in supply chain coordination. The wholesale trading companies included in our study apply a multifaceted set of methods to coordinate master data quality with suppliers. However, Excel files are the predominant coordination tools. These files allow trading companies to accurately define quality specifications for product master data. By defining attributes and macros in spreadsheet files, wholesale trading companies attempt to standardize product master data sets requested from their suppliers. However, a considerable number of files provided by suppliers are incomplete or incorrect. This gives rise to frequent check backs. Furthermore, it is worth stressing, that our analysis of these tools revealed several weaknesses. Some of the Excel files used in the companies covered by our study are difficult to use, partly incorrect or technically outdated. This makes it more difficult for suppliers to provide master data in an appropriate quality.

Numerous incomplete and defective data sets provided by suppliers require frequent check backs. E-mail messages and telephone calls are regularly used to support mutual adjustment by data experts at trading companies and their suppliers.

In some cases, suppliers provide master data sets in EDI messages. Only a very limited set of suppliers provide master data for wholesale customers via customer portals or online product catalogs. Product identification and classification standards are used to a very limited degree in the companies covered by our study. Only one company utilizes a data pool. On the one hand, a more intensive use of standards and tools provided by electronic intermediaries, e.g., data pools and electronic catalogs, may contribute to improving product data quality in inter-organizational product information sharing and to reducing the workload for most trading partners. On the other hand, these tools obviously need to be complemented by bilateral arrangements that account for specific requirements of the particular trading partners.

Our findings confirm the results of previous research [1, 4, 5, 8, 9, 14, 18, 19, 33]. Earlier studies revealed that EDI connections, identification and classification standards, product catalogs, and data pools are not widely adopted in most industry sectors. Instead, most companies prefer Excel files and personal communication to coordinate master data quality in inter-organizational product information sharing.

These phenomena can be explained with experts' perceptions of strengths and weaknesses of the coordination mechanisms and tools described in section 5.1. Personnel in master data teams and procurement staff in the companies covered by our study either do not have sufficient knowledge of standards, EDI technology, product catalogs, or data pools or they are convinced that these resources are too cost-intensive or not flexible enough.

6 Conclusion

6.1 Implications for Practitioners

The insights we gained in our study indicate some interesting options for improvement. We believe the recommendations presented in this section might also be relevant for other organizations facing similar issues.

Only one company included in our study explicitly mentions exchange of product information in framework contracts with trading partners. This could encourage other companies to do the same to raise awareness for achieving and maintaining adequate quality of master data in inter-organizational product information sharing.

The process of coordinating quality of product information with trading partners is only scarcely systematized and automated. A higher level of standardization and automation could help increase process efficiency, improve master data quality, and reduce personnel cost. This, however, would require establishing a well-defined process that is accepted by all trading partners, specifically by master data experts. Further above we have outlined the current state of the process for coordinating product master data quality. Defining and testing an improved process that is more intensively systematized, automated, and accepted by all parties would be an essential improvement. An improved process including automated mechanisms and tools could release all trading partners from manual data entries and cost-intensive rework after having received incomplete or inappropriate master data sets.

We do not expect that such a process can be established in the short term. In the meantime, however, regular meetings of master data experts of selected suppliers and customers could help to improve the exchange of master data with at least some trading partners. Best practices that hopefully result from these forms of cooperation could then be adopted by more trading partners.

6.2 Research Opportunities

Although the nature of our study is such that no universally applicable conclusions can be drawn, our findings at least illustrate the necessity to conduct more in-depth research into coordinating master data quality in inter-organizational product information sharing. There are a number of interesting extensions for future research.

One area is to include more companies in future studies. It would be particularly interesting, to interview master data experts employed at suppliers and their contact partners in trading companies in order to gain more complete insights into benefits and downsides of applying coordination mechanisms and tools in inter-organizational master data sharing. Another option to broaden research is to explore inter-organizational coordination in other sectors (e.g., manufacturing, healthcare etc.) to identify potential differences in coordinating quality of product information.

We also encourage scholars and practitioners to design, implement and evaluate software tools that support coordinating quality of product master data in inter-organizational relations. Such tools could help to define requirements for master data to be exchanged among trading partners. Software tools could support examining the extent to which requirements are fulfilled. Some authors [17, 34–36] have proposed platforms and services for improving quality of shared data in cooperative information systems. The functionality of these tools seems to be limited and none of the tools has been developed to a product that is available on the market. However, the papers may provide an interesting starting point for the design and development of more comprehensive tools. Automated coordination tools could provide workflows for adjusting incorrect data or complementing incomplete data sets between trading partners. Once, such a tool is completed it would be highly interesting to explore whether it can help to reduce costs of coordinating quality of master data and, if so, to what extent.

Abstract. Optimizing the performance and availability of an IT service in the design stage are typically considered as independent tasks. However, since both aspects are related to one another, these activities could be combined by applying performability models, in which both the performance and the availability of a service can be more accurately predicted. In this paper, a design optimization problem for IT services is defined and applied in two scenarios, one of which considers a mechanism in which redundant components can be used both for failover as well as handling overload situations. Results show that including such aspects affecting both availability and performance in prediction models can lead to more cost-effective service designs. Thus, performability prediction models are one opportunity to combine performance and availability management for IT services.

Keywords: IT Service Management, Availability Management, Capacity Management, Performability Modeling, Redundancy Allocation Problem

1 Introduction

IT service providers are faced with the challenge of designing high-quality and cost-effective IT systems in order to stay competitive [1]. In particular, degraded quality of service may cause the violation of service level agreements, leading to penalty costs and loss of reputation for the service provider [2]. Two of the most crucial quality aspects of an IT service are performance and availability [3]. In order to ensure that a service achieves the desired quality level at a minimum of costs, capacity management for performance as well as availability management have to be performed carefully [3].

However, managing the quality and costs of an IT service is difficult as these are complex systems with specific requirements, an architectural mix of diverse hardware and software components as well as skewed workload [1], [4]. In order to have accurate estimates about service quality, an IT service is usually tested before its deployment [5], [6]. Nevertheless, there are decisions to be made in the service design stage and their correction in the deployment or operation stage may be very costly [7], [8]. This applies especially for architectural decisions which have the greatest impact on quality attributes [9].

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Bosse, S.; Müller, H.; Turowski, K. (2017): Integrated Optimization of IT Service Performance and Availability Using Performability Prediction Models, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 76-90

Therefore, performance and availability modeling techniques are effective in the service design stage, as they provide a first estimate about the service's quality level [1], [5], [10]. On the basis of these models, different design alternatives can be compared to minimize service costs [1], especially if alternatives are recommended automatically [4]. For that purpose, optimization approaches can be applied. For instance, in [3] a heuristic for service-component allocations is presented to support capacity management. Other examples include optimizing the redundancy design for availability management by defining redundancy allocation problems (RAP), e.g. in [11], [12].

Despite its advantages, a recent report of Gartner comes to the conclusion that most enterprises under-invest in performance modeling for capacity management [13]. One reason for that may be that most existing approaches for capacity management consider performance in isolation, disregarding dependencies to other quality attributes such as reliability, availability, or scalability [14], which can be subsumed under the term dependability [15]. Thus, performance prediction models overestimate the ability of a service to satisfy its consumers [16]. On the other hand, applying pure dependability approaches will often lead to conservative quality estimates so that cost saving potentials are not addressed [16]. Hence, combined models for availability and performance prediction could depict an opportunity to integrate capacity and availability management in order to achieve a cost-effective and high-quality service design.

For approaches in which both performance and dependability aspects are considered, the term performability modeling can be used. While performability prediction models have been developed to analyze a single system, their possible impact on design optimization considering a large variety of systems has not been researched. Therefore, the question remains if an optimization approach on the basis of performability models would allow for higher cost-effectiveness of IT services than if isolated approaches are applied. In order to answer this question, an optimization problem is formulated in this paper for the capacity and redundancy design of an IT service. A simple Petri net performability model is used to estimate the quality and costs of a service design. In an illustrative example, it can be demonstrated that performability models provide the flexibility to include mechanisms affecting both performance and availability of a service such as an elastic standby redundancy derived from cloud computing concepts, which is not only used in failure but also in overload situations. This leads to a more effective peak-load handing [17] and, thus, to design suggestions with less costs while satisfying performance and availability service level objectives.

2 Related Work

In this section, relevant basics of capacity and availability management as well as performability modeling are introduced as the basis for the optimization problem.

2.1 Capacity Management and Performance Models

The capacity management process is an important part of the design stage in IT service management frameworks such as the ITIL [18]. Its purpose is to ensure that an

IT service meets the current and future performance-related requirements in a cost-effective manner [18]. Related terms are capacity planning and software performance engineering. The process of capacity management relies on performance models estimating the relation between input (workload model, design alternatives) and output variables (e.g. response time, throughput, or utilization) [7]. Performance models can be classified into measurement- and model-based approaches [5].

Measurement-based performance models require existing systems to be observed for at least some of the possible design alternatives [19]. The properties of non-existing systems can be estimated by using machine learning methods such as support vector machines or random forests [20] (black-box approach). Nonetheless, these performance models often lack transferability to other problem classes [5]. In model-based approaches, analytical performance models are used to describe the relationship between input and output variables (white-box approach). Examples are queuing networks [7], queuing Petri nets [4], (generalized) stochastic Petri nets [10], or stochastic reward nets [16]. However, constructing these models requires insight into the performance characteristics of the used system components, which may not be accessible especially for third-party software components [21]. Besides the pure measurement- or model-based approaches, a grey-box approach can be applied, e.g. by using gained knowledge of existing components and design patterns [5] to combine low-level measurements and high-level analytical models [8].

In order to evaluate performance models, the following techniques can be used: prototyping, testing, simulation, or analytical evaluation [5]. While prototyping and testing provide more accurate results, these approaches are also very costly and can only be applied in later lifecycle phases [6]. On the other hand, analytical and simulation techniques can be applied in the design phase of the service lifecycle [5]. Analytical evaluation is faster, but some aspects of the system performance may not be considered (e.g. G/G/n queues). In this case, simulation approaches are more effective [4], [5], [7] which also allow for dynamic analysis of performance metrics [22].

After performance models can be constructed and evaluated, many possible design alternatives should be analyzed in order to find a suitable cost-performance tradeoff [1]. Since these alternatives should be compared quickly [7], an optimization approach can be applied. For instance, in [3] an optimization problem is defined to find the minimum number of computing nodes for a set of IT services, and a component-allocation heuristic is developed to identify (sub)optimal solutions.

2.2 Availability Management and the Redundancy Allocation Problem

Similar to capacity management, availability management is an IT service design process aiming at meeting the agreed availability requirements at minimum costs [18]. A related term is software reliability engineering, which is, however, more focused on single software components than on complex systems of (third-party) components [23]. As in capacity management, black- and white-box availability models can be constructed and evaluated by different methods. White-box approaches for availability modeling include combinatorial, state-space-based, or hierarchical techniques [24].

Basically, the availability of a system can be increased by applying fault removal, fault prediction, fault prevention, and fault tolerance approaches [15] while the latter two can be considered in the design phase [25]. However, preventing faults by increasing component reliabilities is limited [26] and, thus, fault-tolerance has to be applied in order to achieve high-availability, e.g. by introducing redundancy mechanisms [27]. Redundancy means to provide additional components with equal functions to cover faults of the original components. Redundant components may be purchased from another manufacturer or developed by different teams to decrease the probability of common-cause failures (heterogeneous redundancy). Additionally, active and passive (or standby) redundancy can be distinguished.

A component in active redundancy is ready to instantly takeover for a defect component. Passive components are in a lower state of readiness and need some time for takeover. Depending on the state and the time to activation, standby components can be classified into cold-, warm-, and hot-standby [28]. With increasing time to activation, usually failure rate and operational costs of a passive component are decreased [27]. In order to decide which components may require redundancy mechanisms and which type of redundancy has to be used, a redundancy allocation problem (RAP) can be defined. A RAP is a NP-hard optimization problem [29] and is often characterized by the following aspects:

1. A system consists of n required subsystems.
2. In each subsystem, a number of components can be operated in redundancy.
3. Components fail and recover according to random time distributions.
4. For each subsystem, a number of components has to be identified so that availability is maximized or costs are minimized subject to constraints.

In recent years, RAP definitions with increasing complexity have been developed to include characteristics of IT systems. For instance, standby redundancy and its effects have been considered in [12], [28]. RAP are usually solved using (meta-)heuristics [30] such as genetic algorithms, e.g. in [11], [12], [28].

2.3 Performability Modeling and Design Optimization

While isolated performance and availability models are still subject of research, several approaches try to combine both dependability and performance aspects as there are significant relations between those. One reason for this is that availability is not defined as the absence of failures, but as the probability of success [31]. Thus, unavailability is not only caused by failures but also by overload situation which lead to request rejections [19]. Furthermore, when response times increase, users will abort waiting for a reply and will consider the service as unavailable [7]. On the other hand, component faults may lead to degraded capacity of a service.

In order to consider these aspects in a more accurate model of performance and availability, the concept of performability models can be applied [31]. Examples can be found in [5], [10], [16], [19]. However, there is a lack of design optimization approaches that are based on performability models although some RAP definitions are able to address performance aspects superficially since system capacity is formed by the components operated in active redundancy. For instance, multiple component states have been introduced to model performance degradation of components. In order to compute the system performance from component states, the loss of load probability (LOLP) index is used as a measure for unavailability (e.g. in [32]) which has been originally defined for electrical power systems as the probability that demand exceeds capacity. In an IT system, throughput is a related concept [33]. In a parallel subsystem of (active) redundant components, the throughput can be computed as the sum of the components' throughputs. The throughput of a series system is defined as the minimum of the subsystems' throughputs. In order to estimate the availability of the system, the load of the system is set in relation to its throughput.

The disadvantage of this approach is that performance is not considered in detail so that, for instance, response times cannot be analyzed. Furthermore, all subsystems have the same load at every time. In an IT service, however, a subsystem may be visited by a request more than once and the processing time in a subsystem can differ significantly [7]. In addition to that, the LOLP approach leads only to estimates about the mean utilization of components which makes it difficult to get accurate estimates for operational costs which may depend strongly on current utilization as e.g. the power consumption of a CPU. Thus, this approach is not suitable for an effective design optimization for a combined capacity and availability management.

3 The Redundancy and Capacity Allocation Problem (RCAP)

Our study of related work revealed that no suitable design optimization problem has been defined on the basis of performability models. In order to investigate the feasibility of performability modeling for design optimization, a new optimization problem is presented in this section on the basis of the RAP. The objective of the optimization problem is to minimize the costs of an IT service while satisfying mean response time and availability constraints. Although the capacity of a service is determined by the components operated in active redundancy, the problem is named redundancy and capacity allocation problem (RCAP) to underline the differences to classical RAP approaches in which performance aspects are not sufficiently addressed.

In order to demonstrate the opportunities of performability models, two different strategies for components in passive redundancy are considered: in the classical standby case, passive components are activated if and only if another component has failed. In the elastic standby scenario, these components are activated only in case of overloads, which may be caused by load peaks as well as component failures.

3.1 Assumptions

An IT service is consumed by customers that send independent, comparable requests. In order to respond to a request, a sequence of operations has to be performed. An operation is executed in a subsystem consisting of functional equivalent components. Each of these components can serve a number of operations concurrently and the processing time depends on the capacity of the component.

A component can have three states: active, standby (passive), and failed. Initially, a component is either active or standby. In active mode, a component fails and is recovered again after random time intervals. A component does not provide capacity if it is failed and cannot fail if it is in standby mode. If a standby component has to be activated, a random time elapses before the component is set to active mode and may fail. In addition to component failures, the whole service can also be affected by a failure, which leads to the rejection of all requests currently processed (disaster case). All failure, recovery and activation times as well as inter-arrival and processing times can be described by parametric random distributions.

If all servers are busy in a subsystem, operations to be processed are queued until a server becomes available (FIFO strategy). An admission control can be enabled to avoid unnecessary processing if a user will likely abort waiting for a reply by automatically rejecting requests after a certain time in the system (timeout).

The costs of the service are the sum of capital and operational costs. While the former is determined by the acquisition costs for components, the latter costs are compound of the costs arising for recovery activities and the components' operational costs that depend linearly on their utilization levels. Another linear dependency is assumed between components and system operational costs, which is characterized by the power usage effectiveness (PUE) that ranges in practice from 1.2 to 3.0 [34].

3.2 Problem Definition

A redundancy and capacity allocation problem (RCAP) is characterized by a timestep Δt, a factor PUE as well as by random variables R, TTF and TTR describing inter-arrival times, times to failure and times to recover for an IT service. Furthermore, a number of operations o and subsystems n have to be defined as well as a function ops mapping operations to subsystems. Another function S maps the operations to random variables describing the standard service time. In addition to that, a timeout to can be defined for admission control.

A set of components is associated with each subsystem. Each component i is characterized by its number of servers for concurrent operations s_i, a service time norm factor f_i, random distributions TTF_i and TTR_i, a random distribution TTA_i for its time to activation, its acquisition costs ac_i, recovery costs rec_i as well as operational costs for Δt in standby state $standby_i$, in idle mode $idle_i$ and if fully utilized $full_i$.

A solution candidate x to the RCAP consists of $2n$ sets of component selections describing the components to be operated in active as well as passive redundancy for each subsystem. Thus, the optimization problem can be defined as follows:

$$\min_x C(x,t) \text{ s.t. } A(x) \geq A_0 \wedge RT(x) \leq RT_0 \tag{1}$$

Since the costs of a service C depends on the time interval to be considered, a parameter t has to be defined as well as the service level objectives for availability A_0 and response time RT_0.

An overview of all required parameters to define a RCAP are presented in Table 1.

Table 1. Parameter overview for the RCAP

Problem Parameters	Description
$\Delta t \in \mathbb{R}$	Timestep for operational costs definition
$PUE \in \mathbb{R}$	Power usage effectiveness of the IT service
$R: \mathbb{R} \to \mathbb{R}$	Distribution of request inter-arrival times
$TTF, TTR: \mathbb{R} \to \mathbb{R}$	Distribution of time to failure/recovery for the service
$o, n \in \mathbb{N}$	Number of required operations and subsystems
$ops: \mathbb{N} \to \mathbb{N}$	Function mapping operations to subsystems
$S: \mathbb{N} \to (\mathbb{R} \to \mathbb{R})$	Function mapping operations to standard service time distributions
$to \in \mathbb{R}$	Timeout after which admission control is applied
$s_i \in \mathbb{N}$	Number of servers in a component *i*
$f_i \in \mathbb{R}$	Service time norm factor for a component *i*
$TTF_i, TTR_i, TTA_i: \mathbb{R} \to \mathbb{R}$	Distributions of time to failure, recovery, and activation for a component *i*
$ac_i, rec_i \in \mathbb{R}$	Acquisition and recovery costs of a component *i*
$standby_i, idle_i, full_i \in \mathbb{R}$	Operational costs per timestep in standby and idle mode as well in full operation for a component *i*

3.3 A Simple Performability Prediction Model

On the basis of the RCAP definition, a simple performability prediction model is developed that can be used to estimate availability, mean response time, and costs of the solution candidates. Due to their modeling power, a solution candidate is modeled in a generalized stochastic Petri net (GSPN), cf. e.g. [35]. In order to consider arbitrary random variables, these models are evaluated by Monte Carlo simulation.

Thus, a GSPN has to be automatically generated for each solution candidate. First, an arrival transition is defined that generates request tokens. To each subsystem, a queue place is assigned with infinite capacity for collecting incoming requests. Another place collects all rejected requests for the service. For a subsystem, a place and a corresponding processing transition are created for each server of the assigned components and are connected to the queue of the subsystem performing the next operation. The subsystem queue is connected to the server places by immediate transitions which are only active if the component is working. In the case that the corresponding component fails, another immediate transition fires tokens to the rejection place instead. To all transitions, random firing time distributions are assigned according to the component's definition.

In
Figure **1**, an example GSPN of a single subsystem of one active component with two servers is presented. Activation functions (dashed rectangles) are used to prevent requests to be rejected if the component is working or to be processed if it is failed. Request are created by the arrival transition and collected in the queue place. Depending on the component state (failed/working cycle below), requests are rejected or processed and assigned to the next operation queue.

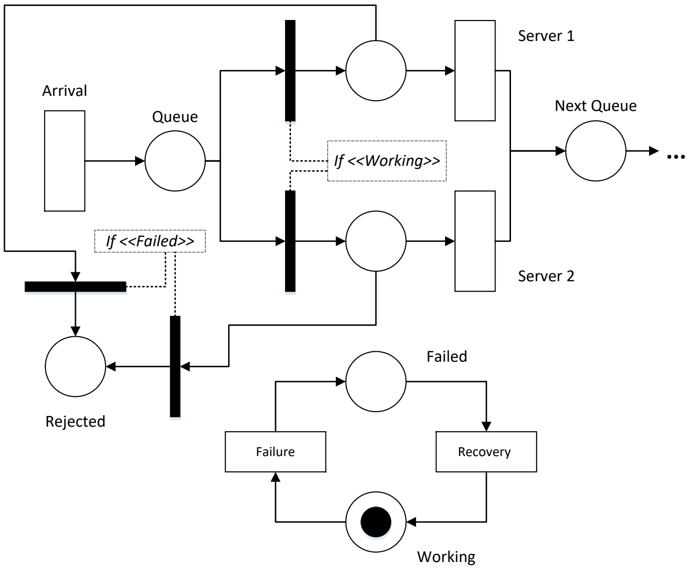

Figure 1. GSPN processing model example with an active component

In order to implement the operation sequence as well as the admission control, tokens are distinguishable (colored Petri net) by their arrival time and the current operation. Based on this information, all tokens that have been longer in the system than the defined timeout are moved to the rejection place. Additionally, a subsystem model such as presented above can map more than one operation since firing times depend on the current operation of the token. After all operations are performed, the token is moved to a place in which completed requests are stored.

While the state of an active component can be modeled by a simple failed/working cycle, for standby components, a standby place is introduced to indicate the current state of the passive component as displayed in Figure 2.

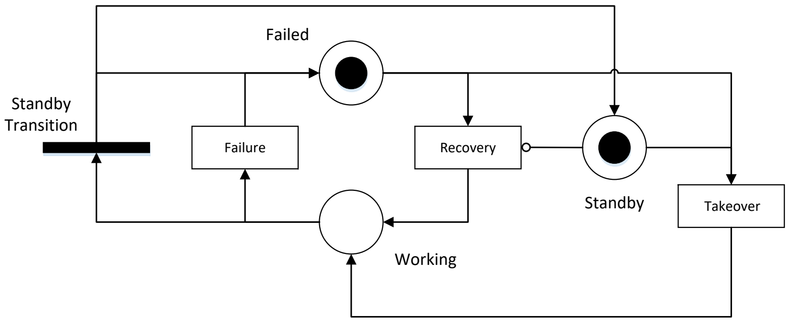

Figure 2. GSPN state model example of a passive component

In standby mode, the state of the component is equivalent to a failure, but recovery is disabled. To the takeover and standby transitions, activation functions are assigned depending on the subsystem characteristics and the chosen standby strategy. In case of the classical standby, the takeover transition is activated if an active component fails. If the active components are recovered, the standby transition is activated and the passive component changes to standby mode. In elastic standby, takeover is activated if the subsystem queue is not empty and all working servers are busy (overload situation). The component is deactivated again if none of its servers are busy.

For each completed request, the response time is the difference between its completion and its arrival time. The mean response time of a solution candidate is computed from all request response times at the end of a simulation run. Availability is defined as the ratio of completed requests to arrived requests minus those in completion. The costs are the sum of acquisition, recovery, and operational costs. Impulse rewards for recovery costs are assigned to recovery transitions. The utilization of a component is computed after each timestep Δt and is used to compute its current operational costs c_i linearly based on values $idle$ and $full$. This value is used in order to estimate the service operational costs C_{op} up to a time *t*:

$$c_i(t) = \begin{cases} standby_i & \text{, if} \ll Failed \gg \\ idle_i + u_i(t) \cdot full_i & \text{, otherwise} \end{cases}$$
$$C_{op}(x,t) = \frac{PUE}{\Delta t} \cdot \int_0^t \left(\sum_{i \in x} c_i(\tau) \right) \mathrm{d}\tau \tag{2}$$

By simulating the behavior of the solution candidate in several independent runs, mean values for response time, availability, and costs can be computed to characterize a solution candidate with statistical significance.

3.4 A Genetic Algorithm to Solve the RCAP

The RCAP defines an infinite search space that has to be efficiently explored for identifying (sub)optimal solutions. Therefore, a genetic algorithm is defined, which is characterized by problem-specific operations for evaluating a solution's fitness, encoding a solution, initializing random solutions, altering (mutation) and recombining solutions as well as selection and termination criteria.

The suitability of a solution to solve the defined RCAP is characterized by its fitness to be maximized. According to [11], a penalty function is used to avoid infeasible solutions in the end. Since costs has to be minimized, the fitness is defined as the negative costs minus penalty:

$$f(x) = -C(x) - \delta \left(\frac{\max\big(0, A_0 - A(x)\big)}{NFT_A} + \frac{\max(0, RT(x) - RT_0)}{NFT_{RT}} \right) \tag{3}$$

In order to scale the penalty, pre-defined near-feasibility thresholds (NFT) are used as well as a factor δ, which is the difference between the minimal cost of all solutions and the minimal cost of feasible solutions (cf. [36]).

For the encoding, a solution candidate is represented by two vectors for the active and the passive configuration. Each vector consists of n integer vectors corresponding to the indices of the defined components for a subsystem. An example encoding for three subsystems may look as follows:

$$\Big(\big((2,1),(1),(2,2)\big),\big((\ ),(1),(\ )\big)\Big)$$

In this solution candidate, two different components are operated in active redundancy in the first subsystem (of the second and the first type in this subsystem), but no component is operated in passive redundancy (empty bracket in the second vector). In the second subsystem, however, two components of the first type in this subsystem are used whereas one is in active and the other in passive redundancy.

Solution candidates are generated by choosing random components for the subsystems. The number of components in a subsystem is randomly chosen according to a pre-defined distribution. If a solution is to be mutated, a subsystem is randomly chosen and a random operation is applied to active or passive sets: with 20% probability, a component choice is exchanged. A component is either added or removed with 40% probability. The remove operation is disabled if a subsystem consists only of one active or zero passive components. For the recombination of two solutions, separate uniform crossovers are applied for the active as well as the passive configuration. Thus, subsystem configurations are exchanged between both solution candidates.

In the genetic algorithm, first a number μ solutions are generated and their fitness is evaluated. In the main loop, λ solutions ($\lambda > \mu$) are created by recombination (whereas fitter solutions are more frequently recombined) and mutation is applied with a certain probability p_{mut}. After the fitness of the new solution candidates is evaluated, μ solutions are selected from those by performing tournament selection for the next loop (generation). In tournament selection, μ tournaments of t solutions are performed in which the kth fittest solution is selected with probability $p_t(1-p_t)^{k-1}$. The algorithm results in the fittest solution after $maxGen$ generations.

4 An Illustrative Example: Sales and Distribution

The advantages of the performability optimization approach are demonstrated in a small and illustrative example describing an IT service with eight operations. For that purpose, the GA, model generation and simulation have been implemented in the java-based simulation framework *AnyLogic 6.8.2*. The simulation results have been verified by comparing test instances with results from Markov-based queuing and availability models.

The operations to be performed describe a standard business process for a delivery from stock scenario with prior lead generation and subsequent material requirements check. Therefore, five different subsystems are involved in this process (cf. Table 2). In order to define service times, data from a standard benchmark for the sales and distribution modules of SAP ERP business applications has been used. In this context, the capacity of components can be measured in the normalized metric SAPS (SAP Application Performance Standard), where 100 SAPS equal 2,000 fully processed order line items per hour. Standard service times have been computed from mean response times of various benchmark results that had been performed over the last ten years and are presented in Table 2. Using the reciprocal of these values as a rate, exponential random variables have been defined for the standard service time of each operation. These times are valid for the mean processing power of all analyzed components which is 5332.62 SAPS.

Table 2. Operations, subsystems, and standard service times of the illustrative example

Operation	Subsystem	Mean standard service time in ms
Maintain Leads	Customer Relationship Management (CRM)	2,451.65
Create Sales Order	Sales and Distribution (SD)	1,415.69
Create Outbound Delivery	Logistics Execution (LE)	1,309.62
Display Sales Order	Sales and Distribution (SD)	883.65
Change Outbound Delivery	Logistics Execution (LE)	1,101.17
Create List of Sales Orders	Sales and Distribution (SD)	1,923.90
Create Billing Document	Billing (B)	2,121.83
Display Stock/Requirements Situation	Production Planning and Control (PP)	557.71

In each subsystem, three possible components can be chosen that are presented in Table 3. The norm factor for the service times is computed by relating the SAPS per server to the mean value of the standard service times. For the computation of operational costs, an energy price of 0.2814 €/kWh is assumed.

Table 3. Available components for the subsystems

Label	*ac* in €	Capacity in SAPS	*s*	*f*	*standby* in ct/h	*idle* in ct/h	*full* in ct/h
A	2,494	11,500	8	3.70	0.02	3.83	6.22
B	21,580	150,000	72	2.57	0.28	2.43	15.67
C	4,669	43,000	16	1.99	0.14	1.58	5.52

All components share the same transition times: time to failure is exponentially distributed with a mean value of 8,760h, time to recover normally distributed with mean 1.73h and a variance of 0.5h and time to activation normally distributed with mean 30s and variance 5s (cold standby). The simulation is run for three years to map depreciation of acquisition costs (26,280h). A *PUE* of 2.0 is assumed, meaning that for every unit of energy consumed by the components a unit of energy is consumed for supporting systems. For an arrival rate of 18,000 requests per hour (exponential distribution of inter-arrival times), the mean response time should be lower than 30s and the availability should be at least 99.95%. The timeout for requests is 100s.

For both the classical and the elastic standby scenario, ten iterations of the genetic algorithm are performed. In each of these iterations, ten generations are conducted with $\mu = 30, \lambda = 60, p_{mut} = 0.2, t = 4, p_t = 0.9, NFT_A = 0.0001$ and $NFT_{RT} = 5s$. Solution candidates are initialized by choosing a normally distributed number of components in each subsystem (mean 3, variance 2 for active and mean 1, variance 0.5 for passive components). In order to evaluate a solution, 25 simulation replications are performed. In Table 4, the mean and standard deviation of the fitness values in the ten iterations are presented. It can be stated that in the elastic standby case solutions with less cost are identified on average.

Table 4. Fitness statistics for ten iterations in both scenarios

	Classical	Elastic
Mean fitness	-215,180.52	-128,415.66
Standard deviation of fitness	54,668.21	49,718.86

A comparison of the fittest solutions of both scenarios over all ten iterations is given in Table 5, using the labels of Table 3 to indicate recommended components for the subsystems presented in Table 2. For each subsystem, the recommended components in active (a) and passive (p) mode are displayed. While availability and response time are comparable in the elastic case, the costs of the service are significantly reduced in comparison to the classical standby scenario. The main reason for this is that fewer components are used in active mode.

Table 5. Fittest individuals in the classical (above) and the elastic standby scenario (below)

CRM		**SD**		**LE**		**B**		**PP**		***A***	***RT***	***C***	***-f(x)***
a	p	a	p	a	p	a	p	a	p	0.9…	in s	in €	
CCAA	A	CCCC		ACC		CC	C	AAAC		99407	25.18	119,041	131,370
AC	C	CC	C	CC		C	C	C	C	99490	24.60	84,231	84,233

These results demonstrate that a classical optimization approach will result in higher costs since capacity for overload situations has to be provided by the active components and standby components are only used in failure cases. In the elastic scenario, however, some of the needed capacity for overload situations can be provided by the standby components while failover is still applicable. Thus, considering a mechanism affecting both availability and performance in an integrated model leads to a more cost-effective service design.

5 Conclusion

In design optimization for IT services, most approaches rely on isolated models for performance or availability estimation. However, defining optimization problems on the basis of performability models considers design mechanics affecting both capacity and availability of an IT service. In this paper, it could be demonstrated that addressing these aspects in an integrated prediction model can lead to more cost-effective design suggestions than if performance and availability optimization are considered separately. Hence, this paper reveals some of the potential of integrated availability and capacity management for IT service management.

Although the developed simulation approach provides accurate results, the runtime of the optimization iterations may exceed several hours due to model stiffness, i.e. the great difference between transition rates of performance and availability state changes in a monolithic model [16]. This clearly affects the scalability of the approach to solve larger problem instances. One solution to this problem without affecting accuracy could be the massive parallelization of the independent simulation replications as well as of fitness evaluations. In this context, the scalability of the approach should be tested in large-scale problem instances in which service and transition times are not exponentially distributed to demonstrate the suitability of the simulation approach.

On the other hand, some assumptions made to demonstrate the feasibility of the applied approach have to be overcome in future work to increase applicability. This includes the assumption of the linear dependency between utilization and operational costs [37] as well as the use of mean response time as an objective while service level agreements normally include percentile guarantees. However, the developed approach can easily be adapted to result in arbitrary percentiles for response time. Furthermore, mean values of replications are used for fitness evaluation of solution candidates. Instead, confidence interval boundaries can be reported which would introduce uncertainty in the optimization. Another limitation is the fixed capacity of the defined components which may not reflect elastic and pay-per-use cloud computing services. This fact may be addressed by defining component capacity as a dynamic range with according costs. Additionally, the defined prediction model is not covering all aspects influencing response time and availability, for instance, operator errors which are reported to be one of the major causes for unavailability of IT systems [38]. Considering these limitations in future work as well as introducing additional quality aspects such as security could lead to even more realistic quality and cost estimates and, thus, to better service designs.

How to Empower Users for Co-Creation – Conceptualizing an Engagement Platform for Benefits Realization

Martin Semmann[1] and Christian Grotherr[1]

[1] University of Hamburg, Department of Informatics, Hamburg, Germany
{martin.semmann, christian.grotherr}@uni-hamburg.de

Abstract. Organizations invest huge portions of their budget in IT with the goal to realize benefits as improving work practice and establishing new processes. To achieve this goal, users are engaged throughout projects by various methods and approaches. Nevertheless, after the completion of a project, users lack power and opportunities to further realize benefits and thus assuring the overall success of a project. To close this gap, we present the concept of an engagement platform that empowers users collectively to induce change initiatives that enhances the realization of benefits in the post-project phase. By doing so, benefits management practices undergo a paradigm shift from recent top-down management towards bottom-up realization of benefits. This change in perspective also incorporates a service systems perspective as it focusses on the dynamic configuration of actors and resources to enable value creation in a complex context.

Keywords: service system engineering, software introduction, technochange, user-generated services, benefits management

1 Introduction

Organizations invest huge portions of their budget in IT with the goal to realize benefits as improving work practice and establishing new processes [1, 2]. To achieve these objectives, IT investments must be well embedded in the organizational context resulting in complex project constellations. Additionally, anticipated benefits of the software can only be created in distinct contexts by various users utilizing the software. Thus, projects contribute to a service system, as a sociotechnical artifact in a distinct organizational environment is instantiated [3]. Following, benefits realization is done by using this sociotechnical artifact in a specific context while integrating various resources and actors [3]. Engaging users is therefore state of practice during projects by various methods and approaches [4, 5]. This engagement is done by selecting some users with a top-down approach within the project. This top-down approach is advantageous to get projects approved and delivered. Whereas a much broader or even general participation is complex, expensive and hard to keep target-oriented during a

Semmann, M.; Grotherr, C. (2017): How to Empower Users for Co-Creation - Conceptualizing an Engagement Platform for Benefits Realization, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 91-105

project. Especially, considering major changes in software as introductions of new software or significant upgrades only representing users can be engaged efficiently throughout the project. Thus, most users cannot actively participate in the adaptation of software and organizational changes. Even more due to the context of use that is defined by the actors involved and the organizational boundaries this limited engagement leads to limited ability to realize benefits entirely. This limitation even increases after the completion of a project, users lack opportunities and power to further realize benefits and thus assuring the overall success of a project [6]. Recent literature reviews on benefits management from a project perspective [31, 32] show that, in post-project phase, there is no established method or concept to support emerging benefits as well as intended but unrealized benefits which is also reflected in a qualitative study [6]. This lack of engaging users is also mirrored as a third of installed software in organizations is estimated to be not used at all [7].

By utilizing a service systems perspective with the users as facilitators of value in context, a bottom-up approach seems more beneficial to enhance capturing of benefits to overcome these limitations in the post-project phase. Especially, regarding varying time lags and emergent benefits that have not been anticipated [4, 11-13]. Based on this perspective, a shift towards a bottom-up approach for enforcing co-creation within the community of users to further realize benefits and thus improving the solution and its value delivered collectively [8, 9]. A promising approach to instantiate such a bottom-up engagement platform is internal crowdsourcing as it aims for collaborative value facilitation within an organization by potentially engaging all users [33]. This active engagement also copes with the need for organizational change that complements new or changed IT to realize benefits [11]. This is also recognized in literature on IT-enabled transformation that emphasizes that capturing benefits is a critical post-project activity [10]. Following this argumentation, the paper answers the following research question: *How can a concept to empower users for co-creation of change initiatives be designed to enhance the possibilities to realize benefits?*

We do so by presenting the concept of an engagement platform that empowers users to collaboratively induce change initiatives that enhances the realization of benefits in the post-project phase. The resulting platform seeks to catalyze the potential of value co-creation as it decidedly addresses the context of users' engagement with the delivered software during the introduction. To enable value creation between actors of the service system, users should be empowered to implement change initiatives and thus, foster timely realization of benefits. This novel approach exceeds common crowd initiatives established for example within innovation management as change initiatives are not only identified and ranked, but explicitly realized within a specific organizational context.

Thus, benefits management practices undergo a paradigm shift from recent top-down management towards bottom-up realization of benefits. This shift has the potential to increase the ability to change organizations and their work practice drastically [14].

As service research [3] as well as design research [15, 16] calls for evidence-based cumulative research, we propose the concept to an engagement platform as the result of the design phase of our design science project. The remainder of the paper is therefore structured as follows: the second section builds up a foundation of the research by defining and summarizing related research. In the third chapter, we describe the methodology used to develop the engagement platform. All components of the concept are derived and comprehensively described in chapter four. The paper closes with a conclusion and outlines future research.

2 Conceptual Foundations

2.1 Service Systems Engineering

Service systems describe a configuration of actors and resources and their interaction [1] in order to enable co-creation of value by sharing resources among actors [2]. This is in line with the definition given by Böhmann et al. who conceptualize a service system as "complex socio-technical systems that enable value co-creation" [3]. Research has recognized the emergent importance of service systems and the need for establishing further research within this field such as service science [1, 4]. This research is supposed to address the interaction between actors regarding human agents with knowledge and skills as well as resources as technology, information, physical artifacts which interact in co-creation [1]. Service systems engineering elaborates therefore on the importance of systematic design and development of such service systems and calls for research on evidence-based design knowledge [3]. Service systems research consequently applies the principles of service-dominant logic which constitutes value creation through collaboration and contextualization [5]. Accordingly, contextualization emphasizes that producer and consumer create value collaboratively by configuring actors and resources specifically in a context [6, 7]. Hence, service systems enable value co-creation through configuration of actors and resources guided by its value proposition [5]. Understanding service systems as configuration of actors and resources with the aim of searching for principles and approaches that can help to improve value co-creation [8] we focus on the integration of these resources in order to foster the end-user co-creation of value within software implementation projects to realize benefits jointly.

2.2 Internal Crowdsourcing

Crowdsourcing is an IT-enabled phenomenon which is based on social IT like wikis, blogs or social networks [9]. Crowdsourcing can be defined as using information technology to connect various potential user groups to accomplished tasks by voluntary crowd workers often motivated by mutual benefits [10]. One main characteristic of crowdsourcing is the location of the crowd, which can be distinguished between external (e.g. communities of interest, customers) and internal (employees). External crowdsourcing has been applied in different industrial contexts as exemplified by the cases of LEGO [11] and SAP [12]. Yet, little is known about building and engaging a crowd within organizations [9]. As shown by Zuchowski et al., internal crowdsourcing has characteristics which distinguish it from external crowdsourcing. For example, the crowd is comprised of employees and is thus long-term oriented rather than independent ad-hoc and short-term-oriented external crowds [9]. An extensive literature review stated conflicting definitions and conceptualizations of internal crowdsourcing in literature [9]. The authors define internal crowdsourcing as “an (a) IT-enabled (b) group activity based on an (c) open call for participation (d) in an enterprise” [9]. This definition is in line with an engagement platform from a service systems perspective and therefore bears the potential to support benefits realization. Another characteristic is the need for organizational culture management skills, because the approach requires an open organization where employees can collaborate and debate with each other without having cultural boundaries [13]. A characteristic of external crowdsourced solutions, on the other hand, is that the design has the potential to reveal ‘outside the box’ information, while an internal crowd may also be suitable to solve contextualized, enterprise-centered problems [11]. In addition to location, the task is an important factor for distinguishing crowdsourcing approaches [14]. Crowds can be engaged to gain access to a diverse knowledge base as tasks vary between low levels of complexity, as considered in research on microtasking or microworking [15], to tasks with increasing complexity such as ranking, sharing knowledge, ideation to design and development of new solutions. While tasks with low complexity can be crowdsourced externally to increase productivity by reducing time and costs, knowledge-intensive tasks with a high complexity will often preferably be allocated to internal crowds as only an internal crowd is fully aware of a given context.

3 Research Design

The research project follows a design-oriented research strategy [16] and is conducted by utilizing the Design Science Research Methodology [17] to systematically and iteratively design, develop as well as demonstrate and evaluate a sociotechnical artifact in a suitable context.

Therefore, the first phase Problem Identification and Motivation aims for defining the research problem and adjusting the target of the solution. This deep understanding of the problem space defines the vision of the to be designed artifact. This research project follows the problem-centered initiation as the practical relevance is shown in the introductory section as well in following chapter. Although a lack of benefits realization targeted by software implementation projects is identified current research does not address this issue. This research therefore aims at developing a concept to empower users for co-creation of improvements to enhance benefits realization after software introductions.

In the following phase objectives of a to be designed solution are derived grounded on a previous study on post-project management in large organizations and research on service systems. The next phase Design and Development utilizes these results as the foundation of the implementation. As scholars call for cumulative research in service research [3] as well as design research [18, 19] we propose a concept as a result of the design and development phase as focus of this research. Nevertheless, as design, development, and demonstration are highly iterative phases, we include insights of the demonstration of early mock-ups and a first prototype that build the foundation of a future evaluation. This evaluation is planned to be guided by the Framework for Evaluation in Design Science (FEDS) [20]. Therefore, in the planned Evaluation phase the artifact is applied in the context of a Microsoft SharePoint introduction within the case organization. Thus, a suitable context to validate its applicability and utility by solving real problems is given [17]. The results gathered throughout this evaluation likely lead to further improvements on the initial concept.

4 Designing Benefit Realization Supporting Components

In the following section the course of the design science research project is described that leads to the design of the benefit-supporting components. The focus hereby lies on the conceptualization in the design and development phase. Accordingly, the first two phases are only shortly described as this project seeks for a cumulative communication of the results as called for by researchers [3, 18, 21].

4.1 Problem Identification and Motivation

Service systems have evolved into key concepts for research in information systems [1, 22]. Many industries such as IT manufacturing and healthcare seek to design effective technology enabled service systems that efficiently allow the configuration of the service system to meet individual needs and to create value in each context [3, 23]. As various studies show, a major problem of software introductions is that the resulting solutions is insufficiently used in organizations and thus, value is not created [24-27]. This lack of use varies from denial of use at all, users establishing workarounds to using a software but not efficiently or even effectively [25, 28, 29].

Despite this general problem description, this project is done in close cooperation with a client organization. The research takes place in a public law institution with 1.800 FTE. During an initiating workshop, the described problem was mirrored in this organization. Thus, a software introduction project was identified that fit to the described problem and has the potential to implement the to be designed concept of an engagement platform. Consequentially, the artifact aims at realizing benefits targeted by the project with a concept to empower users to co-create value within an engagement platform that integrates operant and operand resources within this service system. This is done by identifying possible improvements, discussing these, and applying the improvements collectively to realize benefits.

4.2 Objective of the Solution

With the overall problem definition as foundation for this design science research project, objectives of a solution must be identified. To do so, two approaches were taken. On the one hand, a preliminary qualitative study in twelve large organizations was conducted that evaluated the state of benefits management after a projects result is delivered [26]. The study reveals shortcomings of current practice that lead to implications for the design of the to be designed artifact (O1-4). On the other hand, literature on service systems engineering gives directions on the integration of resources and how actors can co-create value. Based on this research stream, a novel approach is taken that focusses on user-integration to co-create not only ideas for improving a software but also implementing the proposals by applying deep contextual understanding of engaging users (O5,6). The resulting objectives and their related sources are subsumed in Table 1.

Table 1. Objective of the proposed Solution

No.	*Objective*	*Source*
O1	Enforce continuity of benefits management that outlasts projects	[26]
O2	Accompany transition and early usage phases with an ongoing action-oriented approach instead of only a retrospective one	[26]
O3	Identify emergent benefits after the transition is completed and regular work practice is achieved	[26, 30]
O4	Establish ways to deal timely with improvements	[26, 31]
O5	Mobilize resources to enable user-driven change	[3, 32-35]
O6	Establish a platform that allows actors to engage	[33, 36]

The first objective considers the dynamic during projects and afterwards that ownership of benefits is changing dynamically (O1). Therefore, an engagement platform should ensure that change proposals are consistently related to the initiator or a governing actor to be able to take on actions that support progressing with the change. Thus, distinct actors are aware of the benefits related with the change and can monitor its realization. Additionally, they have the ability to communicate the usefulness. Secondly, practical insights show that current benefits management practice is mainly retrospective in the post-project phase. Therefore, a solution needs an action-oriented approach (O2) to enable actors to improve the deployed software according to the specific needs to ensure the realization of value in context. Hence, it is not sufficient to solely collect change requests to propose follow-up projects. As users establish work routines with the introduced software [37], a solution should support users by identifying further unintended benefits (O3). By doing so, users can be more engaged by improving the software and contextualize it based on their specific needs. Analogously, by establishing approaches to timely implement and thus improve the introduced software (O4) users' engagement is likely to increase and as a result benefits realization increases as well. As a major challenge in service systems engineering is the mobilization and integration of resources, a solution should incorporate approaches to do so (O5). Following Breidbach et al., the solution should have touch points that provide structural support for actors to realize the exchange and the integration of resources [36]. Finally, a solution to enable users to improve introduced software needs to be designed as an engagement platform (O6) [33, 36]. Consequently, the solution should facilitate exchange between users.

4.3 Design and Development

To address these objectives and as the third activity of the design science research process a concept is developed with the overall aim to enable end users to contribute to adaption and customization of an introduced software. Hence, the concepts integrate mechanisms to engage all users of a software recently introduced to exchange and integrate resources to improve the software. By striving for this goal a fundamental change takes place as an internal crowd is empowered to change software utilizing a bottom-up approach. This approach leads to empowered users that can propose, interact on, and realize changes to a software. In this context, opportunities are supported, which help to mobilize and access previously untapped resources of users leading to a contextualized adaptation of the software and thus bearing the potential to improve benefits realization [38]. Doing so facilitates and empowers users to build and strengthen capabilities for implementing change initiatives using dynamic resource integration as an internal crowd. This concept shifts benefits realization from strictly formalized processes towards support in collecting experience and perception of users directly affected using the new software.

As this research takes a problem-centered approach, the design is mainly driven by the aforementioned practical and theoretical insights. Due to the strong commitment of the client organization, each iteration that lead to this concept was demonstrated and refined with practitioners. Nevertheless, the concept represents an abstraction and therefore, can comprehensively be adapted to other contexts as well.

Following the objectives, the concept for empowering users to co-create change initiatives and to enhance benefits realization in software introductions consists of three core components. A user joins the engagement platform and follows the concept in a sequence by proposing a change initiative (C1). The second component (C2) aims for gaining crowd-commitment as supporting factor for realizing the change initiative and embody validation by the internal crowd if the change initiative is worthwhile realizing. Last, the third component (C3) supports users to realize change initiatives that are accepted by the crowd and deemed beneficial. However, the concept has an iterative character which allows re-entry in earlier components based on insights gained during the initial change initiative. Possible insights can be further change initiatives, spare change initiatives or insights which impacts the proposed change initiative.

Every component subsumes several functions that aim to transform an expected input into desired output. Subsequently, we describe the three core components of the concept in detail. We thereby focus on functions, their interfaces, cross-sectional dependencies, and design variables that need to be considered for instantiations of the concept in various service systems.

Proposing a Change Initiative (C1)

The aim of this component is to provide an engagement platform for users that enables them to collect ideas for change initiatives (Table 2). These initiatives are only emergent during the use of the introduced software in specific contexts. If for example, a process lacks accuracy during its runtime users can report immediately and contribute a change initiative for the redesign of this process. To propose a change initiative, users specify the change initiative (C1F1). This is done by describing the idea or issue (C1F2) and the related software as well as suggestions how a resolution could be realized on the engagement platform. To join the platform users should first create a user profile with information about skills and to further relate to matching change initiatives (C1F3). By using the platform, the profile will be extended with tags of interest for initiatives a user engaged with and thus represents a user's context holistically. Another mode to join the platform is to anonymously participate on the platform. This design decision must take into the effects of anonymity in communities' consideration as well as relatability of individual opinions. Table 2 subsumes the functions and highlights design decisions made in the organizational context of the project.

Table 2. Overview Component C1: Proposing Change Initiative

Objective O1, O2, O3	
Input idea statement, improvement proposal, solution design	
Functions	*Design Variables*
(C1F1) initialize change initiative	**idea, solution, problem**
(C1F2) describe change initiative	free text, **defined template**
(C1F3) create user profile	anonymous, **single-sign-on**, new profile
Output well formulated change initiative	

Gaining Crowd-Commitment (C2)

The overall aim of this module is to gain crowd-commitment for a proposed change initiative. Thus, users are supposed to engage to co-create suggestions and possible solution designs. Accordingly, one purpose of this component is to build communities of interests. To participate in such a community modes of crowdsourcing can be distinguished in general between the modes 'wisdom of the crowd' and 'marketplace/contest' [39]. With the aim of improving usage of software and with the boundary condition of limited members in the user base it is not suitable to compete against each other. Moreover, the overall aim is to work collaboratively on a solution to an identified problem. This is in line with the guiding definition of internal crowdsourcing which declare an 'open call for participation' [9]. Therefore, the concept should provide opportunities to discover change initiatives (C2F1). This can be instantiated using search and filter functions for new and relevant change initiatives. A more proactive and dynamic way to discover change initiatives is by demonstrating success stories related to user profiles by recommender engines.

Providing feedback for change initiative, developing suggestions and solutions (C2F2, C2F3) as well as rating change initiatives (C2F4) requires engagement between actors (C2F5). To prioritize change initiatives rating mechanisms can be implemented inspired by funding, voting and rating mechanisms. Based on the feedback and a prioritization change initiatives are selected which have particularly high and relevant benefits for software usage. To address a broad range of users, groups of interests and departments these functions must be provided across the organization to give all users the opportunity to participate as well as to involve users (C2F6). Therefore, communication such as blogs or forums are needed. Additionally, opportunities to address single users explicitly with sharing functions or with tagging systems that may suggest potential experts are needed to support communicating change initiatives and to engage users. A web-based information system which provides users a communication infrastructure is needed to allow them to share change initiatives, feedback, design discussions and helping to build solver groups. The participation of users will be strengthened in this way and they can contribute their expertise to provide improvements for a wider range of users. Gaining crowd-commitment does not only aim for gathering feedback for a change initiative but moreover to build a realization team to solve the issue and implement the developed solution design (C2F7). In this regard a user volunteers as a solver and thus teams up with the requestor and other committed users. This (virtual) formation can be supported for example by expertise matching tag systems as well as direct addressing potential solvers.

Table 3. Overview Component C2: Gaining Crowd-Commitment

Objective	O2, O4, O5, O6
Input	change initiative
Functions	*Design Variables*
(C2F1) discovering change initiative	**search function**, **success stories**, recommendations, **filter function**
(C2F2) feedback change initiative	**blog**, forum, instant messaging
(C2F3) develop suggestions and solutions	**free text**, mock-ups
(C2F4) rate change initiative	funding, rating, **voting**
(C2F5) communicating change initiative	**passive**, **active**
(C2F6) involve users, experts	**tagging**, mail, newsletter
(C2F7) building solver-team	**self-organized**, direct communication
(C2F8) govern crowd	**self-regulating**, passive controlling, community-manager
(C2F9) monitoring status change initiative	promote, remove, **provide status**
Output	(virtual) team formation, refined and validated solution design

Further mechanisms should be considered that adopt functions of managing the crowd. For example, in the case of inadequate comments guidance how to govern the crowd are required (C2F8). This might imply the need for community management as well as reporting mechanism. Additionally, by monitoring the status of a change initiative and information about recent activities, community management can actively promote or remove outdated change initiatives (C2F9). The hurdle lies in the activation of users to engage on the platform, discovering change initiatives and to participate with feedback, rating as well as solving change initiatives. Guided by the demand to design an “engagement platform to incentivize certain actors to contribute their resources and enable service-for-service exchange” [33], corresponding motivation, activation and incentive mechanism for users have to be established. Therefore, motivation and incentives can be distinguished between the source of incentive (intrinsic, extrinsic) and the object (monetary, non-monetary) [40] and should be embedded in the instantiation of the concept [41]. However, the willingness and openness to participate on the engagement platform may be restricted by social influences. By designing communication, coordination, motivation and incentive guidelines the boundaries of individual decision making within an organization and closed communities should be considered. Actors act within a structure restricted by social rules and collective meanings, which are part of the organizational culture [42]. This is mirrored as well in the overview given in Table 3 including the design decisions in the case organization.

Realizing Change (C3)

As the overall aim of the concept is to realize change initiatives. As organizational context also embodies limited time for additional activities and lack of access permissions, change initiatives will be implemented jointly by the crowd and transferred to regular operation (C3F1). By providing dedicated time for users or adding additional resources users are empowered to realize benefits for themselves and for other users (C3F2). It is also possible that projects arise, which are equipped additionally with budgets and possibly additional resources and handed over to general project management. Other ways to support realization of change initiatives are crowd mechanism (C3F3) such as task management [43]. Building tasks to split workload and provide the possibility for lightweight participation in the realization process. Further dividing realization projects into small tasks supports automated testing and automatic integration [43]. After users have realized a change initiative, the solution should be tested and evaluated regarding defined acceptance criteria (C3F4). This also depends on the context and thus needs to be defined during instantiation of the engagement platform. After realizing and deploying change initiatives engaged users are informed and rewarded as defined during instantiation of the engagement platform (C3F5).

Table 4. Overview Component C3: Realizing Change

Objective	O2, O4, O5
Input	solution design
Functions	*Design Variables*
(C3F1) realizing change initiative	
(C3F2) enable realization	**attracting experts/consultants/IT**, providing dedicated time
(C3F3) building, assigning tasks	**self-regulated**, supported by tools, only if no additional tools are needed
(C3F4) testing and evaluating change initiative	how (**not mandatory**, acceptance criteria), who (IT department, **user**)
(C3F5) reward participants	monetary, **non-monetary**
Output	realized, deployed change initiative, realized benefits

4.1 Demonstration of a Preliminary Instantiation

The conceptual results of each design and development cycle were already initiated as prototypes and demonstrated within the case company. Starting with a reduced prototype the demonstration of the components and their functionality was initially conducted with a low-fidelity prototype (mock-ups). By extending the concept incrementally based on the preliminary results of the demonstration, the overall concept was instantiated as a responsive web application based on open source frameworks as shown in Figure 1.

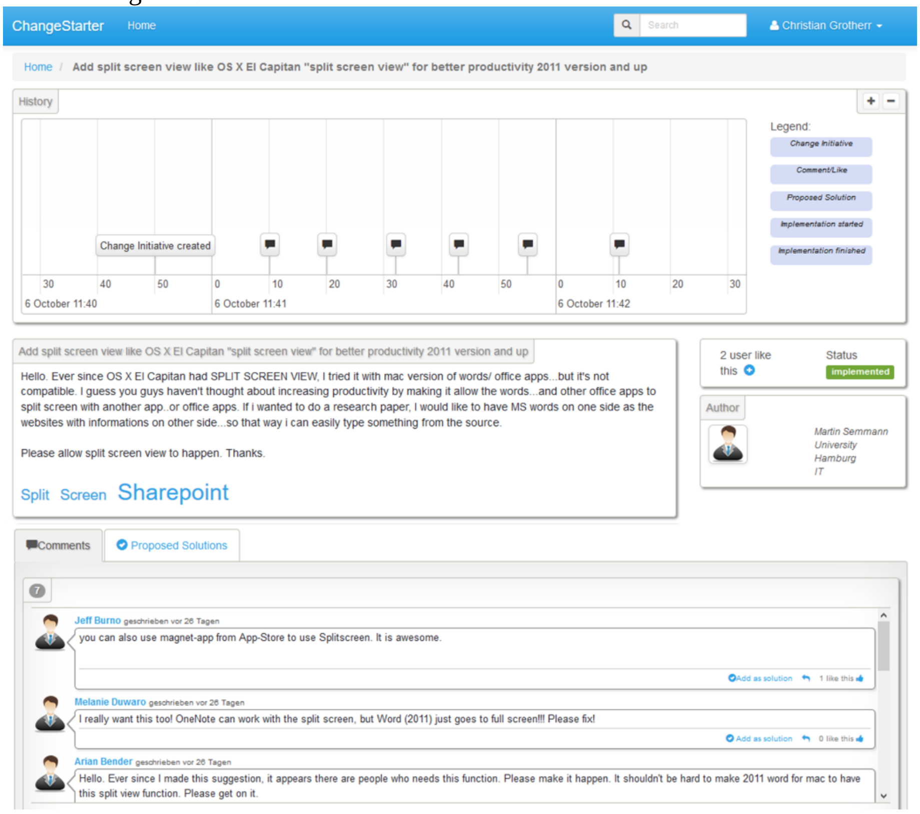

Figure 1. Instantiated User Engagement Platform supporting Benefits Realization

In sum, five workshops were conducted lasting two hours each including highly relevant stakeholders such as the CIO, head of IT operations, senior managers, representatives of the workers' council, and privacy commissioner to gain strong commitment of management as well as workforce.

Within the demonstration phase, feedback was gathered regarding the set of design variables and their manifestation to meet the requirements of the organization like the condition of voluntary and autonomous participation on the engagement platform. The results are highlighted in Table 2 to 4. Additionally, further extensions and improvements of features were discussed. For example, features were added to support discovering change initiatives (C2F1) like search functions and success stories. Despite this, every workshop helped streamlining the overall usability by simplifying the user interface to decrease adaption barriers.

4.2 Evaluation

As the first completed demonstration of the concept and its instantiation was successful, an extensive evaluation is currently planned. This evaluation is will be operationalized at the case organization and is open to all employees. Based on the gained commitment of relevant stakeholders during demonstration phase, we can deploy the prototype within the systems of the client and ensure deliberately low participation. Moreover, the evaluation does not have a dedicated timeframe and thus the internal crowd of the organization can evolve over time. The goal is to include 100 FTEs during the first phase of the evaluation. To achieve this goal, a set of potentially interested users is identified that could act as promotors for the concept within the organization. These users also serve as pre-tester to populate the platform with initial initiatives.

By evaluating the artifact within the organization, feedback is gathered applying qualitative methods such as interviews or thinking aloud to get insights on user's perception [44, 45] as well as gathering usage data. Accordingly, we do not only focus on the technical evaluation but also seek to gain insights on the social consequences of the artifact. Thus, the evaluation will contribute to the ongoing debate on socio-technical artifacts [46, 47]. The experiences and results of the evaluation are directly incorporated into further development and refinement of the concept.

5 Conclusion

Striving for a rise of benefits realization after a software introduction is formally closed, we presented a novel concept of an engagement platform. This concept utilizes a service systems perspective to empower users by a bottom-up approach to propose, engage and discuss and finally implement changes for this software and work routines. By doing so, the entirety of users can improve sociotechnical interaction to enhance the creation of value in context. Consequently, users are empowered to realize benefits that could not sufficiently be addressed during the software introduction project but even more, can deal with emergent benefits collectively. As the design of the concept integrates practice-oriented as well as theoretical insights within a case organization to instantiate the concept, in depth knowledge on the integration of resources in a complex service system as well as engagement strategies can be gained. Thus, this research is a core foundation towards an evaluation that is evidence-based and bears the potential to further improve design knowledge on actor-centered service systems engineering. Additionally, the proposed concept relates to current research on benefits management that seeks to understand how benefits realization can be fostered on actor level.

As a next step, the concept will be evaluated in practice within the introduction of Microsoft SharePoint. Moreover, it is planned to apply the concept to other contexts to assess and further enhance the transferability. Especially, regarding the design variables we seek to identify beneficial combinations to strengthen the engagement of users and thus contribute to the still emerging research on actor engagement in service systems.

Acknowledgement

This research was partly sponsored by the German Federal Ministry for Education and Research in the project ExTEND under the reference 01FJ15125. Further information can be found under: http://www.projekt-extend.de/. Additionally, we thank Philipp Streicher for his efforts to prototypically implement the platform.

Abstract. The character of IT transformed from an attached commodity to the center of new products and services. Especially in technical customer services, new technologies such as smart glasses offer great opportunities to overcome current challenges. Due to the complexity of service systems engineering, guidance on how to design smart glasses-based service support systems is necessary. To overcome this complexity and fill the research gap of design knowledge, we (1) analyze the domain in a multi-method approach eliciting meta-requirements, (2) propose design principles, and (3) instantiate them in a prototype. We follow a design science research approach combing the build-phase with four evaluation cycles obtaining focus groups twice, demonstration with prototype and, based on that, a survey with 105 experts from the agricultural sector. We address real-world problems of information provisioning at the point of service and, thereby, contribute to the methodological knowledge base of IS Design and Service Systems Engineering.

1 Introduction

Over the last decade, there has been an increasing focus on service science coupled with the design of new information and communication technologies [1, 2]. Especially concerning technical customer services (TCS) and their inherent field service, the support by mobile devices is inevitable. Service support systems are needed in order to cope with the wide range of service tasks [3, 4]. This can only be achieved through sufficient support by IT that proactively provide information and empower the service technician [5–7]. Although the (ergonomic and time-saving) potential induced by traditional head-worn-displays has already been discussed in research in the field of maintenance [8, 9], still only few scientific papers exist that address the emerging technology "smart glasses", a mobile eyewear with a display and features such as camera or sensors e.g. for head movement [10] as for example the Google Glass or the Vuzix M100. The existing papers mostly focus on individual and detached aspects, such as technical issues or scenarios like barcode scans [e.g. 11-13], none of them determine the design of a whole system.

We argue that there is a special need to examine the service support based on smart glasses. Based on a systematic literature study, Herterich et al. [14] identified the future research need of analyzing which field service tasks could be supported by innovative mobile technology. In particular the features of smart glasses offer new opportunities and enable the support of service technician (e.g. when free or clean hands are mandatory); thus, a study with focus on the device itself suit recent needs [10]. Nevertheless, to date, little research provides guidance for researchers and practitioners on how to build a smart glasses-based service support system. Against this background, the questions that guide our research are: (1) *What are the meta-requirements for a system that supports TCS in a hands-free way?,* (2) *How should smart glasses-based service support systems be designed that addresses these requirements?* (3) *How does the addressed user group evaluate the system regarding their intention to use it?*.

We followed a design science research approach (DSR) after Hevner et al. [15]. We conducted four evaluation cycles according to the Human-Risk & Effectiveness-oriented evaluation strategy proposed by Venable et al. [20]. By answering the proposed research question and presenting design principles as well as an evaluated instantiation as research artefact [16, 17], we contribute to the knowledge base of IS Design and Service Systems Engineering (SSE). With the several evaluation cycles including experts from theory and practice as well as researching in a real-world scenario, we address the call of SSE for research on evidence-based design knowledge for systems that permeate our society [18]. The derived design knowledge also guide practitioners by implementing a mobile service support system and enables them to create new business models (e.g. customer self-service).

We proceed as follows: First, we introduce the theoretical foundations of mobile service support systems for TCS. In section 3, we introduce our research approach. Next, we present the artefact design comprising the meta-requirements, design principles and the instantiation. In section 5, the results of the final evaluation are presented. We conclude by discussing novelty, practical relevance, theoretical contributions, and limitation as well as giving an outlook for future work.

2 Related Work

For many manufacturers technical customer services (TCS) became a major value-adding resource [4, 19]. In order to assist the service technicians, more and more researchers claim for the need of mobile service support systems [5–7, 20].

Due to the high range of tasks [3, 4] combined with the increasing complexity of high-tech products being subject to their work [21], TCS processes are complex entities. A service process of the TCS involves activities undertaken to realize and deliver the service at the so called point of service [5]. For his work on site he or she is dependent on current information about the whole service process. Conducting a case study, the authors Becker et al. [22] have analyzed information needs within service and manufacturing business processes of a milling/turning machine producer. They focus on how an integration of services and manufacturing can be accomplished by sharing information in service systems. In addition to that, Däuble et al. [23] derived information needs from literature and evidenced their investigation by results of real-world service process observations in the field of the machinery and plant engineering for the intralogistics sector. Thereby, they elicited 13 information needs such as information from the manufacturer, service item information, procedure information or tool information. In line with the authors, we focus on the information provision on site with essential information to fulfill the service tasks.

Agnihothri et al. [20], Legner et al. [7], and Ray et al. [6] focus on the impact of technology use on service performance while Fellmann [24] focus the proper integration of existing IS. Since diverse requirements have to be considered spanning technical aspects like interfaces or integration technology and the functionality of such systems, the development of a service support system is a complex task. In order to respond to this complexity and give guidance for further researcher, Matijacic et al. [5] elicited and consolidated requirements and mapped them to an generalized service process. So, as to embrace this richness, the authors suggest to use three distinct methods to elicit and consolidate requirements relying on different sources (systematic literature study, observations, and expert interviews). Likewise, we used triangulation for gaining the requirements for our smart glasses-based service support system. To guarantee the quality of the service, it is important to process and structure existing data to support the operation and the staff efficiently [6]. Considering the data and information flow between the system and the service technician, a bidirectional channel has to be established. Information is not only provided by the system, generated information and data while executing services are also carried back to it [5].

Additionally, based on a systematic literature study, Herterich et al. [14] identified the future research need of analyzing which field service tasks could be supported by innovative mobile technology such as wearables. This is where Niemöller et al. [10] start. They examine the features of smart glasses and map them to process steps of the TCS to show its potential for service support. We base on this work, when talking about the features such as hands-free interaction with e.g. voice control. Metzger et al. [25] propose to use smart glasses in the context of TCS to model service process during service provision. They also suggest to use smart glasses for a hands-free support during service work; however, they do not state how the system has to be designed.

3 Research Approach

We follow a classical design science research approach (DSR) [15, 26] as it is generally accepted for Service Systems Engineering (SSE) [18]. Böhmann et al. [18] propose that research needs to be embedded within a service system in a real-world scenario and call for the design of novel service systems. In line with the authors, our approach continuously involves experts from TCS as well as observations of real-world process scenarios. Following DSR, we investigated the four phases analysis, design, evaluation and diffusion as shown in Figure 1.

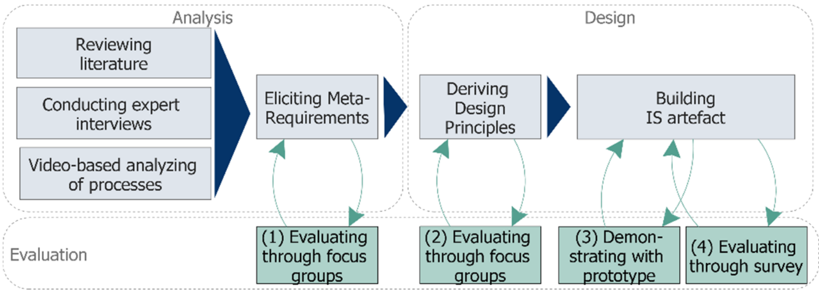

Figure 1. Design science-oriented research approach

Following the argumentations of practitioners (after discussions with several experts from the TCS in the agricultural industry as well as the air-conditioning sector) and service researcher, a need for support TCS trough IT was combined with a hands-free system interaction (cf. 1 and 2). Once the business problem is identified, attributes of the pursued future system have to be investigated and defined [15]. These attributes are usually referred to as *meta-requirements* [17] (cf. 4.1). The meta-requirements were elicited from the analysis of the real-world scenario (process analysis, expert interviews) and the IS knowledge base (systematic literature study). We asked two companies from agricultural and air-conditioning technology to use action cams or smart glasses to capture videos of how they execute service processes. Overall, 10 videos were captured showing different maintenance processes. We chose to conduct a triangulation to combine the different points of views and calibrate and validate our work [27]. The elicited requirements were mapped to the TCS process phase in which they appeared (order preparation, execution, post processing and phase-independent). We received a consolidated list and ranked the requirements by their significance within every process phase (analogously to Matijacic [5]). The highest rated requirements were discussed with the focus group. Next, an information system needs to be designed that meets the identified meta-requirements [17]. We defined the *design principles* (DP) based on the derived meta-requirements and literature, combining wearable computing design (e.g. [28–30]) with implications from service systems engineering and business process management (e.g. [3, 10, 21, 30]). We finalized the DPs catalogue after a second workshop with the same participants as in the first focus group meeting (for evaluating the meta-requirements), when all stakeholders were satisfied (cf. 4.2). Finally, the IT artefact was instantiated (cf. 4.3).

Since the evaluation of design artefacts and design theories is a central and critical part of DSR [15, 31], we combined the build-phase with several evaluation phases. Hence, Venable et al. [32] propose a framework for developing an appropriate evaluation strategy. Following their argumentation, our evaluation strategy is Human-Risk & Effectiveness-oriented. As a result, we have to evaluate our artifact and the design decisions early in a naturalistic setting, conducting formative and summative evaluations [32]. For implementing the evaluation strategy and choosing suitable evaluation methods, we made use of the proposed principles by Sonnenberg and vom Brocke [33]. According to the authors, we conducted four evaluation steps (cf. Figure 1): (1) Within the first evaluation (focus group), we verified whether the research need is important and novel to address a justified research gap. (1) Representing the TCS perspective from practice, three attendees from a small and medium-sized service provider for air-conditioning technology and three participants from large agricultural technology manufacturer with own TCS attended. (2) For gaining insides from a technological perspective, two IT practitioners and two visual technology researcher participated. (3) To bridge the technological and service view, three IS researcher specialized in service science were invited and took up the role as leader of the open discussion. (4) For the design of the content and targeted communication of information, two researchers with specialty in education and media psychology were invited. We received justified design objectives in form of verified meta-requirements. (2) Within the second evaluation (same focus group), we examined the feasibility, clarity, internal consistency and applicability of our DPs to gain a validated design specification. (3) By demonstrating our IS instantiation with a prototype, we proofed the feasibility as well as the suitability while discussing the demonstration with a selected group of expert from research and practice (same focus group plus five service technicians from the mentioned sectors). (4) The ex-ante evaluation cycles informed our work, e.g. that the acceptance of smart glasses plays a major role in the view of practitioners. This is why we demonstrated and evaluated the system on the world's biggest agriculture technology fair; and hence, validated the applicability to real world problems, the generality concerning different user groups as well as the ease of use. First, we explained the system functionalities (example case see Figure 2) and the interaction with the smart glasses (hand and voice recognition) to each individual participant while the participant was wearing the smart glasses her-/himself. After that, every participant could test the smart glasses system individually. After each demonstration, we asked the experts (n=105) about the acceptance by conducting a survey based on the Technology Acceptance Model (TAM) [34, 35].

4 Artefact Design

Meta-Requirements. Through the mixed-method approach we generated an overall of seven meta-requirements (MR). All of them were discussed with our focus group on a workshop. Table 1 describes the MR and their origin from the triangulation.
MR1: Process information. The requirement that was mentioned the most in the conducted interviews and was needed in every step within the video analysis was about

guiding the technician through the process. To ensure quality, some companies are using electronic or paper-based checklists to remind the technician of the most important steps. So, one advancement of a system that helps the technicians in the field is to provide checklists or a step-by-step guidance. Thus, it is raised as our basic MR. MR1 is in line with the information need N5, proposed by Däuble et al. [23].
MR2: Additional information. Besides the step-by-step guidance, we derived the need for additional information attached to a single step from interviews and video analysis. Reasons mentioned for that were: The technician (1) has never or rarely done that particular action before, (2) needs some details about the tools that have to be used for that step, (3) need information about the machine itself, such as technical details or spare part information. MR2 is in line with the information needs N1, N7, and N8 [23].

Table 1. Meta-requirements derived from triangulation

	Meta-requirements	*Interview*	*Process*	*Literature*
Functional	MR1: Process information.	X	X	[23]
	MR2: Additional information.	X	X	[23]
	MR3: Order overview.	X	X	[23]
	MR4: Order details.	X		[23]
	MR5: Feedback integration.			[6] , [5], [25]
Non-Functional	MR6: Hands-free interaction.		X	[14], [10]
	MR7: Usability.	X		

MR3: Order overview. Mentioned by one interviewee and also found in the video analysis, the need for an overview of the orders that the technician has to fulfill is given. When starting to work in the morning, an overview of the orders helps the technician to estimate how much time is calculated per order and how much work has to be done during the day. MR3 is in line with N10 [23].
MR4: Order details. Besides the overview of orders, we found multiple information that is attached to an order (kind of order and who issued it, related machine, machine and service history, maintenance contract) that needs to be provided to the technician. Within the interviews, order details were rated positive. MR4 is in line with N2, N3, N4, and N12 [23].
MR5: Feedback integration. When we evaluated the other six MRs, one challenge arose considering the document basis (the documented service processes) itself, as the service documentations need to be maintained and updated regularly. Within the discussion we found, that the one who know first, if there is something wrong with the processes, is the technician in the field. So, one crucial factor for the system is to include feedback of the technicians (to give advice that there is something missing, wrong or outdated). MR5 is in line with the argumentation by Ray et al. [6] and Matijacic et al. [5] about the bidirectional channel between technicians and administration.
MR6: Hands-free interaction. During our analysis of the technician's work, we asked them to capture a video of the maintenance process for multiple reasons. One of them was to analyze how often they are using one or two hands during the process. With the

two-hand ratio of about 80% (almost 6 of 7.5 minutes) we validated the fact that for most of the steps the technicians need both hands. This lead to our additional MR of a hands-free interaction with the system to ensure that the technician can continue his work while being assisted. MR6 is in line with the claim by Herterich et al. [14] for investigation of wearables in TCS and the analysis by Niemöller et al. [10].

MR7: Usability. During interviews and the workshop, one of the most important concerns about a support system was, that the technicians are distracted or overwhelmed by the system and are not willing to use it. So, one main aspect of the system is to be integrated into the work environment of the technicians with respect to easy and efficient usage. We added this as one MR, although it is not a requirement on functionality of the system but rather a requirement on how every aspect of the system needs to be designed. MR7 was emphasized during the focus group discussion.

Design Principles. We defined design principles (DP) to support the design of the system based on the derived MRs and literature, combining wearable computing design (e.g. [28–30]) with implications from service systems engineering and business process management (e.g. [3, 10, 21, 30]). The seven DPs are described in the following, starting with the ones that meet the non-functional MRs. If not state explicitly, the principles are generic for all smart glasses applications.

DP1: Use voice recognition of smart glasses as main interaction pattern. As the system should be usable during service delivery, a solution that makes sure the hands are free and usable is needed; hence, interaction based on hands such us buttons or gestures are inappropriate and should be complemented with sensor based interaction (following the first principle of [28]). However, the technicians need to interact with the system; for example, to update their progress or bring additional information to the front. After having a look at different interaction approaches, the least disturbing and most versatile interaction pattern is the usage of voice recognition [10]. So, the first DP is the usage of voice recognition as main interaction pattern in order to fulfill the hands-free interaction MR (MR6) and, thereby, generate additional value compared to other devices (as proposed in principle 4 by [28]).

DP2: Keep the menu navigation depth as small as possible. The technician need to find orientation and interact with the system in a very short amount of time to use the system efficiently [5, 21]. Complex software often involves complex menu navigation to enable the adjustment of all details. However, in combination with smart glasses the menu navigation is limited due to small screen area. Additionally, the system is supposed to be used by technicians during work; so, the main mental focus of the technicians is on the service delivery. Thus, our DP is to limit menu navigation depth to keep the interaction simple (in line with principle 3 in [29] and principle 5 of [28]). This contributes to the easiness of use of the software (MR7).

DP3: Always return to the last shown step. Considering the characteristics of TCS processes (complex and branched e.g. due to comprehensive fault detection trees) [3], the technician have to proactively get to the correct step without manual search [21]. So, the system needs to make sure that the progress for every order is saved and loaded correctly. Furthermore, when additional information is displayed or the user is giving feedback, the system needs to make sure that it is returning to the correct step in the process. Together with the last DPs this principle also improves efficiency and easiness to use (MR7). This DP was added after discussion with the focus group (evaluation 2). It is a specific DP for step-by-step guidance related activities.

DP4: Build an order management. Based on the need for an order overview (MR3) and order details (MR4) (which are specific MRs for order related activities), we included this principle. To overcome the missing screen area, the DP contains to build one screen for each day (overview) and one for each order (details). As smart glasses limit the amount of information that can be displayed at once, we propose to separate the details for every order from the overview (following principle 5 of [28]).

DP5: Build one main screen with crucial information about the step. The main functionality of the system is to give step-by-step guidance through the process. The key information for every step needs one screen that is easy to recognize and to understand. However, all important information needs to be included which brings the screen design in conflict between readability and completeness of information. The system designer needs to be aware of this interplay. Overall, when designed correctly, this principle contributes to the MRs step-by-step guidance (MR1) as well as usability (MR7) (following principle 5 of [28]). This is a specific DP for step-by-step guidance related activities.

DP6: Attach additional information such as texts, pictures and videos to specific steps. Every additional information ranging from spare part information, pictures, wiring diagrams, videos, technical details etc. needs to be included into the step-by-step guidance. We propose to attach the information in the data storage directly to the step where it might be needed. The relation between additional information and step might be implemented as many-to-many-relation (m:n) as there might be additional information that assists in multiple steps as well as multiple additional information for one step. With the relation, the additional information would be accessible when needed and makes sure long search periods are unnecessary (in line with [30]). This supports MRs additional information (MR2) as well as usability (MR7) due to easy access to additional information. This is as well a DP for step-by-step guidance related activities.

DP7: Allow direct feedback to one step. Finally, the integration of feedback functionality is essential to ensure data quality of the processes and fast alteration when needed. To design the feedback as easy as possible, we propose to make the feedback functionality accessible directly from the step. Consequently, when sending feedback, the information about the context such as the order information, customer information, information about the step where the feedback was sent etc. needs to be logged and included. This enables the administrator of the processes to assess the context of the problem and adopt the process accordingly (e.g. by changing the process for a special kind of customer). Thus, this contributes to "the fit between business processes and technology" [36] as it enables continuous adaptation. Overall, the integration of feedback contributes to the MR give feedback about content and processes (MR5) as well as usability (MR7) because of direct communication with the process administration. Finally, this is a specific DP for step-by-step guidance related activities.

Instantiation. Based on the DPs, we instantiated our smart glasses-based service support system. All features were implemented on a native android application with the glass development kit based on android 4.4.2 (API 19). For the user interface we used Google Glass card designs that simplified the implementation. Because of the requirement to use voice recognition in the whole application, we further used custom layouts and handler. The interaction was mainly based on voice recognition. However, we implemented a fallback solution via the touch interface of Google Glass in case that voice recognition does not work (e.g. too noisy). *The derived design principles can be implemented on every smart glasses with a display and microphone (for voice-recognition).* The software was optimized to use the feature set of Google Glass. A more detailed discussion on hardware features was published by Niemöller et al. [10].

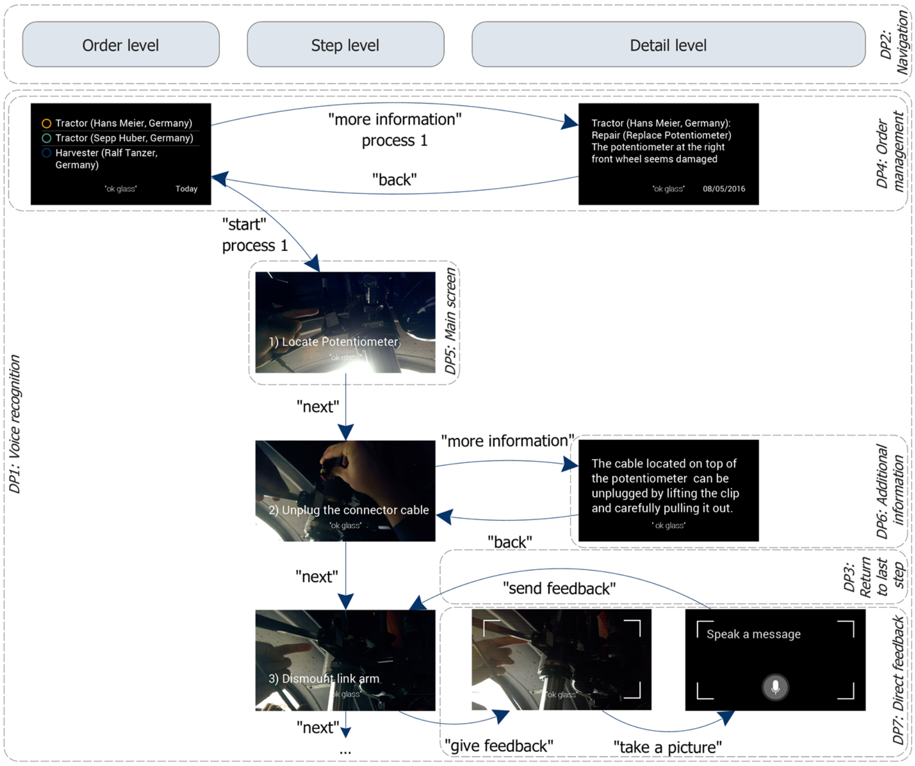

Figure 2. Screens of the smart glasses-based service support system (instantiating DP1-7)

The overall system is structured in three levels of navigation (cf. Figure 2). Following the DP of small menu navigation (DP2), we introduced an order level for the technician to look at the orders that has to be fulfilled. The second level is for the step-by-step guidance. The third one is for details and feedback. When technicians start using the service support system, they start at the order overview (fulfilling DP4). They get some general information about the orders they have to fulfill today (in our example three orders), what kind of machine it is, and the machine location. They get more information about the particular order when using the voice command *more information -> process 1*. In the order details the kind of order (e.g. maintenance, repair [3]) is specified as well as a short description on what the problem is and the timestamp when the order was commissioned (fulfilling DP5). With *back* they return to the order overview and start one order with *start -> process 1*. The step-by-step guidance turns up with the main screen. We designed the main screen as easy as possible with the number of the step, a short description on what to do and a picture in the background that illustrates what to do (fulfilling DP6). They get to the next step by the voice command *next*. When there is more information needed for a particular step, with the voice command *more information* (e.g. for further description of step in text form, video tutorials, pictures of tools) the system shows the attached information to that step (in our example it is a more detailed description; fulfilling DP7). With *back* the technician is taken back to the step. Later on, in step 4, the technician feels that there is something wrong. So, with *give feedback* the feedback module starts. First, a picture of the problem and, second, a message (via speech-to-text) can be recorded that is send to the backend (fulfilling DP8). With the voice command *send feedback* it is transferred and the system returns to the last step (fulfilling DP3).

The system architecture is implemented based on Google Glass with internet connection via Wi-Fi or Bluetooth (connected to a smartphone) and a backend-server that holds the data. For storing data locally (on Google Glass), we use a sqlite-database that is updated through a communication module talking to the backend-server. So, the administration of the processes and orders is done in the backend, whereas the communication module ensured that all data on Google Glass is up to date. We implemented the system in an agile approach and continuously discussed the results with the focus group members. Thereby, we evaluated the general feasibility of the system. Based on the final prototype, we evaluated the acceptance (cf. 5).

5 Evaluation

After having evaluated the single MRs and DPs using focus group meetings to inform our work (formative), we evaluated the system with a larger group of participants based on a demonstration of the prototype and survey (summative [32]). Goal of the evaluation was to proof the generality concerning different user groups and the applicability to real world problems (intention to use based on perceived usefulness and ease of use). We evaluated against the captured MRs. Addressing the five functional MRs, we asked the participants within our survey about whether they perceive the system to be useful (PU) for fulfilling their job. Addressing the non-functional MRs, we asked questions about the perceived ease-of-use (PEU). The wording of the four questions were taken from Venkatesh & Davis [35] and adapted to our scenario (Regarding PU: our system is considered as useful, if the technician feels empowered to fulfill her/his tasks in a higher quality and more efficiently [5, 6, 20] by being better informed [5, 23]). The two concepts are accompanied with one question about the behavioral intention to use (BI). This question gives an overall impression about whether they are willing to accept and use the system as demonstrated. Based on the TAM, both previous mentioned factors PEU and PU are meant to influence the BI. Figure 3 illustrates the statistical model. In total, 105 people participated in our survey. Most of them were male participants (86.7%) while all of them where between 16 and

60 years old (with an average of 31.4 years). Almost two out of three (62.9%) never had experience with smart glasses and the remaining third had experience only once or twice (35.2%). More than half of them (56.2%) are working in the agricultural machine and engineering industry. The remaining participants are working as agriculturalists (10.5%), in the IT industry (4.8%) or in other industries (22.9%).

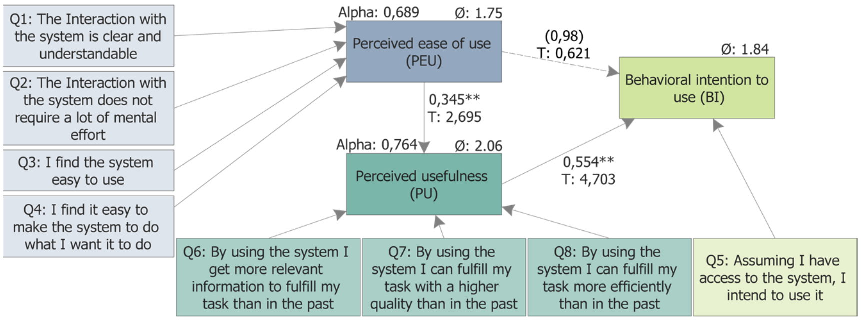

Figure 3. Summary of the evaluation based on TAM

In Figure 4, the factors perceived ease of use (left part) and perceived usefulness (middle part) are illustrated. With an average perceived ease of use of 1.75 which is in between *Highly agree* and *Agree* and no negative voting at all, a positive evaluation is given. So, the deduction that the non-functional MRs are evaluated positive is given. The perceived usefulness of the system with an average of 2.06 (Around *Agree*) is given as well. So, our functional MRs are evaluated positively as in average the participants perceive the usefulness of the system positive. The overall rating of the acceptance is evaluated through the factor behavioral intention to use. As the underlying TAM claim a correlation of behavioral intention to use and actual use, we argue that our system will be used in future if participants are evaluating their behavioral intention to use positive. Figure 4 (right part) also illustrates the results of the survey regarding the behavioral intention to use. With an average of 1.84 (Between *Highly agree* and *Agree*) and 77.1% of the participants rating positive on whether they intend to use the system if they have access to it, a positive feedback is given. Thus, we argue that people would accept and actually use the system in future. Indirectly, this evaluates our MRs and DPs positive as the system got positive feedback while being built on them.

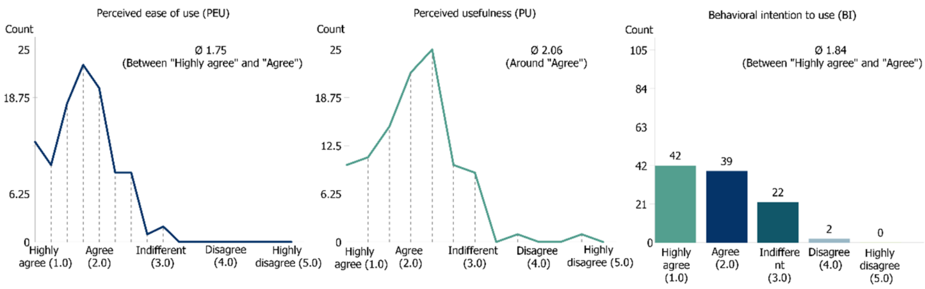

Figure 4. Evaluation results for PEU, PU and BI

Correlations During analysis, we conducted further calculations about correlation of the three factors perceived ease-of-use, perceived usefulness and behavioral intention to use as described in TAM [35]. We validated the significant positive correlation between the PEU and PU (Regression: 0.345, Significance: 0.008). Further, we found a significant positive correlation between PU and BI (Regression: 0.554, Significance: 0.000). However, the proposed positive correlation between PEU and BI could not be verified in our data (Significance: 0.536). One possible reason is the professional context the system should be used in. Thereby, the perceived ease of use alone does not necessarily lead to an adoption of a new system. Nevertheless, the indirect positive correlation through perceived usefulness still exists.

In sum, the evaluation of the system was positive. Thus, we were able to indirectly validate the DPs as the system was based on them and, thereby, the MRs. With our evaluation inspired by the TAM, we were also able to generate a forecast that with the positive feedback on the factor behavioral intention to use it is likely that people will actually use the system in future. The acceptance of the system was crucial for our evaluation strategy to validate the applicability to real world problems.

6 Discussion, Conclusion and Outlook

Conclusion. The effective use of emerging mobile IS can offer great opportunities to overcome current challenges in the domain of TCS. Due to the complexity of service systems engineering [18], guidance on how to design service support systems is necessary. To overcome this complexity and fill the research gap in design knowledge on smart glasses-based service support systems, we followed a DSR approach within this paper through, first, exploring the domain using triangulation and eliciting meta-requirements (RQ1), second, deriving design principles continuously working in an interdisciplinary team of practitioners and researchers (RQ2), and finally, evaluating the acceptance of our designed IS artefact (RQ3).

Novelty and Practical Relevance. We address a real-world problem that consists of the need for hands-free TCS service support through targeted information provision during work. At the same time, since smart glasses are still an emerging technology, little knowledge about the design of smart glasses-based service systems exist. During the evaluation phases, especially on the world's biggest agriculture technology fair, the demonstration of the prototype showed that the formulated design principles and their instantiation address the user's needs. The presented design principles can be transferred to other service domains as well as there are not TCS application specific, but specific to particular activities (e.g. specific design principle for step-by-step guidance-related activities.; hence, it is transferable to every domain where a step-by-step guidance is relevant). Another example are order-related activities which are transferable to every domain, where orders are relevant. Both from the point of practice and from theory, a transfer of the proposed design knowledge to other user groups offer new subjects of research, inter alia regarding value co-creation and new business models as e.g. the sale and delivery of smart glasses-based service support systems to the customer to enable self-services.

Theoretical Contribution. Regarding the theoretical contribution, this research work contributes to the methodological knowledge base of IS Design and Service Systems Engineering, and builds upon existing methods of DSR and findings in design of service systems [5, 6, 14, 23]. In DSR, a theoretical contribution is usually regarded to be in form of prescribing how a specific solution can be designed in order to solve a relevant real-world problem; often presented in form of design principles [37, 38].

Gregor and Hevner [16] argue that the instantiation itself contributes to the knowledge base as the demonstration of a novel artifact can be a research contribution that embodies design yet to be articulated, formalized, and fully understood. We position our work as a new solution, the hands-free information provision trough a smart glasses-based service support system, to solve an existing problem (need for service support due to complex and information-intense TCS processes). We explored the problem domain and formulated meta-requirements. They represent the conditions that should be met by a solution to provide the TCS with needed information while executing their processes without any need to interrupt their tasks.

Additionally, we contribute to the IS research knowledge base by instantiating the suggested methods by Sonnenberg and vom Brocke [33] while following the evaluation strategy proposed by Venable et al. [32] as enhancement of the classic DSR approach. Current discussions in service systems research argue for research to be embedded within a real-world scenario and call researchers to design novel service systems [18]. Hence, with our work, developed in a transdisciplinary team (IS research, service science, education and media psychology as well as practitioners from service providers, manufacturers and IT companies), we meet a research gap and the claim for evidence-based design research [18].

Limitations and Outlook. Although, we discussed our work with experts from two different sectors, the transfer of the design principles to other sectors have to be evaluated further because the TCS domain has a wide area of application. Based on the results of the evaluation cycles, we focused on non-functional requirements and the acceptance of the smart glasses system. Hence, (1) the transfer of additional functional requirements for handheld devices [5] have to be investigated further as their might occur some difficulties implementing for example invoicing functionalities due to the small screen (more natural on the tablet). (2) We have not conducted an evaluation regarding the actual economic and ergonomic benefit yet. Thus, the next step of our research is the evaluation of our instantiation in form of a field test [33] in the TCS of the agricultural technology company and the service provider for air-conditioning.

While analyzing the service processes and information needs of our focus group partner, we discovered that the knowledge base and access to information as basis for our service support system (e.g. handbooks, service manuals, trainings) differ in the considered companies based on different types of service providers and the complexity and variant diversity of their service objects. To sum up, our approach can be considered as first step with more research to come that is specifying new business models, value co-creation driven through new and enabling technology, the level of service integration and hybrid value creation regarding (a) it's influence on information needs and information access and (b) it's implications on service modularization and service design e.g. through integration of the customer.

Abstract. To satisfy service customers and create unique value in a digitized world, companies must strive for exceeding customers' expectations of e-service experience by establishing high e-service quality. However, an increasing amount of e-services is performed by context-aware mobile technology, which is able to sense and react to changes in the user's environment. Although these context-aware services are able to address our personal needs and already determine our everyday live, knowledge on how to develop such services is sparse. In our study, we qualitatively compare three mobile navigation apps based on their user reviews in order to elicit first requirements and design approaches for e-service quality oriented design. Results show that well known e-service quality models are not fully applicable to the case of mobile navigation services.

Keywords: context-aware services, design requirements, e-service quality, user reviews

1 Introduction

In today's fast-paced digitized world, companies increasingly strive for creating unique value to customers in order to distinguish their own service offerings from those of competitors. Attracting, keeping and satisfying customers and making profit are becoming more difficult in times of low to zero marginal costs as one effect of product and service digitization. In the past, value was considered as ratio between service quality and cost [1]. However, Vargo and Lusch offer a new perspective on customer value by introducing the concept of value in use [2]. According to them, service users are both co-creators and judges of service value [1], which implies that how value is perceived is predominantly determined by customer's individual service experience [3]. In this regard, service quality, i.e., the discrepancy between expected and realized service experience [4], is the focal enabler of customer satisfaction [5, 6]. Whereas in a traditional human-to-human service encounter service employees are able to adapt interactively on customer reactions to improve service quality, an increasing amount of services are nowadays based on technology, which rely on electronic interfaces and predefined interaction procedures. In this context, service quality is usually conceptualized as e-service quality (ESQ), suggesting that interaction with e-services,

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Knote, R.; Söllner, M. (2017): Towards Design Excellence for Context-Aware Services - The Case of Mobile Navigation Apps, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 121-135

such as mobile applications or websites, is different to traditional human-to-human service encounters [7, 8].

With the rise of smartphones and the vision of ubiquitous computing, in which computers surround and adapt to the lives of humans without being obtrusive [9], the deterministic behavior of technology-based services, however, becomes increasingly turned upside down. Every modern mobile phone nowadays contains sensors to detect and adapt to changes of the user's physical or logical context, bringing context-aware mobile services a huge step towards non-determinism and ubiquity. Reflecting the new possibilities involved in the autonomous adaption to context information, such as time, location, speed, temperature, calendar entries, relevant news and (especially due to the success of smart watches) even health data like blood pressure and heart rate, adaptability of systems to users' real current needs is finally becoming possible. Context-awareness holds the potential to yield high-quality (i.e., perfect fit to individual users and their contexts) services that anticipate and hence satisfy customer needs in an entirely new manner. Against this backdrop, context-awareness can be considered a new and yet mainly unexplored paradigm that allows service and application designers to meet or even exceed customers' expected service experience in order to achieve high ESQ by design.

However, the question of how to design context-aware applications to meet requirements of high ESQ remains unanswered in scholarly and practical literature. In fact, even requirements that depict ESQ as design goal are sparse. This research gap may have manifold reasons. First, the definition and demarcation of service experience, service satisfaction, ESQ and related terms can be considered a conceptual chaos, since many schools of thought work towards many different directions. This leads to confusion in theory and practice when it comes to identifying the correct concept for a certain problem and its relation to adjacent ones. Second, ESQ as such has not be sensed as explicitly important for the design of (context-aware) services by practitioners, yet. Third, although many empirical data and a huge amount of measurement models exist on ESQ, no requirements or design principles for service and system development have been established based on this foundation. With this contribution, we aim to stress the importance of an ESQ-oriented system design approach. Our work is guided by the research question: *What are requirements and design approaches for high ESQ when developing mobile navigation services, as a subclass context-aware services?* We therefore identify, screen, cluster and analyze user reviews of three successful mobile navigation apps, as an important subclass of context-aware services, with regard to ESQ dimensions. In doing so, we aim at inductively identifying ESQ requirements and design approaches that help developers and requirements engineers to identify what makes the design of the mobile navigation services superior and what to consider when developing context-aware applications with ESQ as an overarching design goal.

The paper is structured as follows: In section 2, we give an overview on the peculiarities of context-aware services and introduce the concept of ESQ. Afterwards, our research approach is described in detail in section 3. Section 4 depicts the results of our study, which are then discussed in section 5. We conclude with a short summary, propose theoretical and practical contributions as well as limitations and next steps in section 6.

2 Background

2.1 Context-Aware Services

Following the vision of ubiquitous computing, one of the first ideas of applications that adapt to changes of their environment was introduced by Schilit and Theimer in 1993, who define the location, people and objects in proximity as well as their history as context of an application [10]. The question "Where you are, who you are with and what resources are nearby" thus characterize the context of an application [11, 12]. Ryan et al. define context as any collection of information about a system's environment, such as location, time, temperature and user identity [13]. Pascoe et al. state, however, that to define context is a complex task which cannot be done by simply listing possible context information [14]. Furthermore, Dey et al. conceptualize context as "any information about the user and the environment that can be used to enhance the user's experiences" [15]. In our work, we build up on abovementioned definitions and regard context as an attribute comprising all information about an entity's physical (e.g., location, temperature, humidity, etc.) and logical (e.g., calendar events, relevant news feeds, etc.) environment which can be captured by sensors. Furthermore, we focus on applications that are able to detect context (context detection) and react to this information by changing their behavior or functionality (context adaption). From a service science perspective, which focuses on the interaction and co-creation between entities within a service system to achieve a certain value, context-aware services play an increasingly important role [16, 17]. Glushko conceptualizes context-aware services as one field for future service design [18]. Nowadays, an increasing amount of technology-based services are aware of and adaptive to context, such as personal fitness, healthcare, disaster warning and navigation apps.

2.2 E-Service Quality

As a key driver leading to satisfied customers and economic growth, quality has its roots in marketing and consumer research, management science, engineering and operations. Golder et al. show that different understandings of quality have emerged in these academic fields [19]. The most pivotal perspective for our approach is obtained in marketing and consumer research which focuses customers' perception of quality. However, due to the heterogeneity of quality perspectives, "no universal, parsimonious, or all-encompassing definition or model of quality exists" [20]. One reason for the complexity of quality is that "objective quality may not exist because all quality is perceived by someone" [21]. In academic literature, the concept of perceived quality was proposed for services in manifold forms [8, 21–25]. Most existing approaches for analyzing and measuring service quality are based on the GAP model introduced by Parasuraman et al. [24] and SERVQUAL, a measurement instrument adopted from marketing [21]. Although they have massively shaped the research on service quality, these approaches have been established for services that encompass human actors only. However, due to digitization, many services are nowadays delivered and consumed through technology, which turns them into e-services. In the context of our study, we follow Riedl et al. who define e-service as “a business activity of value exchange that is accessible through an electronic interface” [26]. Parasuraman et al. correctly find, that service quality literature is dominated by people-delivered services whereas only a limited number of articles deal with customers’ assessment of ESQ, its antecedents and consequences [7]. However, there is a need for separately investigating ESQ, since customer evaluation of technology is different due to technology-based customer beliefs (e.g., technology-readiness) and technological peculiarities (e.g., server problems or connectivity issues) that may influence the quality perception process [7, 27]. Thus, Parasuraman et al. present a multiple-item scale for measuring ESQ called E-S-QUAL [7]. It is constructed and tested for measuring ESQ delivered by websites for online shopping. Despite the basic E-S-QUAL scale, which consists of 22 items in four dimensions (efficiency, fulfillment, system availability and privacy), they developed a scale for customers who have non-routine service encounters with the websites, which consists of 11 items in three dimensions (responsiveness, compensation and contact) called E-RecS-QUAL. Further models include zone-of-tolerance-based IS-SERVQUAL [28], SERVQUAL for E-commerce [29], eTailQ [30], WebQual [31, 32] and SaaS-Qual [33]. To consolidate all previous findings about ESQ and establish a common conceptual model, Blut et al. meta-analyze the most important empirical data [5]. In our work, we use their conceptual model as a starting point for developing coding categories. The meta-analysis conducted by Blut et al. reviews and summarizes a wide range of prior ESQ research and results in a conceptual model of four dimensions: website design, fulfilment, customer service and security. However, previous ESQ research also covered by Blut et al. has mainly focused on the interaction of customers with e-commerce websites [27]. For example, Parasuraman et al. define ESQ as “the extent to which a web site facilitates efficient and effective shopping, purchasing, and delivery” [7]. Thus, there is a huge research gap for investigating ESQ in a non-E-commerce context, such as context-adaptive services.

3 Research approach

In order to identify requirements and good design approaches for excellent mobile navigation apps, our approach is based on the method of Pegano and Maalej, who analyze user feedback from app stores and its impact on the user community [34]. For *data extraction*, we focus on the two biggest app stores: Apple’s AppStore and Google Play. We registered to an online service[1] for crawling app reviews from these platforms (by using e.g., Apple’s RSS feed generator) and converting them to comma-separated values (CSV) files for better analyzability. With this service, we extracted user reviews on top navigation apps on the US market: Google Maps, Waze and Navigon. According to download rate and overall user rating, these apps can be considered best-of-breed mobile navigation services. Our data sample covers the latest 1,500 user reviews (August 21, 2016; 500 reviews per app due to technical restrictions of the web service). The CSV data set contains the date, title and content of the review, nickname of

[1] https://heedzy.com/

reviewer, rating, reviewed app version and device of the reviewer. After extracting the reviews, *data analysis* was started by sorting out reviews with low to no informational value regarding requirements or design approaches for app development (e.g., ”Don’t download!!!” or “I love google maps”). Based on the ESQ dimensions and their definitions meta-analyzed by Blut et al. [5], we started building a category system for our endeavor, following the logic of qualitative content analysis [35]. However, since the meta-analysis mainly comprises studies that investigate ESQ with regard to e-commerce websites, not all dimensions conceptualized by Blut et al. are appropriate for our case of navigation services. This is mainly because (1) e-commerce providers use websites for information and facilitation of order processing whereas (context-aware) applications such as navigation apps are stand-alone e-services with backstage processes far behind the customer’s line of visibility, and (2) in e-commerce value is created through effective and efficient order processing and not by just using an electronic interface which, however, is the case for mobile applications. Hence, initial categorization was critically contrasted with other analyzed literature concerning ESQ. Categories must further fit to our research context and, following our understanding of context-adaptive services as mentioned above, reflect users’ perceptions of the app’s (a) context detection (i.e., gathering context data) or (b) context adaption (i.e., changing behavior based on context interpretation) abilities.

Thus, rearranging categories (i.e., ESQ attributes) from the initial framework was the first step: design was kept since we suggest it is important for app ESQ, especially when context changes (e.g., driving through a tunnel may cause the app to darken the screen to prevent dazzling). Following this logic, also information quality, ease of use, personalization and system availability have been kept from the design dimension, whereas e-commerce specifics (e.g., purchase process) were dropped. Furthermore, all categories regarding fulfilment and customer service were dropped from the initial framework, since they are by definition too e-commerce specific. Security and Privacy were kept since these appear crucial to context data detection. Reviewing prior research reveals that Benlian et al. is closer to our research context than other work in the field, since they provide not only ESQ items for user-to-provider but also for direct user-to-software encounters [33]. Some of these items are transferable to categories that are valuable for our approach. We hence added functional reliability and functional features (i.e., offline usability, search, etc.) as new categories. Search terms were defined, which we used to deductively classify the reviews into our categories. Since we conducted deductive content analysis, categories formed for coding qualitative data ought to be challenged by the actual data during analysis to evolutionarily emerge [35]. We hence inductively found one more category, network data usage. Final coding categories and definitions are presented in table 1. 583 helpful (i.e., related to one or more ESQ dimension and reflecting requirements and/or information about design approaches) user reviews were analyzed.

Table 1. Coding categories and definitions based on applicable ESQ dimensions

Source	Coding Category	Definition
Adapted from [5]	Design	Adaption of the user interface…
	Information quality	Actuality and accuracy of information…
	Ease of use	Intuitiveness of usability…
	Personalization	Fit to user's preferences…
	System availability	Stability during runtime…
	Privacy/Security	Perceived data protection…
Adapted from [33]	Functional reliability	Accessibility of desired functions…
	Functional features	Range of functionalities…
New	Network data usage	Data usage…

... when detecting or adapting to context.

4 Results

4.1 Design and information

In the following, we compare the results for the categories mentioned above by using quotes from user reviews as examples to highlight our interpretation. In this section, we focus on *Design, Information quality, Ease of use* and *Personalization.*

Design. In terms of general application design, Google Maps users clearly stress the superiority of how the app appeals. They found the app very well organized, accurate and convenient. Users tend to connote Google's design with quality, since it is clean and simple. For Navigon, however, the majority of the users accredit the app to have an "awkward" user interface design. Users do not perceive the user interface as contemporary and wish easier access to important menu points and settings to have better control over the service's functionality. *"[...] it seems that the company is relying on their exceptional map data to compensate for an exceptionally bad UI".* Waze, which is a navigation app based on crowdsourcing (i.e., users are able to mark traffic jams, red light cameras or police spots right in time), has been judged by users with both positive and negative evaluations almost equally. The comic style interface is rated as good and innovative by some reviewers, weird and confusing by others.

> *"Good design. Best navigation app ever!"*
>
> *"The UI is so bad that I find it easier to just quit the app and restart whenever I need to change something than to try to decipher the UI elements."*

Whereas Waze users do not explicitly judge design, Google users mainly appreciate the quality of the maps and the satellite imagers. However, when it comes to navigation (i.e., functionality for context adaption), some users find roads hard to identify since they are painted in shades of light and dark grey that are close to each other. Navigation design is considered easy and intuitive instead. Requirements are raised concerning unwanted rescaling of the map when using the 'find my location' button and icon sizes. For Navigon, also neither great concerns nor compliments are posted by the users. One minor requirement is to enlarge road signs (showing speed limit and other information on screen based on the user's location), making them easier to read. Also the Navigon app is perceived as superior in navigation mode. It is considered easy and reactive to users' driving behavior, as it displays the current speed, ETA and speed limit warnings.

> *"In general it works really well, gives accurate instructions and easy to follow graphical instructions that warn of upcoming changes. So I recommend it!!!"*

A minor requirement is raised regarding the text size of current speed, road name, ETA and speed limit in navigation mode. Waze users are also satisfied with the navigation design.

Information quality. Reviews on information quality are mostly related to the up-to-dateness of map material and the correctness of driving recommendations. User reviews on Google Maps reveal that location and road information as well as in-time traffic updates are very useful. Users perceive that the app adapts to their situation when suggesting alternative routes that are faster. Since map data is usually loaded via internet when needed and is updated regularly based on user feedback, traffic news and GPS patterns (e.g., for detecting traffic jam), map data is considered up-to-date.

> *"Real time traffic updates, route updates, and very clear, easy to follow travel instructions makes this app excellent."*

Although some users praise the actuality of its maps, the majority of Navigon users claim that map data is out of date. Furthermore, some users note that the navigation functionality is *"saddled with Microsoft's 'Here' map search which can never seem to find anything".* Waze users do not focus their reviews on road/map data up-to-dateness. However, some users posit that the quality and actuality of map and road data heavily relies on how active and efficient the crowd provides information. Thus, the crowd provides further information about the actual context and determines information quality.

> *"What Waze accomplishes is providing true real-time traffic and routing updates that are as good as the user community deserves. See, many use Waze for its superior alerts and routing capability over other GPS apps. However, it's really only as good as the user community is willing to make it"*

Ease of use. All three apps are described as very easy to use and intuitive by the majority of reviewers. As mentioned above, Navigon is perceived to have a complex menu organization which needs initial settling-in.

> *"Interface is straightforward although the depth of features sometimes requires digging around in settings and experimenting to get the app to do exactly what you want."*

However, all apps provide real-time adaption to context changes by displaying useful options. For example, Google Maps and Waze detect whether other drivers using the app are stuck in a traffic jam. If this is the case, it informs the driver and calculates alternative routes to bypass the overloaded road. Drivers can select a faster route by just clicking on the alternative route as it appears on screen.

Personalization. All apps provide the opportunity to store and recall personal waypoints for route calculation as well as individual points of interest. When the user is close to one of these points and selects the 'discover neighborhood' (or similar) option, the user is located and the distance to her personal point of interest is calculated. However, although it is possible, user reviews reveal that it is still difficult in Google Maps to set multi waypoint routes.

4.2 Functional features and reliability

As done above, in this section, we elaborate more on the findings for the categories *Functional features* and *Functional reliability*.

Functional features. Although the apps work on different mechanisms, all three services provide navigation and location functionalities. Google Maps and Navigon further provide the opportunity to use offline map data for navigation. However, both use different approaches for doing so: In Google Maps it is possible to zoom out of a map to a certain degree and save this section to the phone. Navigon works with downloadable region maps (e.g., for Europe, North America, etc.). In contrast, Waze needs a permanent internet connection in navigation mode to load map material. Although the majority of users appreciate the novel offline functionalities of Google Maps, users negatively rate the inconvenient way how offline maps are saved and used for navigation.

> *"It would really be nice, very helpful and much easier if I could save an entire state worth of offline map data instead of fidgeting with a clunky map screen I have to zoom and position so strategically to make sure I get all the roads, railroads and trails I need to have with me at all times."*

Google users especially enjoy that Maps offers up to three route alternatives with ETA which is calculated from length of the road, average personal speed, average speed on the road but also from traffic jams or construction zones detected. The user may choose from these alternatives, which they find simple and convenient. Further requirements are raised concerning a 'reverse option' to toggle start and destination and disturbing voice directions while using the phone for calls. Furthermore, Waze provides 'social' functionality, such as easily sending ETA to phone contacts while driving.

Functional reliability. Most Google Maps users describe the app extremely accurate with regard to the navigation functionality. However, complaints exist about lost GPS receptions in the middle of navigation and wrongly identified fastest routes.

> *"Quite often, it fails to find the fastest route to a destination. Consequently, I have taken to opening Waze and comparing routes. Around 50% of the time, Waze will find a faster way of getting where I need to go. What is keeping me from using that app full-time is their cartoon interface and ghastly color scheme. Google needs to vastly improve their algorithms for this app."*

Also the majority of Navigon users consider its navigation functionality accurate and reliable. Both Waze and Navigon successfully manage to route around traffic problems when internet access is available. User reviews further reveal that offline availability is becoming increasingly important for users.

4.3 Availability, Security and Network Data usage

This section is devoted to findings in the categories *System availability, Privacy/Security* and *Network data usage.*

System availability. As expected, most criticism on the apps is related to system availability. Although according to the users all three apps basically run stable, many users write reviews to complain about crashes and outages. Besides occasional instances in Google Maps and Waze, in which the apps randomly crash or lose network connection, more common concerns have been raised for the Navigon app. Users complain about data losses after updates.

"Navigon has screwed me again. The latest update wiped out all my Favorites. It also removes all the maps and requires individual downloads by state."

Privacy/Security. Navigon users do not raise concerns about data privacy and security. For both Waze and Google Maps, users complain about regularly established GPS connections even when location based services are turned off in phone settings and the apps are not running. A Waze user writes:

> *"Location Service Always Running even when waze is turned off [...] which is a lack of privacy. There is no need to have location service running all the time in background."*

However, users tend to hazard consequences of neglected privacy for the sake of functionality, how a Google Maps user describes:

> *"Yes, Google is probably collecting my usage data. At this point in my life I don't much care. The convenience of finding places and being accurately guided there true my hopes for anonymity."*

Network data usage. Waze users do not report on network data usage in online mode. Navigon users tend to rate mobile data usage positive.

> *"The data usage is very low - so low, it doesn't put a dent in my metered data (probably 200KB or less each 20 min trip)."*

Google Maps users, however, recently report about high data usage, which is seen as a severe issue.

> *"Recently I left this app on in the background while using walking directions and it used over 6 GB of data within hours, with no warning. This app needs a data warning, cut-off, or data usage metering like the Netflix app recently implemented."*

5 Discussion

As seen in the reviews, how users experience and evaluate context-aware e-services is highly dependent on individual situations and prior experiences. Many users compare service functionalities with what they know (i.e., formerly used apps) and thus build a state of expectation. This state is challenged when using a new app in order to form an evaluation of ESQ. Thus, it is necessary to consider ESQ as an important design goal for app and service development. Our results indicate that user reviews are a useful source of requirements and first hints for respective 'good practice' design approaches, which confirms conclusions of other scholars in the field of requirements engineering [34, 36]. We were able to extract 20 requirements from user reviews related to context-adaption or context-detection, which thus apply to our understanding of context-aware services. Furthermore, 8 of these requirements can be linked to design approaches that could also be identified in our work. Table 2 provides an overview on the requirements (R) and – if existent – design approaches (D) derived from the user reviews and mapped to context-aware services.

Results regarding the *design* reveal that users of navigation apps prefer a simple and straightforward design which is easy to read and handle. Convenience is especially desired since context-aware applications are mostly used to obtain additional information while concentrating on a real world activity, such as driving. The quality of map data in terms of picture resolution and up-to-dateness is crucial for apps which provide location or navigation functionalities. Basic navigation should be enriched with a choice set of alternative routes. Other requirements in this category relate to map scaling and readability. *Information quality* entails the necessity to continuously update context information by balancing requests and informational value. Further, users value accurate context information which can be established by relying on multiple sources of context data. In case the context-aware application relies on crowdsourcing mechanisms (e.g., Waze for navigation), participation must be enabled and should be rewarded to raise information quality. To increase the *ease of use*, important menu points and settings should be conveniently accessible for the reader (e.g., while driving). In case location search and navigation is used in a context-aware application, users should be able to set personal waypoints and find points of interest relevant to their current needs in order to increase *personalization.* Furthermore, the use of location based services also allows for the implementation of *functional features* which users consider valuable. These are offline use of data (e.g., downloading a map for offline navigation), multi waypoint routes, reverse option for start and destination, route alternatives and precedence to more important applications. Especially the last feature is of interest for future work on context-aware services because it necessitates an integrated view on different services, their interaction and prioritization. Users further require *system availability* to be stable twenty-four-seven. Also the application itself should run without errors or crashes in any context. In order to establish *Privacy and security,* users desire control over when the app gathers context data. Although US users tend to neglect privacy and security concerns to obtain outstanding functionality, other (e.g., cultural) contexts may have formed different understandings, which have to be considered, since individual, organizational and cultural factors are suggested to moderate the effects on ESQ [5]. In addition, *network data usage* should constantly rely on few mobile data traffic and prompt a warning in case data capacity is close to user's data plan limit.

Table 2. Requirements and design approaches derived from user reviews

Requirement/Design approach
Design
R1: Simple Design: Context-adaptive applications should have a clean and simple design. Texts should be easy to read.
D1: Use modern and straight design with color contrasts. Refrain from using comic style.
R2: High quality map data: In case the app provides location detection and navigation functionality, high quality map data (i.e., resolution and up-to-dateness) should be provided. Zooming shout be possible on maps.
D2: Refrain from using similar colors for different elements (e.g., light grey for street, dark grey for houses). Provide high-resolution and up-to-date (also continually updated) map material.
R3: Prevent map from unwanted rescaling: If location detection on maps are used, users should have control over the scaling. Unwanted rescaling should be prevented.
R4: Easy to read additional context information: In case context changes, users should receive an easy to read but non-disturbing information (e.g., speed limit warning).
Information quality
R5: Continuous context updates: Users should at any time obtain information about the context which is up-to-date.
D5: Balance between information distribution and server requests. Load new context data (e.g., map data) only when needed.
R6: Accurate context information: Users should receive accurate context information at any time.
D6: Use multiple sources of context data, such as built-in sensors, user feedback, news and information from a crowd of users. Use effective algorithms for calculating fastest routes.
R7: Crowd participation: In case of sharing context information with the crowd, users should be able to easily participate.
D7: Give users easy access to crowd activities. Motivate crowd to participate.
Ease of use
R8: Easy access to important menu points: Important menu points and settings should be easy to access by the user.
D8: Provide short menu on top screen with most important settings which is easy to access while concentrating on real-world activities (e.g., driving)
Personalization
R9: Personal waypoints: In case maps are used, the user should be able to store and recall personal waypoints such as points of interest.

R10: Points of interest nearby: In case location search and/or navigation is used, users should receive recommendations to points of interest nearby based on their interests and current needs. Users should receive information and may let the app navigate to the respective destination.
Functional features *R11: Multi waypoint routes:* In case navigation is used, users should be able to set routes with more than one waypoint. *R12: Reverse option for start and destination:* If route planning or navigation is provided, users should be able to easily toggle start and destination. *R13: Route alternatives:* If navigation is used, users should choose from different route alternatives. ETA should be provided for the routes, too. Route alternative selection should also be available just-in-time, especially when context changes (e.g., traffic jam dissolves). *D13:* Calculate different route alternatives and ETA and provide the top two to three to the user. Users can then select the most appropriate route for them by clicking on one alternative. *R14: Precedence to more important applications:* In case apps are started that need access to hardware resources (e.g., incoming phone calls need access to speaker and microphone), users should be able to configure the app so it gives precedence to these applications (e.g., by stopping voice directions for navigation). *R15: Offline data:* Users should be able to download static data (such as map material or points of interest) to use them with context functionality (e.g. navigation) when no network access is available.
System availability *R16: 24/7 service availability:* Users should be able to access the service whenever they want. *D16:* Optimize network, system and service stability. Come as closest to 100% availability as possible. *R17: App stability:* Users should be able to run all functionalities of the app without failures, crashes and data losses in any context. Updates of the app should not lead to loss of data.
Privacy/Security *R18: Limit context detection:* The app should not gather context information from users, when it is not directly needed for the functionality the user executes. Users should further be able to completely turn off context detection.
Network data usage *R19: Use few network data:* In case no WiFi is available, the app should not use more mobile data capacity than needed for the current functionality. *R20: Data exhaustion warning:* Users should be warned in case network data capacity is high and close to the limit of the user's data plan.

Table 2. (cont.)

6 Conclusion and Outlook

In this work, we investigated how ESQ as main determinant of e-service satisfaction is established for mobile navigation services. By conducting a qualitative content analysis of user reviews for mobile navigation apps, we identified requirements and first design approaches to meet or even exceed customer's expected service experience and thus achieve high ESQ. However, future studies, qualitative as well as quantitative, must show if our categories comprehensively explain the effects of ESQ for context-aware (navigation) services and if requirements and design approaches identified in this study are applicable in a practical development context. Positioning ourselves in the field of ESQ, we are, to the best of our knowledge, the first who not only investigate ESQ from a purely empirical but also from a design perspective. Since reviewing and eliciting requirements from user comments in app stores is an upcoming approach in the field of requirements engineering [34, 36], building up on previous methodical work seems appropriate for our endeavor. However, since our sample is limited we can only shed light on a subset of possible ESQ requirements and design approaches that possibly hide in the mass of user reviews. Future research should investigate other app stores, such as the windows store, as well as cultural contexts other than the US to triangulate our findings. From a theoretical viewpoint, we propose to challenge ESQ theory-building approaches by introducing an inductive approach of qualitative category development. We suggest that ESQ as highly individual, perception-based construct cannot be fully explained by quantitative research only. We show that even a consolidated model of ESQ [5] cannot fully be applied on each case of interest. By further investigating more cases of context-aware services, (e.g., disaster warning systems), a theory covering ESQ for context-aware services will emerge. Furthermore, the accumulation of empirically grounded requirements and design approaches for ESQ-oriented design of such services can be considered as nascent theory of design and action [37]. We further contribute to requirements, software and service engineering practice, since we elaborate on what to consider when designing mobile navigation services with regard to ESQ. User reviews increasingly become an important source for evaluating design approaches and identifying opportunities for improvement. By comparing three good practice designs and consolidating both positive and negative design aspects, we elicit requirements that address contemporary customer needs and enable software and service engineers to establish high ESQ by design.

Recombinant Service System Engineering

Daniel Beverungen, Hedda Lüttenberg, Verena Wolf

Paderborn University, Department Wirtschaftsinformatik, Paderborn, Germany
{daniel.beverungen,hedda.luettenberg,verena.wolf}@upb.de

Abstract. Although many methods have been proposed for engineering services and customer solutions, most of these approaches give little consideration to recombinant service innovation. In an age of smart products and smart data, we can, however, expect that many of future service innovations need to be based on adding, transferring, dissociating, and associating existing value propositions. The purpose of this paper is to outline what properties constitute recombinant service innovation and to identify if current service engineering approaches fulfill these properties. Based on a conceptual in-depth analysis of 24 service engineering methods, we identify that most methods focus on designing value propositions instead of service systems, view service independent of physical goods, are linear or iterative, and incompletely address the mechanisms of recombinant innovation. We discuss how these deficiencies can be remedied and propose a first conceptual model of a revised service system engineering approach.

Keywords: Service engineering, recombinant innovation, (product-)service system, literature analysis, new service development

1 Introduction

The structured design of value propositions—also referred to as Service Engineering or as Product-Service Systems (PSS) Engineering [1–3]—has been a focal area of the Service Science discipline since the 1980s. Ever since, a plethora of methods has been proposed for designing 'services' or 'customer solutions' that consist of services, products, and information technology [1]. Against the properties of 'service' as the basic unit of exchange [4], we will refer to all these methods as 'service engineering' here for short. Most service engineering methods prescribe service design as a top-down engineering process that spans from idea management to introduction of a value proposition onto the market. Subsequently, service is co-created by service providers and service customers, thereby generating value-in-use for the stakeholders involved.

While the relevance of service engineering has increased [5], our understanding of service engineering has also shifted conceptually. In particular, the advent of smart products has enabled companies to offer value propositions that rely on context-specific field data that are made available in real-time. Discussed under the headword 'Internet of Things' or 'Internet of Services', these trends usher a new era of (smart) service systems engineering that is increasingly focused on designing integrated conglomerates

of products, services, and information technology, which jointly provide value propositions based on which service and value-in-use are co-created [4], [6], [7].

However, as opposed to a considerable body of knowledge on service engineering, the value and applicability of the available methods for the era of smart service is questionable for two reasons. First, many of the available methods seem complex, over-engineered and overwhelmingly cumbersome, and require large investments to be made before a value proposition can be offered on the market [3], [8]. Second, most approaches implicitly assume an inside-out perspective that is based on defining (modular) value propositions that service providers offer to their clients [8], [9]. In contrast, the progressing availability of smart products and smart data suggests that many future innovations will be recombinant instead [10]. A recombinant innovation is not designed and brought to market by means of a top-down engineering process, but is developed by combining existing resources and solutions supplied by different stakeholders, and filling the gaps between them to co-create innovative value-in-use in a service system.

The purpose of this paper is to conceptualize recombination as a type of service innovation and—based on this conceptualization—to assess the suitability of existing service engineering methods to foster this type of innovation. We answer the following research question: To what extend do current service engineering methods support recombinant service innovation?

The remainder of the paper is structured as follows. In Section 2, we review and discuss related literature on service engineering, new service development, and (product-)service system engineering, as well as literature on service innovation and service modularization. In Section 3, we explain and justify our research method that includes a literature review and a conceptual analysis of service engineering methods. In Section 4, we report the findings of our conceptual analysis. In Section 5, we propose design principles and present a conceptual service system engineering approach that implements these design principles. Section 6 concludes the paper.

2 Related Research on Service Engineering and Innovation

2.1 Developing/Engineering (Product-)Service (Systems)

The first approaches covering the development of services were published under the banner of "New Service Development" (NSD) in the Anglo-American literature of the 1980s [11]. Johnson et al. [12] outline why "NSD research mirrors that in NPD" (New Product Development) and focuses on success factors, which "address *what* should be done, not *how* it should be done" [12] (emphases contained in the text). NSD mainly focuses on particular issues in service development, e.g. quality [13], [14], prerequisites for services [13], service blueprinting [15], or enablers for service development [12]. The approaches often contain frameworks or (partial) processes without presenting detailed methods or tools for service development [12]. Also, they often focus on a service management or service marketing perspective [11], [13], [16].

In parallel to NSD, another research stream started in the 1990s, transferring know-how from engineering disciplines and software development to service development

[5]. Standardized process models, methods, and tools for product and software development were analyzed and adapted for service development [5]. The aim was to build on advantages of engineering processes like improved efficiency, reduced development time and costs, and increased quality for service development [11].

A center of activities in this research stream was in Germany, where the term "service engineering" was used since the mid-1990s [5]. Here, several initiatives, conferences, and publicly funded projects were initiated since 1994 to strengthen the research activities and competences in structured service development [5]. From the funding program *Dienstleistungen für das 21. Jahrhundert* (Services for the 21st Century), service engineering emerged as an independent focus topic [5].

Several process models for service engineering have been designed in papers and several PhD theses [17–19]. Early approaches feature three to seven steps that can be repeated iteratively. These approaches have close references to product engineering approaches and, therefore, consider service as a product without taking into account other aspects, such as organizational or social impacts [2], [11], [19], [20].
More recent research extends the point of view from designing a value proposition to designing a service system. Scheuing and Johnson [16] already highlight the necessity to convert "the new service concept into an operational entity". Klein [17] develops a systems engineering approach based on considering the service engineering system as a social system. Becker et al. [3] identify different conceptualizations of product-service systems. Böhmann et al. [2] "conceptualize a service system as a socio-technical system that enables value co-creation guided by a value proposition"; it includes "not only data and physical components, but also layers of knowledge, communication channels and networked actors" [2]. Service is a "collaborative process creating context-specific value" and can be supported by information systems [2]. Engineering service systems comprise defining service architectures (i.e., modules of a service system and their interactions), designing interactions in service systems, and mobilizing human, physical, and information resources [2].

2.2 Recombinant (Service) Innovation

Innovation in general can be defined as a discontinuous change and describes a new solution or renewal of an existing solution [21]. As opposed to mere invention, innovation has practical or commercial value [22].

The extant literature conceptualizes six innovation processes [23] that can be either planned, intentional, or unintentional, which emphasizes an innovation's emergent character [24]. These innovation processes are: radical innovation, improvement innovation, incremental innovation, ad hoc innovation, recombinant innovation, and formalization innovation. In theory, most innovations are based on some sort of recombination [22], since hardly any innovation cannot be deduced from prior known building blocks [25]. Therefore, we will focus on recombinant innovation here.

Recombinant innovation relies on combining existing elements to design new services or to generate a new relationship between previously uncombined components [26]. It has been claimed to be a role model for service innovation [24] that can lead to incremental improvements as well as radical changes [27] in service systems.

The four basic operations of recombinant innovation are summarized and visualized in Figure 1. They can be concatenated to build more complex innovation patterns.

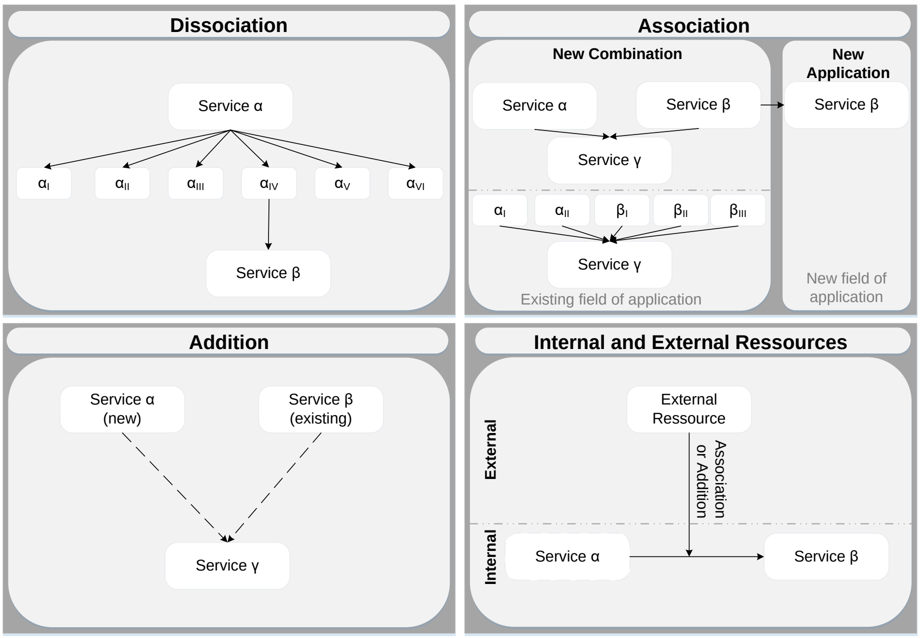

Figure 1. The four basic operations of recombinant innovation

Dissociation and association are two basic principles of recombinant innovation [28]. Association refers to designing a new value proposition by combining (or "associating") two or more existing services. Theoretically, any component can be recombined with any other component [26]. This indicates that the number of new combinations is a combinatorial function of the number of existing ideas [29]. An existing service can also be transferred to another context for which it was initially not designed [21]. Dissociation refers to designing a new value proposition by splitting up an existing one, isolating certain characteristics or a subset of operations, categorizing them, and turning certain elements into marketable services [30]. Services that have been split up into elements can be combined or integrated with other elements that were unconnected before [27]. Another principle of recombination is the addition of new value propositions [29].

Knowledge that is recombined can be drawn from internal and external resources. Internal resources refer to the capability to recombine a company's internal procedures in storing, retrieving, and processing knowledge [23]. Externally, firms retrieve knowledge through their relation with customers, suppliers, and other stakeholders that are involved in a service system [23]. Their relations give them access to valuable resources that cannot be generated internally. If resources possessed by the involved parties are similar, knowledge can be transferred efficiently leading to innovations, which however are rather incremental [31]. Integrating distant resources can lead to innovative breakthroughs, but presuppose that the actors can overcome cognitive disparities to absorb new knowledge efficiently.

Recombinant innovation relies on assumptions. First, it is assumed that a service can be broken down into clearly identified and defined elements [31]. Second, it is assumed that firms have the ability to maintain variety [27]. Third, recombinant innovation operates through continuous and cumulative creation of knowledge [30]. Managing this knowledge is complex [30], since successful recombinant innovation requires formalization and is therefore often built on a modular architecture [32]. This architecture allows the systematic reutilization of elements, which also leads to major resource savings [30]. Fourth, recombinant innovation requires certain competences of the agents, development work, and creativity [23].

2.3 Mass Customization and Modularization of Value Propositions

Mass customization [33] is a well-known strategy to efficiently deal with heterogeneous customer demand, based on configuring (seemingly) individualized value propositions that are composed of pre-defined modules.

Most of these methods include a service engineering process in which an initial set of goods, services, and IT modules are designed, often by defining a catalogue of items that are for sale [34], [35]. The design of modules is based on principles of strong cohesion and loose coupling. A crucial part of the engineering process is to specify modules and configuration rules with a (semi-)formal modeling language [35], [36]. The service engineering process is concluded with publishing a modular service architecture [37] that specifies the available components independent of specific customer requests.

In order to develop a value proposition for a particular customer, a service provider has to identify the needs, wants, and demands [38] of a particular customer, and configure a value proposition accordingly. The configuration process is based on fitting a subset of pre-defined modules together, allowing service providers to offer (seemingly) individual value propositions that fit a particular customer's demand.

3 Research Method

We performed a literature review to elicit what properties constitute recombinant innovation and analyzed which service engineering methods fulfill these properties.

The literature review was performed in line with the guidelines proposed by Webster and Watson [39]. After completing an informal screening phase, we compiled service engineering methods in several electronic libraries by applying German and English search strings. The literature research was conducted in the online data bases "Business Source Complete (via EBSCO Host)", "Association of Information Systems Electronic Library" (AISEL), and "Scopus". In addition, an extensive search was conducted in the journal Service Science, a local university library, and an inter-library loan system. Additional papers were compiled in a forward and backwards search to pinpoint articles that remained unidentified in the initial phase [39]. The search identified 24 methods.

Based on the literature we developed a concept matrix with eight dimensions. The dimensions were derived from the key properties of recombinant innovation and service engineering. Three coders individually used the concept matrix to analyze the identified service engineering methods. The initial inter-coder reliability [40] was measured using average pairwise percent agreement (A_0= 0.861), Fleiss' Kappa (κ=0.676), average pairwise Cohen's Kappa (κ=0.676), and Krippendorff's Alpha (α= 0.677). As all values are above the critical value of α_{min}= 0.667, concordance between the agents regarding the identified criteria can be assumed. Subsequently, we conducted a workshop to discuss and remedy conflicting assessments, until saturation was reached.
From the resulting concept matrix, a conceptual analysis was performed to identify the current state and research perspectives for service system engineering. Conceptual research can be used to initiate theory development and to assess and enhance theory [41]. Based on the analysis, we identify design principles that need to be considered by service system engineering methods and develop a conceptual approach as a prototype that communicates the design principles.

4 Conceptual Analysis of Service Engineering Methods

We use a concept matrix to provide a systematic review of service engineering methods [39]. While the matrix identifies the completeness of each method vis-á-vis theoretical concepts, any gaps and other topics are identified on the population level [39].

Our concept matrix is built on four types of constructs (Table 1). First, we identify addition, dissociation, and association as basic operations of recombinant innovation. Addition refers to recombining an existing value proposition with a novel characteristic. While each service engineering approach adds a new value proposition, we excluded approaches that did not explicitly identify preexisting value-propositions. Dissociation refers to a value proposition that is disaggregated into sub-components that are marketable themselves and/or can be combined with other modules adjacently. Association is a new combination of pre-existing value propositions or transfer of value proposition in a context for which this value proposition was not explicitly designed. Importantly, we submit that assembling pre-defined modules into (seemingly) unique solutions—as often done in modular service architectures—is not association in terms of a recombinant innovation, since modular service architectures often assume a finite solution space. Instead, we consider association to happen at design time, establishing new composite modules and/or new configuration rules.

Second, we identify if a service engineering method applies to designing a value proposition or if it is focused on designing a service system as socio-technical system for value co-creation. Since recombinant innovation often represents a combination of internal and external resources [42], service system engineering should identify the resources contributed by stakeholders in a service system early on.

Third, the type of process is identified as linear, iterative, or prototyping [43]. Linear models are characterized by discrete and consecutive process steps [43]. Iterative models exhibit multiple repetitions of the involved activities [43]. In prototyping models, a value proposition is refined by means of prototypes that communicate design ideas and explore the solution space, as proposed in Design Thinking [44].

Fourth, we identify if a service engineering method comprises the design of value propositions solely or if it also covers the design of value propositions in combination with physical goods. This combination of value propositions with physical goods results in Product-Service System (PSS), which allow the creation of new business models and added values for the customers [45].

Kim, et al. [57]	x	-	x	x	-	Value Prop.	linear	PSS
Müller [45]	x	x	x	-	x	System	linear	PSS

Our literature analysis of (product-)service (systems) engineering methods revealed four insights. First, few methods take a service system perspective, but rather focus on engineering a value proposition. Only ten methods consider the resources of customers, but limit the customers' role to requirements or need elicitation.

Second, using the identified basic operations of recombinant innovations as device of mind reveals that addition, dissociation, and association are seldom included in available service engineering methods. Twelve of the 24 analyzed approaches do not cover one of the stated operations at all, including all considered NSD approaches. Although eleven of the twelve remaining approaches include association, only four methods feature the operation transfer, which shows the largest gap.

Third, value propositions are not always perceived as solutions that can comprise both physical goods and services. Many approaches refer merely to engineering services without reference to any physical goods. Although only eight of the evaluated approaches focus on combining physical goods and services into customer solutions, these approaches became more frequent recently. Since 2006 all developed methods except one target PSS, which reveals a clear trend towards introducing all available types of resources into the co-creation of value.

Fourth, all evaluated approaches represent sequential or iterative processes and do not feature a prototypical approach as it is much discussed in Design Thinking or Software Engineering nowadays. As product development models are often linear approaches, some adapted methods for service engineering retained this structure.

5 Discussion

5.1 Design Principles for Service System Engineering Methods

The design principles are based on the four insights from literature analysis. They can be regarded as theory for design of service system engineering methods [58]. Thereby, the design principles explicitly prescribe how to build a service system engineering approach for recombinant innovation.

Design Principle 1: Take a service system engineering perspective

The analysis reveals that many service engineering methods present processes for designing a value proposition that is offered to a customer, but they refrain from specifying how the co-creation of value would be performed. Many approaches seem to implicitly take a goods-dominant logic perspective [4], [6] in which "services", "customer solutions", or "product-service systems" are engineered as marketable solutions, while refraining to specify the properties of a service system as a socio-technical system. This perspective is in line with methods for product engineering, foremost with the VDI-Standard 2221 [59], according to which many service engineering methods were designed. Even in Service Science, early papers defined a product-service system as "a mix of tangible products and intangible services designed and combined so that they jointly are capable of fulfilling final customer needs" [60]. As a result, "service engineering models, methods, and tools rarely focus on the development of service architectures" [2]. We argue that with the proliferation of technology in all societal sub-systems, integrating fragmented resources in socio-technical service systems will be increasingly crucial to provide superior value-in-use.

In line with this claim, the service-dominant logic of marketing [4], [6] posits that companies cannot offer *service* per se, as they can only offer *value propositions* that are enacted through a value co-creation of service providers and service customers, creating value-in-use for the actors involved. “Service systems comprise service providers and service clients working together to coproduce value in complex value chains or networks” [61]. Later, service systems were coined the basic abstraction in Service Science and defined as “a dynamic configuration of resources, including people, organizations, shared information (language, laws, measures, methods), and technology, all connected internally and externally to other service systems by value propositions“ [7], [61]. (Product-)service systems are socio-technical systems that enable co-creation of value by service providers and service customers [3], [2].

We argue that the design of service systems has to take a broader account than specifying the value proposition offered. But it should also focus the organizational and technological context that is required to turn a *value proposition* into *value-in-use*. Organizational and technological context comprise the assets and core competences that are brought to bear on the co-creation of value by (networks of) service providers and (networks of) service customers, including people, assets, processes, information systems and data, money, and relations with other actors that participate in a service (eco-)system. This view is beyond an abstract ‘implementation’ phase—as included in many current methods—since implementation refers to building up internal resources.

Design Principle 2: Recombine related resources in service systems
The analysis reveals that few of the reviewed service engineering methods refer to all aspects that constitute recombinant (service) innovation. Instead, many methods seem to perceive service engineering as a genuinely creative process that is conducted to design new value propositions from scratch, while not explicitly reusing or integrating solutions that are available in the service (eco-)system. As opposed to this finding, Brynjolfsson and McAfee [10] argue that in our *Second Machine Age* most innovations will be created based on recombining existing resources.

Recombinant innovation differs from configuring value propositions based on predefined modules. Methods for service modularization and configuration [35], [36], [62] usually presuppose that a finite solution space can be designed that is constrained by all permutations of the specified modules. Müller [45] refers to this approach as the *configuration shortcut*. In contrast, our approach is focused on service engineering itself, in which solutions are recombined to identify any missing modules that are required to set up a new value proposition and to co-create value-in-use.

In line with addition, dissociation, association, and transfer as the basic operations of recombinant innovation, we argue that service system engineering methods should explicitly identify the properties of the current service system as well as the value-propositions that can be designed and co-created with these resources. This relational approach goes beyond many available approaches [63], most of which focus on requirements elicitation and analysis. We argue that this perspective is inherently goods-dominant, since it does not put assets and core competencies of the involved stakeholders center-stage. As a result, requirements analysis is often not described as relational process, but as activity that is performed by a service provider alone.

Based on the socio-technical properties of service systems, a relational view on service system engineering would fit assets and core competencies of the involved actors together (association), further advance and detail existing assets and core competencies (dissociation), engineer new value propositions and transform the service system (addition), and apply resources outside their intended context of use (transfer).

Design Principle 3: Conceptualize value-in-use as based on both access to external resources and transfer of ownership of physical goods

Not surprisingly, our analysis refers to different types of service engineering approaches. While many methods in NSD focus on designing immaterial value-propositions, Service Engineering often explicitly integrates physical goods and services. Service research in the latter stream has come a long way from hybrid value-creation [64] to cyber-physical systems that view smart objects as resources in service systems.

Since we expect that many future service systems will be based on data and functionality provided by smart objects, we strongly argue that service systems must be designed to explicitly consider all resources that are available for recombination. Supporting this view, service-dominant logic [4], [6] has long advocated that physical goods are distribution mechanisms for service, since they stem from operand resources that stakeholders contribute to service systems. The rental-access paradigm [65] has highlighted that the core of service (as opposed to transferring ownership of products) is temporary access to resources, which customers do not own themselves.

Design Principle 4: Use prototypes to communicate the design of service systems

The analysis revealed that many methods conceptualize service engineering as a linear or iterative process, but seldom suggest prototypical approaches. Service engineering methods, in particular, feature many steps before a value proposition is offered to a customer. In contrast, innovation literature states that innovation is emergent and can even happen unintentionally or unplanned [24].

Recently, the Design Thinking movement has argued strongly for organizing engineering as a cyclic process that comprises several design cycles, each of which ends with a prototype. Similar approaches have been applied in software engineering for some time, including Scrum and other agile software development methods. A cyclic approach is also in line with the basic tenets of design science research that conceptualize design as building and evaluation [66], or with the cyclic approach presented in Action Design Research [67].

Since future service systems will rely strongly on data and information systems, we propose that they need to be designed with agile methods, as those proposed in software engineering. Service system engineering methods should, therefore, feature cycles of design and evaluation, followed by processes of organizational learning.

5.2 A Service Systems Engineering Approach for Recombinant Innovation

We visualize the design principles by presenting a conceptual method for service system engineering (Figure 2). The method builds on many established concepts of service engineering, since we reviewed all steps that current service engineering methods feature, and reorganized them for compatibility with our design principles. Our method comprises Service System Analysis, Service System Design, and Service System Transformation as its three basic sub-processes.

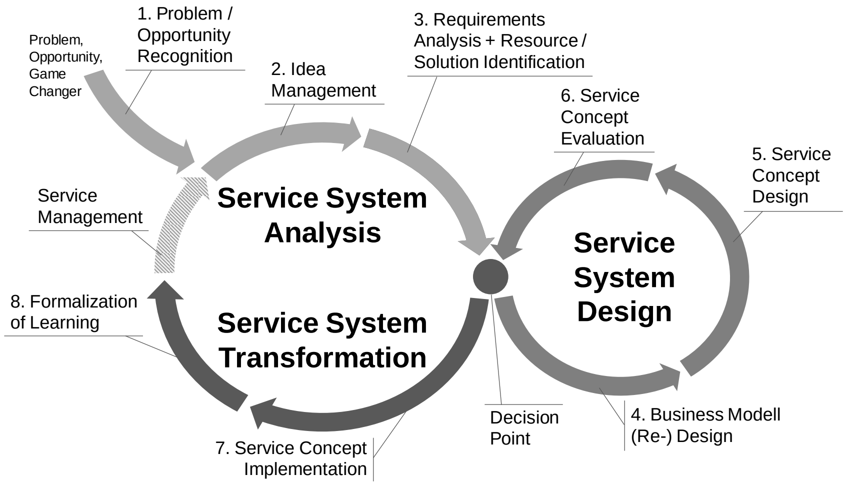

Figure 2: A method for recombinant service system engineering

Service System Analysis is started to remedy a problem or to realize an opportunity by (re-)designing a service system. In Idea Management, different ideas are identified and evaluated to identify those that are worth pursuing in a detailed analysis. Subsequently, an extensive Requirements Analysis is performed. Extending current methods, Requirements Analysis explicitly identifies the resources present in a service system, to enable the involved actors to recombine their assets and core competencies.

Service System Design comprises Business Model Design, followed by Service Concept Design, and Service Concept Evaluation. These activities are organized is cycles, in line with the design science paradigm that conceptualizes design as “to build” and “to evaluate” [66]. The Service Concept Design can comprise physical goods whose ownership is transferred in exchange processes and resources that can be rented/accessed by other actors in a service system.

Service System Transformation comprises implementing the final Service System Concept in order to integrate further resources and learn additional core competencies that are required to co-create the intended value-in-use. Therefore, the service system is transformed as a socio-technical system, beyond designing value propositions and then implementing resources. The service system engineering process is dynamic and focuses on developing viable prototypes as result of each cycle.

A **Decision Point** connects all three sub-processes. After Requirements Analysis is completed, service system engineers can decide to either recombine existing resources (transfer, association) and commence with Service Concept Implementation, or to commence with Service Concept Design (addition, dissociation). At the same time, the decision point marks the judgement to leave the design cycle after a viable Service Concept has been designed that complies with the identified requirements.

6 Conclusion

Based on a conceptual analysis of service engineering methods, our paper offers three contributions to research and practice. First, we provide an update on the methods for service engineering that have been proposed in various research streams in the Service Science discipline. Second, we identified conceptual shortcomings with respect to (a) applying a service systems perspective, (b) considering the basic operations of recombinant innovation that will likely become more prominent in what Brynjolfsson and McAfee [10] have termed the Second Machine Age, (c) considering the transfer of ownership for physical goods and the rental of/access to external resources, and (d) prototypes for designing value propositions. Third, we proposed design principles for service system engineering and visualized them with a conceptual model.

Limitations refer to the lack of generalizability that is inherent to conceptual and qualitative research. While we took precautions to objectify the coding process and attain inter-coder reliability, we acknowledge that other researchers might have come to different assessments of the reviewed service engineering methods.

Other researchers and practitioners can build on our results in multiple ways. First, as an IT artifact the design principles can be subjected to demonstration and evaluation that inform further design cycles. In particular, we are eager to see how the four basic operations of recombinant innovation can be applied successfully. Second, an evaluation could also shed light on how intensively or loosely product engineering and service systems engineering should be intertwined. While a close integration seems favorable to design consistent value propositions, loosely coupling the processes could keep the design of service systems agile, while decoupling them from more inflexible product development processes. Third, researches should investigate if organization do have the necessary resources at their disposal to implement the proposed approach. Concomitant, investigating synergist effects can be another area for future research.

Blueprinting Crowdfunding
Designing a Crowdfunding Service Configuration Framework

Philipp Haas, Ivo Blohm

University of St.Gallen, Institute of Information Management, St. Gallen, Switzerland
{philipp.haas,ivo.blohm}@unisg.ch

Abstract. Crowdfunding gained momentum over the last few years. In contrast to traditional forms of funding, the service provision of crowdfunding platforms is performed within service systems. These comprise a complex combination of IT and non-IT services, different stakeholders, and diverging contexts and purposes. The design and operation of such service systems represents a tough challenge. Therefore, we developed a crowdfunding service configuration framework in the form of a morphological box and derived three dominant design patterns by following a design science approach. Therefore, we followed three iterations, which comprise in total twelve expert interviews, three case studies and the analysis of 161 crowdfunding platforms. The configuration framework extends research on crowdfunding and service science by providing insights in how to support the systematic design of crowdfunding service systems, reducing their complexity, and giving a comprehensive overview over their building blocks.

Keywords: Crowdfunding, Service Systems, Modularization, Design Science

1 Introduction

Crowdfunding represents a new way of funding projects or companies, involving a diverse crowd of private capital givers over the Internet, and is frequently considered a more transparent, easy, entertaining, and democratic way of funding. Therefore, crowdfunding gained momentum during the last few years and began to establish as an alternative way of funding. As a consequence a variety of complementary crowdfunding platforms emerged, ranging from altruistic to profit oriented offerings. These mostly start-up driven crowdfunding platform providers build innovative offerings for both, the utilization of highly specialized niche markets as well as the mass market for financial products. Crowdfunding start-ups use their high degree of automation, the Internet, the web 2.0, and innovative opportunities such as data analytics. In order to grasp these opportunities, the service provision of crowdfunding platforms is performed within service systems. This allows operators of crowdfunding platforms to provide some services by themselves, whereas they may source others from specialized partners (e.g. payment, banking, dunning) within a service system [1].

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Haas, P.; Blohm, I. (2017): Blueprinting Crowdfunding - Designing a Crowdfunding Service Configuration Framework, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 151-165

Despite the huge growth of the crowdfunding market in terms of origination volume and platform numbers, this growth is not distributed equally among all types of crowdfunding. While the market for crowdlending is booming, the market for crowdinvesting is stagnating. Further, the market in general is characterized by a large fluctuation and shows the tendency of consolidation [2, 3]. As crowdfunding comprises a complex combination of services and stakeholders, the design of such service systems represents a tough challenge. Thus, many attempts to design new crowdfunding service systems struggle, as the complexity of the crowdfunding service system can't be overseen and it lacks knowledge about how to systematically design crowdfunding service systems. In order to overcome this challenge the design has to allow the decomposition of the crowdfunding service system into single components. This approach is known from the concept of service modularization [4, 5]. Especially, during early stages of the development of crowdfunding services and the assessment of design choices, guidance is needed. Despite its relevance, research on crowdfunding has largely neglected the topics of how to systematically design crowdfunding service systems [6]. This hampers the development of new crowdfunding offerings, the exploitations of new market niches and the maturation of the crowdfunding industry. Therefore, this paper pursues the research question of *how potential crowdfunding providers can design crowdfunding service systems systematically*.

In order to answer this research question, this paper follows the design science (DS) paradigm [7, 8] by designing a crowdfunding service configuration framework, which takes the form of a morphological box, by combining a component perspective and a functional perspective. The crowdfunding service configuration framework aims at a structured and comprehensive presentation of crowdfunding service systems by presenting ten constituting service modules with in total 24 differentiating parameters and three dominant design patterns – altruism, hedonism, and profit-orientation.

This paper provides especially two theoretical contributions. First, the paper expands crowdfunding research by proposing a crowdfunding service configuration framework, which describes the building modules of a crowdfunding service system. Thus, the configuration framework provides an overview over required service modules and respective parameters. Second, the paper bridges research on crowdfunding with the field of service science. Thus, we contribute to service science, by proposing a framework for the systematic design of modularized services systems. Therefore, we contribute to the call for the design of novel artefacts, facilitating the engineering and management of service systems [4]. For practice, this paper provides guidance for the systematic design of crowdfunding service systems, the decision support for the assessment of required competences, the identification of white spots for business opportunities, and a better understanding of the disruptive potential of crowdfunding.

The paper proceeds as follows. First, we give an overview over the related work regarding complex service systems and crowdfunding service systems. Second, our DSR approach is presented. Third, the iterative design process of the crowdfunding service configuration framework is described. Fourth, we discuss our findings and present our theoretical and practical contributions.

2 Related Work

2.1 Complex Service Systems

A service is a bundle of activities, which takes place between the user and provider of a service within a service system [9, 10]. Service systems can be described as value-co-creation of stakeholders, technologies, and shared information (e.g., language, laws, measures, and methods) [11]. One can speak of a complex service, if multiple stakeholders are integrated into the service system, various interactions between them are necessary, and IT and non-IT activities are combined in order to harness its value [12]. In order to leverage the value co-creation, service systems follow a modular design, which enables the systematic engineering of service systems [4, 13]. Modularization can be described as decomposition of a single object into decoupled single components, which can be combined in various way to create new configurations [14]. Modularization rests upon the basic principles of cohesion and loose coupling [15, 16] and has been already established in the context of service science [17, 18].

2.2 Crowdfunding Service Systems

Analogous to crowdsourcing, crowdfunding can be defined as collective financing by an undefined crowd by means of an internet-based open call [19, 20]. Despite the large attention the topic of crowdfunding has drawn among the financial service industry, research on crowdfunding has largely neglected the systematic design of crowdfunding service systems. Certain studies aimed at the systemization of crowdfunding services systems [20-23]. Tomczak and Brem [24] aimed at conceptualizing an investment model by taking a process perspective on crowdfunding service systems by applying process modeling technique. Wieck et al. [25] made an early attempt to investigate how to develop, pilot and evaluate an crowdfunding service system, in order to support university startups. Liebenau et al. [26], Hemer [27], and O`Sullivan et al. [28] argue that the advantage of crowdfunding service systems lies in their modular ecosystem structure, which enables the bundling and aggregation of various competences within a complex service system. Recently, Haas et al. [6] reported about the implementation of the modular design of a crowdfunding service system.

3 Research Approach

In order to develop a configuration framework for the systematic design of crowdfunding service systems, a morphological box turned out to be a valid form. A morphological box combines a component perspective by listing the building modules and functional perspective by detailing these modules in single functional characteristics. This makes a morphological box a heuristic method for capturing complex issues [29, 30] such as the design of crowdfunding service systems. Besides, morphological boxes have been successfully applied to the context of complex IT services before [31, 32].

In order to develop and evaluate the crowdfunding service configuration framework, which supports potential providers of crowdfunding service system, we followed a design science approach. Design science research is highly suitable in solving a real world problem such as the systematic design of crowdfunding service systems. Therefore, design science aims at the iterative development of an innovative IT artefact. The design science paradigm, as suggested by Hevner [7, 8], aims at rigor and relevance of the proposed design by following three integrated cycles: relevance cycle, design cycle, and rigor cycle. The relevance cycle aims at bridging the design activities with its practical environment. Thus, it helps specifying the real-world problem, eliciting the needs and requirements for solving it, and the recirculation of the designed artefact to the field of practice. The rigor cycle ensures the interconnection between the designing of the artefact with the existing knowledge base. Thus, the design of the artefact is informed by existing theories and knowledge, while new knowledge, resulting from the design, is recirculated to the knowledge base. Surrounded and influenced by the relevance cycle and the rigor cycle, the design circle is situated in the center. The design cycle represents the iterative design activities, which are necessary in order to construct and evaluate the artefact.

We performed three iterations in order to design and evaluate the crowdfunding service system configuration framework. Within the first design iteration, the problem has been specified and requirements have been elicited from the field. Therefore, we conducted a comprehensive study of related literature and performed three expert interviews. All three interviewed experts aimed at engaging in the crowdfunding market by designing an own crowdfunding service system, but struggled, as they were unable to oversee the complexity of the crowdfunding service systems. The interviews led to a first impression of the scope and form of the configuration framework. Within a second phase, three case studies, comprising one illustrative example for each crowdfunding service system archetype – altruistic, hedonistic, and profit-oriented [22] – have been conducted in order to identify the building components and characteristics of crowdfunding service systems. Further, service modularization technique has been applied [16, 33]. Therefore, the identified services within the crowdfunding service system have been described on a process level in order to derive modularization parameters. Afterwards, these parameters are applied in order to identify the actual service modules. Thereby, a first version of the configuration framework has been designed. In order to evaluate the module validity, the framework's comprehensiveness, its applicability, and usefulness, six interviews have been conducted with crowdfunding experts (bank representatives, platform providers, and researchers), which participated in the design of a crowdfunding service system. This led to further refinement of the artefact. Within a final phase, the configuration framework has been applied to code 161 crowdfunding service systems, in order to identify dominant design patterns, which could serve as starting point for the design of crowdfunding service systems. A final evaluation of the configuration framework and the patterns has been conducted by interviewing the three initial experts again. The experts have been questioned whether the configuration framework meets their mentioned requirements and, by looking back, whether the identified design patterns represent suitable starting points for the design of their crowdfunding service systems.

4 The Crowdfunding Service Configuration Framework

4.1 Iteration 1: Problem Specification and Requirements

Within the first design iteration, including all three cycles, the aim was to specify the problem and to elicit requirements for the configuration framework. In order to specify the problem and elicit requirements from the field, three expert interviews and a comprehensive literature study have been conducted. First, we started performing a relevance cycle by conducting three expert interviews in order to get an impression of the problem of designing crowdfunding service systems and in order to elicit design requirements. The interviews were conducted via Skype during June 2016 and were 30 to 60 minutes long. The interviewees came from two different banks and a start-up incubator. All three experts were responsible for the design of crowdfunding service systems in distinguishing contexts. All three struggled with their attempts to engage in the crowdfunding market, as they overstrained with the complexity of the crowdfunding service systems. They annotated consistently that especially during the beginning of their attempts, they longed for support in overseeing alternative options and dependencies. They had to waste a lot of time and resources in order to figure out basic functionalities of value proposition, value creation, and value capturing and assessing the general fit of a crowdfunding type to their desired objectives. The input from the relevance cycle has been expanded by performing a rigor cycle. Therefore, findings from a comprehensive literature study, regarding literature on crowdfunding and complex service systems has been used to inform the elicitation of the requirements and to bridge the different literature streams, in order to enhance the current body of knowledge. After finishing the rigor cycle, we evaluated and refined our recent design activities – the deducted requirements – by interviewing our experts again, in order to ensure comprehensibility, correctness and applicability. Iteration 1 identified three major requirements: 1) Early-stage applicability and reduction of complexity. 2) Structured and comprehensive presentation of crowdfunding service systems. 3) Dominant design patterns as template. Table 1 gives an overview over the identified and evaluated requirements.

Table 1: *Design Requirements*

Requirement	*Description*
Early-stage applicability and reduction of complexity	Crowdfunding is based on components and competencies, which have not been considered relevant so far [6, 26]. Thus, many struggle at early design stages to oversee its complexity and disruptive potential and lack critical competencies. Many different stakeholders are necessary in order to bundle the required knowledge. Therefore, complexity has to be reduced in a heuristic manner, in order to light up the opportunities, objectives, functionalities, and consequences of crowdfunding for the involved stakeholders.

Structured and comprehensive presentation of crowdfunding service systems	Due to its high complexity, the various functionalities and dependencies within the service system are hard to oversee. Therefore, a functional perspective, as well as a component perspective, have to be combined in order to structure the constituting components of a crowdfunding service system. Besides the comprehensive overview over the single services, ensuring flexibility for several configurations is paramount. Therefore, a modular structure of the implicated crowdfunding services within the framework enables the loose coupling and thereby, easy reconfiguration of the components.
Dominant design patterns as template	As crowdfunding service systems can be designed for various purposes, the definition of what to achieve with an own crowdfunding service system and which configuration supports these objectives is often blurry. Providing dominant design patterns have to be identified in order to serve as a starting point for the design activities.

Besides the deducted requirements, Iteration 1 led to a first impression of the scope of the configuration framework and identified a morphological box as a valid and suitable form, due to its ability to capture complex issues, bridging a functional and a component perspective. Its heuristic character reduces complexity and enables early-stage application even for unexperienced co-workers.

4.2 Iteration 2: Designing the Configuration Framework

After specifying the problem and eliciting requirements from the field, we conducted three case studies of the three experts' initiatives for designing a crowdfunding service system, in order to identify the building modules of crowdfunding service systems. These cases represent illustrative examples for each archetype of crowdfunding service system - altruistic, hedonistic, and profit-oriented [22]. In order to collect the data for the case studies and evaluate our findings, we conducted multiple iterative interviews and workshops with the experts and the respective members of the project teams. Further, we studied the business models of each case example by analyzing public information (e.g., website, terms & conditions) and private documents (e.g. business plans, process models). In order to perform a rigor cycle, we studied literature regarding process and ecosystem modelling and service modularization in order to find heuristic methods for their illustrations and analyzes. Thus, we identified three suitable methods - activity chain modelling for processes [34], e3 value for the illustration of ecosystems [35], and TM3 as method for service modularization [16]. We began the design cycle by modelling the customer journey and the ecosystems. We continued by modelling the single complementary activities of each stakeholder, which supports the customer journey or the crowdfunding process. Thereby, participating stakeholders, interfaces, information-, and money flows have been considered and evaluated. Afterwards, the activities have been modularized according to defined modularizing parameters, which aim at ensuring internal cohesion and loose coupling [16]. These parameters have been defined as 1) representing a pivotal topic within the crowdfunding process; 2) represents a closed activity; 3) is performed and provided by one stakeholder. Each identified service module represents a bundle of activities regarding specific processes within the configuration framework. These activities have been grouped by analyzing the intra service module cohesion, in order to identify the major parameters of a service module. The three case studies indicated a robust set of the similar ten service modules with in total 24 differentiating parameters. As the characteristic of the modules differentiate between each of the analyzed service systems, variations of the parameters have been defined. Defining these characteristics as variations of the module, allows the parallel selection of different characteristics for each module, within the crowdfunding service system. In order to ensure completeness and generalizability of our findings we performed another relevance cycle. We extended the identification of further parameter variations to a dataset of 161 crowdfunding service systems, which have been identified by conducting an online search. Search criterions included that: 1) it is active; 2) it is in German or English language; 3) the necessary information are publicly available; 4) it refers to a crowdfunding mechanism (e.g. mentioning the term crowdfunding). We reviewed each module parameter on each of the 161 crowdfunding service systems, included new variations and aggregated similar ones. In total one to six parameter variations have been identified and finally included in the crowdfunding service configuration framework.

Table 2 gives an overview over the identified service modules and the according characteristics.

Table 2: *Overview Service Modules*

Service Module	*Description*
Matchmaking	Matchmaking between capital givers and capital seekers represents a pivotal service within the service system. Therefore, an e-market place is operated in order to provide information, and to register funding decisions. As the matchmaking takes place in a two-sided market, we identified the two parameters capital seekers and capital givers, which showed two respectively three variations. Thus, we identified *individual* and *institutional capital givers* and *individuals, non-profit organizations, and for-profit organizations* as capital seekers.
Crowd Activation	Crowdfunding includes the attraction, activation, and balancing of the 'right' crowd of capital givers and seekers in order to ensure funding success, attractive returns, and to generate thick markets and network effects. Therefore, activating activities are performed online and offline. These two parameters showed three variations respectively – *none, mass advertising and personalized advertising*.
Customer Support	Crowdfunding aims at being more unbureaucratic and easier. Therefore, overcoming initial barriers and to clarify customer issues is addressed by providing comprehensive support for both capital givers and capital seekers. Both parameters showed the same five variations – *none, offline support, online support, personalized support, and automatized support.*

Market Differentiation	Crowdfunding mainly focuses on niche markets and serves the long tail of the financial service industry. Thus, it provides funding for project which cannot be served profitably by the traditional financial service industry. As crowdfunding service systems serve highly heterogeneous needs, a precise market differentiation is undertaken. Thus, we identified three market differentiating parameters – the motivation of the crowd, the market specialization of the service system, and the type of compensation, which is provided by the capital seekers. The motivation of the crowd differentiates between *altruism*, which aims at doing good, *hedonism*, which aims at satisfying own curiosity, and *profit-orientation*, which aims at satisfying monetary expectations. The specialization of crowdfunding intermediaries varies between *sustainability & social action, startup & new business, private consumption*, and *creative projects & products*. The compensations range from a *greater good*, where no compensation is provided, non-monetary *rewards*, *interest*, to proportional *profit-shares* according the success of the supported project.
Investor Relations	Crowdfunding as a more transparent and democratic way of investing aims at fostering communication between capital givers and capital seekers and enables a performance monitoring of the projects. The communication channels between capital givers and capital seekers revealed three variations- *none, traditional communication channels* (such as e-mails, telephone, fax), and *web 2.0 communication channels* (such as social media, blogs, and chats). As a second parameter performance monitoring is implemented by three variations – *none, progress bar*, which shows the actual funding status, or a *portfolio management system*, which enables an aggregated overview over the invested capital or even an automatized (re-)investment process regarding to the portfolio specifications.
Contracting	Contracting is essential for ensuring liability and compliance. Therefore, we identified two major parameters within this service module. First, terms and conditions mainly regulates the use of the crowdfunding service in general. We found four variations – *none, standardized terms of use, privacy policy regulations*, and *payment regulations*. Second, the legal relationship between capital seekers and capital givers after funding success represents a differentiating parameter. This parameter showed the two variations *direct legal relationship*, in the case of a direct peer-to-peer relationship, and *indirect relationship*, in the case of a legal intermediation (e.g., a bank).

Risk Assessment	Overcoming information asymmetries is essential in order to provide funding for capital seekers and reduce default risks for capital giver. Two parameters have been identified – due diligence and feasibility. The due diligence aims at assessing the credit-, and trustworthiness of a project and the capital seekers. The due diligence parameter shows three variations – *none, traditional forms,* by assessing personal data and documents, and *big data analyses*, which includes information based on data analytics (e.g., behavioral information). The second parameter aims at assessing the feasibility of a project, which can be performed by three variations – *none, business/project plan*, and *prototype.*
IT Functionality & Operations	A reliable platform with satisfying functionality is pivotal, as it represents the digital point of contact between capital seekers and givers. Overall, three parameters have been identified. First, the development and hosting of the platform, which shows the three variations *in-house, external service provision*, and *white-label solution.* Second, the registration process for capital givers and seekers, which is performed by the three variations *none, website login (via e-mail and password)*, or *social login* (Facebook or Google). Third, the form of the application can be differentiated into the two variations *web app*, or *mobile app*.
Payment	Payment represents a pivotal service as a fast, reliable, and efficient flow of money can be provided. Four parameters have been identified. First, the actual form of the payment system, which shows four variations – *offline payment* (e.g., cash in-payment), *traditional direct payment* (e.g., credit card), *online direct payment* (e.g., PayPal), and *direct debiting*. Second, the time of the payment, which can be *pre-paid, instant-paid*, and *post-paid*. Third, in case of debt default four variations can be differentiated – *none, notifications, dunning,* and *debt collection.* Fourth, the form of the payment processing – *directly* between the capital giver and seeker or *indirectly* via a financial intermediary (e.g., a bank).
Authentication	In order to meet certain legal regulations, prevent fraud, and reduce risks for capital seekers and givers, know your customer (KYC) services are applied regarding capital seekers and capital givers. Both parameters show four variations – *none, personal offline identification* (e.g., via a post office, notary), *automated digital identification* (e.g., digital passport, CAPTCHA), and personal online identification (e.g., via webcam)

These modules have been summarized within a morphological box, which represents the crowdfunding service configuration framework. For evaluating the proposed design of the configuration framework, with regard to module validity, the framework's comprehensiveness, its applicability, and usefulness, we conducted six interviews in total. Therefore, we re-interviewed the three initial experts plus three additional crowdfunding experts, which participated in the design or operation of a crowdfunding service system as well. One of the new consulted experts came from a bank and two from academia. First, the experts were asked to apply the configuration framework to their crowdfunding service system. Second, we asked them to rate the configuration framework with regard to comprehensiveness, its applicability, usefulness, and whether it meets the design requirements. The evaluation indicated good fit to the design requirements and confirmed comprehensiveness of the stated parameters and characteristics, high applicability for early design phases, and usefulness as it reduces complexity in a heuristic manner. The experts' feedback was taken into account thoroughly and led to further refinement of the configuration framework. The evaluated and refined version is presented in Table 3.

4.3 Iteration 3: Dominant Design Patterns

The three cases and our search for parameter variations revealed fundamental differences in the module characteristics and the module configurations. Nevertheless, we assumed the existence of dominant design patterns, as these differences are related to the basic orientation of the crowdfunding service system, which ranges from altruistic, hedonistic, to profit oriented purposes [22]. A rigor cycle regarding literature on the systemization of crowdfunding service systems revealed that these respective archetypes require different configurations due to differentiating target markets, related risks, legal reasons, and the motivation of capital givers and seekers [6, 21, 24]. Thus, the identification of basic design patterns would serve as a useful starting point for the design of crowdfunding service systems. Therefore, a relevance cycle has been conducted by applying the configuration framework to the 161 crowdfunding service systems from our previous platform analysis, which have been grouped according to its respective crowdfunding archetype – altruism (N=53), hedonism (N=60), and profit-orientation (N=48). Thus, the three groups showed large internal proximity with regard to four service modules, which differentiates clearly against the other groups - market differentiation, risk assessment, payment, and authentication. Thus, performing a design cycle, we defined three design patterns for crowdfunding service systems, which correspond to the three crowdfunding service system archetypes altruism, hedonism, and profit orientation. The predominant parameter variations of the three design patterns are indicated by color-coding in the configuration framework (see Table 3) - altruism: bright grey; hedonism: dark grey; profit-orientation: black.

The altruism design pattern is characterized by altruistic motives of the capital seekers and givers. Therefore, it focuses on sustainable and social caring projects and provides no compensation besides a sense for supporting a greater good. In contrast to the other design patterns non-governmental organizations appear as capital seekers. Typical examples for the altruistic design pattern might be *Benevolent*, *100Days*, or *Kiva*.

The hedonistic design pattern satisfies hedonistic motives and therefore, offers reward-based compensations and focuses mostly on the funding of creative projects. In order to reduce investment risks and to ensure the feasibility of the proposed crowdfunding projects, a feasibility check based on business or project plans or even prototypes is applied. Further, a basic level of activity in the case of debt default is performed by actively notifying defaulting capital seekers or givers. Typical examples for the hedonistic design pattern might be *Kickstarter*, *Startnext*, or *WeMakeIt*.

The most rigid pattern is represented by profit-oriented crowdfunding service systems, due to higher default risks and stronger legal regulation. Capital givers are motivated by gaining profits. Therefore, this pattern focuses on the funding of either start-ups or new businesses, where profit shares a predominant as compensation, or funding private consumption by granting loans and providing interests as compensation. Providing a portfolio-management system for fostering investor relations enables both, risk diversification and maximizing profits. Effective risk assessment is crucial due to the higher risk. Therefore, comprehensive due diligences based on traditional documentary are necessary. In the case of private capital seekers, these due diligences are often extended by data analyses based on the online behavior of the capital seekers (such as online times, previous visited websites, etc.). In the case of debt default, activities regarding dunning or even debt collection are predominant. Due to anti money laundering legislation, KYC activities are necessary in the profit-oriented design pattern. Typical examples might be *Companisto*, *Lendico*, or *Investiere*.

5 Discussion & Implications

This study presents a rigor and relevant crowdfunding service configuration framework in the form of a morphological box, which supports potential providers to systematically design crowdfunding service systems. By applying service modularization technique, we identified ten service modules, which represent required constituting blocks of a crowdfunding service system. This modules can be implemented via 24 module parameters with two to six parameter variations. Thus the parameter variations represent instantiations of a service module within a crowdfunding service system, which represents design choices for the early-stage blueprinting of crowdfunding service systems. Our evaluation showed that the configuration framework is comprehensive, useful, and applicable. Further, we derived three dominant design patterns – altruism, hedonism, and profit-orientation. Thus, this patterns support previous findings of crowdfunding research [22]. We identified strong in-group homogeneity among the characterization of several modules, which differentiates clearly in contrast to the other patterns. These differences can be explained by the basic orientation of the crowdfunding service systems, the differentiating motivation, risk, and legal requirements.

The configuration framework can be applied for both, the design of new crowdfunding service systems and the analysis of existing ones. In order to apply the configuration framework, each module has been assessed according to the desired output of the service system. The dominant design patterns may serve as a starting point. The parameter characteristics are designed as variations. Therefore, one can chose multiple variations for each parameter.

This paper contributes to research on crowdfunding and service science and provides especially two theoretical contributions. First, the paper expands crowdfunding research by proposing a crowdfunding service configuration framework, which describes the building modules of a crowdfunding service system and three dominant design patterns. Thus, the configuration framework and the dominant design patterns provide an overview over required service modules and respective parameters. By empirically deriving the dominant design patterns, thus verifying the appearance of certain design modules in specific contexts, we provide insights in the differentiating designs of crowdfunding service systems. This indicates that specific contexts (altruistic, hedonistic, and profit-oriented) require different modules in order to perform the context-specific service provision. By providing empirical evidence this paper supports and extends previous purely conceptual research on the modular structure of crowdfunding [6, 26, 27]. Further, considering the variety of crowdfunding service systems, the configuration framework may allow for the comparison of crowdfunding service systems on both, a functional and a component perspective, which might provide interesting results for a better understanding of crowdfunding in general and the design of crowdfunding service systems. Besides, the crowdfunding configuration framework possess predictive quality as the dominant design patterns indicate both, intra-group homogeneity and inter-group heterogeneity. Thus, the design patterns can be applied in order to predict the classification of a crowdfunding service systems to a certain crowdfunding archetype.

Second, the paper bridges research on crowdfunding with the field of service science. Thus, we contribute to service science, by proposing a framework for the systematic design of modularized services systems, which has been instantiated on the example of crowdfunding. Therefore, we contribute to the call for the design of novel artefacts, facilitating the engineering and management of service systems [4].

For practice, this paper provides guidance for potential providers to systematically design crowdfunding service systems. Further, it enables the decision support for the assessment of required competences, the identification of white spots for business opportunities, and a better understanding of the disruptive potential of crowdfunding. The three dominant design patterns serves as an initial blueprint for the implementation of a crowdfunding service system. Besides encouraging new market entrants e.g., banks or start-ups to systematically exploit white spots of the crowdfunding market and to develop new crowdfunding offerings, our findings might support established providers of crowdfunding service systems to evaluate their current system configurations.

We hope our study will encourage future research to take up the idea of crowdfunding as modular service systems. This might facilitate future studies to analyze the building modules of these service systems and their interrelations in more detail.

Table 3 Crowdfunding Service Configuration Framework

Service Modules	*Parameters*	*Variations*			
Market Differentiation	Crowd Motivation	Altruism	Hedonism	Profit-Orientation	
	Specialization	Sustainability & Social Action	Startup & New Business	Private Consumption	Creative Projects & Products
	Compensation	Greater Good	Reward	Interest	Profit Share
Matchmaking	Capital Giver	Individuals	Institutional Investors		
	Capital Seeker	Individuals	Non-Profit Organizations	Non-Governmental Organizations	For Profit Organizations
Crowd Activation	Offline	None	Mass Advertising	Personalized Advertising	
	Online	None	Mass Advertising	Personalized Advertising	
Customer Support	Capital Giver Support	None	Offline Support	Online Support	
		Personalized Support	Automatized Support	Peer-to-Peer Support	
	Capital Seeker Support	None	Offline Support	Online Support	
		Personalized Support	Automatized Support	Peer-to-Peer Support	
Investor Relations	Communication Channels between capital givers/seekers	None	Traditional Communication Channel (E-Mail, Telephone, Fax etc.)	Modern Communication Channels (Social Media, Blog)	
	Performance Monitoring	None	Progress Bar	Portfolio Management System	
Contracting	Terms and Conditions	None	Standardized Terms of Use	Privacy Policy Regulations	Payment Regulations
	Legal Relationships after Funding Success	Directly between Capital Seekers and Givers	Indirect (via financial intermediaries e.g., banks)		
Risk Assessment	Due Diligence	None	Traditional (personal data & documents)	Data Analysis	
	Feasibility	None	Business Plan / Project Plan	Prototype	
IT Functionality & Operations	Platform Development & Hosting	In-House	External Service Provider	White-Label Solution	
	Registration Process	None	Website Login (E-mail & Password)	Social Login (Facebook/Google)	
	Applications	Web Application	Mobile Application		
Payment	Forms of Payment	Offline Payment	Traditional Direct Payment	Online Direct Payment	Direct Debiting
	Time of Payment	Pre-paid	Instant-paid	Post-paid	
	Debt Default Actions	None	Notifications	Dunning	Debt Collection
	Payment Processing	Directly between Peers (capital seeker and giver)	Indirect via Financial Intermediaries		
Authentication	KYC Capital Giver	None	Personal Offline Identification	Automated Digital Identification	Personal Online Identification
	KYC Capital Seeker	None	Personal Offline Identification	Automated Digital Identification	Personal Online Identification

Service Modularization in an Evolving Context: A Comparison between the Old and the New World of Automotive Engineering Services in Germany

Florian Müller

University of Bremen, Faculty of Business Studies & Economics, Bremen, Germany
mueller@is.uni-bremen.de

Abstract. Modularity in services has emerged as a promising design approach that offers a sound balance between cost-efficiency in service production and customization. However, the existing literature draws on a narrow scope of service design that considers certain characteristics of service as constraints to the successful adoption of the concept, i.e. service modularization. The growing importance of service as a central logic to explain value creation suggests the need to expand this view and to understand how service modularization and changes in dynamic service contexts may come together. This article makes a first attempt in this direction by exploring service modularization in the light of major restructurings in the field of automotive engineering services (AES) in Germany. Through 22 qualitative interviews with customers and providers of AES, this article presents a conceptual process model that explains how service modularization of AES is propelled by transformational forces in an evolving service context.

Keywords: Service Modularization, Service Modularity, Automotive Engineering Services, Evolving Context, Service Logic

1 Introduction

The increasing significance of service in our modern economy [1] is accompanied by a growing pressure on service providers to become more cost-efficient in service provision. On the other hand, customers are more demanding than ever and expect customized services for their individual needs [2]. Consequently, ambitions to achieve cost reductions and efficiency gains through service standardization [3] are contradicted by the fact that providers need to remain flexible to meet the heterogeneous demands of different customers at once.

From this challenge, service modularity has emerged as a promising design approach to achieve a sound balance between standardization and individualization at the same time [1]. In general, modularity can be viewed as an architectural principle that describes the decomposition of a complex system into smaller parts, i.e., modules that are characterized by a high internal cohesion but are loosely coupled among each other [4]. Standard interfaces between modules enable a high flexibility in the system and ensure that modules can function together as a whole [4].

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Müller, F. (2017): Service Modularization in an Evolving Context: A Comparison between the Old and the New World of Automotive Engineering Services in Germany, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 166-180

As of today, services are rarely considered to adhere to a modular design (except for specific industries like, e.g., logistics and financial services) [1] and the question of the extent to which different services are eligible for an adoption of the concept of modularity, i.e., modularization, is subject of a controversial discussion in the literature [5, 6]. Contrasting viewpoints have especially emerged from an evolving understanding of service. Currently, a large part of the literature limits the role of modular design to the level of service operations. From this narrow scope, certain service characteristics are considered constraints to modularization, e.g., an active customer in service processes [7, 8]. However, the current shift of the academic community towards a service-centric view of the world [5] suggests the need to expand the current view on service modularity and to elaborate on our understanding of how service modularization may take place in the dynamic service contexts of the real world [9, 10].

This article makes a first step towards this direction and explores interrelations between modular service design and an evolving service context at the case of automotive engineering services (AES) in Germany. AES are offered in a project-based fashion by professional service firms to large original equipment manufacturers (OEM) of automobiles for the design, production and testing of technical models for vehicle parts. Recently, industry studies outline a growing dynamic in the automobile industry and changes in the design of AES projects [11]. Considering the need for AES providers to balance contrasting aims of customization and standardization, modularity could be a solution. However, little is known on how contextual changes lead to a higher degree of modularity in services, thus limiting opportunities for modularization in dynamic sectors.

Consequently, the key objective of this research is to identify factors in the broader service context in which AES are developed and rendered that may facilitate modular AES design. Furthermore, the article aims to develop a conceptual model that explains such interrelations. As encouraged by past research, particular attention is devoted to the business relation between customers and providers [1, 12]. To tackle our research aim, we employ a qualitative field study among customers and providers of AES.

The paper begins with a brief outline of our theoretical understanding of service modularization and a brief description of the abductive research methodology. Subsequently, we present an analysis of transformational forces that cause changes in different interconnected layers and facilitate the modularity of AES. Chapter 5 explains how these changes in the design of AES come together with an elevation of the business relation between providers and OEMs. Our findings are summarized in a conceptual process model that illustrates causal relations between different layers of change, before we conclude with a discussion of research implications and future research avenues.

2 Research Background

The paradigm shift towards a service-centric view of service as a central logic to explain value creation raises tensions with the traditional assumption that certain service characteristics constrain modularization. Tensions are especially evident with respect to Service Systems Engineering (SSE) that adopts a systemic perspective at service as a socio-technical system that enables actors and resources to co-create value [13, 14].

The interaction of different parties with a service system allows for a systemic design. However, design choices in the practice are often determined by complex and rapidly evolving business environments [9], so that modularization may create tensions [7].

With respect to modular service design, the emergence of modular financial services [15] has shown that modularization processes may be triggered by changes in the service context, e.g. through technological advances or changes in legal regulations. Yet, little is known on how contextual changes propel modularization processes in the practice. Research on the interdependencies between modularization and evolving contexts seems especially important since scholars are now increasingly concerned with the design of services that are more adaptive to changes in dynamic contexts.

Service modularization is considered the decomposition of a service into smaller parts and a restructuring of these parts in form of service modules [2]. However, the nature of service is highly complex and modular service design shows in various forms [16] and in different dimensions [5]. This study draws on a well-established understanding of modular service design from Pekkarinen & Ulkuniemi [17] who suggest to examine service modularity in three different dimensions (*3D of modularity*): *Modularity in the service organization* refers to the organization, integration and use of internal or external resources in the service production. *Modular service processes* are built from modules based on information processes or physical operations. *Modular service offerings* relates to service elements whose value is separable and visible to the customer.

The industry context in which AES projects are designed and rendered is currently subject to an increasing dynamic. Providers of AES face growing competition and cost-pressure that lead to consolidations in the market [18]. Nowadays, the remaining players in the market offer a wide array of engineering services to a low number of OEMs that traditionally expect customized solutions for their individual needs. For the providers service modularization would be the concluding solution. However, little is known on modular service design in the AES sector. While in automobile manufacturing and supply chain processes, modularity has been a popular concept for many decades [1, 19], prior research outlines several characteristics of the AES sector as natural constraints to modular service designs, e.g., the reliance on complex problem solving during service provision and a close interaction between customers and providers [7, 8]. However, recent industry studies outline the transformative role of digitalization in the AES sector and indicate ongoing evolution in the design of AES projects that could lead to a higher degree of modularity in services [11, 18]. The dynamics of the AES sector create a particular interesting setting for an exploration of contextual variables that influence the application space for modular service design.

3 Methodology

In order to identify facilitators of service modularity in an evolving business environment – a phenomenon that is highly complex and insufficiently understood – a qualitative research design was chosen due to the explorative nature of our research aim. After familiarizing with the current body of knowledge on modularity in services, the research followed an abductive methodology which has been emphasized to be particularly useful to study ill-structured phenomena and to discover new things [20].

Consistent with an abductive approach to case research, collection of data, review of literature and the development of a framework for the analysis of the data were carried out in an intertwined fashion as part of an iterative process. Dubois and Gadde [20] describe this process as systematic combining and matching of existing theory, research framework, empirical world and findings. During this process the researcher moves back and forth between field observations and theoretical concepts in order to enhance both understanding of the field of research and the empirical data [20].

Data collection took place in one phase between December 2014 and June 2015. During this period, 22 semi-structured interviews were conducted among high-level executives within the German automobile industry. Potential interviewees were identified through an industry-specific key word search in the database of a public business network for employee roles and positions that were involved in the rendering of AES projects, which represents a form of judgement sampling [21]. Interviewees were invited to the research by email. This approach resulted in a response rate of 21 percent.

Interviews were carried out personally or by telephone and lasted between 30 and 60 minutes. From the side of AES providers interviewees were mostly CEOs and Business Unit Managers. From the side of the manufacturers interviewees were working as engineering, process or purchasing executives. All interviewees possessed deep industry knowledge due to a long work history (more than 10 years) in the automobile industry. Table 1 gives an overview of the sample characteristics. To increase the reliability of the data, interviews were audio-recorded and transcribed in German language [22] before later during the writing process, relevant quotes were translated into English. Systematics in the analysis and interpretation of the interview transcripts was supported by employing MaxQDA, a professional software for qualitative data analysis that was used to assign codes to relevant text passages in the interview transcripts.

Table 1. Sample Characteristics

Perspective	*Engineering service provider (P)*							*OEM (C)*			
Employees	0-1000		1001-5000			5001-15000		>15001			
Firm	P1	P2	P3	P4	P5	P6	P7	C1	C2	C3	*Total*
# Interviews	1	3	2	2	2	1	1	5	3	2	22

As given by the abductive approach, collection, analysis and interpretation of empirical data were carried out in parallel to the development of the scope and aim of the research and the research framework, so that the interview guidelines and the coding scheme evolved in the course of our study through multiple iterations of application, interpretation and adaption [20].

At the beginning of this process, a tentative research framework was derived from the literature on service modularity that comprised basic interview questions and a tentative coding scheme for the systematic analysis of the data. The first set of interview questions aimed to improve our general understanding of the design of AES and the dynamic context in which AES are offered and produced. Complementary perspectives of customers and providers at AES were considered to support this aim. Correspondingly the tentative coding scheme allowed us to examine the adherence of AES to basic principles and effects of service modularity e.g., loose coupling, reuse, bundling, flexibility and standardization [16, 23], in each of the 3 dimensions of service modularity

[17]. This approach gave our interpretation of the data orientation and still allowed the necessary flexibility to explore modularity in AES with an open mind.

During the research process the scope of the research and the research framework were narrowed and adopted to our findings. To give an example, when we denoted that several interviewees highlighted causal relations between modularization and regulatory changes, the coding scheme was enhanced with new codes to examine this relation throughout all interview transcripts. Likewise, over time codes were added to classify the variety of changes in the context of the AES sector into different layers (industry context, service design and business relation). Layers are an outcome of the abductive approach and help to lower the complexity in the outlined industry transformation. Further codes were added to capture causal relations between layers and temporal reference of statements (past, present and future). A continues comparing of findings with the literature on service modularity revealed a research gap with respect to how modularization processes interrelate with changes in evolving contexts.

Finally, after the aim of the research and the framework were refined in the course of a continuous direction and redirection of the study, the research process was ended when the scope of the research, the applied research framework and the empirical findings gave a sound and coordinated impression. At this point, interviews yielded only little additional insights and indicated a sufficient theoretical saturation [20]. In a last step, the findings were summarized and integrated into a conceptual process model.

4 Transformational Forces and Facilitators of Service Modularity

Interviewees from providers of AES and OEMs outline an ongoing transformation of the global automobile industry that manifests in a rapidly evolving business environment of the AES sector. Consistent with prior studies [11, 18], it has become evident that processes of digitalization and socio-economic change are major forces behind the current restructuration. In the course of our research, we denoted that changes in the AES industry could be located on three different interconnected layers: layer of the *industry* (1), *service design layer* (2) and, layer of the *business relation* (3). The layers evolved in the course of the abductive research approach. This chapter provides a brief outline of the three different layers of change and subsequently with a more differentiated understanding of key transformational forces.

The first layer comprises changes in the context of the automobile industry (industry layer). Changes concern multiple actors in the market and e.g., lead to AES providers becoming less dependent on the OEMs in terms of how they render their services.

Second, several changes can be denoted in respect to the design and rendering of AES projects (design layer) that allow for standardization, reuse and decoupling of service elements that were closely intertwined and tied to the approval of the OEMs in the past. Such changes were considered indications of an ongoing modularization of AES.

Third, we observe a shift in different socio-psychological characteristics of the *business relation* between AES providers and OEMs that elevates the longitudinal exchange relation between the parties onto a new level, e.g., in terms of trust and control.

Interviewees suggest a close relation between changes in different layers that connect to the increasing adherence of AES to principles of modularity. To gain deeper insights into how changes relate across different layers and to identify changes in the context that facilitate modularization processes in the practice, next we present a more differentiated view at four major transformational forces that were outlined by the interviewees in close relation to changes in the design of AES:

- *OEMs adapt their traditional core competencies (development and manufacturing)* to new challenges of the digital age. This is especially shown by the OEMs increasing their investments into IT-related competencies, i.e., software development, while they leave the amount of technical engineering capacity on a constant level. Since the number of car variants has spiked in recent years and leads to an ever-growing demand for engineering capacity in the market, OEMs outsource more and more of their engineering activities and allow their providers to play roles that are more important in the automotive value creation chain.
- *Engineering projects grow in complexity and extent.* In the past, the OEMs' outsourcing strategies aimed at creating a large number of smaller engineering projects in order to yield cost-reductions. Today, OEMs attempt to bundle closely related engineering activities to larger project extents. Interviewees attributed shift in the outsourcing strategy to a rise in the complexity of in-car electronics, i.e., sensors and IT in modern automobiles that demand for a closer alignment of different engineering activities and increases the effort for the management and integration of different engineering projects.
- *A change in the legal regulations of service contracts* demands for a clearer separation between real project contracts and body leasing. Despite a clear differentiation between the workforce of customer and provider is requested by the law, this request was loosely handled in the past. It has been a common practice for AES providers to deploy their engineers directly on site at the OEMs. Interviewees outlined that the control of the legal request for a clearer differentiation would now suddenly be taken serious. As a first effect, service contracts now need to be specified in more detail. As a second effect, providers have to lower the proximity to their customer by relocating a majority of their workforce into their own office spaces.
- In recent years, *AES providers have shown a significant growth* in turnover and in the number of their employees. This growth is paralleled by an *increasing diversification* in the customer portfolio of many providers and in the variety of services offered. Several providers outlined opportunities from them to yield synergies from cross-customer learning and a growing dependency of the OEMs from external engineering expertise in certain technological fields related to AES.

To underline the strength and velocity of these transformational forces, several interviewees differentiated between an *"old world"* and a *"new world"* of AES. In this respect, a major breaking point between both worlds can be located between the years 2014 and 2015. The following sections present an analysis of AES design in the light of the outlined industry transformation in three dimensions of modular service design. The terminology (old world/new world) is thereby adopted to compare two contrasting service settings that determine the potential for modular service design of AES.

4.1 Service Modularity in AES Processes

AES processes are traditionally characterized by a high degree of interaction between customer and provider who co-produce the service in close collaboration. During the analysis of our interview data, we observed changes in the interaction between the parties as well as in the controle and influence that the parties exert at the course of AES processes. The first change concerns *the authority over the extent and the intensity in the interaction*. In the old world, customers traditionally decided over their own role in the service process. In this role, they fulfilled a strong supervision function and determined the level of their involvement during service production. In the new world, providers and customers negotiate a work mode that lowers the controlling effort for the customer and gives the provider longer times of autonomous service production.

"Now, we have to find a balance between working in quiet without being disturbed by the provider and reporting to the customer as that we nowadays have to control the intervention of our customers. […] we had to establish our own reporting and project management processes to offer our customers more orientation, so that any developments for them do not come as a surprise. In this way, we impede that the customer interferes on a regular base, as it was a common practice in the past." (P1, CEO)

Interviewees stated that OEMs increasingly expect their providers to manage the necessary level of interaction between the two parties (e.g., for decision-making). In the new world, providers need to find an efficient level of interaction that is beneficial for both parties. At the same time, providers need to ensure a sense of control for their customers and update them with reliable information on the project progress on a regular base. Consequently, we see an enlargement of the interval of *customer-provider interaction*. In the old world, interviewees outlined a continuous dialog during service production and discussion on a low level of technical detail that led to many serial iterations through previously completed process steps and serial discussions. Providers expressed the need to concentrate the interaction at shorter and more efficient periods, i.e., to organize the interaction in a more *punctual* manner.

As a third change, OEMs handover some of the *service process authority* to their providers. In the old world, providers engineering activities were closely supervised by the OEM. Providers thus, could only exert a limited influence at the technical solutions. In particular, the alignment of dependencies between design decisions and other parties (e.g., other projects and departments) was usually under OEM authority. Interviewee comments suggest that customers in the new world are increasingly handing over this responsibility to their providers, who need to manage interdependencies, carry the risk over design decisions and thereby increasingly produce the service in full authority.

Table 2 summarizes the outlined changes in the process dimension. In the new world providers increasingly manage the interaction between them and their providers and gain more control over the customer interference with the actual engineering work. This encloses a larger space to providers for the modularization of internal processes for the development of technical drawings. In the new world, providers find more space for process standardization and have more freedom in the organization of (mostly human) process interfaces. Standardization is thereby introduced in a part of the value creation process that remains hidden from the customer, e.g., through automatization of repetitive tasks and the introduction of standards in the setup of internal projects. In addition, the interaction with the customer becomes more standardized. More process authority allows providers to introduce internal standards into controlling and reporting processes and the development of replicable routines for the preparation and presentation of alternative solutions to the customer. These service elements are decoupled from the customized parts of the service and thus become available for use in different service projects. By drawing on combinations of standardized and customized services processes, providers maintain the necessary flexibility to meet individual expectations of the customer with respect to how the interaction between both parties is organized, while also increasing efficiency in major parts of the value creation process.

Table 2. Facilitators for achieving modularity in AES processes

Facilitator	*Old world*	*New world (trend)*
Authority over customer-provider interaction	Customer	Provider
Interval of customer-provider interaction	Short	Longer (punctual)
Service process authority	Customer	Provider

4.2 Service Modularity in AES Organizations

AES providers typically compose their internal resources (the majority consisting of human engineering capacity) along two different organizational dimensions. The first dimension mirrors key phases of the automobile product development process. Providers draw on competence teams that are organizational units specialized in phase-specific requirements and demands, e.g., competence teams possess knowledge and skills of advanced development, series development or simulation and assurance. As a second dimension, providers align their competences with different technological spheres of the automobile, e.g., interieur, exterieur or chassis development. Consequently, the combination of both dimensions (process and technology) forms a matrix organization. In theory, this service organization allows combinations of competencies along the technological and process dimension. However, in practice providers outlined several limitations with respect to opportunities to offer services based on combinations of different competence fields. Interviewees outlined additional combinatorial constraints that hardened the integration and connection of separate competences in the old world. However, we see several of these obstacles being reduced or even eliminated in the new world.

The first change concerns the *physical proximity between customer and provider*. AES providers typically draw on a decentralized engineering capacity that distributes across different service branches from which most lie in close distance to the development and manufacturing centers of the large German OEMs. In the old world, providers' had to integrate physically into the organization of their customers to enable co-production of the service on site of the customer in close collaboration. Thus, an important premise for successful service provision was that a large part of the provider's engineering workforce had deep knowledge of the customers' internal processes and was highly familiar with the decision-making culture of the customer.

"Until now many services were offered as projects in pretense, as that in theory responsibility and authority over our employees lay with us, but in reality it laid with the customer. Our workforce was at the customer's site, they were sitting in the customer's office space and the customer directed them to do this and to do that. […] At the moment there is a big movement, so that the manufacturers seek to reach a spatial

separation between them and their external engineering providers." (P3, BU Manager)

The number of provider employees working on site of the customer has significantly lowered in response to a recent tightening of compliance regulations and providers gain more authority over the course and outcome of their services:

"It is increasingly our decision which work packages we produce and where we do this. This is a major change that one can currently observe in the market." (P7, CEO)

This reduction of the proximity between the workforce of providers and OEMs leads to a concentration of the interaction between both parties at fewer *(human) interfaces*. In the old world, OEMs often discussed technical and project management decisions directly on the lower levels of the provider hierarchy. In the new world, much of the communication runs through a considerable lower number of well-networked intermediaries. Project managers often fulfill this function and manage the communication between their own project teams and the OEM. They often maintain a personal relation to relevant stakeholders that allows them to facilitate decision making within the internal organization of their customers. Finally, interviewees denote a "professionalization" of the IT and data management systems (DMS) for the organization and exchange of technical models and project related data but also a growing heterogeneity of these systems. While in the old world, customers usually had the authority over the DMS and providers were connected through remote- or on-site-access, OEMs in the new world often expect their providers to have their own IT-infrastructure in place and to manage the data exchange in full authority. Other interviewees expect a growing importance of third party DMS-solutions in the future. In this respect, IT-security, efficiency in the collaboration and compliance regulations are seen as contrary aims that yet remain an unsolved problem. To become more flexible and less dependent from OEM-specific premises providers are beginning to invest into their own IT.

The outlined changes (cf. Table 3) lower the barriers for providers for drawing upon their full range of competencies and engineering capacity when offering services to different OEMs. In the new world, it is increasingly the decision of the provider where and by whom certain engineering activities are carried out, so that value-creating activities are decoupled from the location where services are offered. This suggests the emergence of modular organizations that enable providers to offer a wider set of competencies at different service branches irrespectively of where the underlying engineering capacity are located. Providers can build upon their workforce from different corporate sites to put up the necessary capacities and the variety of competencies that are required to handle the complexity of larger projects in full authority. Modularity in the organization is also shown by the fact that providers stated to outsource a growing amount of repetitive engineering activities to other countries to yield cost reductions - a trend that is strengthened further by lowering barriers for the exchange of data.

Table 3. Facilitators of modularity in AES organization

Facilitator	*Old world*	*New world (trend)*
Physical proximity	High (integrated)	Low (dispersed)
Extent of customer-provider interfaces	Many interfaces on a low level-hierarchy	A few higher-level intermediaries
Data management authority	Centralized at the customer	Decentralized

4.3 Service Modularity in AES Offerings

AES are typically offered as highly customized service projects. Customization proceeds throughout the course of the service process and begins with a tender and proposal phase. Interviewees characterized the process of customization as a reciprocal dialog between customer and provider in which both parties negotiate the value of the service offering. Our findings show three significant differences between the old and the new world with respect to the process of customization and the decomposability of AES offerings.

First, several interviewees outlined that in the old world providers were mainly offering their engineering capacity to the customer and thus had only limited opportunities to offer combinations of their competencies. Providers indicated that the growing complexity and extent in AES projects further propel a shift in the focus of their offerings from capacity towards competencies:

"In simple words, we observe a transition from a focus at [engineering] capacity to competence. […] When projects become larger, the customer's confidence into the provider becomes more important, particularly into the providers' project management capabilities" (P3, Business Unit Manager)

Consequently, providers see growing opportunities to offer combinations of different competencies and to bundle engineering activities to larger service packages, which in the old world were offered as separate projects. Interviewees highlighted that their customers would increasingly expect them to enrich the value in their offerings through the integration of additional support services, such as more sophisticated project management processes that can lower the customers' controlling effort.

We further observe a change in the influence that providers exert at the design and the extent of service offerings. Analysis of our data revealed that in the old world, the boundary conditions for later service provision (e.g., interfaces to other projects and project content) were merely determined by the customer independently of the provider. Providers were mainly concerned to design an initial offering (delivered in written form as a project proposal) that matches the customers' requirements. In contrast, several interviewees outlined that customers would increasingly invite providers to integrate themselves during the specification of the tender, allowing them to participate in the fundamental design of their service offerings in a very early phase:

"What now defines our work is early integration of suppliers. […] Many suppliers offer this preparatory effort for free to take predominant positions during the commissioning phase. Then the coming tasks are put to the agenda and we consider in common who performs which task by oneself or in cooperation with a partner." (C2, Chief Engineer)

Finally, the customization process of service offerings develops from a persistent refinement towards a guided implementation of dynamically created configuration options during which the offering evolves incrementally from different customer choices. Providers and customers switch between phases of requirement specification, preparation of alternative options and subsequent decision making with the customer, which is in many ways a different work mode compared to the old world, where the solution went through a less structured process of direct and continues refinement.

The three outlined changes (cf. Table 4) facilitate modularity in AES offerings.

Providers stated that the offering of combinations of their competencies becomes a key to remain competitive in the marketplace. In this regard, providers outlined the importance for them to display the value inherited in different combinations as part of larger offerings. Providers gain new opportunities to influence project requests before official commissioning and can thereby incorporate interfaces between project parts that in the old world were often distributed among different providers. In this way, providers described ways to implement internal standards for collaboration and communication to increase efficiency in service production. On the other hand, providers point out the need to obscure the true degree of modularity in their service offerings to their customers in order to reap internal synergies. Competencies in the AES industry can be viewed as service modules, whose evaluation, selection, integration and rendering is part of a collaborative customization process between customer and provider. In the new world, this process is often guided by the provider.

Table 4. Facilitators of modularity in AES offerings

Facilitators	*Old world*	*New world (trend)*
Role of provider competencies in the offering	Lower	Higher
Provider influence on service project design	Lower	Higher
Nature of the customization process	Continuous	Incremental

5 Regulating Variables of Service Modularity

Changes in the design of AES – such as a lowering of the physical proximity between providers and OEMs – come together with a shift in the business relation between the two parties. In this respect, interviewees outlined changes in various socio-psychological factors, e.g., in terms of trust, expectations, appreciation, control and responsibility. While in the old world, providers were merely regarded as enhancements of the engineering capacity of the large OEMs, interview comments such as the following suggest that the relationship between the two parties elevates onto a higher level and the emergence of genuine engineering partnerships:

“The relation between engineering service providers and the manufacturers changes from one important point of view. One cannot speak about normal suppliers anymore, instead it must arise partnerships at eye level. […] Providers have to prove themselves for real partnerships to emerge.” (C1, Head of Engineering Processes)

OEMs are now narrowing the scope of their own technical development activities and thus need to share larger proportions of project-related authority and risk to handle the complexity of engineering projects. This makes OEMs more dependent on the skills and resources of their providers. Interviewees stated that OEMs have to let loose when commissioned project amounts are increasing and that they need to have more faith into their provider’s competencies and capabilities to carry out projects to full extent in own responsibility. Deeper analysis of our interview data suggests four major changes on the layer of the business relation.

First, providers outlined that their customers would increasingly expect them to act as advisors who demonstrate a yet unknown level of *sovereignty* in their services provided. This achieve this, providers need to develop a more profound understanding of interdependencies between their individual engineering projects and the complex project environment of the OEMs in which these projects are embedded.

The second change concerns the level of *confidence* of the customer into the capabilities of the provider. A high manager of an OEM indicated that an elevated level of confidence would be a premise for them to lower their control over their providers' engineering activities during service provision. Providers who seek to take over larger and more complex extents have to prove themselves as reliable and capable to manage the complexity of interdependencies within the project environment of their customers in own authority and create high service value over longer periods.

Thirdly, in return customers stated that they would demand from their providers a stronger *commitment* to take over larger financial risks in engineering service projects and manage these risks in own authority. Providers confirmed this and indicated an increased need for the development of improved risk management techniques to handle risks in service projects but also on the level of the project portfolio.

Finally, we see an increase in the *recognition* of the providers' competencies in specific technical fields of knowledge, e.g., in the field of lightweight construction. OEMs are recognizing the value that lies in the value of competencies, instead of viewing them as sole engineering capacity.

Providers, who successfully manage change in these four regulating variables will encounter a larger freedom to design their service production according to their own account and based on principles of modularity. However, OEMs indicate that providers who fail to manage the transition towards genuine partnerships are endangered to become subcontractors by the larger providers. They cannot expect to reap the same potential of service modularity as those providers in the first-tier.

6 Discussion and Conclusions

This paper examines service modularization in the rapidly evolving AES industry and presents an empirically grounded comparison between two contrasting service settings, in which AES projects are developed and rendered. Findings are aggregated into a conceptual process model (Figure 1) that locates changes in the AES sector onto three different layers of change. The industry-specific process model outlines four key transformational forces in the context of the German automobile industry (1) that lead to the formation of modular service designs in the AES sector alongside each of the three modularity dimensions (2). However, modularization comes together with changes in the business relation between customers and providers of AES. Closer analysis shows that changes in the design of AES and changes in four different characteristics of the business relation are mutually dependent, so that these factors are considered to regulate the potential for modular service design (Layer 3).

As to the consequences of the transformation, controversial views can be denoted. Providers outline both positive as well as negative effects on them. On the one hand, they appreciate the development of genuine partnerships and opportunities for them to implement projects in full authority. Providers expect increasing opportunities to offer their services to new customers, e.g., to OEMs located in the US and in Asia. On the other hand, providers indicate that modularization enhances comparability of service offerings, which further reinforces the cost-pressure on providers that face increasing international competition. In this respect, some providers stated that they would mainly aim to achieve standards in service processes and organization but mask the full extent of modularity in their service offerings to reduce comparability in the marketplace. In general, modularity of AES is less a suitable strategy for providers to outperform competitors and rather becomes a prerequisite to remain competitive in the marketplace.

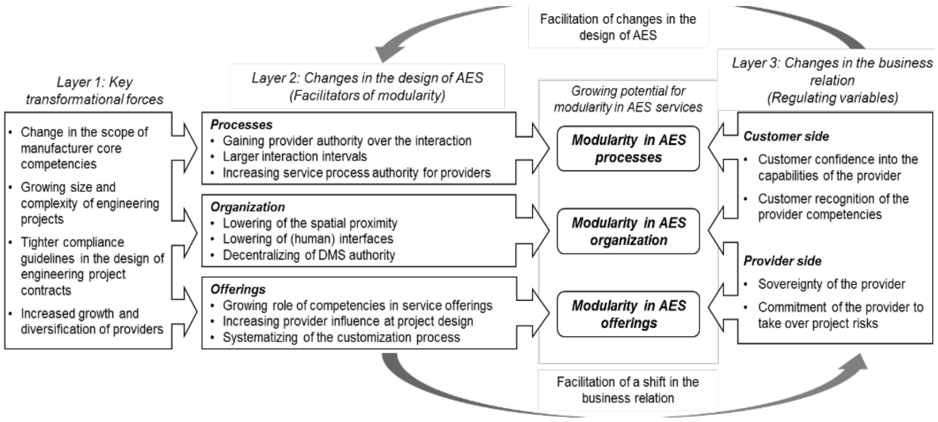

Figure 1. Causal relations between different layers of change and service modularity in AES

6.1 Theoretical and Practical Implications

Theoretical implications concern our understanding on the role of evolving contexts in service modularization processes. While existing research on service modularity is traditionally concerned with modularity in a specific context, this article is one of the first that examines how service modularization may be propelled by transformational forces in an evolving industry context [5]. The presented process model (Figure 1) offers an overview on several variables in the context of the AES industry that determine the potential for service modularity. Considering rapidly evolving contexts in our digital age [9], our findings underline the need to further elaborate on the role of modularity from a service-centric view [13, 14]. In this respect, in line with recent research in the field of service innovation, our findings underline the importance of modularity as an important theoretical design construct in the field of SSE [13, 14] that may contribute to our understanding of the relations and interactions of multiple actors in service ecosystems [10]. Contrary to the frequent assumption that modular service designs are necessarily an outcome of a systematic modularization initiative in a specific service context, the case of AES shows that an adoption of the concept, i.e. modularization may be driven by design choices created from changes in dynamic business environments. In this respect, networked business relations should receive further research attention to develop more comprehensive modular design strategies for services [1]. The presented facilitators of modularity on different layers of change offer an interesting launch point for such research endeavors.

As for the *managerial implications*, the presented conceptualization of three different interconnected layers of change outlines a path for AES providers to develop a modular service design while also becoming more independent of their customers. In order to manage the transition to the new world of AES successfully, providers have to facilitate and manage changes on the layer of their business relations and in the design of their services in close coordination. Providers in this relation highlighted the role of a wide-reaching network to decision makers within their customers' organization and improved communication skills on the level of project managers. The outlined differences between the old and the new world of AES can be regarded in this respect as a development target for the design of AES at which providers can align the facilitation of design changes along the three modularity dimensions and elaborate on the systematic reshaping of their business relations. However, findings also show that providers need to consider the extent to which they reveal the degree of modularity to their customers. A modular service design, whose architecture is fully transparent to the customer, may expose the provider to a high cost-pressure, because customers can easily compare service modules with other offerings in the marketplace.

6.2 Limitations and Future Research Avenues

Our study is beset with some *limitations* that can motivate future research. First, this study builds upon a large set of data that allowed us to identify general changes in AES. However, generalizability of our findings is likely to be limited to the German AES industry until additional empirical studies have validate the presented causal relations in other service contexts. Second, despite the concept of the three dimensions of modularity is widely recognized, it leaves room for interpretation in terms of what modules are comprised of and how they can be identified in the practice. Because a universal definition of service modularity has not yet emerged [5, 6], we differentiated between modularity in three dimensions (3D of modularity) [17] and enhanced this understanding by the general effects and principles of service modularity - in particular those defined by Dörbecker & Böhmann [16], Bask et al. [6] and Tuunanen et al. [23]. While, this broader interpretation of modularity in services allowed the identification of several modularity effects and principles during the analysis of the interview data, our findings suggest the existence of different forms of modular service design.

To summarize, this study contributes an empirically grounded conceptualization on service modularization in the e context of the German AES sector that explains how service modularization and changes in an evolving service context may come together.

Abstract. The emergence of data-driven business models calls for their systematic design and evaluation. In this paper, we focus on a first step towards a Cost-Benefit-Analysis of data-driven business models. Within data-driven business models, data act as enabler for the development of innovative services. However, to justify internal funding of new services, an assessment of the financial impact for the service at hand is often required. We approach this by identifying drivers of cost and benefit based on the Service Business Model Canvases of twenty cases. Based on the results, all drivers and their associated models for quantification were consolidated into a single meta-model. With this, we provide a basis for the economic assessment of service ideas and their refinement during the design process.

Keywords: Data-driven Business Models, Profitability, Service Engineering, Cost-Benefit-Analysis, Smart Services

1 Introduction

Many services have been proposed to transform product-oriented into service-oriented businesses [1, 2]. To systematically design and communicate ideas for new service business models, the Service Business Model Canvas (SBMC) has been proposed by Zolnowski [3]. With the ongoing digitization of service delivery processes, a new class of data-driven services has emerged [4]. While the SBMC is not restricted to data-driven services, it obviously can be used for this purpose as well.

One of the key characteristics of component based business model representations [5], like the Business Model Canvas (BMC) [6] or the SBMC [3], is their qualitative nature, which is very suitable for developing and refining the business logic of an idea [3, 7]. However, to justify internal funding of service engineering initiatives, an assessment of the financial impact for the planned service is required. To this end, various cost items for service provision have to be considered as well as savings through process improvements and revenues through additional offers to customers. Assessing these factors in early stages is challenging but helpful for decision making.

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Zolnowski, A.; Anke, J.; Gudat, J. (2017): Towards a Cost-Benefit-Analysis of Data-Driven Business Models, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 181-195

In this paper, we develop a concept for the quantification of data-driven business models (DDBMs). For this, we provide a basis for the economic assessment of service ideas and their refinement during the design process. Hence, we answer the question "What factors need to be considered in a Cost-Benefit-Analysis of a data-driven business model?" To answer this question, we analyze twenty case studies to identify factors that are relevant to describe and evaluate business models. Based on the results, all factors and their associated models for quantification were consolidated into a single meta-model. With this, we strive to improve the overall service design process in practice.

Within this contribution, we focus on a refinement and assessment of business model ideas but do not address the issues of finding a good value proposition, price model or partners. However, with our integrated model, we can support showing the (financial) impact of the design decisions made in the SBMC.

Furthermore, we acknowledge the relevance and importance of non-financial benefits [8-10], especially for innovative offers such as data-driven services. However, in this paper we focus explicitly on the financial dependencies in a DDBM.

The paper is structured as follows. Firstly, we introduce our conceptual foundations with regard to a DDBM. Then we explain the research methodology and introduce the applied case studies. This is followed by the results of the analysis of the cases. Thereupon, a cost-benefit analysis model for a DDBM is proposed and discussed. The paper ends with a conclusion and an outlook.

2 Conceptual Foundation

2.1 Service Business Models

Considering business models, there is a variety of different understandings and definitions [3, 7, 11]. Due to the lack of definitional clarity, alternative conceptualizations of business models exist (e.g. [12-14]) that result in conceptual diversity like a variety of ontologies and representations. Common ontologies for business models are e3-value Ontology [15] and the Business Model Ontology [16]. Representations can be distinguished in two research streams. The first research stream comprises a more flow-oriented perspective on business models. A prominent example for this stream is the e3-Value method [15]. The second research stream comprises a system-level holistic view on the business logic of an economic entity or offering [7]. The most prominent example for this stream is the (BMC) [6].

Fostered by a service based change in value creation [17, 18], business models are also discussed in service research [3, 19, 20]. Service business models are different from product based business models because of the specific characteristics of service. In general, service is a process between interacting parties for the benefit of another party. Especially, the interaction is of high relevance. Known as value co-creation, it is one key aspect of service [18, 21]. Additionally, service value has a unique and phenomenological character [18, 22]. Furthermore, the interaction of service results in a mutual integration of resources and activities. Possible resources that have to be integrated are e.g. skills, knowledge, physical resources and decisions [23, 24].

Because of their specific characteristics, representations for service business models differ from representations for traditional business models [3, 25]. One service specific business model representation is the SBMC. The SBMC highlights the integration of different actors within a service business model and thus, allows focusing on the strategic relevant co-creation in the business logic of service-based business models. As overall logic, the SMBC focuses on the contribution to and benefit of each actor. This logic is applied in the seven dimensions value proposition, relationship, channels, revenue stream, key resources, key activities, and cost structure. In the dimensions customer and key partners, the different actors are defined [3]. The SBMC is displayed in **Figure 1**.

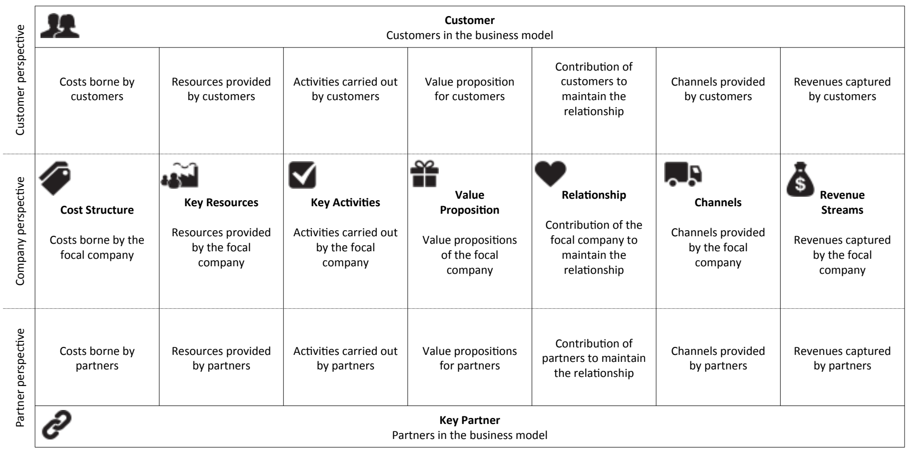

Figure 1: Service Business Model Canvas [3]

2.2 Data-driven Services

Based on the service oriented paradigm new services like data-as-a-service or analytics-as-a-service emerge [26, 27]. Within DDBM, data act as enabler of such innovative services. With enabling technologies, like sensor technology and cloud computing, companies can exploit data from and about their customers. In their own environment companies get enabled to generate new profitable know-how based services [28, 29].

Requiring such new technologies Veit et al. [30] state that "a business model is digital if changes in digital technologies trigger fundamental changes in the way business is carried out and revenues are generated." The BITKOM [31] quotes in their report a similar definition whereupon business models are digital if changes of digital technologies do have fundamental consequences for the business processes and the revenues of the company.

According to Hartmann et al., DDBM is defined as "a business model that relies on data as a key resource" [26]. Brownlow et al. [32] similarly state that "data is obviously fundamental to a DDBM" and Bulger et al. [33] agree, that "data should be central to the business." These definitions are rather simple and differentiate business models on their use of data or not. A more complex perspective on DDBM is proposed by Schüritz and Satzger [4]. According to this, there is no DDBM per se; rather, there is a continuum of options how to provide data-driven service. Hence, there is a smooth transition between business models that use little data and those that enrich all areas of its business model with data analysis [4]. Thereby existing data or new data can be used to either create new business models or enhance existing ones [31]. In the latter case either the value creation, the value proposition or the value capturing or combinations of these can be enhanced by data [4]. For the purpose of our research, a complex differentiation of DDBM is not necessary. Thus, we chose to define DDBM according to Hartmann et al. [26].

The most relevant aspect during the design of a DDBM is the value that should be attained by the data analysis. Hence, the why and how [33] need to be examined. This includes defining the used data. For this purpose, Mathis und Köbler [34] developed a data canvas. The canvas distinguishes between batch and stream as well as internal and external data. Internal stream data do provide the most value since they allow a constant monetization and the data are accessible at any time without any restrictions" [34]. However, to be able to exploit the analysis potential data needs to be well integrated into the business model [33].

2.3 Cost-Benefit Analysis

To make the decision if to invest in a project, a Cost-Benefit-Analysis (CBA) can be performed [35, 36]. A CBA is an established tool for assessing the economic benefit of an investment. As such, it can support decision making on whether a service provider should proceed with the engineering and implementation of a new data-driven business model or not [35, 36]. Due to the complexity of service [37], a systematic capture and analysis of CBA-related factors is a desirable goal. To facilitate end-to-end engineering of smart services, we propose to enrich the qualitative perspective of component based business model representations, in particular the SBMC, with quantitative information. Existing work dealing with business models do not provide means for quantification. Moreover, currently profitability modelling does not include the customer perspective in detail.

One example of a method for assessing data-driven services for connected products was proposed by Anke and Krenge [38]. They propose a meta-model for "Smart Services" from which a business case is derived during the modelling process. In their work "Smart Services" are understood as digitally provided services for connected products. Therefore, "Smart Services" are data-driven services that rely on data which is at least partly provided from connected products, i.e. the Internet of Things. While the meta-model of Anke and Krenge is not directly related to a business model, it provides a connection between service design and its financial evaluation. We therefore will use it as foundation for the concept presented in this paper, as we consider the data-driven business model that might consume data from sensors and the Internet of Things as well.

3 Methodology

In order to design a framework for early-stage profitability assessment, this research applies the following method: first, we identify quantifiable influence factors from a consolidated list of influence factors of digital services on service business models. This list was gained through a multiple case study [39], conducted by Zolnowski et al. [40]. The focus was placed on international companies that successfully developed and implemented successfully data-driven innovations.

The identified cases cover (1) the improvement of the customer orientation, (2) process optimization, (3) optimization of resource consumption, and (4) the collection of information to complement and accelerate decisions. In sum, twenty cases from seven industries were selected and analyzed. Thirteen cases were identified from data of a consulting company and seven cases were derived from literature and public information. The chosen cases cover data-driven innovation projects in different industries (see **Table 1**).

Table 1. Description of the analyzed cases

Companies	*Company description & Examples for implemented data-driven innovation projects*
Three automotive companies	**Two** German automotive manufacturers >70,000 employees (2014) **One** from the automotive parts industry >30,000 employees (2014)
	Project: Predictive Maintenance by expansion of sensors on assets; Optimization of processes by data integration
Seven manufacturing companies	**Three** German companies >6,000 employees **Two** German companies >63,000 employees **Two** American companies >80,000 employees
	Project: Predictive Maintenance by expansion of sensors on assets; Service innovation and use of Internet of Things; Optimization of processes by data-driven forecasting
Five logistics and transportation companies	**One** joint venture, 51-200 employees (2014) **Four** companies, 1800-5.000 employees (2014)
	Project: Coordination of infrastructure by real time data of players; Tracking of assets by expansion of sensors
Two retail companies	**One** German retail company >17,000 employees (2014) **One** Swiss food company >300,000 employees (2013)
	Project: Optimization of disposition by analysis of market data
One insurance Company	**One** American start-up, 201-500 employees
	Project: Product innovation in car insurance by use of Internet of Things
One energy company	**One** German electric utility company > 50,000 employees (2014)
	Project: Predictive Maintenance by expansion of sensors on assets
One telecommunication Company	**One** Swiss telecommunication provider >20,000 employees
	Project: Coordination of infrastructure by data of passenger traffic

The results of this work are shown in **Figure 2**. This figure shows the identified influence of data-driven innovation projects on the business models of the analyzed companies. The effects are symbolically illustrated by gray boxes and grouped if being similar with bold titles describing aggregated types of effects. Because of the networked character of a DDBM, all influences are differentiated according to their impact on customer, company, or partner. Thus, elements that have a direct influence on the customer, are classified to the customer perspective.

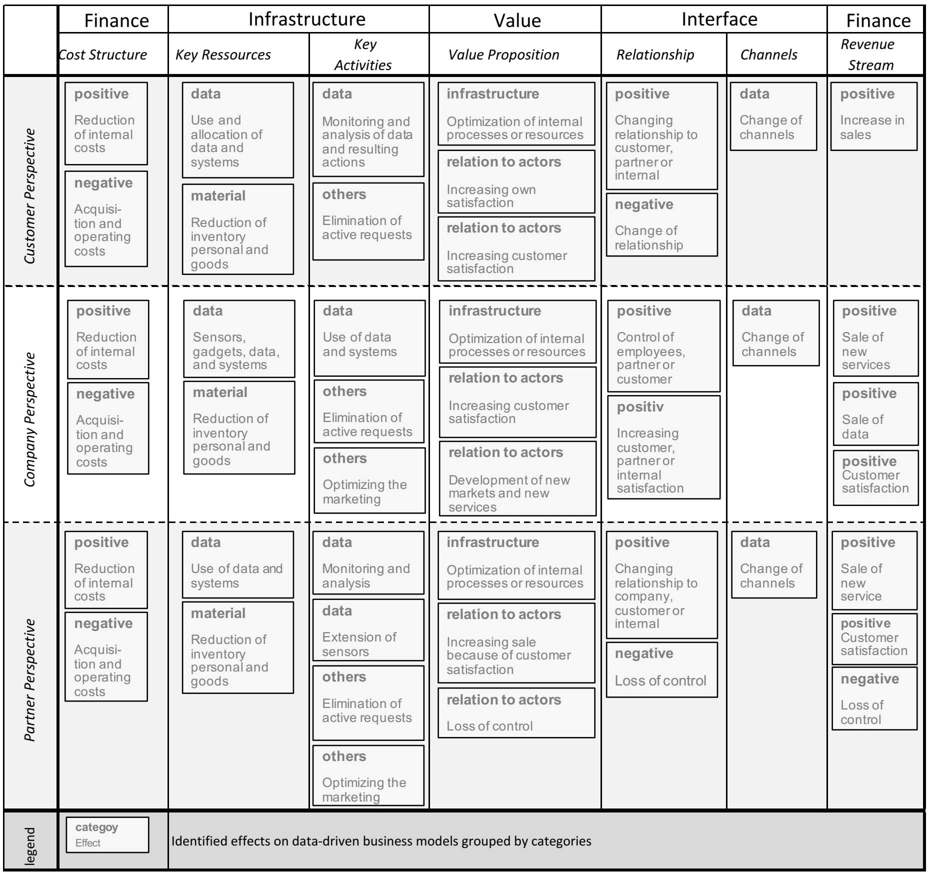

Figure 2: Identified effects of data-driven innovation projects [40]

In the next step, we analyzed the identified influence factors according to their quantitative or qualitative nature. This was necessary to identify those factors that have a quantitative influence on the costs and benefit of the DDBM. Based on this information, we were able to determine the influence factors for a CBA of a DDBM on an empirical basis. To summarize, the proposed CBA model adapted for the DDBM is developed in the following steps:

1. Categorization of quantitative influence factors from twenty case studies into cost, revenue and savings.
2. Development of a parameter set to simplify the capture of relevant inputs and derive the financial values for identified influence factors.
3. Integration of the parameter sets into an integrated meta-model, based on the meta-model proposed by Anke and Krenge [38].

The remainder of this paper is structured as follows: In section 4, we conduct step 1 and 2, while section 5 covers step 3 followed by a discussion of the results. The paper concludes with an outlook on further research questions.

4 Case Analysis

4.1 Identification and classification of CBA-related parameters

In our multiple case analysis, we were able to differentiate between qualitative and quantitative influence factors on the business models. Qualitative factors comprise effects like increasing customer satisfaction or change of relationship that cannot be translated directly to a countable metric. However, influence factors with a quantitative nature enable a direct analysis of countable and monetary consequences. These factors comprise effects like reduction of internal costs or sensors, gadgets, data, and systems. As already stated, we acknowledge the relevance and importance of non-financial benefits [8-10]. Nevertheless, in this paper we focus on quantitative influence factors and exclude qualitative influence factors intentionally. Within these factors we are able to distinguish between three classes of effects. In the following, we present the results of our multiple case analysis according to the identified classes (1) costs, (2) revenues, and (3) savings.

4.2 Costs

There are a variety of costs that can be directly related to the development and management of a DDBM. This includes all necessary preparation and the use of data and systems (including the influence factors different use of data and systems; monitoring and analysis of data, actions; and extension of sensors in the key activities and use and allocation of data and systems; sensors, gadgets, data, and systems; use of data and systems in the key resources). Especially in the development phase, the improvement or implementation of infrastructure is an important cost factor. For example, in a manufacturing case, customers have to implement remote services hardware in their machines to collect data and enable the connectivity between the customer's machines and the provider's servers. A driving force for the improvement or implementation of new infrastructure is the lack of sensors, actuators, and connectivity in older machines. Highly depending on the industry, these elements can already be part of an existing infrastructure or they need to be added. However, all three elements are enabling technologies for the DDBM. Sensors are necessary to monitor machines and collect data. Connectivity establishes a link between the systems of the customer and provider to transmit the collected data, and actuators enable the provider to remotely take control or even change things automatically based on data. If relevant infrastructure is missing, companies having no or limited experience and are often surprised about the advancement in sensor technology. Off-the-shelf products can cost a few cents per sensor. Even equipping an existing product with an additional sensor can result in marginal extra costs. However, if customized sensors are required, development costs can reach several hundred thousand Euros.

Besides the infrastructure, specialized software can be necessary for a DDBM. As our cases show, such software can be developed, purchased, or leased. Alternatively, cloud services can be applied. According to the respective decision, in many cases the costs occur on-demand, recurring, or for the development of the software. Integrated in this software, algorithms enable the processing of the data. These algorithms can be highly individualized and need to be developed, maintained, and processed by the provider or other partners. This also applies to the resulting reports of this process.

To enable the whole DDBM, the connectivity between all actors and their infrastructure and software is of high relevance. According to the type of connectivity, e.g. permanently or recurring, the actors have to calculate with different pricing models.

According to our analysis, the influence of infrastructure, software, and connectivity have an important influence, with a direct effect on the focal company, the customer, and partner. Hence, in order to introduce a DDBM, invests into all factors are needed in the entire service system.

4.3 Revenues

As our cases show, in a DDBM, revenues can be enabled for any actor. From a company perspective, revenues can be generated from sales of new services and possibly also from the sale of data to third parties. Despite an existing relation to a customer, an increase in revenue is not mandatory with existing customer satisfaction. In our cases we were able to identify companies that establish completely new DDBMs that were offered to the customers. For example, a manufacturer facilitates higher safety standards by offering the tracking of tools in the maintenance process of the customer. This leads to an increase of responsibility through employees and avoids occurrence of abandoned tools.

But also customers and partners are enabled to generate additional revenues. By facilitating existing or enabling new processes, they can improve their existing or establish completely new business models. Target of these operations is to increase sales or to exploit economies of scale.

4.4 Savings

Beside of revenues, another positive economic effect are savings. In particular, the implementation of a DDBM allows for optimization of processes or reduction of assets, which both lead to lower costs by the reduction of inventory (key resources).

From a company's, partner's, and customer's perspective, DDBMs have direct influence on the operational processes. The processes can be optimized in a different manner. In one case, the provider gathered data about his and the customer's processes. Based on his knowledge, he was able to provide consulting services to his customer and to optimize his processes. Another case illustrated the elimination of active requests. Within this case, manual requests and process executions were replaced by automatized processes. This led to a reduction of operating costs.

Additionally, a reduction of inventory, personnel, and goods is possible. In particular, we observed a reduction of resources by an optimization of resource planning and hence, adjusted resource utilization.

5 A Cost-Benefit-Analysis Model for DDBM

5.1 Parameter Categories and financial quantification

In general, a CBA considers all costs and benefits to assess the economic value of an investment project. Cost refers to the financial effort required to build and operate a DDBM system. For all effects created by the investment project at hand, monetary values have to be assigned. Benefits can be either additional revenue or cost savings, e.g. through improved process efficiency. In the context of business models, we expect a CBA to support in experimentation and finding better solutions through an additional evaluation criterion. As a foundation for the CBA model, we use a series of payments, which contains the net cash effect per planning period.

As we take the perspective of the service provider, we build our model based on the quantitative factors of the focal firm identified in the previous section. The required elements and their relationships will be expressed as a UML class-diagram meta-model, which is why we use the terms class and attributes in the description below. The complete meta-model is shown in the next section.

Cost is already expressed in monetary values. However, it is usually difficult to estimate a total value. Therefore, we propose to break down cost into various more concrete items, which can be estimated with higher confidence. As we have identified cost items that are relevant for a DDBM, this helps to create a CBA model for these scenarios. We differentiate between one-time, recurring constant, and recurring-growing cost. For simplification, growth rates are fixed per period (see Table 2).

Table 2: Translation of costs into the capture model

SBMC Factor	*Capture Model*
Acquisition and operating costs	Operating costs are recurring, and can be both constant and growing. We use the `OperationCost` class to describe cost of various `CostTypes` and `PaymentIntervals`. For all costs related to the use of external services, such as weather info, messaging etc., we provide the `ServiceVariableCost` class. It relates to the `Functions` and their usage of `ExternalService`. `Functions` can also use `DataPoints` from connected `Devices`. As the latter are provided from connected products, these can be modeled as `Device` with attributes for `costPerMBTransfer`, `devicePrice`, `initialDeployment` and `growthPerYear`.
Sensors, gadgets, data and systems	Equipment of all kind has to be purchased (one-time cost), so type of equipment, price and quantity capture these cost. In the model, these are captured in the `InitialInvest` class.

Revenue is created by providing value to customers. It is also already expressed in monetary values. As with costs, we propose to break down revenue into more concrete offers with a single price. This helps decision makers to describe the service in a more specific way and see the impact of various configurations (see Table 3).

Table 3: Translation of revenues into the capture model

SBMC Factor	*Capture Model*
Sale of new services	An `Offer` can be modelled with a `offerName` and `price`, which can be interpreted as subscription or transaction-based price. The quantity is defined using the `CustomerDemand` class, which contains attributes for `customerGroupName`, `initialYear` and optional `growthRatePerYear`.
Sale of data	

Savings refer to reduction of cost at the service provider. They can be created through process efficiencies, reduction of stock, resource consumption etc. To quantify these effects, the internal organization of the service provider has to be known in great detail. However, this would increase the complexity of the CBA model greatly. Therefore, we propose to model savings as relative improvement to a certain level, which can be expressed by three simple parameters. In the following table, we list the identified SBMC parameters by category, and show how we quantify them. Please note, that the factor "Reduction of internal costs" is not explicitly mentioned, as it is covered by the four factors listed in the table (see Table 4).

Table 4: Translation of savings into the capture model

SBMC Factor	*Capture Model*
Reduction of inventory, personnel and goods	To quantify these effects, we use the Savings class, which can be instantiated for every relevant savings effect. It is modelled with the name of the factor, its `initialLevel` as monetary value and the `reductionInPercent` to capture the savings effect.
Elimination of active requests	
Optimizing the marketing	
Optimization of internal processes or resources	

5.2 Integrated Meta-Model

All factors and their associated models for quantification were consolidated into a single meta-model, which is depicted as a UML class diagram. Class diagrams are an established way of representing the structure of domains semi-formally. Classes represent entities and their attributes. Relations are expressed with associations, which can also be qualified with cardinalities to show how many instances of one class can be related to a certain number of the associated class.

Our integrated meta-model is depicted in **Figure 3** below. It adapts and extends the smart service and business case model proposed by Anke and Krenge [38]. All white classes are part of the quantification model described in the section above. The classes with grey a background are used to describe the basis for calculating the CBA. From the original model, we mainly reused the parts concerning the `DataPoints` from `Devices`, their usage in `Functions` which are subsequently bundled in `Offers`. Furthermore, the concept of `ExternalServices`, their usage as well as `Projects` were part of the original model. Our extensions are mainly related to `Savings`, the `SMBC_Factor` relation and `InitialInvest`. Also, the modelling of cost was extended to enhance flexibility.

The starting point is a `Project`, which contains a number of `planningYears`, a `name` and a derived attribute `financialResult`. It is calculated from a series of payments, which is represented by `ProjectYears`, which in turn contain derived attributes for `revenue`, `cost` and `savings`. Costs can either be manually specified `OperationCost` or automatically calculated using the class `ServiceVariableCost` for data transfer and external services. This only applies to services (Offers), which are modeled using `Functions`, `DataPoints`, `Devices` and `ExternalServices`.

For a concrete project, the meta-model has to be instantiated. The service designers start with a qualitative design of the DDBM in a SBMC. Each factor in the SMBC can then be represented by either an Offer, Savings or Cost item. The quantification of each item is achieved through the parameters described in section 5.1.

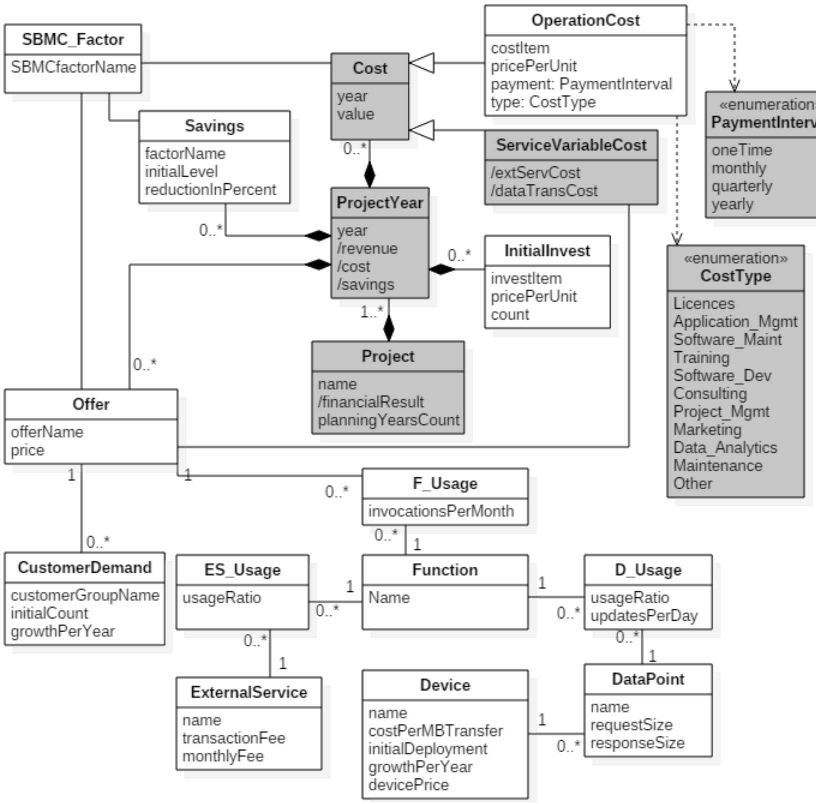

Figure 3: Integrated Meta-Model

5.3 Discussion

The high complexity and qualitative nature of service make it difficult to judge the financial impact of services, like of a DDBM, in early conception stages. While methods for financial decision making, like Net Present Value or Return on Investment, are well established, they are rather generic and not linked to the specific development of business models. Our proposed meta-model establishes links between the qualitative dimensions of the SBMC and main drivers of business value in a DDBM, i.e. new offers, savings and associated cost. To support the refinement of a SBMC, the model includes parameters (e.g. prices, costs and quantities), which are sufficiently detailed to allow for a first estimation during the design process. As these factors were derived from case studies focusing on data-driven innovation projects, our meta-model is designed to facilitate the development of a DDBM. This is expressed through dedicated elements that must be considered during the development.

In summary, an integrated meta-model divided into three states was derived. To apply this meta-model, firstly, a user has to develop a business idea and fill out a SBMC. Based on this information, a refinement of the business model with Cost-Benefit-Analysis related parameters has to be conducted. To allow an assessment of a DDBM innovation project, we propose concrete influence factors (see `CostTypes` and `PaymentIntervals`) that have to be considered in its specific CBA. In addition to the costs, we were able to derive potential savings and revenues in DDBM initiatives. Finally, a business case can be derived and decision can be taken, whether to proceed with the implementation of this service or not. To improve the creation and refinement of models as well to perform calculations, a software tool can be of great benefit. We see the development of the meta-model as a starting point to develop such a tool in the future.

6 Conclusion and Outlook

In this paper we propose a first step towards a Cost-Benefit-Analysis of data-driven business models and therewith address an important issue of companies in the field of existing service development and service engineering initiatives [35, 36]. We analyzed twenty case studies on data-driven innovation projects and derived influence factors that have an impact on a business model. A set of parameters was developed that allow identifying relevant inputs and deriving financial values for the included factors. As an extension of the existing smart service model [38], an integrated meta-model was derived that if being applied allows for the quantitative evaluation of a DDBM. This method enables decision makers to evaluate and calculate their business case for a data-driven innovation through refinement of a business model.

Our integrated meta-model provides a theoretical contribution as it helps researchers by fostering the understanding of financial dependencies in data-driven innovation processes towards new business models. By analyzing data-driven innovation projects, we were able to determine quantitative influence factors that have a direct monetary impact on a DDBM. Based on this knowledge, it is possible to create, shape, and improve tools and methods that foster service innovation and the design of a new DDBM. Practitioners can utilize these results in order to foster the development of data-driven innovations in their servitization efforts. Moreover, they can analyze different innovation projects in regard to their financial effects and thus, better intercept business potentials.

Nevertheless, also some limitations have to be considered. Firstly, this paper focuses on quantitative influence factors in the development of a new DDBM. This decision was made purposely and need to be addressed in further research. Hence, qualitative influence factors must be considered and their impact added to the meta-model. This includes qualitative criteria, such as improved customer satisfaction, loss of control, competitive advantage. The twenty case studies on data-driven innovation projects analyzed in this paper could be extended with new cases in further research.

Besides addressing these limitations, further research should focus on the practical application in a field experiment and/or lab experiment to evaluate the meta-model and its benefits. Equations need to be developed allowing the computation of the overall benefit. Subsequently, instructions describing how to apply the meta-model in a concrete scenario could be developed.

Abstract. Nowadays, many companies face problems because of cultural differences, especially in multinational settings. Traditionally, national cultures have so far been identified by questionnaires asking participants about e.g., their values. These invisible elements of culture become manifest in tangible artifacts such as concrete actions or structures, e.g., rituals and organizational charts. Process models serve as a graphical representation of processes precisely describing activities, responsibilities and process flows. Thus, we anticipate that the behavior becoming apparent in process models provides insights into national characteristics. Consequently, the goal of this paper is to develop an approach to measure national culture in process models. Based on Hofstede's (2010) cultural dimensions, we define metrics that can be applied to process models. We demonstrate the use of these metrics by applying them to a process executed both in a German and an Indian company. Our analysis confirms a correspondence of the metrics' results with Hofstede's findings.

Keywords: National Culture, Business Process, Measurement Approach, Case Study

1 Introduction

National cultural characteristics and their influence on collaboration, both within and among companies, is an important research area in times of globalization [1,2]. Neglecting cultural peculiarities may lead to disastrous consequences. A plane crash involving Avianca Airlines in the 1990's, which was, ultimately, caused by a specific cultural behavior of the crew members may serve as a warning example. In this crash, the co-pilot did not challenge a wrong interpretation of the instruments by the flight captain because he came from a country where subordinates are generally afraid of expressing disagreement with superiors [3]. In IS research, problems caused by cultural differences have been addressed, too. For example caused by different communication styles (in Japan and the US) leading to poor information sharing or caused by different norms for decision-making (Mexico and South Korea) [4].

To make a global collaboration setting more beneficial for all parties, it is essential to be aware of all cultural peculiarities and differences of the individual stakeholders, e.g., customers and suppliers in foreign countries [2]. As all of these stakeholders are

Wehner, B.; Falk, T.; Leist, S.; Ritter, C. (2017): Measuring National Culture by Analyzing Business Processes: A Case Study in Germany and India, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 196-210

connected by business processes, the analysis of cultural peculiarities in relation to business processes is a promising research area. Schein [5] highlights that "*for purposes of cultural analysis, the organizational processes by which such behavior is made routine*" (p. 26) can be used. Business processes are generally captured by process models in various process modeling notations, all of them aiming at graphically representing the actual process as closely as possible. Thus, we anticipate that different cultural aspects can be identified in these process models, as they reveal the behavior, responsibilities, and the sequence flow of tasks.

To date, research has assessed national culture by the use of questionnaires (e.g., [6,7]), asking respondents about their beliefs and assumptions. As questionnaires are very time-intensive, expensive and the intended behavior is only analyzed, a measurement approach that reflects observable behavior on the basis of the employees' daily routines complements questionnaires with new aspects. For example, details on the hierarchy in a company can be inferred [8] when analyzing who makes decisions in a process model. In this paper, we analyze process models by means of metrics, as metrics are a well-known means to identify influencing factors on processes [9]. We anticipate that an analysis of business processes in terms of culture will provide a company with valuable insights into the cultural attitude of the process participants, e.g., if employees culturally fit to the tasks they perform. This knowledge can then contribute to various phases of the BPM lifecycle: To design a process that is perfectly aligned to the cultural attitude of the process participants, to determine a cultural fit of two companies' processes during mergers and acquisitions [10] or to analyze if culture is the origin of process performance problems, a correlation that has recently been identified [11]. Altogether, the goal of this paper is to develop a measurement approach applied to business process models, which in a first step measures selected national characteristics. The resulting metrics form the basis for discussions about discrepancies between national culture and its manifestation in companies.

The remainder of this paper is organized as follows: in section 2, we provide an overview of culture, business process management and measurement of national culture. Section 3 presents the operationalization of the cultural dimensions, the deduction of metrics, and the process of data collection. In section 4, we apply these metrics to process models of two companies, one from Germany and one from India, and present the results. The insights gained from the application of the metrics are discussed by comparing them to the comprehensive study by Hofstede [6] in section 5. The last section gives a summary of our research, names limitations and proposes options for further research.

2 Conceptional Background

2.1 Culture

Culture is a rather diffuse concept with different meanings depending on the context [12]. A definition often used, as it comprises the general aspects of culture, was evolved by Schein [5] with culture being referred to as shared values of a group, which can be recognized in actions and structures.

Culture can generally be presented as an iceberg model [13], with both visible and invisible elements. Invisible elements are *Underlying Assumptions* (e.g., ideology, feelings, taken-for-granted beliefs [13,14]) as well as *Espoused Beliefs and Values* (e.g., morale, ethical norms) [1,5], often subsumed by researchers under the term values [14,8]. Invisible elements of culture manifest themselves in tangible *Artifacts* [5], which represent the visible elements such as concrete actions or structures (e.g., behavior, organizational charts) [13]. According to the range of influence, different levels of culture can be defined, e.g., national, organizational, and subgroup culture [1,14]. Each cultural group shares characteristics distinguishing one from another [6].

Basically, the culture in a company is influenced by the deeply embedded national culture as well as the particular organizational culture [10]. However, the organizational culture is always subject to the basic assumptions of the national culture. This has been demonstrated in various cases by Schneider [15], who analyzed human resource practices in multinational companies. In these cases, national characteristics had a stronger influence on work practices than corporate identity. This fact was also confirmed by other surveys (e.g., [16]). Even though there will always be a coherence between organizational and national culture, Hofstede et al. [17] point out that they are also distinctive due to different cultural dimensions (a list of dimensions is presented in [14]).

In this paper, we focus on national culture that is stable over time [2] and difficult to influence as it represents the basic behavior and values of a particular society [1] and has a predominant effect on people as compared to the organizational culture [10,15]. Even though the concrete personal behavior of individuals belonging to a national group may differ, generally valid tendencies can be observed for certain cultural dimensions [6,8].

2.2 Culture and Business Process Management

Culture has been identified as an important aspect of BPM [18,19], too, and the number of publications linking the two topics has indeed increased in recent years. Research in this area can be classified on the basis of two dimensions: the interrelation between culture and BPM and the referenced cultural group. In this respect, the main emphasis lies on organizational culture and its impact on BPM activities or business process performance (cf. [20,21]). Besides, the concept of a distinct *BPM culture* was identified and its values operationalized [22].

The role of national culture in BPM has been much less highlighted in existing research. Authors dealing with this topic analyze the national influence on BPM [23] and the application of BPM concepts in different national contexts [19,24]. Central to BPM is the notion of a business process consisting of a cohesive sequence of functions that create an output by adding value to the input and thus fulfil an organizational task [25]. Business processes represent a socio-technical system in which humans collaborate and carry out the single tasks to achieve the process output [26].

2.3 Measurement of National Culture

So far, national culture in a broader sense has been assessed by means of surveys, asking respondents questions about their feelings, beliefs, morale, or how they would behave in certain situations [6,7]. Well-known examples are a survey by Hofstede [6] with approx. 116,000 respondents in 76 countries and the GLOBE study with 17,300 interviewees in 63 countries [7]. Questions in cultural surveys generally target the two layers of *Underlying Assumptions* and *Espoused Beliefs and Values*. As a result, visible *Artifacts* are not dealt with. An important category of visible *Artifacts* are process models graphically representing business processes using semi-formal modeling techniques. In a process model, the process is decomposed into a set of interrelated activities that are logically and temporally connected. Using semi-formal modeling techniques helps to increase the specificity of the description and to avoid the ambiguity, which, for instance, natural or narrative texts often imply [27]. Therefore, process models precisely describe the interaction among people, technology and organizations with the aim of improving the effectiveness and efficiency of organizations. Whereas to-be process models represent how people should interact from a management or process owner view, our analysis focuses on as-is process models. As we want to capture the real behavior of people and how they execute their tasks and activities, we analyze the process in its current form. Since as-is models describe this behavior, they reflect the culture of individuals in a country, thus being different from models of other nations. This difference is expected to be detectable and can be measured for each national dimension.

3 Measurement Approach

Our approach is based on predefined metrics that are applied on to business process models. The definition of the required metrics comprises three steps: first, we analyze the operationalization of cultural dimensions in general. Second, three national dimensions by Hofstede et al. [8] are presented and then used to deduct metrics to measure them. Finally, we describe the process of data collection, which is the basis for the calculation of the metrics.

3.1 Operationalization of Cultural Dimensions

The best-known classification in national cultural research are the dimensions by Hofstede et al. [8] (cf. [2,14]), which represent the basic behavior and nature of national cultures: Power Distance, Uncertainty Avoidance, Individualism, Masculinity/Femininity, Indulgence, and Long-Term Orientation [8]. Further studies expand these basic dimensions by detailing or extending them, by e.g., assertiveness, performance, and humane orientation [7], time orientation, and locus of control [14]. As Hofstede describes the most popular conceptualization of national culture [28,29], we take his taxonomy as a basis. In this first step, we develop metrics for the dimensions *Power Distance*, *Uncertainty Avoidance* and *Individualism*, as these were identified as fundamentally distinguishable between nations [6] and are very well defined so that it is possible to derive metrics. In the next section, these dimensions are explained in detail.

We follow the approach by Harvey [30] who operationalized the dimension *Uncertainty Avoidance* to assess differences between design documents and actual design practice. He defined particular characteristics of the dimension *Uncertainty Avoidance* and discussed the differences in each characteristic. We transfer and formalize this approach as follows: Generally, each cultural dimension (CD) comprises several characteristics (C) that can be measured. Metrics (M) are defined to measure the extent of each characteristic. Afterwards, the metrics are aggregated (Agg) for each cultural dimension to obtain a tangible value that can further be interpreted and compared. Figure 1 provides an overview of all components of our measurement system (cf. [30]).

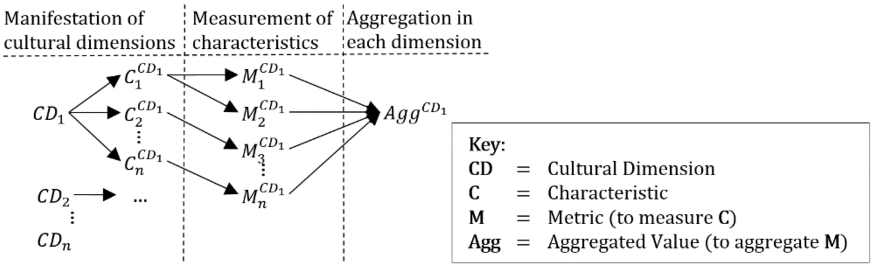

Figure 1. Measurement Approach

To obtain the values for the metrics, the business process models are analyzed. There is a great variety of process modeling notations, the most popular ones being BPMN, EPC and the UML Activity Diagram. Even though different notations exist, most of them offer similar key elements: functions, organizational units, application systems, information objects and connectors [25]. These elements are used to calculate the metrics by analyzing the semantics and the syntax of a process. Elements can be classified with regard to semantics by their element type and by interpreting their labels. Syntax is analyzed to identify sequential, parallel, or alternative process paths (see section 3.3).

3.2 Deduction of Metrics from National Dimensions

The three aforementioned cultural dimensions (CD) by Hofstede et al. [8] are manifested in well-defined characteristics (C). In each dimension, we derived the characteristics analyzing the definitions and descriptions [30]. Furthermore, we analyzed the single items of the questionnaire by Hofstede et al. [8] to stay as close as possible to the original intention of each dimension. As there is also a manual available on how to calculate each dimension on the basis of the questionnaire items, the relevant items in each dimension were selected[1]. Both the definitions and the items in the questionnaire were finally used to derive characteristics that can be developed to metrics, which, in turn, can then be applied to process models. In the following, the deduction of the dimension *Power Distance* is presented in detail and the deduction of the metrics from the other two dimensions is summarized.

[1] The questionnaire and the manual how to use it are available at: http://geerthofstede.com/research-and-vsm/vsm-2013/ (last access: 24.10.2016)

In a cultural group, the power of individuals is not equally distributed. *Power Distance* is defined as the extent of this power and the degree as to which the less powerful accept the existing distribution [6]. In the questionnaire, four questions are asked (item numbers m02, m07, m23, and m26) to calculate the Power Distance Index (PDI) as it is originally named [8]. The questionnaire asks e.g., how important it is for employees to be consulted by their boss in decisions involving their work (m07) and how often subordinates are afraid to contradict their boss (m23). On the basis of the definition and the questionnaire items, two characteristics can be defined: acceptance of unequal distribution of power and unequal distribution of power. With regard to process models, they do not 'betray' any personal feelings, and it is not possible to identify the degree of acceptance of inequality by the less powerful ones in them. Thus, we focus on the extent of unequal distribution of power. The original intention to measure the extent of unequal distribution of power can be identified by looking at single functions, which can be performed by an organizational unit either on a lower or on a higher level. These tasks are checks of results, which is a source of contradiction (m23) and making decisions (m07). If a check is performed by a superior and not by a regular employee, the power is focused on a higher level in that particular case. Thus, the derived metric for a whole process indicates the share of check functions performed by organizational units on a higher level in relation to all check functions performed within the process ($PD_1 = \frac{|CF_{HL}|}{|CF|}$). The assignment of the right to make decisions is the second area for which to show the distribution of power depending on the hierarchy level of organizational units. The metric indicates the share of decision functions that are performed by organizational units on a higher level in relation to all decision functions in the process ($PD_2 = \frac{|DF_{HL}|}{|DF|}$). For both metrics, a high value indicates high *Power Distance*.

Uncertainty Avoidance deals with the unpredictability of situations. It is defined as the extent to which individuals try to avoid uncertain situations by relying on common norms, rituals and practices, e.g., by using standardized documents [6,30]. Additionally, the items m16, m20, m24, and m27 in the questionnaire to calculate the "Uncertainty Avoidance Index" (UAI) are in focus, e.g., the question as to which extent an employee agrees with the statement if one can be a good manager without having precise answers to a question a subordinate may raise (m24). To measure the first characteristic (avoidance of uncertain situations), we explicitly search for functions dealing with quality issues, e.g., the use of a checklist or the four-eyes principle. Quality functions are usually meant to document a current state or to check for a deviation from the outcome, which indeed reduces uncertainty in the specified topic. Thus, if the share of quality functions in relation to all functions is high, a high degree of uncertainty avoidance is measured. In addition, information objects in process models, e.g., checklists, indicate a reduction of uncertainty. The second metric for this characteristic shows the share of quality documents in relation to all documents in a process.

Individualism refers to the intensity of the interdependence of the members of a cultural group and to the extent of people taking care of each other. In individualistic societies, members look after themselves and their direct environment only, while people in collectivistic societies belong to groups. For example, people working in project teams with a high degree of interdependence and a lot of meetings form a collectivistic group [6]. With regard to the questionnaire, e.g., the item was chosen which asks how important it is for an employee to be surrounded by likeable people in a pleasant working atmosphere (m05). The intensity of interdependence can be identified in a process model by looking at the organizational units of each function. Functions with more than one organizational unit show the interaction among them, e.g., the participants of a meeting. A small share of those functions in relation to all functions indicates a small degree of interdependence and an individualistic attitude. While databases are often used to share information, they also represent a form of individualism if they are not shared among employees. Employees create their own data storage, e.g., a sales person who stores product data on his own device when traveling. The metric measures the share of isolated databases in relation to all databases. A high value indicates that the data is not available to other employees. The degree as to which people take care of each other is not directly measurable, as process models do not show in what way people interact. In each dimension, two metrics were derived on the basis of the definitions and questionnaire items. Thus, our metrics follow the same intention that Hofstede [6] measured with his questionnaire.

3.3 Process of Data Collection

To apply these metrics on process models, their elements have to be analyzed (section 3.1). Figure 2 illustrates an exemplary analysis of a business process model with the cultural values extracted from it. In general, all objects of a process model have to be analyzed either individually or in combination with connected objects. An example is a decision function that can be identified by a subsequent XOR-connector (syntax). Still, the semantics of the function needs to be assessed for final classification to a variable, as also a check function is usually followed by an XOR-connector (see Figure 2). Thus, for each metric, we present a detailed procedure of how to gather the values.

Check functions (CF) are identified by a semantic analysis of two consecutive functions, with the first one producing a result that is checked in the second one. For example, in Figure 2, the quantities and times in the product development list are checked. If this check is performed by an organizational unit of a higher hierarchical level, there will be a value for variable CF_{HL}. Continuing the example, the check of quantities and times is performed by the technical managing director, while, prior to that, the quantities and times were determined by a technician. As a technician is a subordinate of the technical managing director, there is a difference in hierarchy.

Decision functions (DF) are identified by analyzing the syntax and the semantics of the functions and the process flow. Decision functions are followed by alternative process paths indicated by “XOR” or “OR” connectors, e.g., the decision whether a product will be developed or not. Depending on the organizational unit that performs the function, different decision functions can be identified: DF_{HL} indicates a decision made by an organizational unit of a higher hierarchy level than the other organizational units in the process, e.g., a managing director. Quality functions (QF), e.g., the creation of a product specification, can be identified by a semantic analysis of functions. Functions that are performed by only one organizational unit ($F_{OU=1}$) can be identified by a syntactical analysis of the related organizational units that perform a function individually.

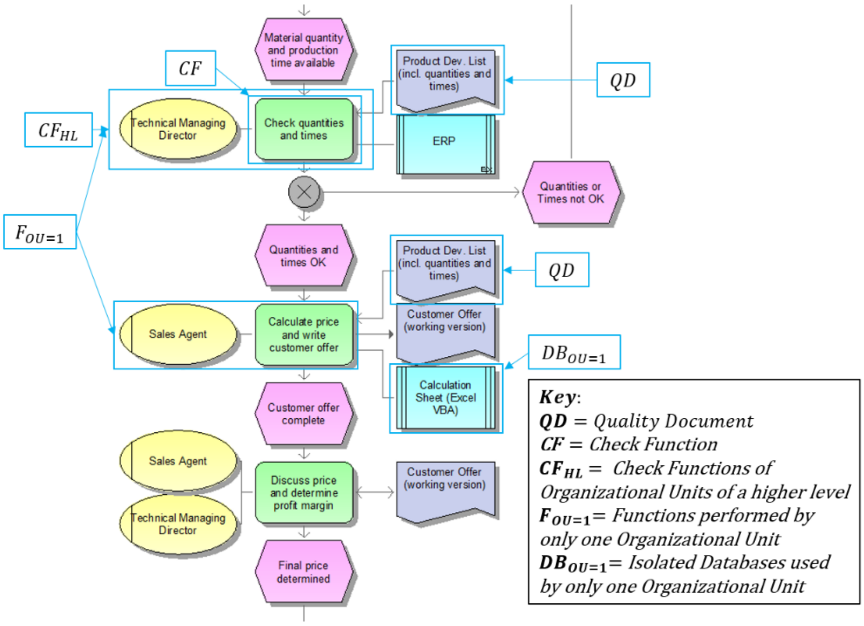

Figure 2. Example of the Data Collection

In addition to functions, information objects are used to measure cultural characteristics. Quality documents (QD) are a subset of all documents (D). They can be identified by selecting those documents that deal with quality issues, e.g., checklists or test reports. Furthermore, isolated databases ($DB_{OU=1}$) can be identified by determining the connection between databases and organizational units. If a database is used by only one organizational unit, it is referred to as an isolated database.

4 Application of Metrics

4.1 Business Processes from Germany and India used for the Application

As cultural values are only meaningful by comparison [8], the metrics derived were applied on business processes of two small and medium-sized enterprises (SMEs) in Germany and India. Both act as suppliers developing and manufacturing similar small electronic components, e.g., transformers, coils, converters.

Out of all business processes, the customer-specific product development process was chosen for the cultural analysis, as both companies develop similar products, which have an analogous complexity and a similar quality required of the output. Due to the high number of products (approx. 350 in each company) that have been developed so far, a high degree of process standardization is available, too, and a similar number of employees performs this process, 11 in the German and 12 in the Indian company. Finally, this process was chosen because it is completely non-automated. Thus, all these similarities ensure the comparability of the German and Indian process so that the cultural characteristics based on human behavior may be fully concentrated on.

The process models we used for our cultural analysis were created in a prior project using the EPC. Even though they were modeled by one and the same modeler, in accordance with identical modeling guidelines and at a comparable level of detail, it was necessary to understand all the details of the processes and check if they were up-to-date. For this purpose, we conducted personal interviews with both the German and the Indian employees involved in the processes. In addition, we were informed about all documents and information systems during on-site visits. On this basis, we slightly revised the models and assured that our analysis was based on the "as-is" models.

The customer-specific product development process starts with a customer asking for a custom-tailored product in the form of a request or tender sent to the SME. This step is followed by an initial design and a subsequent quotation submitted to the customer. In case the customer places an order, the SME designs the product and builds a prototype, which is sent to the customer. After the approval of the prototype, production is planned and initiated. The final steps comprise invoicing and handling of payments. This process is executed in both companies, with some differences regarding the actual process flows and responsibilities. The individual processes are comprised of 60 functions in the German and 71 in the Indian company. Against this background, the values of the variables were independently assessed by two researchers and their results compared afterwards, being identical in almost all cases, showing only slight differences for the rest. The differences were discussed with a third researcher. If no final decision could be made, the differences were discussed with the two companies until a consensus was found to ensure a maximum degree of objectivity when applying the metrics.

4.2 Results of the Application

The values of the variables to calculate the metrics were collected by way of a semantic and syntactical analysis of the processes for both the SMEs as described in section 3.3. We analyzed all objects of both business processes and classified them to the variables that are needed to calculate the metrics. For example, as shown in Figure 2, the Technical Managing Director performs the function *check quantities and times*, which was classified to CF_{HL}. Table 1 shows the defined metrics including a short description, the absolute numbers gained from the process analysis, and the calculated metrics for the German and the Indian company for each cultural dimension. According to our measurement approach, the values of the individual metrics are aggregated for each cultural dimension as well.

Regarding the cultural dimension *Power Distance*, the aggregated value Agg^{PD} is determined by calculating the average of PD_1 and PD_2. Possible and expected values range from 0 (low) to 1 (high Power Distance) for each metric and thus for the aggregated value, too. In the Indian company, 50% of the check functions and even 72% of the decision functions are performed by higher level organizational units, while in the German company only 29% of the checks and 22% of the decisions are made by their counterparts. The aggregated value is 0.61 for the Indian and 0.25 for the German company. Based on these values, we can state that the process reflects a higher Power Distance in the Indian than in the German company.

The aggregation for Uncertainty Avoidance is determined by calculating the average AggUA of the two metrics associated with this cultural dimension. For the two metrics, possible values range from 0 (low) to 1 (high Uncertainty Avoidance), which is also valid for the aggregated value. UA1 reveals that the German process has a share of 28% of quality functions, which means that almost one in three of all functions is quality-related. The Indian process shows a lower share of 17%, which equals less than every fifth function. This tendency is also reflected in the share of quality documents (UA2) with 50% in the German and 16% in the Indian company. In summary, the aggregated values of 0.39 in the German and 0.17 in the Indian company reflect a higher avoidance of uncertainty in the German company.

Table 1. Application of the Derived Metrics (*OU=Organizational Unit)

			Absolute Numbers		Calculated Metric	
	Metric	Description	Ger.	India	Germany	India
Power Distance	$PD_1 = \frac{\lvert CF_{HL} \rvert}{\lvert CF \rvert}$	Check Functions of OUs* of a higher level / Check Functions	$\frac{2}{7}$	$\frac{4}{8}$	0.29	0.50
Power Distance	$PD_2 = \frac{\lvert DF_{HL} \rvert}{\lvert DF \rvert}$	Decision Functions of OUs* of a higher level / Decision Functions	$\frac{2}{9}$	$\frac{8}{11}$	0.22	0.72
Power Distance				Agg^{PD}	0.25	0.61
Uncertainty Avoidance	$UA_1 = \frac{\lvert QF \rvert}{\lvert F \rvert}$	Quality Functions / Functions	$\frac{17}{60}$	$\frac{12}{71}$	0.28	0.17
Uncertainty Avoidance	$UA_2 = \frac{\lvert QD \rvert}{\lvert D \rvert}$	Quality Documents / Documents	$\frac{8}{16}$	$\frac{4}{25}$	0.50	0.16
Uncertainty Avoidance				Agg^{UA}	0.39	0.17
Individualism	$Ind_1 = \frac{\lvert F_{OU=1} \rvert}{\lvert F \rvert}$	Functions performed by only one OU* / Functions	$\frac{50}{60}$	$\frac{50}{71}$	0.83	0.70
Individualism	$Ind_2 = \frac{\lvert DB_{OU=1} \rvert}{\lvert DB \rvert}$	Isolated Databases used by only one OU* / Databases	$\frac{1}{2}$	$\frac{1}{3}$	0.50	0.33
Individualism				Agg^{Ind}	0.67	0.52

The aggregated value of the dimension *Individualism* is determined by building the average (Agg^{Ind}) of the metrics Ind_1 and Ind_2, with 1 indicating a high degree of Individualism and 0 indicating a high degree of Collectivism. The metric values show that in the German process 83% of all functions are performed individually, which indicates a higher degree of individualism than in the Indian process with value of 70% (Ind_1). In the German company, 50% of all databases and 33% in the Indian subsidiary are only used individually (Ind_2). The aggregation Agg^{Ind} results in a value of 0.67 in the German and 0.52 in the Indian company, indicating that the German company is more individualistic than the Indian company.

In summary, all of the derived metrics were applicable on the modeled processes in both the German and the Indian companies, and a clear tendency for each cultural dimensions was identified.

5 Discussion

As we have demonstrated in the previous section, it is possible to identify and measure cultural dimensions in business process models. We operationalized three of Hofstede et al. [8]'s cultural dimensions in process models by deriving metrics analyzing the use and structure of process model elements. Our analysis of the results (see section 4.2) revealed a clear diversity between the German and the Indian process models regarding our cultural metrics. Even though we cannot interpret the derived values as absolute numbers, a clear tendency of the three cultural dimensions for each of the two process models is obvious. For a better interpretation of our results, we opposed them to the findings of the comprehensive study by Hofstede et al. [8] regarding the three cultural dimensions in the two countries Germany and India (see Table 2). Hofstede et al. [8] use a scale from 0 (low) to 100 (high) to rate their cultural dimensions. In comparison, our metrics' values range from 0 (low) to 1 (high). While this means that we cannot directly compare the two scales, we can compare the values of the two countries against their respective scale to reveal a tendency in each cultural dimensions.

Looking at *Power Distance*, Hofstede states a value of 35 for Germany and 77 for India, indicating that Germany has a lower Power Distance than India [6]. Our analysis of the process models comes to a very similar result as our metrics classified the process models of the German company (0.25) showing a lower Power Distance than the ones of the Indian company (0.61). *Uncertainty Avoidance* has a value of 65 in Germany and 40 in India according to Hofstede, displaying a higher avoidance of uncertainty in Germany. These findings are congruent with our measures: The analyzed process models evidence that there is a higher avoidance of uncertainty in the German company (0.39) than the Indian one (0.17). Hofstede's third cultural dimension rates the degree of *Individualism* in a society. His survey states a value of 67 for Germany and 48 for India, reflecting a higher Individualism for Germany in comparison to India. Our results are in accordance with this tendency as we calculated 0.67 for Germany and 0.52 for India using our metrics.

Table 2. Comparison of Calculated Metrics and Survey Results by Hofstede et al. [8]

	Aggregated metrics			Survey by Hofstede et al. [12]		
	Germany		India	Germany		India
Power Distance	0.25	<	0.61	35	<	77
Uncertainty Avoidance	0.39	>	0.17	65	>	40
Individualism	0.67	>	0.52	67	>	48

We see a contribution of our research to both theory and practice. From a scientific point of view, cultural aspects in BPM have mostly been disregarded [18], even though culture has a direct influence on process performance [20]. Our metrics are a new instrument to measure national culture in process models and thus contribute to this research gap of BPM. Up to now, cultural research has largely relied on surveys, which primarily focus on the layers of *Underlying Assumptions* and *Espoused Beliefs and Values*. In contrast, our proposed metrics focus on the layer of *Artifacts*, thus allowing for further aspects of cultural research to be investigated. In addition, due to the fact that our metrics are well-defined and the data collection instructions are quick and easy to apply in a real-life context, the extraction of the underlying process variables is very cost-effective as compared to e.g., questionnaires. Since the necessary information is inherent in BPM systems and data collection is in many cases automated, e.g., gathering the as-is process using process mining algorithms, we therefore expect a broad application basis. Our metrics contribute to practice in other areas, too. Looking at BPM in particular, the metrics can be applied to support the different phases of the BPM life cycle:

(1) In the design phase, the process modeler creates a process that has to be aligned to the national cultures of the users involved. For example, they can be applied in - especially international – mergers and acquisitions (M&As) that play a predominant role in times of globalization [31]. There, cultural “collisions” [10] are observed, which are seen as a possible reason why 50 to 60 percent of M&As fail eventually [31,32]. In this regard, our approach helps to assess the national differences in the companies involved by calculating and comparing the metrics of the processes to be merged. Thus, our metrics help to highlight the cultural compatibility and to detect cultural collisions before the actual process harmonization takes place. A high degree of cultural equality between the companies’ processes will lower integration costs and help employees to easier adapt to the new, joint processes. Finally, the failure rate of M&As can possibly be reduced. The same reasoning is valid for outsourcing initiatives. A close cultural fit of the insourcer’s processes with the ones of the outsourcing company may be seen as an indicator of a seamless integration. Besides the harmonization of two processes, the modelers of a process may calculate our metrics on its own processes and compare the values to benchmarks and reference values. A modeler can then check whether the process they design fits the cultural expectations in advance ensuring a high rate of adoption among the users. In addition, the importance of culturally aligning a business process that involves users from several different countries and cultures is obvious. For example, it is necessary to consider the national culture when designing offshoring processes [10], or when transferring an IT-system to a subsidiary in a foreign country [33].

(2) Our metrics also contribute to the analyze phase of BPM. When a company experiences problems with their process performance, e.g., right after implementing a new process, our metrics help to analyze whether cultural issues are the cause of these shortcomings. In fact, there is empirical evidence, that culture affects the process quality (survey, cf. [20]). Thus, our metrics support a company by indicating whether a business process fits the cultural needs and expectations of all parties involved. For example, when employees from different countries work together, problems due to their different cultural backgrounds may be expected, which affects multinational companies in particular [29]. By comparing the metrics to a benchmark or reference value, possible causes may be identified, which can be further evaluated in an upcoming BPI initiative.

(3) In the improvement phase, the culturally induced causes for a decreasing process performance can be eliminated. In this regard, the descriptions of the metrics help to identify improvement possibilities and, thus, to define measures to align the process to the employees’ expectations. Further, the comparison with benchmarks or reference values give further hints in which cultural dimension the roots of the problems may

particularly be. In summary, as described above, we are convinced that our metrics are a new means to make culture a tangible construct from a BPM perspective.

6 Conclusion

In this paper, we present a measurement approach to identify national culture in business process models. We defined six metrics for the national dimensions *Power Distance, Uncertainty Avoidance* and *Individualism*. Further, these metrics were applied on to business process models of a German and an Indian company. We demonstrated that our metrics are applicable and that they provide further insights into the cultural characteristics of the two companies. We derived tendencies of the characteristics for the German and Indian companies and compared them to those of Hofstede et al. [8]. By applying our metrics in two companies in Germany and India, we can support the theory that it is possible to measure cultural characteristics in business processes.

The proposed approach for measuring national culture based on business process models contributes to both research and practice. So far, cultural research has mainly relied on surveys to measure underlying assumptions and espoused beliefs and values for identifying national culture. We contribute by presenting a measurement approach to measure culture based on documented actions and behavior, thus providing a transparent, independent and unbiased analysis of the underlying cultural dimensions. For practice, we see several areas of contribution. In the design phase of BPM, our metrics support the modelers e.g., by checking whether the process they design fits the cultural expectations of the involved parties. Our metrics can also support in the process analysis phase, e.g., by potentially identifying cultural problems causing performance issues. Furthermore, the analysis of the national culture in process models can be applied when measuring the cultural fit of two companies, e.g., at mergers and acquisitions.

However, our research is not without limitations. The processes in a company are not only subject to national culture, but also to other influencing factors that affect the process design. In each particular setting, these factors need to be analyzed in detail. Especially the interdependence of organizational culture and national culture – even though distinguishable due to different cultural dimensions [17] – needs to be analyzed. Further, as objects in a process model may be seen as boundary objects, literature from this adjacent field will be considered, too, in our upcoming research [34].

In terms of further research, our approach has to be expanded and evaluated: First, for a better interpretation and evaluation of the resulting values, further applications of the metrics in different companies, business processes, and countries are necessary. Second, we will investigate further characteristics which are capable to operationalize characteristics in the dimensions *Power Distance, Uncertainty Avoidance* and *Individualism*. Third, to expand our approach, we will define metrics for further cultural dimensions like e.g., *Masculinity, Indulgence* and *Long-Term Orientation* [8]. Fourth, it is necessary to apply the metrics to further settings to allow for a better evaluation and to establish a benchmark value for each individual country, process type, and industry. Last, even though process models are a means of quality documentation in companies, their quality and topicality cannot always be ensured. Thus, we will define requirements to determine which processes our metrics suit best, e.g., to identify the influence of different modeling notations on our metrics.

Abstract. Business Rules (BR) und Business Process Management (BPM) sind eng miteinander verzahnt. Dennoch gibt es nur vergleichsweise wenige Forschungsbeiträge, die sich mit dem Grad der Integration beider Domänen befassen. Auf der Basis des Six-Core-Elements-BPM-Framework wird die Integration von Business Rules mit dem BPM anhand einer State-of-the-Art-Analyse der Literatur untersucht und evaluiert. Die Analyse deckt aktuelle und zukünftig mögliche Entwicklungen auf und stellt im Besonderen einen starken Fokus auf die Erforschung methodischer Ansätze fest. Während das Design und die Implementierung von BR und Geschäftsprozessen im Mittelpunkt stehen, werden organisationale Faktoren wie People und Culture kaum betrachtet. Auch kann ein strategischer Bezug der Integration beider Domänen kaum festgestellt werden.

Keywords: Business Process Management; Business Rules; Literaturanalyse; State-of-the-Art

1 Einleitung

Die informationstechnologischen Entwicklungen der letzten Jahre haben zu einer voranschreitenden Digitalisierung geführt und fordern Unternehmen und ihre Angestellten zunehmend zu einer anhaltenden Effizienzsteigerung, einem erhöhten Automatisierungsgrad sowie einer verstärkten Veränderungsbereitschaft heraus [1]. Business Rules (BR) können an dieser Stelle unterstützen, indem bewährte Vorgehensweisen als Regeln dargestellt und unabhängig von dem ursprünglichen Wissensmedium zentral verfügbar gemacht werden [2]. Sie fungieren als explizite, deklarative Regelwerke [3], die das Geschäft in seiner Struktur und auch in seinem Betrieb anleiten können [4]. Dagegen definiert das Business Process Management (BPM) Verfahrensregeln zur *prozeduralen* Darstellung von Prozessen [5].

Damit die Formulierung der operativen Geschäftsanforderungen via BR eine direkte Auswirkung auf betriebliche Informationssysteme hat, bedarf es einer Verknüpfung beider Domänen [4]. Während der Zusammenhang von Geschäftsregeln und Geschäftsprozessen in [6, 7] vertieft werden kann, gibt es trotz der Abhängigkeiten zwischen BR und BPM in der Literatur derzeit keine systematische Auswertung des aktuellen Status-Quo der Integration beider Domänen.

Auf der Basis einer selektiven Literaturanalyse soll ein thematischer Überblick über aktuelle Forschungsgegenstände gegeben, der State-of-the-Art ihrer Integration herausgearbeitet, aktuelle Entwicklungen aufgezeigt, sowie potentielle Forschungsrichtungen abgeleitet werden. Ausgewählte Literatur wird den sechs Kernelementen des Six-Core-Elements-BPM-Frameworks nach [8] zugeordnet. Jede der sechs Kernkategorien verfügt wiederum über fünf *Capability Areas*, die dessen Inhalte in erhöhter Granularität konsistent wiedergeben. Das Framework bildet die holistische Managementdisziplin des BPM vollumfänglich ab und kann daher als geeignete Bewertungsgrundlage für die Integration von BR und BPM herangezogen werden.

Durch die Zuordnung ist schließlich eine Evaluation des Abdeckungsgrades der BR-Forschung gegenüber der BPM-Forschung möglich. Eine Diskussion, die neben dem Grad der Abdeckung Aussagen bezüglich aktueller und zukünftiger Forschungsschwerpunkte evaluiert, rundet den Beitrag ab.

2 Business Process Management und Business Rules

Das *BPM* findet seine Ursprünge in der statistischen Prozesskontrolle [9], die betriebliche Abläufe in den Mittelpunkt der Aufmerksamkeit des Managements stellt und auf Basis statistischer Methoden Performanceprobleme zu isolieren versucht [10]. In den letzten Jahren ist BPM zu einer umfassenden Managementdisziplin herangewachsen, die einen integrierten Ansatz zur Verbesserung der Unternehmensleistung durch das Management von Geschäftsprozessen bereitstellt [10]. Im Zusammenspiel mit den Grundideen des Business Process Reengineering haben sich die *Identifikation*, *Modellierung*, *Analyse*, *Verbesserung*, *Implementierung*, *Ausführung*, *Monitoring* und *Änderung* von Geschäftsprozessen als Hauptaktivitäten des BPM herausgestellt [10]. BPM stellt ein interdisziplinäres Forschungsfeld dar, das ein breites Spektrum an Aspekten aus unterschiedlichen Forschungsrichtungen zusammenfasst und deshalb in einem ganzheitlichen Kontext betrachtet werden sollte [11–13].

BR sind meist implizit in aufbau- oder ablauforganisatorischen Unternehmensstrukturen enthalten. Sie repräsentieren die Logik des Geschäftsablaufs und bilden das Wissen ab, das in Unternehmensabläufen implementiert ist [2]. BR können als Bestandteil von Geschäftsprozessen betrachtet und aus diesen extrahiert werden [7, 14–16]. BR sind im Gegensatz zur prozeduralen Darstellung von Prozessen innerhalb des BPM deklarativer Natur. Während in der Literatur Interpretationsspielraum bezüglich der Definition von BR herrscht, soll in dieser Arbeit der Ansatz nach Ross [17] vertreten werden. Demzufolge ist eine BR ein Statement, das Aspekte des Geschäfts explizit definiert oder einschränkt. BR sind atomar und können sowohl aus der geschäftsseitigen als auch der informationstechnischen Seite betrachtet werden. Von Halle [18] ergänzt, dass BR einen einschränkenden, leitenden, vorschlagenden, kalkulierenden oder schlussfolgernden Charakter haben können. Prozesse und BR können anhand eines Managementansatzes organisiert werden [19].

BR bilden das Kernwissen über Prozesse ab, während das BPM sequenzielle Abläufe darstellt [2]. D. h., BR stehen in Beziehung zu Wissen und Steuerung, BPM hingegen im Kontext zu Aktivitäten und Ressourcen [7]. Der deklarativen Beschreibung von Tatsachen, Bedingungen und Restriktionen der BR stehen prozedurale Sequenzen von Prozessen gegenüber [6]. BPM ist isoliert betrachtet nicht in der Lage, Entscheidungslogik auf Detailebene abzubilden. Die Integration von BR ermöglicht es im Kontext von BPM dennoch, Regeln in sequenzielle Prozessdiagramme einzubinden und gleichzeitig von einer deklarativen Beschreibung der Geschäftslogik zu profitieren [6, 20, 21].

3 Forschungsmethodik

Um den Integrationsgrad von BR und BPM herauszustellen, wird eine selektive Literaturanalyse durchgeführt. Angereichert mit den Empfehlungen aus [22, 23] baut die Literaturanalyse auf dem in [24] dargestellten Prozess auf, der aus den Phasen *Problemdefinition*, *Literatursuche*, *Literaturauswertung*, *Analyse*, *Interpretation* und *Präsentation* besteht. Um den Anspruch auf Aktualität und Qualität einer wissenschaftlichen Literaturanalyse zu gewährleisten, beschränkt sich die Literatursuche auf Publikationen, die in *Journals*, auf *Konferenzen* oder als *Working Paper* veröffentlicht wurden. Iterative Suchvorgänge zeigten, dass sich die Ergebnisse der Suchanfrage *"Business Rules" AND "*Process*"* bzw. *"Business Rules" AND "Business Process*"* (IEEE Xplore) weitestgehend innerhalb des Betrachtungsgegenstands bewegten. Um ein möglichst umfassendes Bild zu Forschungsanstrengungen im Rahmen des Betrachtungsgegenstandes zu bieten, erfolgte die Suche in acht etablierten Fachdatenbanken (vgl. Tabelle 1) aus den Bereichen der Wirtschaftswissenschaften, Wirtschaftsinformatik und Informatik. Beiträge, deren Publikationsmedium zum Zeitpunkt der Suche nicht Teil der Rankingkategorien A+ bis C des VHB JOURQUAL-Rankings der Teilgebiete Wirtschaftsinformatik [25] oder

Operations Research [26] war, wurden grundsätzlich ausgeschlossen. Ausnahmen wurden für einzelne Publikationen gemacht, die sich entgegen dieses Selektionskriterium dennoch als äußerst relevant herausstellten.

Die Beiträge wurden im Rahmen der Auswertungsphase von den Autoren anhand ihres *Titels*, der *Keywords* und des *Abstracts* unter Zuhilfenahme folgenden Grundsatzes auf Relevanz hin geprüft: Die Domänen BR und BPM oder Aspekte dieser Domänen bilden den zentralen Betrachtungsgegenstand der Forschungsarbeit und stehen im engen oder weiten Zusammenhang miteinander. Ein enger Zusammenhang umfasst die zusammenhängende Betrachtung beider Domänen. Ein weiter Zusammenhäng ergibt sich, wenn eine Domäne den Schwerpunkt der Betrachtung darstellt und die andere Domäne indirekt im Betrachtungsgegenstand enthalten ist.

In der Analysephase ordneten zwei der Autoren die relevanten Titel unter Betrachtung ihrer Kerninhalte unabhängig voneinander einer oder mehreren Kategorien des BPM-Rahmenwerks nach [8] zu. Unstimmigkeiten wurden in einer abschließenden Diskussion gemeinsam konsolidiert. Nicht zuordenbare Titel wurden in eine separate Kategorie „Others" eingeteilt, die nicht Teil des Rahmenwerks ist.

4 Ergebnisse und Auswertung der Literaturanalyse

4.1 Übersicht

Eine Konsolidierung und Bereinigung der 563 Suchtreffer identifiziert insgesamt 78 als relevant eingestufte Forschungsbeiträge, die im Zeitraum von 1994 bis 2016 veröffentlicht wurden. Tabelle 1 zeigt eine Auflistung von Typ und Quelle der Beiträge.

Tabelle 1: Verteilung der Suchtreffer auf Datenbank und Publikationsformat

Tabelle 2 enthält alle relevanten Forschungsbeiträge. Die Anzahl der *Zitationen* (laut Google Scholar, Stichdatum 18.08.2016) bilden das Ordnungskriterium der Tabelle. Neben der Kategorie *Beitrag* (Referenz auf den Artikel) klärt die Tabelle zudem über das Erscheinungs*jahr* und den *Typ* des Forschungsbeitrags auf: Journal (*J*), Konferenzbeitrag (*K*) oder Working Paper (*WP*). Die Inhalte der *BPM-Kategorie* stützen sich auf die Kategorisierung des angesprochenen Six-Core-Elements-BPM-Frameworks [8] (vgl. Abbildung 1). Die Zuordnung der Beiträge in Tabelle 2 erfolgte mittels Buchstaben (für die Kategorie des BPM-Frameworks) und Zahlen (für die zugehörige Capability Area). Die Kategorie *Others (O)* wie oben eingeführt fasst nicht zuordenbare Forschungsbeiträge zusammen.

Abbildung 1: The Six Core Elements of BPM nach [8]

Beiträge auf Konferenzen sind derzeit das wichtigste Medium (70,5 %). Etwa jede fünfte Publikation (21,8 %) wird in einem Journal veröffentlicht. Die übrigen Publikationen sind Working Paper.

Weiter fällt eine ungleichmäßige Verteilung der Forschungsbeiträge in die Kategorien des BPM-Frameworks auf. Während viele Autoren im Bereich der *Methods (M)* publizieren, wird den Kategorien *People (P)* und *Culture (C)* kaum bzw. keine Beachtung geschenkt. Die Anzahl sowie die Zitationszahlen der identifizierten Forschungsbeiträge zeigen, dass BR im Kontext des BPM bereits seit 2004 diskutiert werden. Eine vorangeschrittene Integration kann jedoch lediglich in einzelnen Subkategorien (vgl. Kapitel 4.2) erkannt werden. Im zeitlichen Verlauf lässt sich ein erster Forschungsschwerpunkt im Jahr 2011 erkennen, der jedoch nicht weiter anhält.

4.2 Darstellung des State-of-the-Art

Der State-of-the-Art der Integration von BR und BPM wird in Abbildung 2 Kategorie-basiert dargestellt. Aufgrund von Mehrfachzuordnungen übersteigt die Gesamtanzahl der in Abbildung 2 aufgeführten Beiträge (95) die tatsächliche Menge der Beiträge (78).

Die visualisierte Darstellung zeigt, dass sich ein Großteil der Forschung auf die Erforschung und Evaluation methodischer Ansätze *(Methods)* fokussiert (72,63 %), während die übrigen Kernkategorien *Strategic Alignment*, *Governance*, *Information Technology*, *People* und *Culture* mit einer Zuordnungsrate von insgesamt 23,16 % vergleichsweise geringe Beachtung finden. Beiträge, die keine Zuordnung finden konnten, sind in der Kategorie *Others* (4,21 %) eingeordnet.

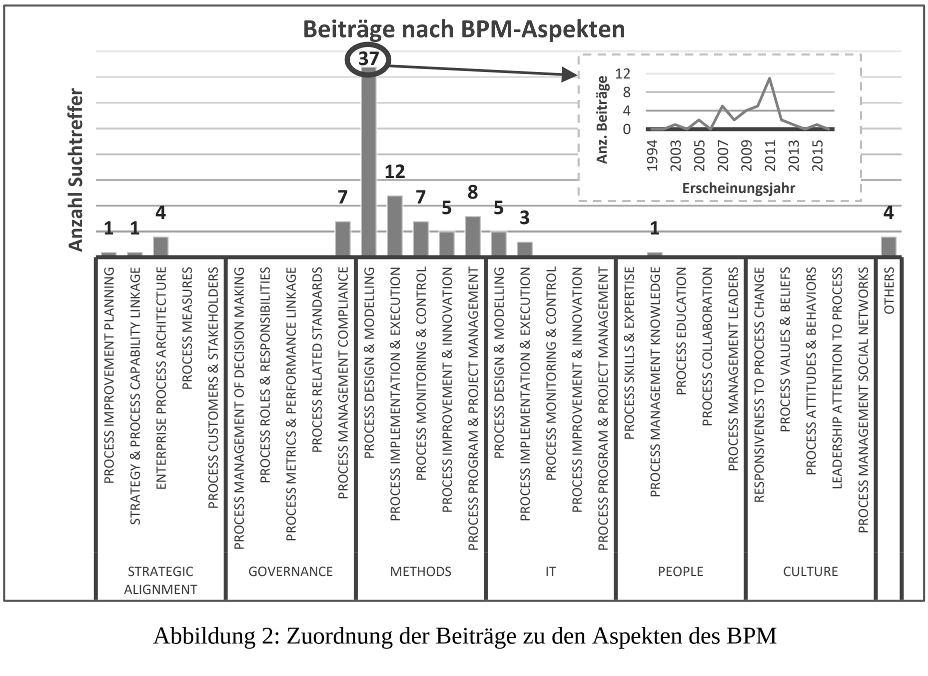

Abbildung 2: Zuordnung der Beiträge zu den Aspekten des BPM

Strategic Alignment

Die Kategorie *Strategic Alignment* beschäftigt sich mit der Ausrichtung von Unternehmensabläufen an die Unternehmensstrategie.

Im Kontext zu BR stehen besonders *integrierte Architekturmodelle* im Fokus, die durch die Integration unterschiedlicher Modellierungsansätze für Geschäftsprozesse und BR [99] sowie die Verbesserung der Adaptionsfähigkeit von Unternehmen anhand von Konzepten für serviceorientierte Architekturen [35, 60, 96] motiviert werden. Integrierte Architekturmodelle sollen einer mangelhaften Interoperabilität, langen Umsetzungszeiten und hohen Kosten entgegenwirken [60] und somit den Grundstein für eine bessere vertikale und horizontale Integration von Strategievorhaben legen. Die Integration von BR vereinfacht die Implementierung neuer Abläufe, reduziert Kosten und verbessert das Alignment zwischen Strategie und Geschäftsprozessen [60].

Governance

Aktivitäten im Bereich *Governance* beschäftigen sich vorwiegend mit der Festlegung von Rollen und Verantwortlichkeiten sowie dem Prozess der Entscheidungsfindung innerhalb des BPM [8]. BR thematisieren in diesem Kontext die Unterkategorie *Process Management Compliance*, indem sie ein regelbasiertes Monitoring sowie eine regelbasierte Validierung von Geschäftsprozessen ermöglichen [35, 42, 49, 84].

Compliance Prüfungen, die sich den Mitteln des Process Mining bedienen, können so um regelbasierte Ansätze erweitert und die Auswertung von Event-Logs durch den Einsatz von BR beschleunigt werden [42]. Zudem können BR zur einfachen und schnellen Validierung von Prozessabläufen im Rahmen von Modellierungstätigkeiten herangezogen werden [49]. Außerhalb des Compliance Checking finden BR in dieser Kategorie bisher keine weitere Aufmerksamkeit. Aufgrund des deklarativen Charakters von BR könnten weiterführende Diskussionen besonders in der Capability Area *Process Management of Decision Making* Mehrwert schaffen.

Methods

Als *Methoden* des BPM werden Techniken und Instrumente beschrieben, die eine Ausführung spezifischer Aktivitäten entlang der Lifecycle-Phasen des BPM erlauben [8]. In dieser Kategorie teilen sich 69 Artikel auf jede der fünf Capability Areas auf.

Besondere Aufmerksamkeit gilt dabei dem *Design & Modeling*, in dessen Zusammenhang Fragestellungen zur Darstellung von BR innerhalb des BPM diskutiert werden [33, 36, 39]. In diesem Kontext stellt die Object Management Group mit der Decision Model and Notation [100] einen Standard zur Modellierung von Entscheidungsszenarien bereit. Abbildung 2 lässt erkennen, dass die Diskussion in dieser Capability Area ab dem Jahr 2011 abflacht. Zur Mühlen und Indulska [6] kommen zu der Feststellung, dass eine Kombination von SRML und BPMN für eine integrierte Modellierung von BR und Geschäftsprozessen als adäquat betrachtet werden kann. Dies darf jedoch im Hinblick auf diese Subkategorie nicht mit einer abgeschlossenen Erforschung gleichgesetzt werden.

Themenstellungen, die sich ergänzend mit der Ausführbarkeit von BR im Kontext des BPM beschäftigen, finden sich in der Capability Area *Implementation & Execution* wieder [34, 43, 47, 51, 52, 101]. Hier geht es im Besonderen um die Fähigkeit von BR, ausführbare Geschäftsprozesse zu implementieren.

Veröffentlichungen der Unterkategorie *Process Monitoring & Control* beschäftigen sich vornehmlich mit der Verifikation von Geschäftsprozessen auf Basis semantischer Rahmenbedingungen, die in Form von BR repräsentiert werden [29, 30, 84]. Im Bereich *Process Improvement & Innovation* geht es um die Adaption und Verbesserung von Geschäftsprozessen unter Zuhilfenahme von BR [53, 75, 77]. Zudem werden Möglichkeiten des Outsourcings von Geschäftsprozessen in die Cloud mithilfe sogenannter Business Rule Management Systeme diskutiert [91].

Beiträge der Capability Area *Program & Project Management* untersuchen verschiedene Modellierungsansätze zu BR und BPM und stellen diese unter Berücksichtigung einer anschließenden Bewertung einander gegenüber [6, 27, 28, 45].

Information Technology

Die *Information Technology* befasst sich mit Informationssystemen sowie Software und Hardware, die eine Durchführbarkeit der Methoden des BPM gewährleisten [8].

In Bezug auf BR werden Programme zur Adaption von Geschäftsprozessen [46] sowie Softwarelösungen für das Management von BR evaluiert [88]. Zudem wird die toolbasierte Modellierung von wissensintensiven Unternehmensabläufen diskutiert [31, 82] und Methoden sowie Softwaretools zur Transformation von BR [51] bewertet. Damit werden insbesondere die Capability Areas *Design & Modelling* und *Implementation & Execution* bedient. Eine Diskussion von BR im Bereich *Monitoring & Control* sowie dem eher organisationalen *Program & Project Management* findet nicht statt.

People

Die Kategorie *People* betrachtet Menschen als wesentlichen Bestandteil in Unternehmensabläufen und beschäftig sich mit deren Fähigkeiten und Erfahrungen in Bezug auf spezifische Prozessanforderungen [8]. Im Kontext zu BR kann ein thematischer Bezug lediglich zu einer Fallstudie hergestellt werden, die Herausforderungen der Implementierung von BR-Ansätzen u. a. vor dem Hintergrund der Nutzerakzeptanz sowie der Kosten-Nutzen-Effizienz untersucht [93]. Nichtsdestotrotz wäre insbesondere die Abbildung von *Skills & Expertise* ein Aspekt der sich gut zur Ressourcensteuerung von BPM mit BR unterstützen ließe.

Culture

Die Haltung gegenüber Prozessverbesserungsmaßnahmen sowie die Werte eines Unternehmens werden im BPM-Framework unter der Kategorie *Culture* diskutiert. In der durchgeführten Literaturanalyse konnten jedoch keine Zusammenhänge zwischen BR und Inhalten dieser Kernkategorie gefunden werden.

Others

Arbeiten, die sich den Aspekten im Framework nicht zuordnen ließen, wurden in die Kategorie *Others* eingeordnet. Die Kategorie Others ist kein Bestandteil des eigentlichen Frameworks. Hier wird beispielsweise die Integration von BR und BPM betrachtet, indem eine Kategorisierung von BR ausgearbeitet wird [7].

4.3 Diskussion

Die vorangegange Literaturanalyse zeigt, dass BR aufgrund ihrer deskriptiven Natur als ein adäquates Werkzeug zur Darstellung, Umsetzung und Überwachung von strategischen Initiativen fungieren. BR können Prozessarchitekturen durch die Integration ihrer eingekapselten Logik agiler gestalten und durch ihre steuernde Charakteristik bei der Ausführung von Prozessen unterstützen. Ursache-Wirkungs-Analysen profitieren von der inhärenten Logik der BR, während ihr lenkender und einschränkender Charakter in der Entscheidungsfindung bei der Ausgestaltung von Prozessen unterstützen kann. Auch Prozessmanagement-Initiativen profitieren von BR, indem diese in der Entscheidungsmodellierung Berücksichtigung finden. Entsprechend findet eine integrierte Betrachtung von BR und BPM vorwiegend im Bereich Methods statt. Eine isolierte Betrachtung der Domänen BPM und BR würde höchstwahrscheinlich zu einem identischen Ergebnis kommen.

Neben dieser stark funktional orientierten Betrachtung, die sich in den meisten Anwendungsfällen auf die Wertschöpfung des Unternehmens beschränkt, werden BR im Kontext organisationaler Faktoren (*People* und *Culture*) kaum diskutiert. Da BR für Menschen lesbare Regeln abbilden und von Fachabteilungen gepflegt werden sollen, sind diese beiden Kategorien jedoch hochrelevant. Die Autoren empfinden es daher als nötig, dass sich neben der methodischen Auseinandersetzung auch eine Diskussion bzgl. organisationaler Aspekte von BR etabliert. In einer isolierten Betrachtung zeigt das BPM im Gegensatz zu BR bereits eine erhöhte Sensibilität für entsprechende Faktoren. So stellen diverse Publikationen die Berücksichtigung der Faktoren *People* und *Culture* als erfolgskritisch hinsichtlicher der Erreichung BPM-spezifischer Ziele heraus [102–106]. Analog zum BPM müssen auch BR-spezifische Methodiken zunächst von ihren Anwendern (People) interpretiert werden, bevor eine Umsetzung in einer organisationalen Umgebung (Culture) erfolgen kann.

Die Literaturanalyse deutet jedoch darauf hin, dass BR und damit auch die Integration von BR und BPM den Schritt von einem technisch getriebenen Thema hin zu einer organisational verankerten Methodologie noch nicht vollzogen hat. Diese These stützt auch der Fakt, dass sich BR im Bereich *Governance* bislang nur wenig etabliert haben, da es hier in aller Regel um nicht-automatisierbare Entscheidungen des BPM oder BR-Management geht.

Wir schlagen daher eine Erweiterung des derzeit eher methodisch orientierten Forschungsdialogs auf den Aufbau eines adäquaten Verständnises zur ganzheitlichen, integrierten Betrachtung von BR und BPM vor, um somit die organisationale Einordnung der Themen in den Unternehmenskontext zu fördern.

5 Zusammenfassende Erläuterungen

Die vorliegende Arbeit gibt einen thematischen Überblick zur Integration von BR und BPM und stellt aktuelle Entwicklungen sowie künftig mögliche Forschungsrichtungen heraus. Die Auswertungen deuten auf eine vorangeschrittene, aber ungleichmäßig verteilte Diskussion der Integration von BR und BPM hin. Ein großer Fokus liegt auf der Erforschung von Methoden, die insbesondere spezifische Darstellungs- und Modellierungsformen von BR im Kontext des BPM betrachten.

Die Auswertung der Literaturanalyse zeigt deutlich, dass die Integration von BR und BPM keinesfalls als abgeschlossen angesehen werden kann und weiterer Forschungsbedarf besonders in geringer erforschten Kerngebieten wie *People* oder *Culture* wünschenswert wäre. Darüber hinaus sollten vorhandene Forschungsthemen validiert und erweitert werden. Die Literaturanalyse zeigt zudem Raum für eine Vertiefung von Ansätzen bzgl. der Identifikation und Extraktion von BR sowie dessen Einsatz zur Identifikation von Prozessschwachstellen und im Bereich der Governance.

Detecting Compliance with Business Rules in Ontology-Based Process Modeling

Carl Corea[1], Patrick Delfmann[1]

{ccorea,delfmann}@uni-koblenz.de

Abstract. Extending business processes with semantic annotations has gained recent attention. This comprises relating process elements to ontology elements in order to create a shared conceptual and terminological understanding. In business process modeling, processes may have to adhere to a multitude of rules. A common way to detect compliance automatedly is studying the artifact of the process model itself. However, if an ontology exists as an additional artifact, it may prove beneficial to exploit this structure for compliance detection, as it provides a rich specification of the business process. We therefore propose an approach that models a rules-layer ontop of an ontology. Said rules-layer is implemented by a *logic program* and can be used to *reason* about the compliance of an underlying *ontology*. Our approach allows ad-hoc access to external ontologies, other than similar approaches that are reliant on a redundant logical representation of process model elements.

Keywords: Compliance Management, Business Rules, Business Process Models, Business Ontologies

1. Introduction

Compliance management is an important part of business process modeling (BPM), aimed to ensure that the company practices which can be entailed from the respective process models are compliant to regulations and business rules [13]. This especially holds for sectors subject to a high degree of regulatory control, such as the financial industry or healthcare [2], [13]. As an example, vendors of financial services may want to warrant that their process for granting loans does not violate any laws or obligations. Compliance management therefore supports *improving* business processes, as potential violations can be eliminated after they have been found, e.g. through re-modeling the business process [3].

The necessity for compliance management has yielded the rise of *automated* approaches, as trying to investigate large company processes for compliance violations *manually* can be seen as an unfeasible task for humans [13]. Following [10], a core notion of such automated approaches is the study of the business process model itself. Such business process models are typically represented through graphical modeling languages such as Event-driven Process Chains (EPC) [26], in order to provide a suitable balance between specification and readability. However, using such languages

Corea, C.; Delfmann, P. (2017): Detecting Compliance with Business Rules in Ontology-Based Process Modeling, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 226-240

to model business processes, as well as limiting compliance management to this artifact, can bare restrictions in regard to the semantic interpretation of the process model [25]. Although languages such as EPC offer some guidelines towards how to encode process syntax and semantics, the content of the models ultimately lies in the responsebility of the process modeler [21]. Especially when collaboratively creating process models, this can result in different interpretations of the process semantics due to problems such as ambiguity in human language [9], [25]. These different interpretations of the process model can pose potential problems, if they are meant to be analyzed as a central corpus in the scope of compliance management [7], [25].

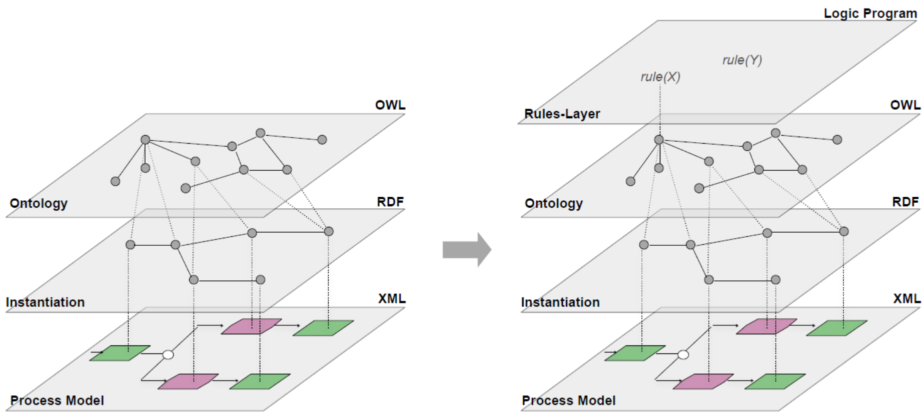

Figure 1. 4-layered framework adapted from [25]

To conquer the problem of different interpretations of business processes, works such as [7-8], [20], [24-25] have proposed to use ontologies to create a shared terminological and conceptual understanding of process models. Ontologies, which Gruber [16] defines as a formal and shared specification of a domain of interest, are a central object of interest in scientific fields such as the Semantic Web [18], which is why works such as [7-8], [20], [24-25] have proposed it may prove as beneficial to investigate applying this object for business process modeling. A main advantage of using ontologies in BPM is that a process model is extended such that machines can access it in a way useful for humans [18]. To this aim, elements of the process model can be annotated to ontology concepts, which is also referred to as *semantic annotations*. This promotes the understanding of the overall business process, as the process model is linked to a conceptual and terminological understanding shared by the modelers. Following [25], ontologies can be furthermore extended by the modelers. For instance, relevant policies or business rules can directly be included in such an ontology, explicitly *specifying the relations between the business process and such regulations*. Concluding, this report investigates utilizing such an ontology as an artifact for compliance management, as an ontology can be considered as an advanced basis for this form of process-oriented compliance management.

This is clarified in figure 1. On the left, which shows the three-layered model for a semantic annotation by [25], we see a business process which has been related to a business ontology. The lower layer represents the classical business process - in this case an EPC diagram. The upper ontology comprises terminological concepts relevant for the respective business as well as their relations. The intermediate instantiation is used to assign elements of the business process to ontology concepts. I.e. instances of the business ontology are used to define the semantics of the EPC model elements. In this paper, we aim at providing an approach which layers a specification of business rules ontop of a business ontology. We refer to our approach as a 4-layered framework, meaning that our contribution extends the existing framework by [25]. This can be seen on the right of figure 1, which shows a rules-layer that can access the underlying ontology. There has been recent attention on combining rules and ontologies in the field of the Semantic Web, due to the complimentary characters of these components [23]. While there is no clear standard yet on how to combine these components, there is a consensus in literature that logic programs can be used to express rules over underlying ontologies [6], [15].

As a result, logic programs can be applied to formalize business rules which can then directly access the vocabulary used in the underlying ontology. Due to the fact that the mentioned ontology is connected to the business process itself, the business rules expressed in the logic program can also access the actual business process itself. Thus, the approach proposed in this report allows to apply the amenities of logic program reasoning in the context of compliance management. By layering rules ontop of already existing business ontologies, detecting compliance is not limited to analyzing the artifact of the business process model itself, but rather the more sophisticated description present in the business ontology can be exploited for verifying compliance in business processes.

The contributions of this report can be summarized as follows. At first, we show that our framework is a novel approach on combining business rules and business ontologies by motivating the 4-layered framework in the context of related work in section 2. Furthermore, after providing a brief recap on how to create semantic annotations for business processes, we show how the business ontology can be integrated into a logic program in order to ensure that company processes adhere to business rules and regulations in section 3. We illustrate our approach and also provide a demonstration in section 4. Finally, our discussion is concluded in section 5.

2. Related Work and Motivation

There have been numerous proposals for automatedly detecting compliance of processes with regulations or business rules [10]. One major school of thought are graph-based approaches [7], [10]. Here, graph-patterns which represent business rule violations are defined o graphically modelled, e.g in approaches like BPMN-Q, eCRG or DMQL[7]. Consequently, a pattern search can be applied to the graph-structure representing the business process in order to find respective violations. It is important to realize that mentioned graph-based approaches focus on analyzing the artifact of the business process model itself.

As mentioned, process models can be linked to business ontologies. In result, next to the artifact of the business process itself, the company may have a second artifact of a business ontology, which can be used as a basis for compliance management. This has been proposed by works such as [7-8][20][24-25], due to the sophisticated semantic structure offered by ontologies. Our approach is therefore an extension to works such as [25], which tries to capture the possibilities that are potentially present.

A main concept of our approach relates to defining business rules as logic expressions. Many others have already proposed using logic expressions instead of graph-based approaches. For example, there is a broad consensus in academia, that temporal logic is suitable to check process models against business rules [10]. While we do not disagree with this claim, we would like to point out that there are limitations of using temporal logic for this aim that have been identified by works such as [10]. For example, investigating process elements with complex annotations or dependencies can be seen as a very complex task [7], [10]. We therefore argue, that using temporal logic for compliance checking should not be taken as self-evident. Authors like Gruhn and Governatori also agree that such formalisms rooted in temporal logic may suffer from some limitations in compliance checking and have therefore proposed other families of logic for this use-case [13], [17].

Said authors have shown that logic programs can be used to validate syntax or compliance in business processes. Following [22], using logic programs to verify business rules is applied as follows: At first, a *new* logic program is derived from a process model. To clarify, the logic program is independent of the original process model. All model elements and their relations are *redundantly* translated into a logic representation. Only then can the logic program reason about compliance. In our approach, we propose to layer a logic program ontop of the already existing process ontology. In this way, process elements do not have to be redundantly translated into a logic representation of an independent logic program, but rather business rules in the form of logic expressions can directly access the underlying ontology and reason about the compliance of the ontology, respectively the business process itself. In case of changes to the business process or the business ontology, our approach is therefore still able to verify compliance without the effort of having to repeat a redundant translation of changed elements.

Works such as [6], [15] have investigated integrating logic programs and ontologies. Said works are however for the Semantic Web and are not specifically aimed at business process management. [8] have also proposed an ontology-driven approach to detect compliance with rules. Here however, they do not investigate using logic programs in order to express regulations and rules.

To the best of our knowledge, our approach is the first to study the intersection between *(a) using rules to detect compliance based on the artifacts of both a process model and a business ontology,* and *(b) using logic programs to implement these rules*. The framework therefore allows to exploit logic program reasoning relative to a business ontology, without having to translate elements of the business ontology into a redundant logical representation in a respective logic program. Table 1 positions our approach in the above mentioned intersection.

3. Layering Rules Ontop of Business Process Ontologies

This section introduces modeling a rules-layer ontop of a business ontology.

3.1. Ontology-Based Process Modeling

Following [25], the scientific results in regard to extending information with semantic annotations can successfully be applied to BPM. Said authors employ a three-layered approach, combining the actual *business process model* with a *business ontology* through an intermediate *instantiation*, as can be seen in figure 1.

The ontology classes define terminological knowledge relevant to the company. For example, *entities* such as organizational units, tasks, events, services or rules and their individual *relations* can be modeled. It is important to realize, that companies do not necessarily have to model such an ontology themselves. Works such as [20] have already proposed reference ontologies that can be re-used and adapted to individual company requirements. In this work, we assume that the ontology is stored in the web-ontology language format (OWL)[1], which is the W3C standard for knowledge representations. Hence, next to the already introduced *terminological* knowledge, *axiomatical* instances of ontology concepts can be created. This is shown in figure 2, which provides an exemplary business ontology. One can observe that this ontology is subdivided into classes (e.g. Unit) and instances (e.g. Production and Sales), whose relationships are defined by this OWL graph-structure.

As a next step, instances of the business ontology are used to define the semantics of process model elements. We want to emphasize that this approach can be applied to arbitrary process models [25].

A process model is defined by element types and specific elements of such types [4]. The ontology can therefore be used to define the semantics of element types, also referred to as *language constructs,* and elements, also referred to as *model elements*. Language constructs, such as events, functions or connectors, should be modeled in the

[1] https://www.w3.org/TR/owl2-syntax/

reference ontology as can be seen in figure 2. As mentioned, the language constructs represented in OWL can be furthermore extended to fit individual company needs. For instance, EPC events could be specialized to create unique and distinguishable event types relevant to the company. Next, model elements can be represented in the ontology through an instantiation of the previously defined language construct classes. Figure 3 illustrates mapping an EPC diagram to a business ontology excerpt. As can be seen, the ontology comprises all relevant EPC language constructs, represented through the respective ontology classes. Every model element resided in the business process model is assigned to an ontology instance. In this way, ontology instances represent the individual model elements from the viewpoint of the business ontology [25]. As a main result, this approach has generated a conceptual viewpoint for the EPC diagram by making the process model accessible in the ontology. This viewpoint could already be exploited to pose conceptual queries regarding the business process. Assuming an OWL ontology, the W3C query language SPARQL[2] can be employed to answer such queries [18].

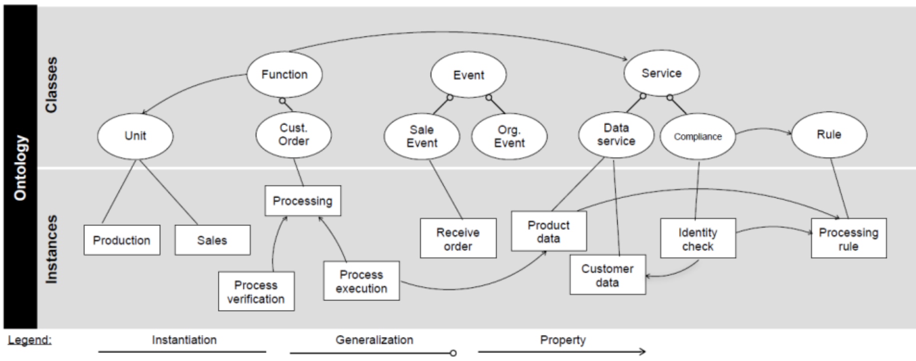

Figure 2. Exemplary business ontology

The model elements of the EPC diagram can now be assigned to further ontology concepts in order to create richer semantic annotations and therefore foster the semantic understanding of the business process, as individual model element semantics and their relations can be explicitly defined. Following [25], a major advantage of this approach is that copious constructs offered by the OWL formalism can be exploited to define formal semantics of great granularity. For example, the possibility to model generalizations or properties such as transitivity, symmetry or inversion between OWL instances allows to use sophisticated reasoning capabilities to analyze process models.

Business ontologies can be modeled or extended according to company needs. Consequently, business rules or regulations and their relation to the business process can be incorporated in the ontology. In result, the business ontology can be seen as an advanced artifact to use in the scope of compliance management [7], [25]. This leads us to our proposal, namely to extend the framework by [25] by modeling a rules-layer ontop of the ontology-layer. This rules-layer should offer the possibility to express

[2] https://www.w3.org/TR/rdf-sparql-query/

business rules and regulations relative to the business ontology and verify their compliance accordingly. To this aim, we propose to utilize a logic program formalism in order to implement said rules-layer, which we introduce subsequently.

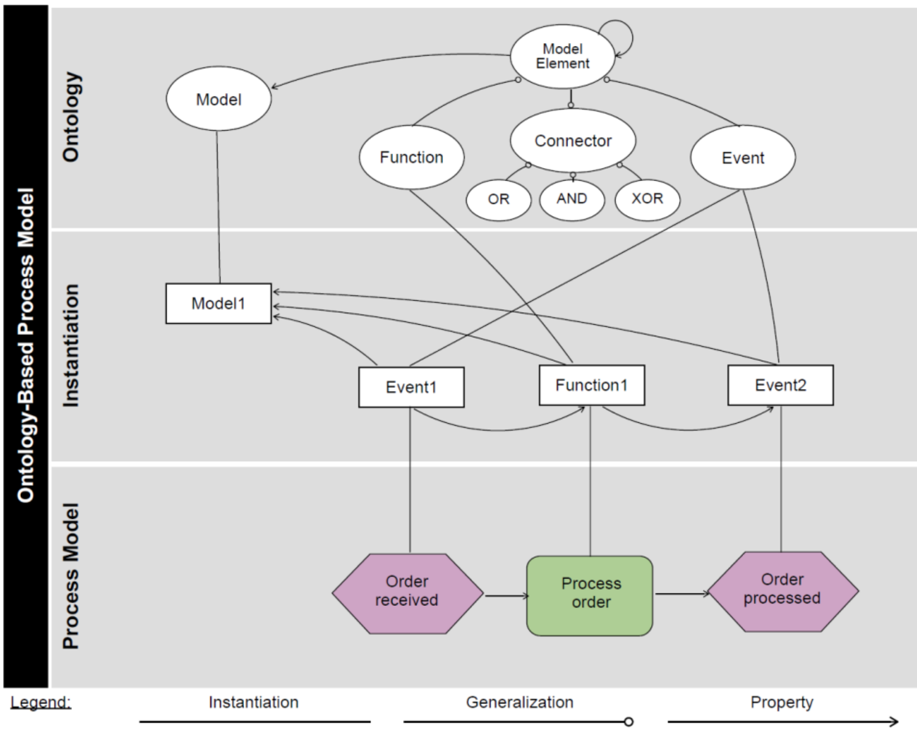

Figure 3. Mapping an EPC diagram to an ontology

3.2. DL-Programs

The Semantic Web architecture allows to model rules ontop of knowledge representations, i.e. ontologies [18]. In this way, the complimentary characters of these two layers can be used to promote automated processing mechanisms. As an important design choice, the rules-layer and the ontology-layer should be interoperable but abstracted from each other, as dictated by the Semantic Web architecture [18]. While there is no clear standard yet on which technologies to use for combining rules and ontologies, there have been several proposals [6].

What is important in the context of this work, is that research suggests that the mentioned rules-layer can be implemented by logic programs [15]. To clarify, logic programs can be used to express rules that mention the vocabulary of an external ontology, i.e. a description logic knowledge base. Thus, the sophisticated reasoning possibilities offered by logic programming can be used to infer information regarding ontologies - more specifically business ontologies. Again, as there are many families of logic, many proposals have been made as to which form of logic programs to use in order to express rules for underlying ontologies. For a detailed survey, please see [15]. As a design choice, we have chosen an approach by [6] entitled *DL-programs*. DL-programs are a formalism able to extend logic programs with description logic expressions. More specifically, they allow to combine normal programs and description logic ontologies, respectively answer-set semantics with first-order semantics. Therefore, they meet our requirement of being able to express business rules and regulations relative to a business ontology.

Recap of Logic Programming. To recall logic programs in general, a logic program is defined as a tuple $\boldsymbol{t} = (\mathbf{P},\mathbf{C})$, where **P** is a set of predicate symbols and **C** is a set of constants [23]. The rudiments of this signature can be used to express *rules*. Such a rule *r* consists of a *premise* and a *conclusion* of the general form

$$\mathtt{head} \longleftarrow \mathtt{rule} \tag{1}$$

meaning that the head, or conclusion, of *r* is true, if the body of the rule is satisfied [23]. If the body of *r* is empty, *r* is referred to as a simple fact. The head and body of the rule can be used to compose formulas of the form

$$h \longleftarrow a_1, \ldots, a_n, \mathit{not}\ b_1, \ldots, b_m \tag{2}$$

where each h, a_i and b_i are so-called *atoms*. Such an atom is defined as $p(t_1, \ldots, t_m)$, where p is a predicate symbol of **P** and every t_i is either a constant from **C** or a simple variable, the latter denoted by a capitalized character. Note that every a_i is a so-called positive atom, and every b_i is a so-called negative atom, indicated by the *not*.

As an example, the following logic program in figure 4 could be used by a financial service to define rules regarding account values.

```
(i)     account(a, 100)
(ii)    account(b, -100)
(iii)   positveBalance(A) ⟵  account(A,B), B > 0
(iv)    error(A) ⟵  account(A), not positiveBalance(A)
```

Figure 4. Exemplary logic program

The first two lines of this logic program are simple facts, stating two accounts entitled *a* and *b* and their respective account balance. The rule in (iii) is used to verify if an account has a positive balance. Here, the capital *A* and *B* represent variables, respectively the account name and account balance. The body of this rule, i.e. the premise, is satisfied if *B* is positive, meaning that only in this case *positiveBalance(A)* could be concluded. A customer account may be required to be of positive balance due to business requirements. Hence, the rule in (iv) models a violation of this requirement. The head of this rule - *error* - is true as soon as there exists and account which is not of *positiveBalance*. As the account named b represents such a case, the depicted logic program can be used to entail that an error is present.

Answer-Set Semantics. The use of variables allows to entail that an error is present for account *b*. This is an example of so-called *answer-set* semantics of logic programs [23]. In early research on logic programs, variables were not included, meaning that rules consisted of simple forms similar to a ⟵b. Such logic programs can be used to entail so-called *well-founded* semantics [11], which can be seen as simple *proofs*. Other than such simple proofs, a paradigm shift to answer-set semantics, which can be traced back to the works of Gelfond and Lifschitz [11], has allowed to define *answer-sets*. These answer-sets can be understood as a model satisfying a logic program. Consequently, an answer-set $M = \{ \ account(b,-100) \ \}$ can be derived from the exemplary logic program. As a result, the financial service could benefit from such an answer-set to identify specific accounts violating the business rule regarding a positive account balance [11].

Introduction to DL-Programs. Continuing our exemplary logic program, computing an answer-set was limited to facts and rules *contained* in this logic program. In order to allow the logic program, i.e. the rules, to reason about information in external ontologies, they have to be extended in such a way that they can *access* said external knowledge bases.

DL-programs [6] represent such an extension of logic programs that allow to access vocabulary of underlying ontologies. A DL-program consists of a normal program *P* and an external knowledge base, i.e. ontology, *L* [6]. While *P* is a finite set of rules based on predicates and constants as introduced, the ontology comprises concepts, roles and individuals. In result, such a DL-program can use a business ontology as a knowledge base *L* and layer a logic program *P* ontop of it.

A question that may arise is how exactly *P* can be extended to access concepts, roles and individuals in *L*. To this aim, [6] have proposed to extend the rules of *P* with so-called *DL-atoms*. While it is not our intent to elaborate on the syntax of such DL-atoms in great detail, it is sufficient to realize that DL-atoms are of the general form:

$$DL[Q](t) \tag{3}$$

Inspecting this complex more closely, the sequence *DL* signalizes the beginning of a DL-query. One can observe that such a DL-query consists of *Q*, which may refer to a *concept* or *role* of the knowledge base *L*. The *(t)* is a simple logic program *term* as introduced earlier, i.e. a constant or a variable. By extending the logic program *P* with the DL-query *DL[Q]*, it can refer to a vocabulary *Q* of an external ontology. As an example, figure 5 shows a DL-program based on the following logic program *P* and knowledge base *L*:

```
L:
(i)         event ⊑ modelElement
(ii)        event(e1)
(iii)       event(e2)

P:
(iv)        evt(X)  ⟵ DL[event](X)
```

Figure 5. Exemplary DL-program

In this example, a business ontology *L* contains terminological knowledge about the language construct *event*, as well as axiomatical *event* instances. The logic program rule in (iv) shows how a DL-atom is used to extend a logic program rule. It is important to realize, that *event* in square brackets of the DL-atoms in (iv) refers to the *event* concept of the business ontology L. I.e. knowledge contained in the ontology L does not have to be *redundantly* expressed as a fact in P, but rather the DL-program allows a logic program P to access an ontology L in an *ad-hoc* manner. To conclude, regarding the logic program P, an answer-set $M = \{ evt(e1), evt(e2) \}$ could be directly entailed by the means of using (iv) to match the variable X in the head of the rule with the variable X in the DL-atom. This answer-set could then be processed in additional rules of P.

As can be seen in the example, DL-programs allow logic programs to access the information stored in an external business ontology. This facilitates powerful and expressive ways to process knowledge bases by the means of rule bases formalized through logic programs [6]. In our opinion, enabling a rules-layer to access a business ontology in an ad-hoc manner is a stronghold of our approach which we discuss consequently.

4. Compliance Checking Approach

This section demonstrates how DL-programs can be used to express business rules in order to detect compliance based on both the artifacts of the business process model as well as a business ontology.

4.1. Framework Architecture

Creating an Ontology-Based Process Model. Figure 6 provides an overview of the framework architecture. The proposed approach extends the three-layered model by [25]. On the left, the process model is connected to a business ontology by instantiation. We denote this as an *ontology-based process model*.

Next, the rules-layer consists of a logic program expressing business rules. The specific business rules may originate from business requirements or external regulatory policies. The rules-layer can directly access the ontology using the DL-program formalism. The rules of the logic program can therefore infer information about the entire ontology-based process model, as the ontology is connected to the process model. The proposed approach is therefore capable to detect whether a process model complies with business rules. This is depicted by the compliance detection component. Here, the DL-program is applied to infer answer-sets of compliance violations. To clarify, these answer-sets consist of *ontology-instances* violating rules of the logic program. These answer-sets therefore also reflect specific *process model elements* violating these logic program rules, respectively business rules. These sets of process model elements can consequently be browsed by the modeler and remodeled according to rules and regulations.

A barrier for the implementation of our approach is the necessity for the artifact of an ontology-based process model. Companies must annotate their processes to an ontology. While a company could perform this task manually, there are existing approa-ches showing that this task can be supported automatically [5]. In [5], the authors show that identifiers of processes and ontologies can be terminologically standardized and thus matched accordingly. This lowers the effort that has to be invested by companies. Undoubtedly, the initial creation of an ontology-based process model has to be considered by companies. However, in our opinion, modeling company processes geared towards a business ontology helps to create a shared understanding across the entire organization. On the long-term, this can be seen as beneficial for the scalability and maintenance of business processes [8].

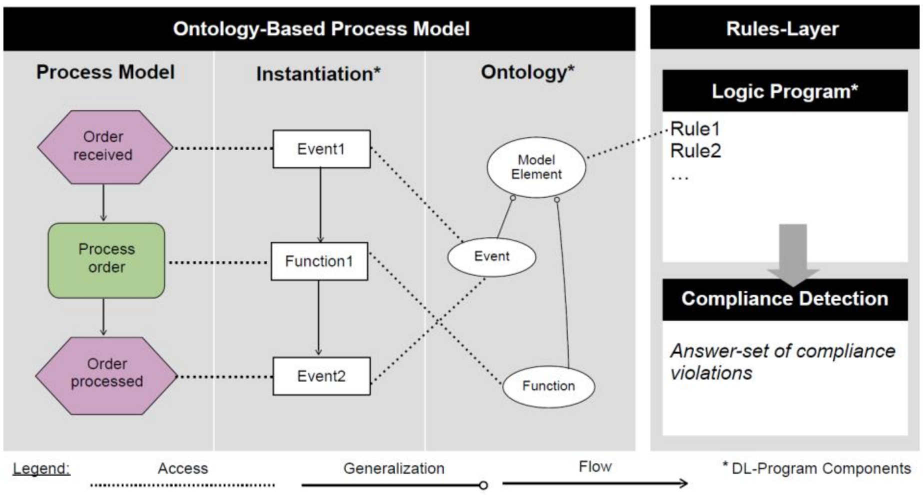

Figure 6. Framework architecture

Expressivenes. While temporal logic can be used to verify compliance, it still suffers from limitations [13], [17]. The expressiveness of our approach therefore aims to conquer some of these limitations, while not sacrificing any amenities. This is achieved through the instantiation. As shown in figure 6, every process model element is represented by an ontology instance. All flows between process model elements are also captured in the instantiation. This means, the execution semantics of the process is encoded in the ontology and can be processed accordingly. In result, sequences, loops or gateways can also be processed by our approach. Van der Aalst et al. [27] have categorized different types of compliance rules. It is beyond the scope of this report to discuss this categorization, but it is used here to specify the expressiveness of our approach in relation to said categorization. So far, we have successfully implemented rules of the categories *existence, precedence, chain precedence, response, between, exclusive, mutual exclusive, inclusive, prerequisite* and *corequisite*. A clear limitation are cardinality restraints or parallel processes. For further details on the DL-formalism, please see [15], as this paper introduces the syntax of DL-queries that are the foundation of compliance checking in our approach.

4.2. Demonstration

To demonstrate our approach, the following exemplary scenario was implemented. We envision a scenario where a company wishes to apply our approach to ensure a business process complies to a business rule. For simplicity, rules and business process will be kept minimal. We assume that the company conducts the task of *paying a bill* within their process. It is furthermore assumed, that a corresponding business rule demands that during this process the bill is *checked* before it is paid. Assuming that the exemplary company aims to create ontology-based process models, figure 7 depicts artifacts which can be utilized in the scope of compliance management for our scenario. Given that a modeler has created the process model in figure 7 (i), our approach allows to detect whether this model complies with the mentioned business rule as follows.

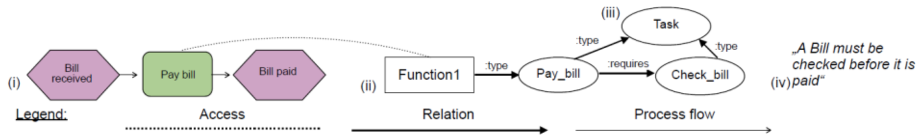

Figure 7. Artifacts available for the compliance management scenario

In (iii), the ontology is depicted as an OWL graph-structure. The company has modeled an ontology class *Task*, which is specialized into *Check_bill* and *Pay_bill*. It is important to realize that these are not instantiations, but simply a specification of the two concepts, which are *tasks*. An instantiation is shown in (ii). The ontology in (iii) was extended by a business rule, indicating that the concept of *Pay_bill* requires *Check_bill*. In this context, the edge labelled *requires* encodes the business rule in (iv). Intuitively, the process model in (i) does not comply to the company policy in (iv), as the bill is not checked before it is paid. The company can implement a DL-program based on a logic program encoding (iv) and the business ontology in (ii)-(iii). Figure 8 depicts this DL-program. For simplicity, namespaces for standard W3C vocabulary such as *OWL:class* are omitted. In the ontology, the class of a *Task* is defined. This is performed analogously for *Check_bill* and *Pay_bill*. Figure 8 also shows how a process model element can be serialized as XML exemplarily. In our scenario, as the modeler has only modeled the task *Pay_bill*, we may only create this single instantiation. The *required* relation, meaning that *Pay_bill* requires *Check_bill*, is also serialized. A logic program can then be layered ontop of this serialization, as shown in figure 8. In the first line of this logic program, an ad-hoc access to instances of the ontology is defined. The *task* in the head of the rule is a logic program predicate, whereas the *Task* in the body of the rule directly refers to the ontology concept by the means of the DL-atom. Line two of the logic program shows a specification of the aforementioned business rule. Here, we can *conclude* an error, if there exists an instance *X* requiring an instance *Y*, and there is no such instance *Y*. The DL-atom in the body of the rule also directly mentions the *required* vocabulary of the ontology. Thus, this relation already present in the ontology can be accessed directly as opposed to being redundantly represented in the logic program. In result, the logic program can correctly infer that an error is present, through the answer-set *M = { error("Pay_bill", "Check_bill") }*. Such inferences can not only be drawn theoretically, but also by many logic program reasoners such as RACER or Hermit [7]. [6] provide a web-interface[3] allowing to enter DL-programs. The serialization as shown in figure 8 can be entered in this web-interface in order to

[3] https://www.mat.unical.it/ianni/swlp/

conclude that mentioned error is present. In our opinion, this shows that our approach can successfully be applied to implement our scenario, namely to detect wether a process model complies to a business rule. Given the artifact of an ontology-based process model and a logic program encoding rules and regulations, the technology to conduct compliance management on the basis of our approach is ready to use.

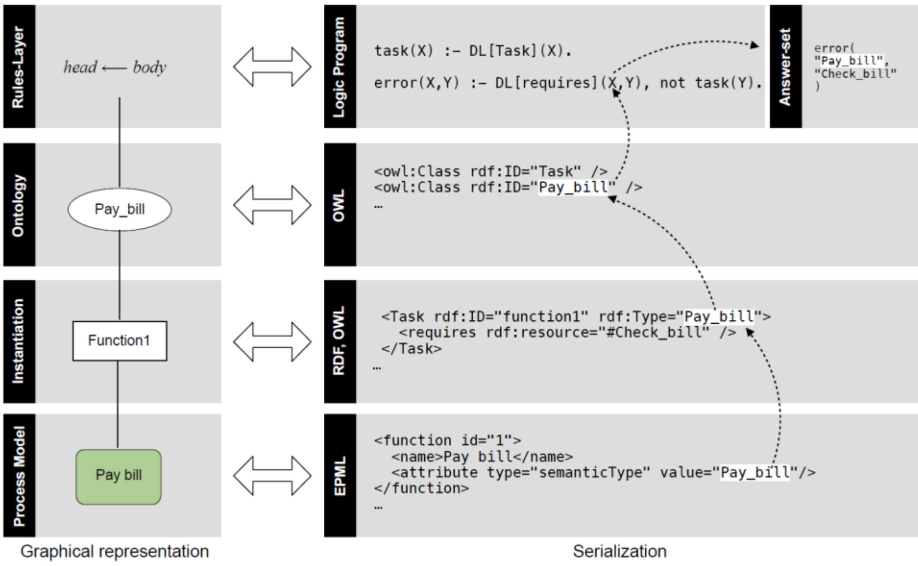

Figure 8. DL-program to entail process model elements that violate business rules

Our example covered a rule that checks existence. This can be extended to model different types of compliance rules, as mentioned in the subsection on expressiveness. For example, one could verify that the *Pay_bill* function is executed between two events, or that a function A is limited in precedence over a function B.

5. Conclusion and Outlook

The contribution of this paper is an approach capable of verifying if a business process complies with business rules, based on analyzing the artifact of a so-called ontology-based process model. The proposed approach allows to (a) specify business rules as logic program expressions relative to an external business ontology, (b) utilize logic program reasoning to find process model elements violating these rules and (c) access information stored in the business ontology directly, i.e. without a redundant transformation of ontology-instances into a logic program representation.

An exemplary implementation of our approach shows that our approach can be successfully applied to find sets of process model elements violating business rules. Future work is to be directed to apply our approach to large-scale process models and business rules. However, the success of using DL-programs for Semantic Web datasets [6] leads us in our belief, that applying our approach to business related data-sets should pose no significant computational problems per se.

A clear limitation of our approach is, that it is dependent of (1) a business ontology connected to a process model and (2) a logic program rule base. Following [7], implementing these artifacts is not yet significantly performed in practice. Literature however strongly suggests the potential of using these artifacts for process modeling and compliance management [7], [13], [20], [22], [24-25]. We therefore see great research potential in assisting companies to create and manage these artifacts. Works such as [5] show that these tasks can be supported automatedly.

As a conclusion, incorporating semantics in the scope of compliance management can contribute towards finding violations in business processes and therefore aid the improvement of company process. Here, using logic program techniques to *reason* about business *ontologies* assists the automated detection of compliance violations. Our approach, allowing an ad-hoc access for rules relative to a process model, lowers the effort that has to be directed towards this aim by companies.

Evaluation of a Pattern-Based Approach for Business Process Improvement

Thomas Falk

University of Regensburg, Department of Management Information Systems, Regensburg, Germany
thomas.falk@wiwi.uni-regensburg.de

Abstract. Although many approaches for business process improvement (BPI) are available and have proven their usefulness, it is often stated that they do not provide sufficient methodological support for all phases of a BPI initiative. To close this gap, a pattern-based approach has been suggested as a suitable means to directly support the "act of improvement" and to provide systematic guidance. However, what is missing is an evaluation that provides well-founded insights into the qualities and benefits of this approach. Therefore, this paper presents the results of a laboratory experiment which was conducted to assess the impact of the BPI-Pattern Approach on a process improvement project. The findings, which are based on a number of hypothesis tests, confirm a positive influence on both effectiveness and efficiency when the BPI-Pattern Approach is used.

Keywords: Business Process Improvement, BPI Pattern, Evaluation, Laboratory Experiment

1 Introduction

Business process improvement (BPI) together with its related methods and techniques remains an important topic in research as well as for practitioners. Among the major drivers prompting companies and other organizations to change their processes are cost savings and increased productivity as well as the need to improve products, customer satisfaction or organizational responsiveness to stay competitive [1].

As a result, there is a plethora of different approaches supporting the improvement or redesign of business processes, e.g., *BPI* according to Harrington [2], *Business Process Reengineering (BPR)* [3], or *Six Sigma* [4], to name but a few well-known examples. Existing approaches provide extensive methodological support for e.g., mapping processes, identifying problems and their root causes, etc. However, when it comes to the actual improvement, i.e., the transformation of a process from its "as-is" to a desired "to-be" state, they often rely on creativity, personal skills and experience for the development of an enhanced process design [5], [6]. This pivotal phase of BPI, the so-called "act of improvement", lacks systematic methodological support [7] as tangible instructions on how to achieve substantial improvements are missing [8]. To address this problem, a BPI-Pattern Approach was suggested that systematically

Falk, T. (2017): Evaluation of a Pattern-Based Approach for Business Process Improvement,
in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung
Wirtschaftsinformatik (WI 2017), St. Gallen, S. 241-255

supports the “act of improvement” in BPI initiatives [9], [10]. Its core components are a catalog of BPI-Patterns, which convey proven knowledge and instructions of how to achieve process improvements, together with a selection process to guide the identification and selection of appropriate patterns for a given situation. This approach was developed following the design science paradigm [11], [12] and its applicability was already demonstrated by a case study [10]. However, what is missing is an in-depth evaluation of the usefulness and advantageousness of the new pattern-based approach in comparison to conventional practices. Therefore, the paper at hand describes a laboratory experiment, which was conducted to quantitatively evaluate the effectiveness as well as the efficiency of the BPI-Pattern Approach. The results gained from the experiment allow for a better assessment of the potential benefits of using BPI-Patterns for process improvement in practical settings.

The remainder of this paper is organized as follows. Section 2 covers conceptual basics of BPI, the BPI-Pattern Approach, and the evaluation phase in design science research. Section 3 introduces the research model including our hypotheses and describes the design, materials and implementation of the experiment. The results are presented in section 4 and their implications discussed in section 5. Section 6 provides a short summary of the findings and an outlook on further research.

2 Conceptual Basics

2.1 Business Process Improvement (BPI)

The improvement of business processes has become a core task in many organizations and is an integral part of the business process lifecycle [13]. Its overall aim is to make processes more effective, efficient and flexible [2], e.g., by reducing costs or cycle times, and thus to yield competitive advantage. Process improvement is considered as essential for creating sustainable value for customers or innovating products and services [14], and organizations link the improvement of their processes to their business strategies [15]. Existing approaches for process improvement are manifold (see e.g. [2-4], [16]) and have proved their usefulness.

However, it appears that none of them adequately supports the user through all the stages in an improvement project, especially when it comes to the “act of improvement” [7]. This very phase is at the heart of any BPI project where the transformation of a process from its “as-is” state to a desired “to-be” state takes place. Actual instructions on how to improve a process in respect of given objectives (e.g. reduce costs, shorten cycle time, etc.) are very scarce and generic [8], and thus many improvement approaches rely on human creativity and personal experience [17]. Even though one “brilliant idea” can bring about significant improvement, its occurrence is always uncertain and often depends on the know-how of individual key players. The development of substantial improvements remains a major challenge in BPI projects and lacks sufficient methodological guidance [7], [18]. To better support BPI performers, structured methods and techniques are required [19] as well as guidelines describing the necessary changes that have to take place [20]. The use of a pattern-based approach for BPI is one possible solution that meets those requirements.

2.2 BPI-Pattern Approach

The concept of patterns is widely used in IS (e.g., design patterns in software development [21], workflow patterns [22], etc.). In the field of BPI there are several works that address the topic of how patterns can be utilized for the improvement of business processes. One group focuses on the collection and description of generic improvement measures (cf. [23-25]). A second group deals with the question of how to run or organize improvement projects (cf. [26], [27]). Because of their inherent characteristics, the use of patterns is also a promising approach for supporting the "act of improvement". Patterns are suited to precisely describe a working solution for a problem in a specific context [21], which is based on proven knowledge [28], but, at the same time, they are generic enough to be reused in many similar cases [29]. Thus, so-called BPI-Patterns guide through the application of an improvement action and help to overcome the shortcomings of existing BPI approaches as mentioned above.

A BPI-Pattern Approach supporting the "act of improvement" is suggested by Falk et al. [9], [10]. It consists of two main components that are both integrated in a software tool: a *pattern catalog* as a repository of improvement propositions and a step-by-step *selection process* for identifying and selecting suitable patterns. The patterns themselves are derived from BPI literature, case studies or experience from real-life projects [30]. In addition, their applicability and effects have been substantiated by means of a simulation [31]. A standardized template comprising the attributes as defined by the underlying data model [9] ensures a consistent description. Its core attributes reflect the definition of a BPI-Pattern as a reusable *solution* for a certain *problem* in a business process within a certain *context* [9] and comprise instructions on how to change the process' elements (e.g., activities, resources, control-flow, etc.) to transform it from its non-satisfactory "as-is" to a desired "to-be" state. The application of a BPI-Pattern has an *effect* (positive, neutral, negative) on the performance dimensions (cost, time, quality, flexibility). An example of a BPI-Pattern that has a positive effect on cycle time is "Parallelize Activities" where formerly sequentially ordered activities are performed simultaneously. The software tool not only allows for the management of the pattern catalog but also guides the user through the selection process. There are two alternative starting points depending on whether the BPI project is targeted at predefined objectives that should be achieved or driven by problems that are detected in the processes. By matching the effects of the patterns with the goals of the improvement project, only those patterns that show the desired outcome are regarded further. Based on the identification of problems together with a root cause analysis, patterns solving or at least mitigating those particular problems are filtered. Either way, both possibilities require the execution of both steps, i.e. if patterns are first to be selected according to their effects, the next step is to look at the problems and vice versa. Afterwards, the contexts of the patterns are checked against the environmental conditions in the case at hand to make sure that they are applicable in the given situation. Finally, the remaining patterns that are candidates for implementation are prioritized, and a decision has to be made by the user which pattern(s) will be applied in the end. That way, the BPI-Pattern Approach provides a systematic, tool-assisted means to support the "act of improvement".

2.3 Evaluation in Design Science Research

Design science research (DSR) is characterized by the creation of artefacts for a specific purpose that solve practice-oriented problems [11], [32]. The evaluation of those artefacts is an integral part of the DSR methodology [12] and considered vitally important to prove the usefulness of the developed artefacts [33]. To perform an evaluation, a number of strategies making use of various evaluation methods (e.g. interviews, simulation, experiments) have been suggested [34-36]. Experiments as a method are particularly suited for a systematic assessment of an artefact's qualities [37]. For the evaluation of the BPI-Pattern Approach, a laboratory experiment was preferred to other evaluation methods because of the following reasons: In a laboratory environment, confounding variables can be better controlled or be eliminated [38]. In contrast to case studies, e.g. the participants are more homogenous and can be assigned to the groups randomly, the "as-is" process to be enhanced as well as the provided information are exactly the same, etc. In addition, a laboratory experiment shows a relatively high internal validity, which allows to determine if changes of the dependent variables (e.g. improvement effectiveness) result from changes of the independent variables (e.g. use of pattern-based approach) or not [39].

3 Evaluation of the BPI-Pattern Approach by an Experiment

For the evaluation of the BPI-Pattern Approach (see section 2.2) and to answer the question regarding its utility a laboratory experiment is conducted (cf. [37-39]). The focus of the study is on both the effectiveness and efficiency when seeking to improve existing "as-is" business processes. For that purpose, the experiment builds on a comparison of two groups: one group uses the BPI-Pattern Approach to identify potentials for improvement and generate process changes in a guided and structured way whereas the second group (control group) works without a systematic approach but is free in using creativity and innovative ideas to enhance the process (one factor with two treatments). As a general principle a completely randomized design was chosen where the subjects are randomly assigned to the groups. The setup of the laboratory experiment is explained in detail in the following section.

3.1 Experimental Design

Our research model (see Figure 1) is based on the underlying assumption that the use of a systematic improvement approach, such as BPI-Patterns, leads to better results (e.g., cost or cycle time reductions) [20], [25], and reduces the overall effort of identifying such improvement possibilities and developing the new "to-be" process design (i.e. time savings in process improvement projects) [23]. The quality of the results increases when tried and tested patterns are used, a concept which is already successfully used in other fields (e.g. software development) [21]. It seems reasonable that this is equally valid in the context of BPI and experiences so far are promising [23], [24]. Based on these assumptions, the following pairs of hypotheses (see Table 1) can be stated which are to be tested by means of the laboratory experiment.

Table 1. Hypotheses on the effects of the BPI-Pattern Approach

Improvement Effectiveness:	
H_0a:	The use of the BPI-Pattern Approach does not generate better improvement solutions than relying on creativity skills.
H_1a:	The use of the BPI-Pattern Approach does generate better improvement solutions than relying on creativity skills.
Expenditure of time:	
H_0b:	The use of the BPI-Pattern Approach does not reduce the time needed to identify improvement potential and to develop an enhanced "to-be" process design.
H_1b:	The use of the BPI-Pattern Approach does reduce the time needed to identify improvement potential and to develop an enhanced "to-be" process design.
Improvement Efficiency:	
H_0c:	The use of the BPI-Pattern Approach does not increase the time efficiency when developing an improved process design.
H_1c:	The use of the BPI-Pattern Approach does increase the time efficiency when developing an improved process design.

All elements of the research model have to be operationalized for the purpose of the actual experiment at hand. It is based on a single binary, independent variable, which is whether a participant is supported by the BPI-Pattern Approach or not. The dependent variables are 1) *Improvement Effectiveness*, 2) *Expenditure of Time*, and 3) *Improvement Efficiency*. *Improvement Effectiveness* is defined by the extent to that the "as-is" process has been improved; i.e. the process performance of the newly developed "to-be" process exceeds the level of the "as-is" process. For complexity reasons this variable has been narrowed down to the dimension time and considers reductions in the average total processing time per process run (in percent). The instrument used for measuring are the adapted "to-be" process models, handed in by the participants. Total processing time is calculated by adding up the processing times of all process activities applying the probability of execution of the respective process path for weighting. *Expenditure of Time* quantifies how much time (in minutes) is needed to complete the "act of improvement", i.e. the very phase where improvement potential is identified and an enhanced process design is developed. The participants are guided by a road map and have to fill in the precise time when they start or finish a specific task. Finally, the variable *Improvement Efficiency* expresses how much improvement could be achieved per time unit and is calculated as achieved process improvements relative to the time needed for their development.

In addition, the research model covers the following factors which have a possible influence on the outcome: *Methodological Knowledge*, *Domain Knowledge*, *BPI Experience*, *Process Understanding*, and *Problem Detection*. To largely eliminate the influence of those factors, we deliberately chose students taking a particular course in process modelling as subjects. Hence, they have a similar background regarding their theoretical and practical skills in process modelling, analysis and improvement which helps to keep the confounding factors stable. Since the focus of the experiment is on evaluating the effect of the BPI-Pattern Approach alone, it is hereby prevented that the participants' diverging personal experience gain too much influence on the experiment results. The aforementioned factors are measured using a set of questions within a questionnaire. The variables *Methodological Knowledge*, *Domain Knowledge*, and *BPI Experience* are covered by a number of questions (e.g., „How often do you deal with BPI?"), each of them having a four-item, ordinal scale with point values assigned. To gather information on *Process Understanding*, open questions as well as true/false questions about different facts in the "as-is" process are used. To determine the degree of *Problem Detection*, the participants had to fill in a free text field to answer the question "What problems could you identify in the 'as-is' process that may cause long processing times?". The value for this variable is calculated as the portion of problems identified by the participant in relation to all problems that are contained in the process model. Because those variables addressed by the questionnaire have a potential impact on the results of the experiment, it is important that they are controlled or at least made explicit so that they can be taken into account when analyzing and interpreting the results [38], [39].

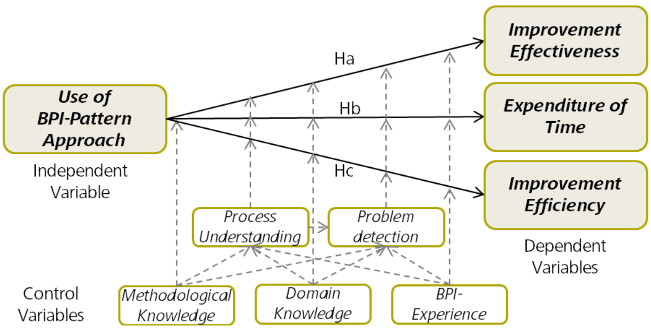

Figure 1. Research model

3.2 Implementation

The experiment was conducted in form of a fictional BPI project working on the matriculation process of a German university that has been slightly adapted for the purpose of the experiment. It has to fulfil certain criteria such as being representative of a practical and realistic BPI case, being sufficiently complex to be resistant to overly obvious or trivial enhancements, but at the same time remaining manageable within the scope of a laboratory experiment. The predefined goal of the project was to alter the given matriculation process such that its processing time is reduced as far as possible but the process still fulfils its core tasks as requested. The participants in the experiment, undergraduate students attending a bachelor's degree course in business process modelling, were randomly assigned to one of two groups: group A used the BPI-Pattern Approach to support the "act of improvement" whereas group B worked without BPI-Patterns. Because the same process model was used for all tests due to comparability reasons, the assignment to the groups was strictly alternative. Otherwise, learning effects while working on the process with one method would have corrupted the results when the second method was used afterwards. In total, 47 students participated in the experiment, 23 in group A and 24 in group B, thus leading to a balanced design with equal group size.

The participants in Group A, who worked with the BPI-Pattern Approach, used a prototypical tool that supports the management of the pattern catalog and especially the selection process of applicable BPI patterns based on certain criteria, such as desired effects, problems to be solved, or contextual requirements (cf. section 2.2). For the purpose and scope of the laboratory experiment the tool was populated with a catalog of 12 different BPI-Patterns. Beyond that, all participants were provided with the same materials: information about the project goals and the measurement of the performance indicator processing time, a textual description of the “as-is” process together with some fixed requirements that cannot be changed, and transcribed excerpts of interviews with the process owner and employees. Furthermore, a process model in eEPC notation was provided both as a paper-based and as a processable electronic version in ARIS Business Architect. The chosen process consisted of 41 process steps and contained several decision points, branches and loops (24 AND/XOR connectors) to express an adequate level of complexity. The process model, besides the graphical representation of the process flow, contained in particular information about the processing time (in minutes) of each activity and the probability values attached to decisions (XOR connectors) during the process operation. In addition, details about the organizational units involved, the requested or created documents, and the required data were provided. The participants’ task was to improve the provided “as-is” process model using the ARIS business architect, by either using the BPI-Pattern Approach or relying on brainstorming and individual creativity skills. There were four major improvement possibilities (e.g. eliminating redundant tasks, re-arranging existing activities in a more logical order, etc.) being supposed to be identified by the participants. Improvement suggestions beyond that, regardless of whether made by group A or B, are also considered as long as they meet the requirements specified in the materials of the experiment. The created “to-be” process models together with the filled in questionnaires have been submitted to the researchers at the end of the experiment.

Guidelines on how to proceed in course of the experiment were provided on a form sheet which instructs the participants and lead them through the experiment step by step. In addition, the procedure was explained by the researchers to the participants before the actual experiment started. Thus, it was ensured that every participant clearly understood the course of action and followed the same standardized steps while working on the fictional process improvement project.

All materials used in the experiment had been pretested before by three fellow researchers as well as a test group of eight students whose state of knowledge compared to that of the actual participants. Both tests provided valuable feedback which was used to refine the concerned materials and/or instruments and confirmed that the provided information, questions and tasks are clear and understandable.

4 Results

Subsequent to the experiment, the 47 submitted “to-be” process models and the questionnaires were carefully examined by two researchers independently. In so doing, each process model was double-checked by a fellow researcher; first without knowing the results from one another to avoid any bias, afterwards, the results were compared against each other to settle different interpretations. Four of them had to be excluded because they were either incomplete, showed data inconsistencies, or allowed for diverging interpretations. Hence, 43 applicable results, 21 in group A and 22 in group B, remain for further analysis and are described in the following.

Table 2. Results of the experiment: values of the dependent variables

Variable	Group	N	Mean	Std. Deviation	Std. Mean Error
Improvement Effectiveness	A: with BPI-Patterns	21	.214467	.1114372	.0243176
	B: without BPI-Patterns	22	.142259	.1136285	.0242257
Expenditure of Time	A: with BPI-Patterns	21	27.05	8.680	1.894
	B: without BPI-Patterns	22	28.27	6.734	1.436
Improvement Efficiency	A: with BPI-Patterns	21	.00810481	.000913604	.000913604
	B: without BPI-Patterns	22	.00512436	.000940070	.000940070

Since we are interested in the effect of the BPI-Pattern Approach in isolation, it is an important question if the observed effects on the dependent variables result from changes of the independent variable or are otherwise attributable to external, confounding factors. Therefore, as a first step, we analyzed the values of the control variables for both groups. Altogether, the two groups in the experiment were quite homogeneous; both, the mean values and the distributions were almost identical. This is also the reason why no statistically significant correlation between any of the control variables and the dependent variables could be verified. A regression analysis based on models that contain the control variables only, shows no significant results (F-test with p-values between .078 and .673) and reveals that such models cannot provide a reliable explanation for the changes observed in the values of the independent variables. Including “Use of BPI-Pattern Approach” as an independent variable increased the model quality as explained further below. The model assumptions, e.g. Gauss-Markov theorem, are sufficiently satisfied; the residues are independent and approximately normally distributed. Based on the aforementioned points, we can fairly assume that the changes we observed, e.g., for effectiveness or efficiency, are referable to the BPI-Pattern Approach. Both foster a high internal validity of the experiment’s results.

To evaluate the impact of the BPI-Pattern Approach on business improvement initiatives, the values for the variables of interest, namely Improvement Effectiveness, Expenditure of Time, and Improvement Efficiency, were measured. Hereafter, the mean values of both groups are compared to determine the effects of the BPI-Pattern Approach. Table 2 shows the values of the arithmetic mean, the standard deviation, and the standard error of the mean for groups A and B, respectively. To test our three hypotheses, which we posed at the beginning of section 3.1, a two-sample t-test was used. According to a Kolmogorov-Smirnov test, the variables are normally distributed for each group. The results of these hypothesis tests are shown in Table 3. In addition, a nonparametric Wilcoxon-Mann-Whitney test, which is more robust than the t-test, was conducted and shows the same results.

Table 3. Hypothesis test for Ha, Hb, and Hc

Variable	t-test for Equality of Means					95% Confidence Interval of Diff.	
	t	df	Sig.	Mean Diff.	Std. Err. Diff.	Lower	Upper
Improvement Effectiveness	2.103	41	.042	.0722076	.0343413	.0028540	.1415612
Expenditure of Time	-.518	41	.607	-1.225	2.363	-5.997	3.547
Improvement Efficiency	2.271	41	.028	.002980446	.001312497	.000329805	.005631087

Improvement Effectiveness is represented by the reductions in processing time comparing the new "to-be" process design with the original "as-is" process. The mean values for the degree of improvement are approx. 0.21 and 0.14 for group A and B, respectively, whereas the standard deviation shows similar values with group A lying slightly below group B. The results show a significant increase of the improvements that were achieved when the BPI-Pattern Approach was used during the experiment. The significance level is above 95% and the lower and upper bound of the 95% confidence interval show the same sign. This leads us to reject the null hypothesis H_0a and to support our assumption that the use of the BPI-Pattern Approach increases the improvement effectiveness, i.e. it generates better improvement results than by relying solely on e.g. creativity skills. The regression model including the independent variable as well as control and moderator variables is significant at p=.039, with "Use of BPI-Pattern Approach" having the strongest influence (p=.026 on "Improvement Effectiveness".

Regarding the second hypothesis, the use of the BPI-Pattern Approach would reduce the time that is needed to develop an enhanced "to-be" process design, the results are inconclusive. Based on the p-value of .607, the null hypothesis cannot be rejected. Moreover, the lower and upper bound of the confidence interval change signs. Therefore, no clear statement can be given about the influence of the BPI-Pattern Approach on the expenditure of time that is needed to improve a business process. However, the average time span needed for the "act of improvement" was slightly lower in group A than in group B (27.05 vs. 28.27 min) and the bigger part of the 95% confidence interval lies in a negative range. Moreover, the regression analysis regarding the variable "expenditure of time" resulted in a negative coefficient (β = -1.537) for "Use of BPI-Pattern Approach", indicating, even if not statistically significant, that possible time savings due to the use of patterns can still be assumed but are subject to further scrutiny.

Improvement Efficiency is addressed by the third hypothesis and expressed by the improvements achieved in relation to the time needed for their development. The observed results reveal a significant relationship between the use of the BPI-Pattern Approach and the variable improvement efficiency, which is on average 1.6 times higher for group A using the patterns ($\approx$ 0.008) as compared to group B not using the patterns ($\approx$ 0.005). Both the signs of the lower and the upper bound of the confidence interval are positive and, thus, confirm the direction we expected. Again based on a two-sample t-test, which reaches a significance level higher than 97%, we reject the null hypothesis H_0c and conclude that the use of the BPI-Pattern Approach increases the time efficiency when developing an improved process design, i.e. “more” improvement can be achieved per time unit. Moreover, the improvement efficiency is more reliable when patterns are used since the standard deviation in group A is lower than those in group B. The regression model for improvement efficiency is even highly significant (p=.004) whereby the two variables Use of BPI-Pattern Approach (p=.009) and Methodological Knowledge (p=.012) show a significant influence.

To get a deeper understanding of the results as well as to point out some implications related to the practical usefulness, they are discussed in more detail in the following section.

5 Discussion

The purpose of our laboratory experiment was to thoroughly evaluate a BPI-Pattern Approach in accordance with the DSR methodology and to determine its capabilities in supporting the “act of improvement” in a process improvement project. The overall results support the conclusion that the pattern-based approach possesses some advantages as all three dependent variables covered by the experiment tend towards the better values in case the BPI patterns are used (see Figure 2). The positive influence on two of them, namely improvement effectiveness and improvement efficiency, is statistically significant in addition. However, the effect size becomes more relevant at a practical level and can only be judged considering the particular characteristics of the business process which has to be improved. For example, a 1%-reduction in time or cost for a mass production process may result in a major impact whereas for other processes with just a few instances the changes have to be many times greater to be of practical relevance. In our case, the average difference in improvement effectiveness between the two groups equals approx. 61 man-days and, thus, has indeed a material impact. In addition, the business process that has to be improved may be an important factor which influences the performance of the BPI-Approach, e.g., based on its structure, complexity, or the type of problems that have to be solved.

The use of the BPI-Pattern Approach increases the improvement effectiveness, which was confirmed by the statistically significant results of the experiment. Taking a closer look at effectiveness, the use of patterns is no guarantee that significant improvements or any improvement at all can be achieved. In our experiment, we found cases where the processing time could not or barely be reduced in both groups even if the participants had applicable patterns at their disposition (see Figure 2(1)). In addition, the case showing the highest degree of improvement occurs in group B, without patterns. A possible explanation is that the BPI patterns primarily aim for incremental, evolutionary enhancements whereas the control group was free to develop more radical improvements, too. This effect could even strengthen when, unlike in the experimental setting used here, teams are assigned to develop the “to-be” process design. In this case, the group dynamics when creating improvement solutions will have some influence on creativity and thus on the improvement effectiveness.

However, what could be shown for the group which used the pattern-based approach is, that if a problem in the "as-is" design of the process was detected correctly, the probability that this problem was solved or at least partly addressed was much higher than in the control group working without patterns. This indicates that the BPI-Pattern Approach significantly increases the chances of finding and successfully implementing a solution, presumed such a one exists.

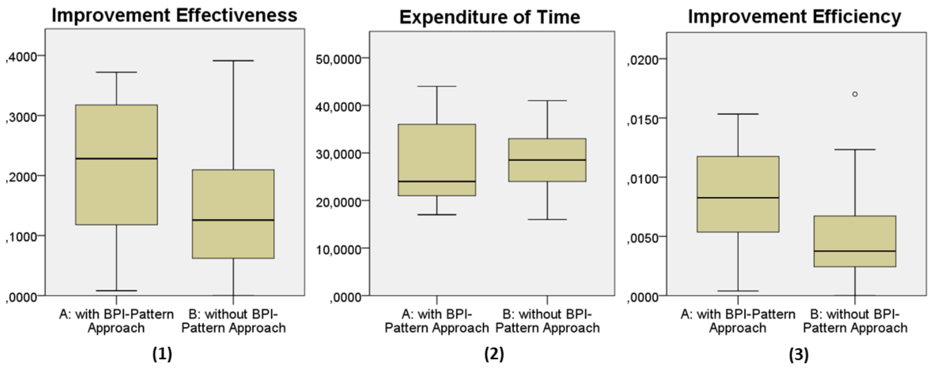

Figure 2. Box plot diagrams of the three dependent variables for group A and B

Even though the arithmetic mean (A: 27.05 min; B: 28.27 min) and the median (A: 24 min; B: 28.5 min) of the variable Expenditure of Time are slightly lower when the pattern-based approach is used, the effect is far weaker than anticipated and thus not statistically significant (see Figure 2(2)). In addition, not a single participant from group A (with patterns) passed through the "act of improvement" in less time than the fastest of group B (without patterns). Similarly, the maximum time in group A exceeds those in the control group. This indeed contradicts our initial expectations, but there are several explanations for these findings. On the one hand, the BPI-Pattern Approach was quite a new method the students were not trained on (participants had obtained a short introduction the week before the experiment started). Because of learning curve effects the results may change when the approach is used over and over. On the other hand, it is easily conceivable that participants who had no BPI-Patterns provided "gave up" if they could not find an adequate solution within a certain time interval. In contrast, the other group continued searching the pattern catalog for patterns that fit their needs.

It is often argued that structured guidelines and a formalized procedure, both provided by the BPI-Pattern Approach, would facilitate process improvement and make redesign projects more efficient [23], [24], [40]. This effect was also clearly detectable in the results of our experiment (see Figure 2(3)). The regression model explaining the dependent variable improvement efficiency shows a high significance which can be ascribed to the BPI-Pattern Approach and the degree of methodological knowledge of the user. What is different to the theoretical considerations in literature is that this is not mainly due to time savings but rather because of implementing more effective improvements. Another topic, discussed by researchers, is that a systematic improvement approach almost necessarily leads to some kind of improvement if only sufficient time and effort is invested [41]. This can be approved based on our observations as we found a significant positive correlation between time and improvement within group A (with BPI-Patterns), but not for the control group. The findings indicate that if one searches long enough some kind of improvement solution will be found, presumed the pattern catalog contains suitable patterns which fit the problem.

Business process improvement projects are often dominated by external advisors who play the role of method experts and contribute the methodological knowledge that is inevitable to successfully run such a project. However, it is recommended to better involve the concerned employees to exploit their domain-specific knowledge as well as to minimize the resistance to change which is a common phenomenon in many organizations [27]. Pattern-based approaches are seen as an instrument to especially support novices by providing step-by-step guidance and conveying expert knowledge they can build on. The data gathered during the experiment clearly classify the participating bachelor students as BPI novices showing relatively low values for Methodological Knowledge, Domain Knowledge, and BPI Experience. However, the overall results of our evaluation show that even such novices in BPI can achieve considerable improvements based on the BPI-Pattern Approach.

The findings of our research revealed insights into strengths and weaknesses of the analyzed approach, too. Examining the data gathered during the experiment we identified possibilities to further improve the BPI-Pattern Approach. First, a number of participants in group A correctly identified the relevant process performance problems but could not find the corresponding match in the pattern catalog. Thus, the problem selection process and the problem description template should be better aligned. Second, those patterns providing more than one example to explain their functional principle were rated to be easily comprehensible. Adding a reasonable number of examples (e.g. covering different application domains) would probably advance the identification and adoption of the patterns.

6 Conclusion

In this paper we present the findings of a laboratory experiment which was conducted to evaluate a BPI-Pattern Approach according to the principles of design science research. As a result, it could not only be demonstrated that the approach works in the particular setting provided in the experiment, i.e. the design science artefact fulfils its purpose as intended, but also that it supports the “act of improvement” better than other approaches. This statement is based on the test of three hypotheses, a regression analysis and further inspection of the experimental results. Two of our three assumptions are supported at a statistically significant level and the experiment confirmed that the BPI-Pattern Approach has a significant positive influence on both improvement effectiveness and efficiency. This makes the BPI-Pattern Approach a valuable asset when seeking for the improvement of existing business processes.

The contribution of this research is twofold and provides valuable insights for theory and practice. From a scientific point of view, it provides evidence that the newly developed artefact, the BPI-Pattern Approach, works as intended. We were able to confirm the common assumption that a more structured approach for BPI would generate better results (cf. [20], [24]) which could be explicitly demonstrated for the experimental scenario. Furthermore, the experiment helped to verify some of the qualities which are ascribed to patterns in general, such as providing guidance to novices [42] or reducing the effort of developing solutions [23], [24]. The contribution for practitioners is that the practical benefit of the BPI-Pattern Approach has been experimentally verified. Hence, it can be considered as a new instrument which expands the existing toolbox of methods, techniques and approaches that are used in improvement initiatives.

However, we still see some limitations which require further research regarding the evaluation of the BPI-Pattern Approach. There possibly exist other factors that have not been taken into consideration but may influence the effects of the pattern-based approach, and therefore should be part of future studies. These include but are not limited to e.g. usability aspects of the used software tool, the level and the complexity of the business process that has to be improved, the impact of group dynamics and teamwork etc. It would also be interesting to repeat the experiment with experienced BPI experts and to determine whether there are any differences regarding the approaches' benefits compared to our rather unexperienced user group. A long-term study could be used to validate if the advantages of the approach are stable over time or decrease e.g. because users have memorized the patterns and gained expertise.

The positive results of the evaluation refer to the particular setting which includes a number of simplifications due to the experimental design (e.g. number and size of the processes to be improved, number of available BPI-Patterns in the catalog etc.). Although the exemplary scenario was based on real-world data, the use of other evaluation methods, such as field experiments or case studies, which are able to capture the manifold interdependencies occurring in practice, is recommended to validate the findings in the context of real-world applications.

Systemizing Colour for Conceptual Modeling

Jeannette Stark, Richard Braun and Werner Esswein

Technische Universität Dresden, Germany[1]
(Jeannette.stark, Richard.braun, werner.esswein)@tu-dresden.de

Abstract. Colour is used in many conceptual models and is discussed intensively since MOODY has published his 'Physics of Notation'. Yet, choosing the right colour for a construct is difficult but crucial. Using a colour for a certain construct which is not appropriate can lead to visual stress as well as too much or too little emphasis on that construct. The aim of this paper is to give a systematization of colour for conceptual modeling by reviewing theories of colour vision, colour harmony and visual attention. Based on this review we provide colour combinations for different conceptual modeling colour scenarios.

Keywords: Colour, Hue, Conceptual Modeling, Pop-out, Perceptual Discriminability.

1 Introduction

Conceptual modeling constructs are mainly distinguished on the basis of the shape [1]. In BPMN 2.0, for example, shape (and to a small extent also texture) is used to derive the majority of constructs [2], which is useful, as shape has a significant impact on object recognition [3]. Yet, shape alone does not produce a high visual distance between modeling constructs and thus, leads to a low perceptual discriminability as only one visual variable is used to encode visual information. This makes it hard for model users to distinguish between constructs [1]. Redundantly using visual variables can help to increase perceptual discriminability and allows positive effects such as a faster detection of modeling constructs [1]. When visual variables are discussed for redundant coding, in most cases also the visual variable colour is included ([2],[4-6]). Colour is very powerful as differences in colour can be detected three time faster than shape and are more easily remembered [7-8]. Also experiments from visual attention confirm that colour dominates other variables [9-10].

So far, colour has been discussed to visually distinguish matching operators in Business Process Models (BPMs) [6], to produce a pop-out of chunks and of model elements [11] as well as to encode further information [12]. Colour has also been tested empirically for conceptual modeling in [6] and [13], who have shown that if colour is used, significant positive effects on comprehension for novices can be achieved. Yet, the application of colour still remains subjective. In studies that use colour for

[1] This research is supported by the Graduate Academy of TU Dresden, financed by the excellence initiative of the German federation and the federal states.

conceptual modeling, colour is not selected systematically. [13] argues that assigning a certain colour to a model element is very difficult due interrelations between hue and brightness. Even for designers choosing the right colour combination is very difficult. They often look for inspiration from sources such as art or colour palettes [14] and that way, try to avoid disharmonious colour combinations but rather create attractive ones which according to [15] works better than unattractive ones. Yet, designers of modeling grammars do normally not wish to spend time for being inspired which is why a systematization of colour for conceptual modeling would be helpful for them.

In this study we address the gap of a missing colour systematization for conceptual modeling by elaborating scenario-specific colour combinations that modelers can use during the modeling process if their modeling tool allows assigning a specific colour, that tool-designers can implement in their tools and that designers of modeling grammars can use when assigning colours to their constructs. We do not draw requirements for colour combinations from every possible perspective but limit our study to theories of Visual Attention (to derive scenario-dependent colours), of Colour Vision (to derive general and scenario-specific requirements) and of Colour Harmony (as in most cases several colours for several constructs are selected that should harmonize with each other). We do not discuss cultural-dependent colour perception as is recently discussed for conceptual modeling in [16] and remark that colour combinations of this paper are rather elaborated for a western context. We further do not treat semantics of colours which are also very cultural dependent.

This research uses design science [17] as research method. Following the research method discussed in [18] the paper is structured as follow: We start with a first initiative by reviewing conceptual modelling colour scenarios in section 2. Based on the colour scenarios we continue with a requirements analysis from theories of Visual Attention (section 3.1), Colour Vision (section 3.2) and Colour Harmony (section 3.3). Colour combinations for scenarios are presented as artefact and are implemented by giving an example in section 4. So far we have not evaluated the colour combinations but will present an idea of how this can be done in section 5, which further provides a short conclusion and an outlook of future research possibilities.

2 Colour in Conceptual Modeling

Colour has been used for different purposes in conceptual modeling: Production of a pop-out, a high visual distance as well as to encode further information (see table 1). [11] and [13] have used 3-4 colours to **produce a pop-out** of certain modelling elements and to visually distinguish further elements. While [11] made entity-types pop out from the rest of ERD-constructs, in [13] a pop-out effect is used for two chunks of BPMs. Also in [6] a pop-out of matching operators is discussed. Yet, in their model a great number of operators are visually distinguished by colour, which is why we argue that they rather aim to **produce a high visual distance** between operator pairs, as a pop-out can only be achieved for very few elements [13]. Further studies that use colour to produce a high visual distance for modeling constructs are [2], [19-21]. Colour is also used to **encode further information** in a non-redundant way in [12],[22-24]. The number of colours in these studies varies to 2-9 different colours.

Table 1. Colour application scenarios in conceptual modeling

Purpose of Colour Application	*# of colours*	*Mod. Gram.*	*Lit.*
Scenario 1: Pop-out of model elements and high visual distance of further objects			
Pop-out for important constructs: Pop-out for Entity-Types + high visual distance for Relationship-Types and Attributes	3	ERD	[11]
Pop-out for important chunks: Pop-out of parallel and alternative chunk + high visual distance for further chunks	4-6	BPM	[13]
Scenario 2: High visual distance			
High visual distance of *varying numbers* of operator *pairs:*	varying	BPM	[6]
High visual distance of a *fix number* of constructs:			
e.g. Gateways, DataObjects, Events	-	BPMN	[2]
e.g. Process, object, Team	9	UCM	[19]
e.g. Container, Link, Container Unit	2-9	WebML	[20]
e.g. Stages, WorkUnitKinds	4-8	SEMDM	[21]
Scenario 3: Encoding new information (non redundant application of colour)			
Start and Endpoint, nodes that require user's interaction	4	BPM	[22]
Debit and Credit information in places	4	Petri Nets	[23]
States of activities and delay indicator	5	BPMN	[12]
Coloured tokens and states	-	Petri Nets	[24]

3 Requirements for the scenarios

Requirements in this section are only discussed for scenario 1 and 2 as in conceptual modeling it is already consensus that colour should not be used in a non-redundant way [1-2]. In the next subsection requirements are derived from Visual Attention.

3.1 Requirements from Visual Attention

Colour is an effective variable to guide human attention [25], and can be used to produce a pop-out for the most important constructs of a model. A pop-out effect (as seen for the red entity types of fig. 1) is reached when visual variables are used in a way that parallel processing is facilitated [26]. In this case, visual information is perceived very fast, in less than 200ms, which allows working memory to efficiently process information. Yet, as shown by attention researchers such as [27], parallel processing is not a rigid state but a pole on a continuum, having serial processing as the other pole. Conditions for parallel and serial processing are discussed by [11] for conceptual modelling (see fig. 1). Colour can affect parallel or serial processing based on the number of unique values, its rang in feature hierarchy, its difference in value intensity and its similarity to other colours.

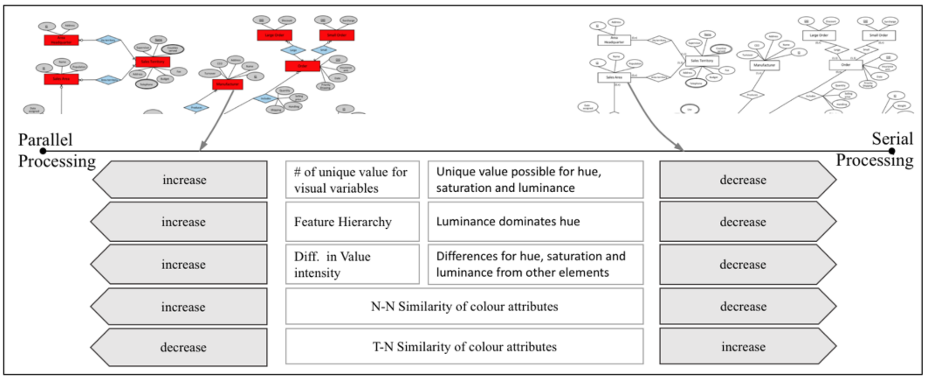

Figure 1. Continuum between parallel and serial processing on the basis of [11]

An element that is characterized with a unique value, such as circular for shape (fig. 2b), is in most cases further placed on the parallel side than an element with no unique values. That way, the circle in b) attracts more attention than the red circle in a), that does only have values which also appear in distractor elements. According to the theory of **Feature hierarchy** the visual system appears to have a hierarchy for visual variables (e. g. luminance dominates hue [25] and hue dominates shape [9]). That way, a unique value for hue (as in c) would lead to a more parallel place than a unique value for shape (as in b). A further condition concerns the **numbers of unique values**. In d) luminance is introduced as a further unique value besides hue (as in c). That way, the target element in d) is characterized with more unique values (hue und luminance) which leads to a more parallel position than the target element has in c). Working on the condition **differences in value intensity** does further help to move the element further to the parallel pole. In e) we have further increased the luminance difference between target and distractor elements and have, that way, increased parallel processing. When discussing differences in value intensity between target- and distractor elements, we implicitly talk about similarity (target-non-target similarity or T-N similarity). Besides T-N similarity also similarity between distractor elements matters (non target-non target similarity or N-N similarity) [27]. A target element is placed more on the parallel side with distractor elements having a high similarity (as is the case b-d) instead of having a lower similarity (such as in f).

For the two scenarios a different position of the modeling constructs along the continuum is required. For the pop-out scenario [13] discusses to place the constructs that should pop-out as far to the parallel side as possible (see fig. 3). Further constructs can be distinguished by giving them a position which is close to the serial processing side to avoid interferences with the pop-out constructs. For the high visual distance scenario all relevant constructs can be placed as much to the parallel processing side as possible. Based on the different positions within the scenarios the two scenarios require a different work on the conditions which are summarized in fig. 3 as requirements from Visual Attention.

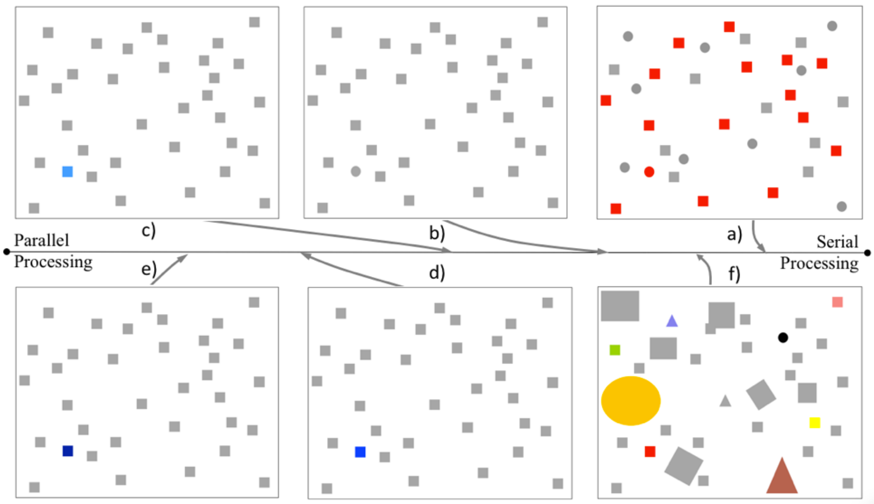

Figure 2. Examples to place elements along the continuum

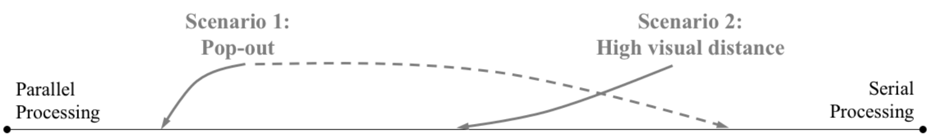
For the pop-out scenario placing the most important constructs close to the parallel processing side can be achieved by creating a unique value for luminance which is highest in feature hierarchy and holding this value constant among other constructs. That way, a clear focus is achieved with the most important variable of the feature hierarchy (req. 1 & 2). Furthermore, a greater number of unique values should be created with hue and saturation (req. 3) and value differences should be set as high as possible (req. 4). If possible, sufficient differences in value intensity of non pop-out constructs should be regarded, too, to further visually distinguish these constructs (req. 5). For the high visual distance scenario, a pop-out is not required for the constructs but visual distances should be arranged as high as possible which requires unique values for those constructs with sufficient luminance and hue contrast (req. 1 & 2).



Req. 1: Use sufficient luminance contrast between the pop-out colours and non pop-out colours

Req. 2: Use constant luminance for non pop-out colours

Req. 3: Produce futher unique values for pop-out colours

Req. 4: Sufficient difference in value intensity between pop-out and non pop-out colours

Req. 5: Sufficient difference in value intensity for attributes of non-pop-out colours to further distinquish non pop-out elements

a)

Req. 1: Use sufficient luminance contrast between the colours

Req. 2: Use sufficient hue contrast between the colours

b)

Figure 3. a) Scenario-related positions along the continuum and b) requirements from Visual Attention

3.2 Requirements from Colour Vision

Implications from colour vision have already been discussed within 38 guideline for computer graphics in [28]. In this work we discuss 13 of the more general guidelines of [28] which can also be applied for conceptual models (on papers and on screens) and whose focus fits to our domain.

Human colour vision is trichromatic [29]. The retina has three types of colour-sensitive photoreceptors that are referred to as S, M, and L cones, which are sensitive to **s**hort- , **m**iddle- as well as **l**ong-wavelength of the spectrum [30] and are usually termed blue, green and red. We perceive colour by combining the three receptor inputs into a unique triplet and thus, perceive colour depending on the ratio of the three cone-responses. S, M, and L-cones are not equally distributed among the retina but occur in relation of 1:20:40, which means that the sensitivity to red and green is much higher than to blue [31]. A difference in contrast sensitivity has also been measured for the neural channels that distribute colour information to the brain. In this process S, M and L-wavelength are transformed into an achromatic and two chromatic signals [32]. While the achromatic signal represents the sum of the cone responses, the two chromatic signals define colour differences in red-green and yellow-blue. These channels differ in contrast sensitivity, too. The achromatic channel offers highest contrast sensitivity and the yellow-blue channel the lowest, which can be explained with the relative distribution of cones in the central fovea [28].

In consistency with the chromatic and achromatic channels, HERING proposed his **opponent colour theory** of colour vision around 100 years ago [28]. He noted that certain hues never occur together such as red-green or yellow-blue in the sense that a colour is not described as reddish-green. Based on these observations HERING argued that there is something fundamental about those pairs of colours [30] and used these colours together with white and black to define a system of six elementary colours (see fig. 4a). Out of this system three perceptual dimensions can be derived to describe colour [30]: Hue, colourfulness and brightness. While hue defines if an area appears to be similar to red, green, yellow and blue or to a combination of those colours, colourfulness describes to what extend an area appears chromatic. Brightness gives information about the extend an area emits of reflects light [33].

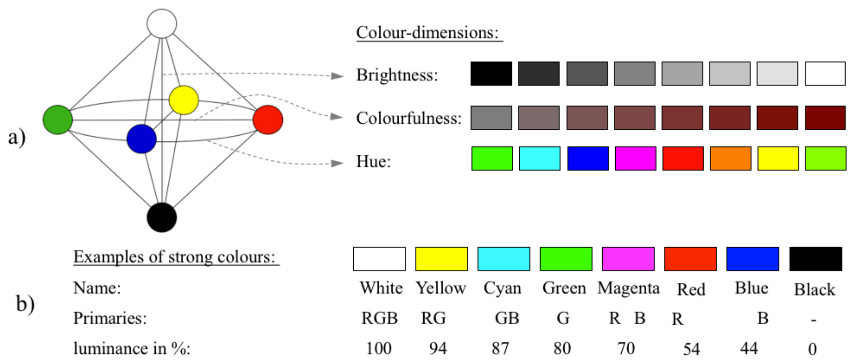


Figure 4. a) Colour dimensions, and b) examples of strong colours (on the basis of [28])

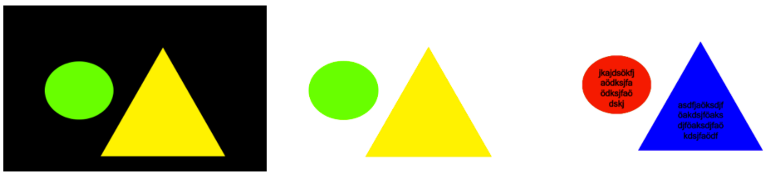
Further terms that are used in this paper are saturation (which defines colourfulness in relation to the brightness of similarly illuminated white [33]), and luminance (which determines brightness sensitivity of the human eye [34]). While green, red and blue represent primary colours that can directly be detected by S-, M-, and L-cones, secondary colours present a ratio of the primary colours [28]. In fig. 4b) saturated primary and secondary colours are ordered according to their luminance. These colours with luminances close to that of fig. 4b) are further referred to as strong colours. According to [28] bright **strong colours** can be used to claim for attention [28], which is also the aim of pop-out colours (see fig. 5a). Yet, these colours are discussed for a black background which allows sufficient luminance differences. In conceptual modeling a black background is not common, which is why strong colours should rather contrast to a white background (which is not achieved in b). Fig. 4b describes strong colours which are helpful to select a pop-out colour that offers enough contrast to the background. While a white background has a luminance of 100% a sufficient contrast is offered in saturated red (54%) or saturated magenta (70%). Saturated blue also offers a high difference, but if text is used inside the constructs, it cannot be read (c).



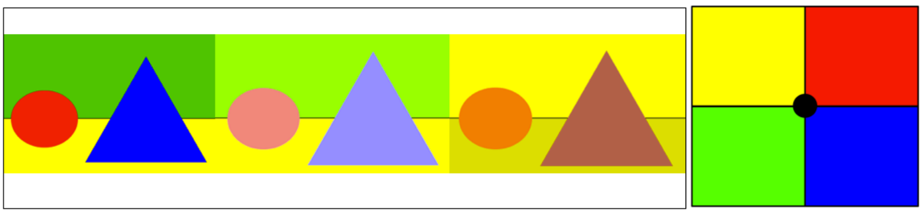
a) b) c)

Figure 5. a) Las Vegas effect: bright, strong colours on a black background, b) the same colours on a white background and, c) colours with a sufficient luminance contrast.

A certain colour appearance of an element does not only depend on the element's own colour attributes but also of colour attributes of neighboring regions or elements [28]. According to **simultaneous contrast**, colours shift in appearance when the colour of the background changes. These shifts follow HERING's opponent theory of colour vision. That way, a light background induces a stimuli to appear darker and smaller and a dark background induces a lighter and larger appearance. Furthermore, red induces green, green induces red, yellow induces blue, and blue induces yellow [30]. That is why [28] suggests to use a neutral mid-gray background, whenever accurate visual colour-judgment is required. Yet, since in conceptual modeling white has always been used as background and an accurate judgment of colours is in most cases not required, we have decided not to use the grey background as a colour guideline.

Looking at strong colours can fixate a coloured image on the retina, which temporarily reduces the sensitivity of photoreceptors and leads to **afterimages** [28]. This can be experienced when fixating the gaze on the black dot of fig. 6d) for at least 10s. When looking on a white paper afterwards an afterimage with the same layout but complementary colours can be observed. That way, in formerly red regions of the image cyan emerges because the response of long-wavelength (red) is temporarily suppressed which leads only the medium- (green) and short- (blue) wavelength to emerge [28]. This is why generally it is not recommended to use large areas of bright colour [35].

Strong colours can also lead to a **depth contrast**. When light is passing through the lens it is refracted into its spectral components. Depending on the wavelength, spectral components converge beyond (red) or in front of the retinal surface (green and blue). That way, to reach a focus on red colours the lens have to become more convex while a focus on blue or green colours requires the lens to become less convex like seeing an object which is far away. This is why, for most observers red appears to advance and blue to recede [36] which can lead to unwanted depth effect when putting strong red and strong blue on neighboring areas. Yet, this effect also can be used to impose colour contrast for a pop-out effect (see fig. 5c). While strong colours are very useful as pop-out colours, these colours should be used very carefully for the high visual distance scenario. In this case we need to place the constructs as far as possible on the parallel processing side without producing visual stress (which we accept for the pop-out scenario when moving the constructs even further to the parallel side). A strong colour combination used for large areas such as in fig. 6a) imposes visual stress due to too much contrast. We can avoid visual stress by using two strategies: First, using colours with a high luminances above the level described in fig. 4b does lead to a colour which is not strong and which would (due to the high luminance-level) not produce too much contrast to a white background (b). When using this strategy, colours should still have enough luminance differences as luminance is highest in feature hierarchy and is thus, important to discriminate between elements. Second, using low hue differences also leads to reduced contrast, which in turn reduces visual stress (c). Moreover, the size of the constructs matters. As visual stress occurs when using strong colours for large areas we should consider that colours for smaller areas need also to be stronger.



a) b) c) d)

Figure 6. a-c: Visual stress within the high visual distance scenario, and d) example for the afterimage effect

If **text** is required within a coloured object then legibility becomes important, which is usually facilitated with a sufficient luminance contrast ratio between text and background. If coloured text on coloured background cannot be avoided the luminance contrast ratio should be at least 3:1 and preferably 10:1 [28].

Human observers with nondeficient colour vision depart to some extend from the standard spectral responses which is why human observers do not see a given colour in exactly the same way [28]. **Colour blindness** further leads model users not to perceive colour the way it is intended it to be seen. Approximately every 12. male and every 100. female adult in Europe is colour deficient [37]. In most cases the kind of colour-deficiency is dichromatism, where one of the three cone pigments is missing.

Dichromats have problems discriminating hues [38], which is why it is recommended not to use hue alone to discriminate between elements. A further restriction of colour concerns the **number of colours** that should be used. Two factors restrict the number of colours [28]: The ability to simultaneously process a certain number of colours and the ability to discriminate between different colours. MILLER has estimated that humans can simultaneously process 7 +/-2 elements in working memory [39]. Recent research estimates this amount lower to 3-4 items [40]. According to research in psychophysics we can differentiate around 7-10 colours [41-42]. Based on those limitations a general limitation of 5-7 colours is given by [43], which seems reasonable based on the number of colours we can differentiate and process. Implications of the description of Colour Vision for conceptual modeling are summarized in table 2.

Table 2. General guidelines for colour application (based on [28])

1.	Be aware that strong colours in neighbouring and in big areas can produce visual stress from unwanted depth effects and afterimages.
2.	Do not use the blue-yellow channel alone for fine details.
3.	Do not use hue alone to encode information
4.	Be aware that colours of neighbouring areas change the appearance of colours.
5.	Do not use coloured text on coloured background.
6.	Limit the numbers of colours to 5-7.

Based on these general guidelines also implications for the pop-out scenario as well as for the high visual distance scenario have been discussed and are summarized in fig. 7.

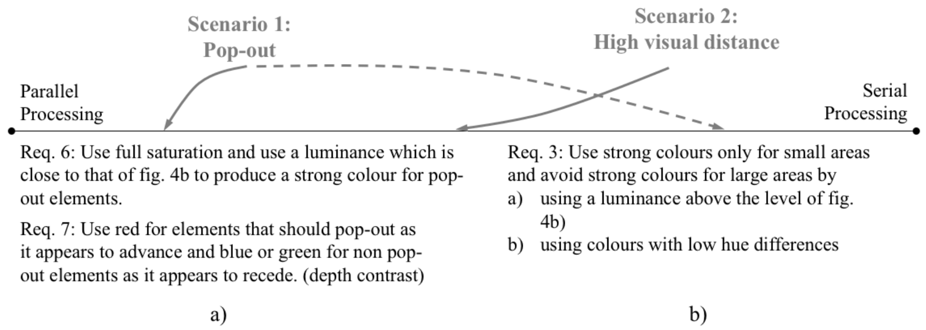


Figure 7. Scenario-specific requirements from colour vision

3.3 Requirements for an effective combination of colours

When applying the rules of section 3.1 and 3.2 there is still a lot of subjectivity in choosing the right colour combination for model elements. Yet, choosing harmonious colours is difficult and crucial [14]. Especially, when tasks need to be solved under stress a visual graphic, used for this tasks, works better if it is designed aesthetically and harmoniously [15]. Choosing the right colours has been challenged for already a long time starting with the ancient Greeks. Modern colour theory has began with the colour wheel that has been proposed by NEWTON and was further developed by

GOETHE. Later, hue templates on colour wheels were developed [44]. MATSUDA, for example, created a set of eight hue templates that describe areas on a colour wheel in which harmonious colours can be selected. Hue templates can easily be rotated around the colour wheel which leads different harmonic hue combinations to appear and are often used as a starting point by designers [14]. A plethora of colour theories address colour harmony beyond just hue. Many of these theories suggest that colours are harmonious if one colour attribute contrasts while the others remain fixed [14]. That way, the Munsell system suggests colour sets being fixed in value and hue but vary in saturation to be harmonious [45] while the Ostwald system proposes colours with equal white or black content as harmonious [46]. Those suggestions were only tested in recent years (see for example [47]) and have led to contradictory results although a few trends have been found [14]: Colours harmonize if they are characterized with same hue, equal or similar saturation as well as contrasting lightness value. In recent years a broad empirical basis through social colour networks, such as Adobe Kuhler [48] and COLOURLovers [49], has emerged that offer millions of colour palettes and have been used by colour scientists to test their theories. Both social colour networks allow their users to create colour themes consisting of 1-5 colours as well as rating, commenting and modifying them. Based on the contradictory results from theories of colour harmony we decided to use colour palettes from two social colour networks that have also been used in colour studies (Adobe Kuhler as well as COLOURLovers).

4 Colour combinations to create a pop-out and a high visual distance

To exemplarily show how colour combinations can be used for the different colour scenarios, we have searched colour palettes that have at least 100 “likes” or “loves” in COLOURLovers or Adobe Kuhler. These colour palettes have further been assessed according to the requirements of section 3 for scenario 1 (pop-out) and 2 (high visual distance). Those colour palettes that best fulfilled the requirements were chosen as colour combination for conceptual modeling. Fig. 8 and 9 give an overview of most appropriate colour combinations for the scenarios and shows to which extend these combinations fulfill the requirements. For the pop-out scenario we found 11 and for the high visual distance scenario we have extracted 22 colour palettes. The colour combinations for the pop-out scenario can be found on the left side of fig. 8 and are evaluated according to specific pop-out requirements as well as legibility as a general requirement of section 3 on the right side of fig. 8. We found two colour combinations that provide two pop-out colours (on the top of fig. 8) and nine colour combinations with only one pop-out colour (on the bottom of fig. 8). The remaining colours within these colour combinations can be used to visually distinguish elements that should not pop-out and are ordered from smaller to larger elements. Within the separation of one-pop-out colour combinations and two-pop-out colour combinations the colours are ordered according to how they fulfil the requirements of the section 3.

Scenario 1: Pop-out

Legend:
pop-out colour | colour to produce visual distance

X_z: criterion is fulfilled

Figure 8. Pop-out colour combinations

The colour combinations for producing a high visual distance are summarized in fig. 9 and are further distinguished in colour combinations for large (top of fig. 9), small (in the middle) and a combination of large and small areas (on the bottom). The colour combinations are further ordered based on how many colours they offer and on how they fulfill the requirements of section 3. The colour combinations on the bottom of fig. 9 for large- and small-area colours are further distinguished based on the application for large- and small-areas. That way, the small-area colours are presented on a gray background while the large-area colours are presented on a white background. In most cases not every colour of the palette fits into the scenario which is why these colours are depicted in black in fig. 8 and 9. For a better understanding of fig. 8 and 9 we exemplarily show how these colour combinations can be used for conceptual modeling. Therefore, we discussed the lifecycle diagram discussed in [21], p. 200 using the graphical notation of ISO/IEC 247744. This lifecycle diagram uses colour to visually distinguish the modeling constructs (scenario 2). In its original version on the left side of fig. 10a) this diagram imposes visual stress by using eight different colours (4 line and 4 background colours for the constructs). By limiting colours of the resulting model (on the right side of fig. 10a) to the background colours we have reduced visual stress. The original background colours further fulfils the requirement 3a) by using colours that are above the luminance level of strong colours.

Scenario 2:

Large-area colours

X_z: criterion is fulfilled O_z: criterion is partly fulfilled

z: min. luminance diff. (%) in req. 4 and hue distance in degree in req 5

						Readability of black-coloured text	No use of strong colours (req. 3)	High luminance or low hue differences (req. 3a&b)	Sufficient luminance contrast between colours (req. 1)	Sufficient hue contrast (req .2)

Figure 9. Colour combinations for producing a high visual distance

Yet, the combination of colours might not seem harmonious to every user. This is why we have chosen a harmonious colour combination from fig. 9b with higher luminances for the larger elements using FFF9B8 and FEDEA2 (ranging from 88 to 96%) and lower luminances for smaller elements using A7D3D2 and A7D3D2 (ranging from 79-83%) to produce a stronger contrast to the white background. For these colours the min. luminance difference is 4% and luminance is used in a range of 17%. Hue differences are not as high as in the original model. We have used a hue distance of at least 107° to other colours for the process kind, as this construct is probably the most important construct. The other hues only range about 33° and do that way not produce to much contrast, and hence visual stress.

Figure 10. a) example model discussed in [21] before (left) and after (right) using a harmonic colour combination, b) details of harmonic colour combination

5 Conclusion

With this paper we have discussed requirements from different fields of theories for two different conceptual modeling colour scenarios. These requirements were further used to assess harmonic colour combinations of two different social colour networks. Moreover, we have shown exemplarily how these colour combination can be used to assign harmonic colours to a conceptual model. We found that using harmonic colour combinations defined in social colour networks has advantages and disadvantages. On the one hand, by using only colours that have been rated as good we can make sure that the model that uses these colours appears harmonic which is important for problem solving [15]. On the other hand, requirements drawn in section 3 were often not fulfilled. That way, luminance differences between pop-out and non pop-out constructs as well as hue contrast between colours for producing a high visual distance can be optimized if colours are picked individually instead of using a colour palette. This trade-off of using colour-palettes still needs to be evaluated. The experiment described in [13] might offer a starting point (by using colours from fig. 8 in the experiment model) for an evaluation of effects that might result from using colour palettes for the pop-out scenario and might give further insights of the trade-off of using colour-palettes.

Abstract. This contribution introduces the concept of Situational Reference Model Mining, i.e. the idea that automatically derived reference models, although based on the same input data, are intended for different use cases and thus have to meet different requirements. These requirements determine the reference model character and thus the technique that is best suited for mining it. Situational Reference Model Mining is based on well-known design principles for reference modeling, such as configuration, aggregation, specialization, instantiation, and analogy. We present a procedure model for Situational Reference Model Mining and demonstrate its usefulness by means of a case study. Existing techniques for Reference Model Mining are examined and mapped to their underlying design principles. This way, we are not only able to provide reference model designers with concrete guidelines regarding their choice of mining technique, but also point out research gaps for the development of new approaches to reference model mining.

Keywords: Reference Model Mining, Reference Model Design, Reference Model Design Principles, Reference Model Construction, Inductive Reference Model Development

1 Introduction

Reference models can be considered as special conceptual models that serve to be reused for the design of other conceptual models [1, 2]. They provide a template for process models in a certain industry and thus facilitate a resource-efficient implementation of the respective process and its adaption to the individual needs of an organization. This way, companies may benefit from best practices and industry-specific experience. The use of reference models is associated with a higher quality of processes and process models, as it simplifies internal communications by introducing a common terminology and considerably reduces the resources required for business process management [3].

Given a reuse-oriented conceptualization of reference models, their main purpose is to serve as an orientation in the design of new business process models. In this context, we decipher two general design processes [4]. Deriving an individual model from a reference model is known as "Design With Reuse" (DWR), i.e. an existing

Rehse, J.-R.; Fettke, P. (2017): Towards Situational Reference Model Mining - Main Idea, Procedure Model & Case Study, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 271-285

model is used as a blueprint offering guidance to the process model designer by giving suggestions for both content and design of the individual model. On the other hand, "Design For Reuse" (DFR) describes the process of constructing a (reference) model for the purpose of being reused, i.e. composing model parts and domain knowledge, such that they achieve a certain degree of universality.

Considering a model construction process, there exist several different techniques for deriving a conceptual model from another one. These so-called design principles describe how the content of the original model is adopted, adapted, and extended in order to create a new model. Five design principles are described in the literature [2]. Each configuration, instantiation, specialization, aggregation, and analogy may be used in the context of reference modeling and applied to both DFR and DWR.

Not every design principle may be applied to every reference model, nor may every intended target model be derived by any design principle. The principles differ in terms of concretization and usability. For example, the Configurable EPC (C-EPC) constitutes an application of the configuration principle to Event-Driven Process Chains [5]. Instead, the choice of model design principle depends on the situational circumstances, i.e. the requirements posed to the target model and the construction process itself. These factors also determine the character and thus the choice of an appropriate reference model for a certain application context.

Considering the situational circumstances and requirements is especially important when designing a reference model inductively, i.e. deriving it (semi-)automatically from a set of individual process models (Reference Model Mining). Besides the input models, the reference model content and character is determined by the choice of the mining technique. Different mining techniques yield different models, even when applied to the same set of input models. As the desired outcome depends on the intended reuse of the mined model (Design With Reuse), the situational circumstances also determine the recommended, or preferable, mining technique (Design For Reuse). This concept is called "Situational Reference Model Mining (S-RMM)", i.e. extending RMM towards consciously considering the situational context when designing and using a reference model.

In this contribution, we follow a design-science research approach [6] in order to elaborate how existing concepts in reuse-oriented reference modeling can be applied to the relatively new field of Reference Model Mining. How to develop guidelines for reference model designers? What constitutes a context for applying S-RMM? Which concrete mining techniques instantiate which principle?

Therefore, we introduce important foundations in reuse-oriented reference modeling, reference model design principles, and reference model mining in Section 2 and analyze Related Work and the emerging research gaps in Section 3. Section 4 introduces the concept of S-RMM by explaining the conceptualization and idea, defining a procedure model, and analyzing existing mining techniques regarding their application in a situational context, in order to give concrete guidelines to reference model designers. In Section 5, the procedure model and accompanying guidelines are applied in terms of a case study. The paper is concluded with a discussion and an outlook in Section 6.

2 Foundations

2.1 Reuse-Oriented Reference Modeling

Reusing a reference model entails adopting the contents of a model as well as adapting and extending them to fit the specific application context. Figure 1 outlines a reuse-oriented reference model construction [2, 4]. In a typical model construction process, the model designer creates a model according to the user's requirements, employing specific methods. The construction process is influenced by both the model quality (effectiveness) and the required time and cost (efficiency). Reference models can be understood as tools that foster both the effectiveness and the efficiency of model construction. They include contents that are relevant for different application contexts ("Design For Reuse") and may serve as the basis for several construction processes ("Design With Reuse"). As the model contents do not have to be newly constructed and have already been applied, both effectiveness and efficiency are increased.

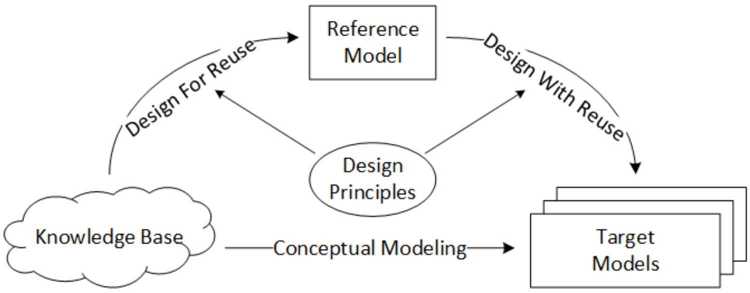

Figure 1: Reuse-Oriented Reference Modeling (cf. [2, 4])

2.2 Reference Model Design Principles

A design principle is a rule that describes how the content of one model is used in the construction process of another. This entails adopting as well as adapting and extending the model content. In his conceptualization of reuse oriented reference model design, vom Brocke identifies configuration, instantiation, specialization, aggregation, and analogy as particularly relevant [2]. As we base our work on this contribution, these are the principles we examine here. Others such as modification are specified in [7] and further elaborated in the discussion section.

- Configuration: Model parts are adopted according to the parametrization of the process domain. Individual model parts are selected and derived from a configurable component.
- Instantiation: General domain aspects are designed as a framework providing generic placeholders for plugging in model parts, considering the requirements of the application domain.

- Specialization: Entire contents of a generic model are adopted into a specific model, allowing individual modification and extension. The resulting model contains all contents of the individual model.
- Aggregation: Contents delivered by various part models are adopted into the new model, composed and extended as necessary. The resulting model is composed of the individual model parts.
- Analogy: Seemingly similar solutions are employed in a creative way to tackle new problems. The individual model is used as orientation for the design of the resulting model, such that they are perceived to be coinciding in certain aspects.

2.3 Reference Model Mining

Reference Model Mining describes the (semi-)automated derivation of a reference model from a set of individual models by identifying commonalities in a set of input models and constructing a new model on that basis (as illustrated in Figure 2).

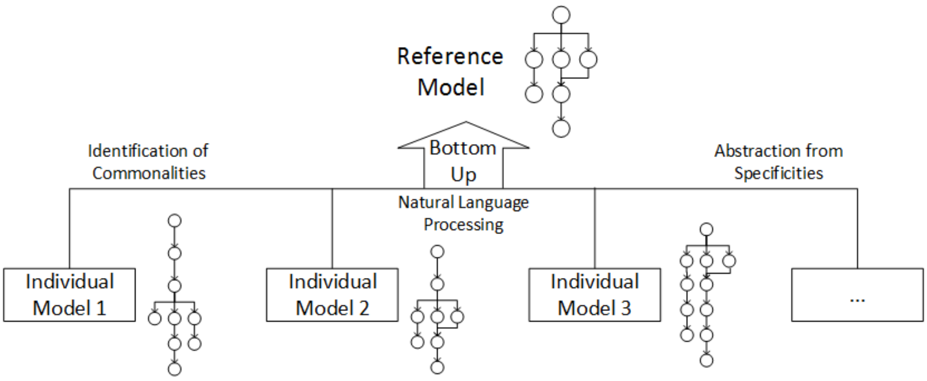

Figure 2: Reference Model Mining

3 Related Work

The concept of situational reference model construction based on design principles is not new, but has yet only been elaborated for deductive reference model development [1, 2]. Inductive reference model development has only recently gained attention in research, so there is little methodological seminal work. Fettke defines a seven-stage-framework for reference modeling methods [8]. First ideas towards S-RMM are presented in [9], where the choice of an appropriate mining technique is discussed.

A number of contributions describe concrete techniques and approaches to Reference Model Mining, but do not take on a methodological perspective, reflecting on the ways of model construction and the requirements of specific use cases. Process variants may either be mined in relation to an existing reference model or without one [10]. Different similarity measures, such as frequents common substructures [11] or heuristic approximations of the Graph-Edit Distance [12], are used to determine input model commonalities. Other approaches employ configurable process models [13], genetic algorithms [14, 15], or Process Model Abstraction [16]. While all of these contributions make the case for Reference Model Mining in general, none of them acknowledge the differences between existing approaches or indicate in which context their suggested technique would especially valuable. Different mining techniques employ different similarity measures (e.g. structural [12] or semantic [9]) and construction methods (e.g. deterministic [11] or heuristic [15]), resulting in differences between the mined reference models. In addition, due to restrictions on the input models, not every technique may be applied to every set of input models. Some contributions describe the influence of a certain parameter on the resulting reference model. For example, a frequency threshold as in [11, 12], will determine the model size and thus the character. The higher it is, the smaller and the more generic the resulting reference model. This is related to the underlying design principle, but not explicitly mentioned as such.

Some authors apply Situational Reference Model Mining by inductively developing reference models for a certain use case in a certain domain, without explicitly considering a generic procedure model or specific design principles [17-19]. Other techniques could generally be applied for Reference Model Mining, although that is not their primary use case. For example, Process Model Merging is primarily intended for process consolidation, but a consolidated model can also be interpreted as a reference model [20]. The same holds for Process Model Integration, especially in a hierarchical way [21]. If the reference model development is targeted towards certain quality aspects, it might make sense to choose it accordingly from process model configurations [22].

Our intention here is to extend the existing concept of RMM to consider the situational context, i.e. the intended target models, when choosing and executing a mining technique. Therefore, we want to create unified guidelines for S-RMM, which reference model designers can use for an easier and better application of Reference Model Mining. Depending on their individual use cases, designers should be able to make informed choices on their design principles and suitable mining techniques.

4 Situational Reference Model Mining

4.1 Idea and Conceptualization

Figure 3 describes the main idea behind S-RMM by extending and substantiating the reuse-oriented reference model design process from Figure 1. In Reference Model Mining, the reference model is automatically derived from a given set of input models, using a certain mining technique. The reference model is then used for the construction of the target models in a certain application context. Depending on the situational circumstances and the target model requirements, a certain design principle is applied to derive the target model from the reference model. This design principle poses certain restrictions and requirements to the reference model design, which is mainly influenced by the choice of the technique that was used to mine the reference model in the first place. Hence, the choice of mining technique is ultimately determined by the situational context of the reference model application.

Reference Model Mining itself is a way of constructing a reference model, i.e. an instantiation of Design For Reuse. Depending on the choice of mining technique, different techniques are used to determine the input model commonalities and construct the reference model. Hence, the choice of mining technique determines not only the content, but also the character of the reference model. It restricts the application of design principles for target model derivation, i.e. Design With Reuse, which is a use case for Reference Model Mining.

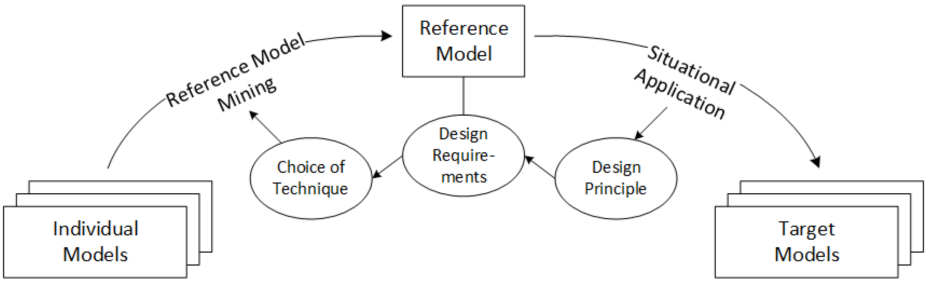

Figure 3: Main Idea behind Situational Reference Model Mining

4.2 Procedure Model

A general procedure model for Situational Reference Model Mining is shown in Figure 4. It is built around the conceptualization of S-RMM in Figure 3. The procedure model describes a generic execution process of an S-RMM application. It consists of ten steps, each of which belongs to one of the two generic design processes. DWR is concerned with the target model construction (i.e. the reference model application), whereas DFR focusses on the reference model construction (i.e. the actual mining). The generic S-RMM process starts with Design For Reuse, where seven steps are executed, and continues in Design With Reuse, with three steps.

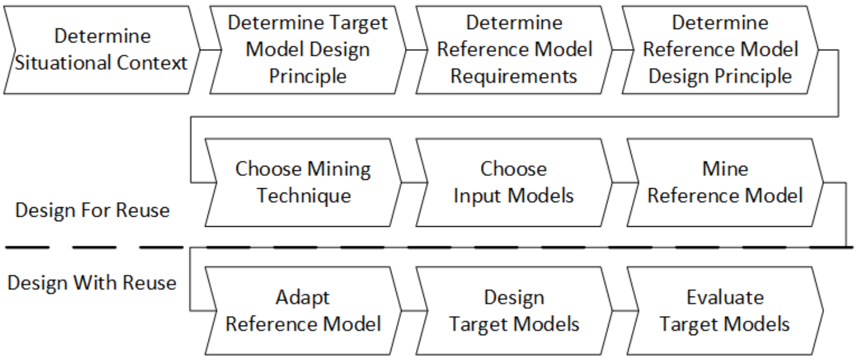

Figure 4: Procedure Model for Situational Reference Model Mining

1. Determine Situational Context: As a basis for any S-RMM application, the situational context has to be analyzed by determining the intended use for the target models and the required characteristics that follow from it. These may include defining the type of process, type of model, process domain, modeling language, level of abstraction, scope, or other target model characteristics. The situational context is also mainly influenced by the available input models, as their characteristics determine which design principles may be reasonably applied.
2. Determine Target Model Design Principle: Depending on the situational context and the inferred requirements, the target model design principle is chosen, based on the assessment which of the five principles satisfies the requirements the best.
3. Determine Reference Model Requirements: From the chosen design principle follow several requirements to the design of the reference model design. These are mainly independent from the situational context, as they follow mostly from the principle itself. For example, applying configuration requires a configurable reference model, while instantiation calls for generic process interfaces that can be individually specified.
4. Determine Reference Model Design Principle: Depending on the required design of the reference model, the process designer has to choose the design principle that should be applied in the mining process in order to fulfill these requirements.
5. Choose Mining Technique: Choosing an applicable and appropriate reference model mining technique is influenced by the chosen reference model design principle, but also the situational context that was previously analyzed, as the reference model has to fulfill a number of constraints. If several techniques qualify, it might be necessary to compare the resulting reference models to determine the best fit for the situational use case.
6. Choose Input Models: Usually, a set of input models is selected prior to beginning the mining process, as they determine the situational context. However, due to possible restrictions and requirements, the final set of input models can only be selected after the mining technique is chosen.
7. Mine Reference Model: The reference model is obtained by applying the mining technique to the chosen set of input models. As they depend on both the input data and the situational context, potential parameter configurations have to be individually determined to yield the best-fitting reference model.
8. Adapt Reference Model: As reference model mining techniques are usually fully automated, the resulting model may not fulfill all the requirements derived from the situational context. Hence, it may have to be manually adapted, for example by adding, deleting or renaming nodes, or complementing the reference model with deductively developed model parts.
9. Design Target Models: After the reference model is finalized, it can be used for the target model construction. Therefore, the design principle determined in step 2 is now applied to the reference model. Each target model undergoes a separate construction process, where the individual model requirements are addressed in the best possible way.
10. Evaluate Target Models: The goal of applying the S-RMM procedure model is to design a reusable and thus useful reference model and use this as a basis for high-

quality target models. Hence, in the last step, the target models are evaluated against the requirements derived from their intended use case. This step may lead to individual adaptations of the target models, but may also serve to enhance the reference model for further reusing. In addition, this step allows process designers to reflect on the S-RMM process as a whole, pointing out eventual improvements.

4.3 Analysis of Existing Mining Techniques

Table 1: Analysis of Existing Mining Techniques

Target Model Design Principle	Reference Model Requirements	Input Model Characteristics	Reference Model Design Principle	RMM Techniques
Configuration	Subsumes different characteristic values of a domain aspect (e.g. different process types).	Belong to the same domain, but describe different instantiations (e.g. subdomains).	Aggregation	[9-13, 20, 21]
			Analogy	[10, 14, 23]
Instantiation	Contains generic interfaces acting as placeholders for certain domain aspects (e.g. activities).	Come from the same domain, but differ in certain domain aspects that can be abstracted.	Aggregation	[16]
Specialization	Contains only universally applicable, contextually adaptable domain aspects.	Contain identical fragments representing universally valid domain aspects.	Aggregation	[9-12, 20]
			Analogy	[14, 23]
Aggregation	Requires several models, each covering one aspect relevant to the application context.	Originate from different backgrounds, but complement each other in terms of content.	--	
Analogy	Contains fragments that are directly applicable in target model context (i.e. in content and level of abstraction)	At least one is generic enough to serve as the basis for reference model design. The others can e.g. be derived variants.	Configuration	[13, 22]
			Aggregation	[9-12, 21]
			Analogy	[14, 23]

In order to provide a guideline for applying the procedure model for S-RMM, we analyze existing mining techniques regarding their underlying principles and requirements, as summarized in Table 1. For each target model design principle, we list the necessary reference model requirements and input model characteristics, such that this principle is applicable. Then, we suggest corresponding reference model design principles and, for each pair, a suitable mining technique. The analysis is restricted to those combinations of target and reference model design principle that are described in section 2.2 and actually substantiated by a mining technique, not those that generally exist or make sense.

Table 1 suggests both techniques that are specifically devised for Reference Model Mining (or Inductive Reference Model Development), such as Process Variant Clustering [10], and techniques that are originally intended for another use case, but can be employed accordingly, such as Process Model Merging [20]. Selection criteria were that the described technique (a) takes a set of models as input, (b) outputs a single model that is in some way based on the input models, (c) is fully automated, and (d) describes a domain-independent method that can be applied to any set of input models. This excludes methodical frameworks such as [8], partially manual approaches such as [17], or empirical, domain-specific reports such as [18]. The table is not intended as a complete list or a state-of-the-art analysis of Reference Model Mining, but as a complementary guideline to our procedure model.

5 Case Study

To illustrate the concept of Situational Reference Model Mining, we apply it in a case study. Figure 5 shows three auditing processes for three different types of retail business (wholesale, warehousing, central processing), translated and slightly adapted from their documentation in the Retail-H reference model [24]. These models will serve as both the target models and the individual models in our case study.

Determine Situational Context. Our target models treat the same process (auditing) in three different sub-domains of the retail domain, i.e. wholesaling, warehousing, and central processing. We assume that the objective is to design an inclusive reference model for auditing processes in retail, including all the differentiations in terms of business type. This means that the reference model should include the specificities of auditing in all three processes. Another option would be to design a model containing only those components that are present in all the input models, i.e. an excerpt.

Determine Target Model Design Principle. Since we intend to design an inclusive reference model, which represents several different sub-domains, the reference model scope is larger than the scope of the target models. Hence, parts of the reference model are irrelevant for each target model and should be deleted. Configuration appears to be a suitable design principle for the derivation of the reference model, as it allows for the selective adoption of applicable model parts and their adaption to the individual situation.

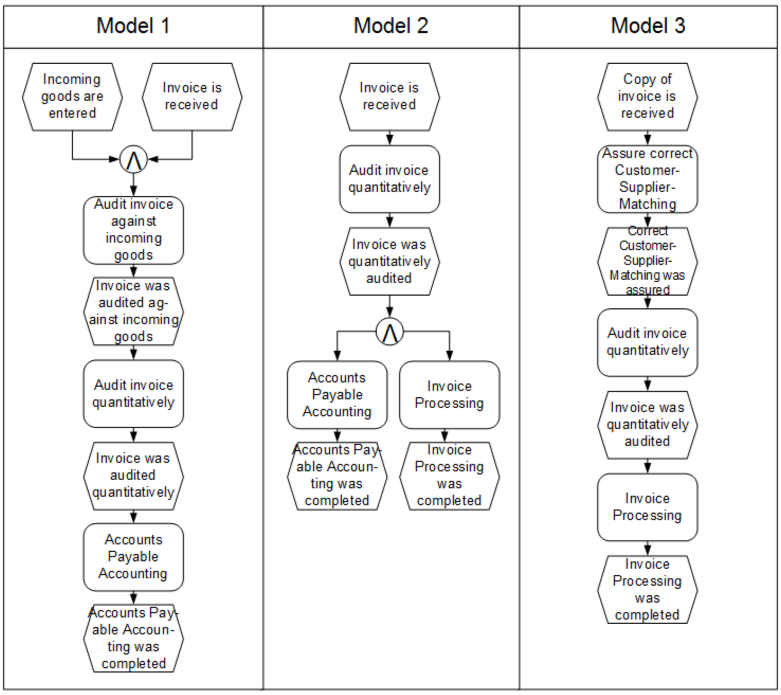

Figure 5: Example Models used for Case Study

Determine Reference Model Design Principle. Aggregation entails adopting and composing parts of several individual models, such that the resulting model subsumes the input models. Since all input models are equally considered, it is an applicable design principle for the reference model. If one input model were used as the basis for the reference model design, specialization or analogy would be more appropriate.

Choose Mining Technique. An inclusive reference model should be mined with a technique that preserves both the elements and the semantics of the individual model. The objective of Process Model Merging [20] is to construct a consolidated model out of a set of process models that share common fragments. As merged models are meant to subsume a set of process model variants, the mining technique is suited for our use case here.

Choose Input Models. For our case study, our input models are equivalent to the set of target models. As the merging algorithm is defined on Event-Driven Process Chains, it can be applied straightforwardly. A pairwise mapping between the input models is required as additional input. We assume that nodes carrying an identical label are mapped onto each other. Process Merging is defined on model pairs, however, the merging order should not have an influence on the resulting model.

Mine Reference Model. We mine the reference model by first merging model 1 and model 2 and then merging the resulting model with model 3. The resulting reference model is shown on the left of Figure 6.

Adapt Reference Model. Technically, the resulting reference model could be used for configuring the target models. However, the model is not syntactically correct, as an event ("Invoice is received") is followed by an XOR-connector. Hence, we adapt the model manually to include the differentiation between the warehousing and wholesale sub-domain. This way, we yield a syntactically correct EPC, which can be configured in the next step.
Design Target Models. The three target models are derived by configuring the adapted reference model. In our use case, this means that those model parts that are irrelevant for the individual sub-domain are removed from the model and the remaining relevant model parts are reordered and connected to form a valid EPC. If applicable, OR-connectors should be configured to be semantically precise.
Evaluate Target Models. In our use case, the target models were predefined, so there is no need for an evaluation in terms of process implementation. However, we can state that both chosen design principles were applicable to the use case. Configuration and aggregation are a suitable pair, but configuration could also be matched with specialization or analogy.

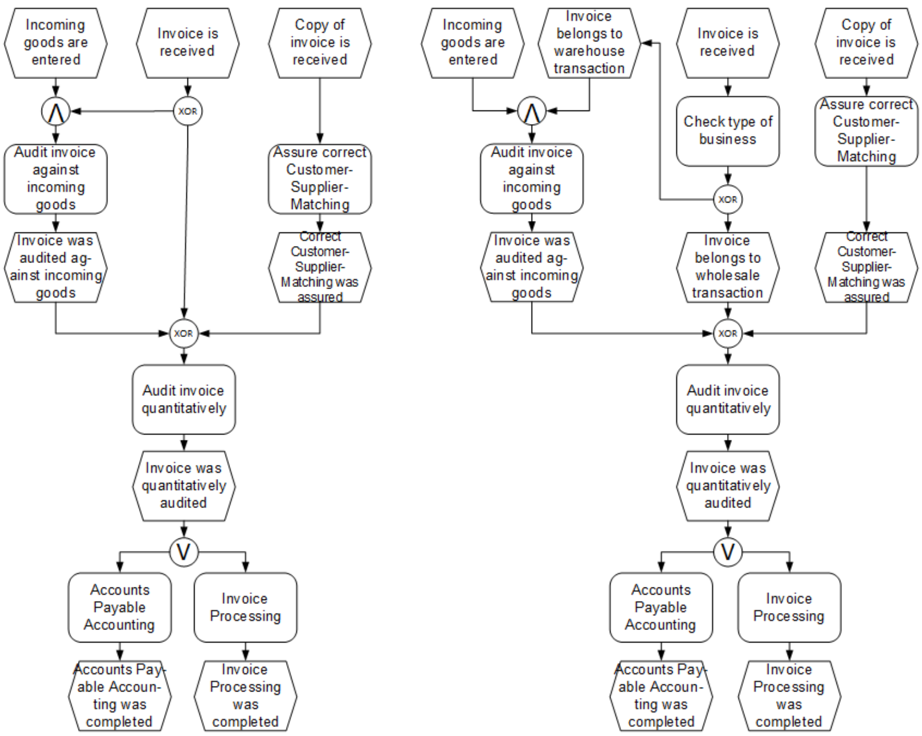

Figure 6: Merged reference model

6 Discussion and Conclusion

In this contribution, we introduce the concept of Situational Reference Model Mining. Based on the idea that the requirements to a reference model and thus the optimal mining technique depend on the situational context, we intend to give reference model designers a guideline for choosing the right mining technique for their individual purpose. As this idea has not yet been elaborated in the respective literature, our procedure model is intended as a first recommendation for a concrete approach. This way, we intend to increase the practical applicability of Reference Model Mining and make its advantages available to a wider range of users.

Our first assessment of S-RMM allows for several observations. First, different mining techniques yield different reference models, both in content and design, even when they are applied to the same set of input models. Parametrization may or may not be a decisive factor in reference model construction. The influence of parameters on the reference model contents and design has to be determined individually for each technique. For example, the order in process model merging should not influence the resulting model, while a frequency threshold (as for example in [11, 12]) determines whether a reference model is the intersection or the union of the input models. In this case, the parameter value also determines the design principle. Depending on the relative frequency of the reference model elements, configuration, analogy, or specialization are applicable. This is why multiple mining techniques apply to several combinations of target and reference model design principle, as seen in Table 1.

The results of the case study in section 5 underline our initial characterization of S-RMM. In order to apply Process Model Merging in a contextually meaningful way, we had to make a number of assumptions, such as the intended use of the reference model, the target models, and the related design principles. While all assumptions made above form a reasonable use case for reference modeling, there exists a plethora of other potential use cases, where the same input models would yield completely different results. Also, we saw that the combination of target and reference model design principle is not sufficient to choose an appropriate mining technique. As shown in Table 1, Process Model Merging is only one of many applicable techniques for the combination of aggregation/configuration. Applying another technique might not yield a reference model as the union of the input models, as seen in Figure 6. Nevertheless, it might be a meaningful reference model in a number of use cases.

Our analysis of existing mining techniques in Section 3.3 shows that the aggregation principle is predominant in reference model construction, while configuration is the mainly followed principle in reference model application. This is not surprising, given the nature of reference model mining. When deriving a reference model with a certain degree of universal applicability from a set of input models, aggregating their common features is evident but not the only technique to achieve a meaningful model. Basing the reference model on an input model and adapting it to reduce the difference to the remaining ones realizes the analogy principle, as for example in [10]. On the other hand, a reference model that aggregates aspects from different sub-domains has to be configured in order to obtain a model that applies to only one of them. However, aggregation may also yield the most common fragments (such as Process Model Intersection in [20]), where specialization or instantiation are appropriate design principles. To conclude, although aggregation/configuration is prominent, the pairwise combination of construction and application principle is not automatically given, but depends on the characteristics of the mining technique.

The analysis in Section 3.3 also shows that the instantiation principle is underrepresented in Reference Model Mining. Only if the reference model is constructed by means of process abstraction, the target models may be derived by means of instantiation. This is due to the fact that most existing approaches to Reference Model Mining are not capable of handling input models with varying degrees of abstraction. Hence, the abstraction level remains the same across all the input models and the reference model. The generic placeholder elements necessary for instantiation cannot be derived from differing, but more specific input models.

Our analysis also reveals that currently there exists no applicable technique for deriving the reference model by means of aggregation. That is because aggregation draws on several conceptual models covering different aspects of the situational context that are to be composed in the target model. None of the existing mining techniques is explicitly set out to mine several different reference models covering different aspects of the defined domain. However, such a scenario is realistic, for example when the reference model is supposed to cover a large domain, which should be divided into sub-domains to ensure the reference model applicability.

In this contribution we draw on the five principles configuration, instantiation, specialization, aggregation and analogy, as defined in [2]. However, these are not the only principles to be considered for reference model design. For example, Delfmann suggests modification as another design principle, allowing all changes to the reference model that do not result in erroneous or inconsistent models [7]. Besides that, principles like elimination or union might also be useful for reference model design. Elimination would allow designers to delete unnecessary elements from a reference model, whereas union would merge several models, without aggregating their contents.

Our analysis of existing mining techniques in Table 1 also acts as a gap analysis, identifying further research potentials and objectives and allowing for a more structural design of new mining techniques. The main motivation for this contribution is to increase the practical applicability of Reference Model Mining. Currently, there exist a number of publications that focus on technical and methodical aspects, as well as a few implementations, but few concrete suggestions for their application. By coining the term “Situational Reference Model Mining”, we emphasize that the choice of technique is relevant, i.e. they cannot always be interchangeably used. The procedure model, in combination with the analysis of existing techniques, is supposed to be a guideline for both reference modeling researchers and practitioners. However, it has not yet been evaluated by being applied in a large-scale context. Gaining more experience in practical applications of existing RMM techniques remains one of the major objectives of further reference modeling research. Our underlying assumptions, however, should be critically assessed. For example, in some cases it could make sense to develop situationally adequate target models instead of choosing an appropriate the mining technique.

Collaborative Business Process Management – A Literature-based Analysis of Methods for Supporting Model Understandability

Andreas Hermann, Hendrik Scholta, Sebastian Bräuer, Jörg Becker

University of Münster, ERCIS, Münster, Germany
{firstname.lastname}@ercis.uni-muenster.de

Abstract. Due to the growing amount of cooperative business scenarios, collaborative Business Process Management (cBPM) has emerged. The increased number of stakeholders with minor expertise in process modeling leads to a high relevance of model understandability in cBPM contexts. Despite extensive works in the research fields of cBPM and model understandability in BPM, there is no analysis and comprehensive overview of methods supporting process model understandability in cBPM scenarios. To address this research gap, this paper presents the results of a literature review. The paper identifies concepts for supporting model understandability in BPM, provides an overview of methods implementing these concepts, and discusses the methods' applicability in cBPM. The four concepts process model transformation, process model visualization, process model description, and modeling support are introduced. Subsequently, 69 methods are classified and discussed in the context of cBPM. Results contribute to revealing existing academic voids and can guide practitioners in cBPM scenarios.

Keywords: Business Process Management, Collaborative Business Process Management, Model Understandability, Literature Review

1 Introduction

Business Process Management (BPM) is a discipline that combines computer science and management science and has gained a considerable amount of attention over the last decades [1, 2]. The growing importance of cooperation due to globalization and the trend of blurring organizational boundaries lead to collaboration in BPM [1, 3–5]. *Collaborative Business Process Management* (cBPM) is concerned with the management of business processes across organizational boundaries [4]. Since cBPM integrates different collaborating organizations [5, 6], the number of stakeholders involved in business process modeling activities is high. However, since not all relevant stakeholders are experienced in process modeling and the particular notations [7], the models might not be fully understood by all stakeholders [8]. Clearly, there exists a gap between modeling experts and inexperienced stakeholders like domain experts [8–10]. This gap needs to be bridged to guarantee success in cBPM projects [11–13].

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Hermann, A.; Scholta, H.; Bräuer, S.; Becker, J. (2017): Collaborative Business Process Management - A Literature-based Analysis of Methods for Supporting Model Understandability, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 286-300

For addressing this knowledge gap, a considerable amount of research in the field of business process model understandability has been conducted [14, 15]. Many of these contributions are experimental works focusing on factors that influence model understandability [14]. Researchers investigate factors of modeling languages, model characteristics, model content related factors or personal factors that influence model understandability [7, 16–19]. For example, Figl et al. investigate the influences of routing symbols of modeling languages on process model understandability [19]. Reijers and Mendling observed that model characteristics such as the average connectors degree or the overall density of a model affect its understandability [7]. Furthermore, Mendling and Strembeck found out that long element labels influence model understandability negatively [16].

Researchers recognize the relevance of cBPM on the one hand and model understandability in the context of BPM on the other hand. However, there is currently no review that analyzes methods implementing concepts for supporting model understandability in BPM and evaluates the methods' suitability for cBPM. This paper's objective is to identify existing methods in the intersection of the topics model understandability and BPM and to discuss the general applicability of these methods in the context of cBPM. Therefore, we have performed a structured literature analysis and address the following research question: *What are methods supporting model understandability in BPM and to what extent are they applicable to cBPM?* Our results provide a comprehensive overview of the last decade's academic work on the topic of model understandability in BPM and a discussion on the usage in cBPM. Practitioners can use it as guidance for identifying potential methods supporting their business. Academics can rely on our work to identify academic voids and plan future research.

The remainder of this paper is structured as follows: Section 2 presents the underlying research background on cBPM and model understandability. In Section 3, we describe the applied research method. We derive concepts for supporting model understandability and provide an overview of methods that implement these concepts in Section 4. In Section 5, we combine model understandability and cBPM by discussing the methods' applicability for cBPM. Finally, in Section 6, we draw a conclusion and present potential future work.

2 Research Background

2.1 BPM and cBPM

BPM is concerned with operational business processes and their management, improvement [2], re-design, analysis, or support with information systems (IS) [18]. An increasing importance of global value chains leads to a trend of blurring organizational boundaries in the context of BPM [3, 4]. Against this background, cBPM is an expansion of BPM that strives to cover business processes across inter-organizational boundaries [20].

cBPM can be described as the management of (collaborative) business processes across organizational boundaries involving actors from inside or from outside an organization [4]. Hence, in comparison to traditional BPM, cBPM incorporates an *increased number of stakeholders* since it affects not only a single organization but also at least one additional organization [5]. Besides, since organizations with a similar business model rather tend to compete than to collaborate, the *group of stakeholders possesses a high degree of heterogeneity.*

Consequently, the collaboration comprises organizations with different product portfolios and from different domains, which strive to deliver more value to their customers. Due to the increased number of stakeholders, the higher degree of heterogeneity, and the resulting need for coordination, cBPM has to cope with *more complex business processes* [3]. Increased complexity in the execution of business models also affects the modeling and thus results in *more complex process models* in cBPM [3]. Process models have to capture the more sophisticated control flow relations in these business processes and have to integrate different modeling conventions in the participating organizations [3].

Additionally, in contrast to traditional BPM, *privacy* plays a more important role in cBPM since confidential information of one organization must not cross organizational boundaries [20]. Therefore, certain information in process models must be kept secret to cooperating organizations [20].

In consequence, it is especially challenging in the context of cBPM to reach a common understanding of the process models among relevant stakeholders [21]. Although model understandability is relevant in traditional BPM, the mentioned reasons increase its importance in cBPM, but likewise, impede its achievement.

2.2 From Model Quality to Model Understandability

Business process models as central artifacts in BPM [2, 5] are the basis for the development of process-oriented IS [22, 23]. Process models have to possess high quality to obtain IS of high quality [24–26]. Model understandability can be considered as a factor of model quality [14, 15]. Some quality frameworks [27, 28] include the dimension *pragmatic quality*. Pragmatic quality is concerned with the degree to which a model is correctly interpreted or understood by an end-user or stakeholder [27, 29]. Accordingly, understandability is often referred to as a factor of pragmatic quality [14, 15, 25, 30, 31].

Pragmatic quality is defined as the "correspondence between the model and the […] interpretation of the model" [29, p. 94]. So-called *pragmatic means*, introduced by Lindland et al. [27], can be applied to reach the goal of pragmatic quality, i.e. understanding a model. In this sense, pragmatic means make a model more understandable [27, 29]. Pragmatic means are model animation, model simulation, model visualization, model transformation, model filtering, model abstraction, model translation, model explanation, as well as aesthetics for diagram layout, model paraphrasing, and participant training [27, 32]. Based on pragmatic means, we derive concepts that support model understandability and analyze methods that implement these concepts.

3 Research Method

The literature-based analysis conducted in this work is based on the approaches for systematic literature reviews proposed by Webster and Watson [33] and vom Brocke et al. [34]. To further define the scope [34] and to articulate the contribution of the work in detail [33], vom Brocke et al. [34] propose the application of the taxonomy for literature reviews by Cooper [35]. The paper's taxonomy is visualized in Table 1. The gray cells in the table below represent the focus of this literature analysis.

Table 1. Classification (gray cells) of the present literature-based analysis following [34]

<table>
<tr><th>Characteristic</th><th colspan="6">Categories</th></tr>
<tr><td>focus (1)</td><td>research outcomes</td><td colspan="2">research methods</td><td colspan="2">theories</td><td>applications/practices</td></tr>
<tr><td>goal (2)</td><td colspan="2">integration</td><td colspan="2">criticism</td><td colspan="2">central issues</td></tr>
<tr><td>organization (3)</td><td colspan="2">historical</td><td colspan="2">conceptual</td><td colspan="2">Methodological</td></tr>
<tr><td>perspective (4)</td><td colspan="3">neutral representation</td><td colspan="3">espousal of position</td></tr>

<tr><td>coverage (6)</td><td>exhaustive</td><td colspan="2">exhaustive and selective</td><td colspan="2">representative</td><td>central/pivotal</td></tr>
</table>

This paper's search process follows the guidelines for literature reviews as proposed by vom Brocke et al. [34]. The approach includes the four phases: journal search, database search, keyword search and backward and forward search. Webster and Watson [33] propose a topic-based search across all relevant journals. Since it includes a large number of electronic articles and provide access to leading IS journals, Elsevier Scopus was selected as database.

To search for relevant publications, the search string in Figure 1 was used[1]. The search string comprises three constituents: Terms from the cBPM literature, terms related to pragmatic means respectively model understandability, and additional terms that are used to further limit the scope on process modeling respectively conceptual modeling. The search string was applied on the 24th October of 2016 and led to 2448 results.

After this keyword search, the results were evaluated regarding their relevance [34]. For this purpose, vom Brocke et al. [34] propose an analysis of the titles, abstracts or full texts of the search results. A title-based analysis of the total results led to 102 results considered as relevant. Based on their abstracts, these 102 publications were then analyzed in detail concerning their relevance for answering the research question. This procedure led to 43 relevant methods from 43 publications.

In addition to a keyword search, Webster and Watson [33] recommend a forward and backward search based on the evaluated results of the keyword search. Using the results of the keyword search, a one-level backward and forward search was conducted, which included referencing and referenced works of the 43 publications that were

---

[1] The search string uses the syntax of Elsevier Scopus. It includes the Boolean operators OR and AND. The * is a wildcard symbol. The search was limited to the following subject areas which are considered as being relevant: Computer Science, Engineering, Mathematics, Decision Sciences, Multidisciplinary and Business, Management and Accounting.

considered as relevant. Performing the backward search and the forward search with the database Google Scholar led to 26 additional methods from 14 publications. Our literature search finally resulted in 69 methods from 57 publications that were considered relevant.

4 Supporting Model Understandability in BPM

4.1 Concepts for Supporting Model Understandability in BPM

Following the search process, the relevant results were synthesized and analyzed using a concept-centric matrix [33]. The concepts for this matrix were derived in two different ways: Deductively with pragmatic means and inductively based on the search results themselves. Since pragmatic means are instruments making a model more understandable, they represent appropriate concepts for classifying the search results. For clarity and for facilitating a better discrimination between the concepts, similar pragmatic means were grouped together. The relevant concepts for this literature analysis that were derived from pragmatic means in this manner are *process model transformation*, *process model visualization*, and *process model description.* Besides, the search results led to some results that are best classified as the concept *modeling support*. The pragmatic mean *participant training* stretches across all concepts. Figure 2 visualizes the concepts.

Modeling support (I). The concept *modeling support* is not directly derived from any pragmatic means. However, the analysis of the search results led to a number of methods that are best assigned to this additional concept. Correspondingly classified methods strive to support model understandability already during the construction process of the model. Consequently, this concept comprises contributions providing a new or extended modeling language [36], a special modeling tool [37], or a method that uses existing modeling notations in an innovative way [38]. Methods that integrate the use of collaborative technologies such as commenting, audio-communication, video-communication, and chatting functionalities into the modeling process are also assigned to this concept [11]. In contrast to this, methods that operate on already constructed models are not part of this concept.

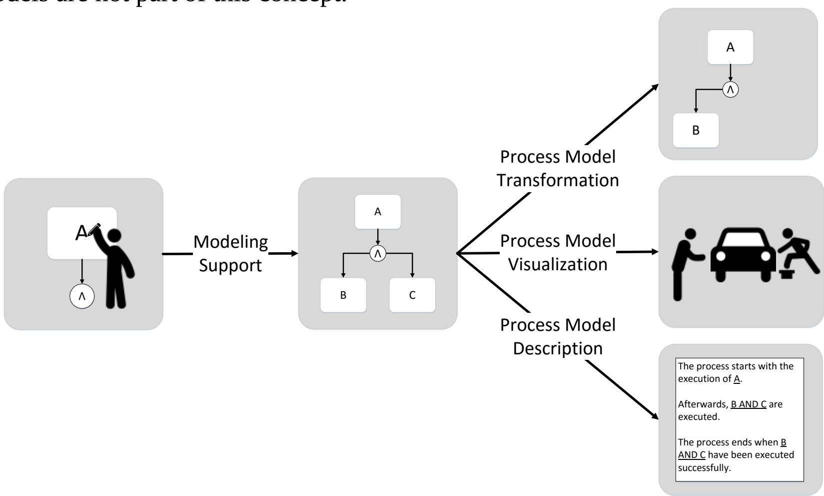

Figure 2. Concepts for supporting model understandability

Process model transformation (II). The concept *process model transformation* is derived from the pragmatic means *model transformation* and *aesthetics for diagram layout.* The means *model abstraction* and *model filtering* are also the basis for this concept since they are concerned with abstracting a model [29] or filtering out irrelevant model elements. This concept aims at the generation of specific views on models. As a result, transformation methods reduce model complexity [39], support the overall model understandability, and hence facilitate activities like the communication of the model to involved stakeholders [40].

Process model visualization (III). The pragmatic means *visualization*, *simulation*, and *animation* are the basis for the concept *process model visualization*. This concept comprises the alternative visualization of a process model's content. In other words, elements of a process model are depicted by alternative visual representations of non-model elements that substitute the original model elements. This concept also covers process animations. The use of visualization mechanisms enables an improved and understandable process model representation [9, 10, 41]. Whereas model transformation (II) relies on restructuring or visualization with alternative model elements, model visualization makes use of non-model elements.

Process model description (IV). *Process model description* comprises the pragmatic means *model paraphrasing*, *explanation*, and *translation* [27, 32]. This concept covers textual descriptions or explanations of a process model to raise its understandability. This, for instance, includes the automatic generation of textual descriptions capturing the process logic as depicted in a process model. The generation of natural language process model descriptions with explanatory character supports model understandability as it allows focusing on process model semantics rather than syntax. In contrast to the concepts (II) and (III), this concept makes use of texts and does not incorporate graphical elements.

4.2 Methods for Supporting Model Understandability in BPM

The identified literature was classified using the concepts explained above. The classification is presented in a concept-centric matrix (see Table 2) as proposed in [33]. The previously introduced concepts are not disjunctive. Consequently, a method can be assigned to more than one concept.

Modeling support. In total, there are 35 methods supporting the modeling process, which can be divided into three different groups, namely a) tools using collaborative technologies (No. 31-33, 38-53), b) methods providing new or extended languages (No. 9, 11-13, 16, 65) and c) tools using existing modeling languages (No. 6, 8, 17, 19, 29, 55-56, 58, 60, 63). Tools using collaborative technologies facilitate process modeling with the support of collaborative technologies such as commenting or text- and/or audio-based chats for supporting model understandability. Some methods of this concept focus on new modeling languages claiming to be less complex and easy to understand. Methods using existing modeling languages try to support model understandability by employing those languages in specific ways or adapting some existing modeling methods for process modeling.

Process model transformation. In total, the literature search led to 41 methods that are concerned with process model transformation. 22 out of 41 methods focus on altering the model's physical structure (No. 1-7, 10, 11, 14, 15, 18, 23, 25, 30, 42, 49, 51-53, 64). Generally speaking, these methods abstract from insignificant process model information, i.e. they focus on relevant information and omit irrelevant parts of a process model. In contrast, 28 out of 41 methods change the model's presentation, i.e. its appearance, scheme or layout (No. 6, 14, 19, 25-27, 31-36, 42, 48, 51-53, 56-62, 66-69). A transformation of a model's presentation does not change its physical structure to highlight relevant model information [39].

Process model visualization. The concept-centric matrix indicates that nine methods enable some kind of process model visualization. In this set of methods, the simplest form of process model visualization is accomplished by the use of additional non-model images (No. 20, 26). Advanced methods (No. 33, 31, 28, 32, 55) make use of 3D virtual world environments for visualizing a process model in a real-world like representation. The visualization of the token flow (No. 37, 66) in a process model is also a relevant implementation of this concept. The displayed token flow represents the execution order of activities to aid the analysis or validation of a process model.

Process model description. Five out of 69 methods are concerned with the generation and integration of process model descriptions capturing the process logic. Methods of this concept differ in the modeling language support and in the fashion, how they create process model descriptions. Methods can be generic as well as modeling language specific. Starting with a process model, descriptions are generated and integrated either automatically based on sophisticated algorithms (No. 21-22, 25, 54) or manually following specific guidelines (No. 24).

5 Discussion

According to the research question and based on the characteristics of cBPM presented in the research background, we discuss the concepts and their methods for supporting model understandability regarding their applicability in cBPM.

Modeling support and cBPM. Due to the increased number of stakeholders in cBPM [4], collaborating techniques for modeling are required. Therefore, modeling methods that integrate collaborative technology are promising (e.g. No. 32, 39). However, these methods support the modeling process that is mainly performed by modeling experts instead of domain experts. Thus, the increased semantic complexity perceived by domain experts is not overcome and can only be addressed by communication between domain experts and modeling experts.

The group of methods that provide new or extended modeling language strives to increase model understandability by focusing on reduced syntactic complexity of the modeling language (e.g. No. 13). However, new modeling languages require extensive implementation efforts as existing modeling practices need to be reorganized which is especially relevant in cBPM settings with many diverse stakeholders.

Another group of methods focuses on existing modeling languages that are used in specific ways (e.g. No. 6, 29). Such methods could lead to a closer integration of modeling experts and domain experts during the model creation. An advantage is less implementation effort since these languages may already be in use.

Process model transformation and cBPM. Methods that modify the model's physical structure to abstract from insignificant details reduce the complexity of process models. In this way, the diverse domain knowledge of the many participating stakeholders [5] is addressed as personalized model views contain only relevant process logic. Furthermore, these methods are relevant to preserve autonomy and privacy of collaborating organizations, which are of increased importance in cBPM [89]. They allow the omission of sensitive and confidential internal information (e.g. No. 3, 23).

Transforming the process model's presentation allows for tailoring the model elements to the specifics of stakeholders. However, the increased model complexity in cBPM [3] is not completely addressed as the number of activities and control flow relations is not reduced by changing its presentation. Especially, the aspect of privacy issues in cBPM settings is not targeted by those methods since they do not hide model elements. Therefore, these methods are only applicable in combination with structural transformations to ensure privacy (e.g. No. 6, 14, 25).

Process model visualization and cBPM. The visualization of process models overcomes difficulties in understanding modeling language elements, i.e. the syntax of language elements [10]. Consequently, visualizations allow focusing on model semantics rather than syntax. To handle the increased semantic complexity in cBPM [3], visualization methods can be used since they abstract from model syntax and thereby decrease complexity for domain experts with low modeling expertise. In contrast, process model transformation methods rely on the model syntax and are therefore less appropriate in cBPM.

Since processes are more complex in cBPM scenarios [3], more complex methods are required for increasing model understandability in general. Hence, within the group of methods for process model visualization, 3D virtual environments are superior to less comprehensive methods (e.g. No. 31, 33). However, confidentially of private activities remains an open issue in all methods that are subsumed under this concept.

Process model description and cBPM. The set of methods that create process model descriptions strives to increase model understandability by natural language representations of process models. The translation of process models to natural language reduces the relevance of understanding formal modeling syntax. In consequence, these methods are more effective than methods for process model transformation to increase model understandability in cBPM in general.

Apparently, generic methods are superior to methods that are dedicated to a specific modeling language. Many diverse stakeholders with different modeling conventions are involved in a cBPM scenario. Therefore, methods that can handle different modeling languages are recommended (e.g. No. 22, 25). Besides, privacy requirements are more easily met with manual instead of automatic methods.

6 Conclusion

The aim of this paper was to derive concepts for supporting model understandability in the context of BPM, present exemplary implementations of these concepts, and discuss their suitability in cBPM contexts. The identified concepts *process model transformation*, *process model visualization*, *process model description* and *modeling support* are promising to be useful for cBPM-specific issues, although to varying degrees. Process model transformation is useful for specifying views to hide confidential information, process model visualization and process model description are suitable to increase the model understandability for domain experts with low modeling experience and methods supporting the modeling itself provide valuable mechanisms for the collaborative development of business process models. In total, 41 implementations for model transformation were detected; nine methods deal with model visualization, five methods focus on model description and 35 implementations provide modeling support.

This paper contributes to research by providing an overview of methods for addressing model understandability that allows for the identification of academic voids and presenting four categories to classify such methods. Practitioners can use our results as guidance for the use in cBPM scenarios. In future research, our paper can be extended by a detailed comparison of the analyzed methods related to each concept. Additionally, the methods can be empirically validated regarding their applicability in cBPM contexts. Besides, it can be investigated whether factors that influence model understandability differ from traditional BPM to cBPM.

A Meta Model Based Extension of BPMN 2.0 for Mobile Context Sensitive Business Processes and Applications

Julian Dörndorfer[1] and Christian Seel[1]

[1] Hochschule Landshut, Computer Science, Landshut, Germany
{julian.doerndorfer,christian.seel}@haw-landshut.de

Abstract. Smart devices like smartphones or tablets have become ubiquitous, which affected many daily work activities like maintaining contacts via a mobile CRM anywhere, anytime. Thus, business processes can now be executed independently of an employee's location. In addition, mobile devices have the possibility to measure physical quantities through sensors, like location or acceleration. Moreover, the connection to wireless networks made it possible to query context information like customer history. These context information can be used to adapt mobile business processes and the mobile application that support them. But in order to use this advantage, mobile sensor data has to be reflected in the business process model. As current languages for process aware information systems, such as BPMN, do not support the influence of mobile context information, we propose an extension of the BPMN that will enable the modeling of mobile context sensitive business processes.

Keywords: Business Process Modeling, Context, Mobile Business Processes, DSML, BPMN Extension

1 The Impact of Context on Mobile Business Processes

The modeling and implementation of business processes is a standard approach in Information Systems theory and practice [1–5]. In the last few years, mobile devices like smart phones, tablets, wearables, etc., affected both the work of employees and employers and thus the modeling and conduction of business processes. In a survey by Intel Research [6], 47% of employees stated that they used smart phones for their daily tasks in the workplace. 18% of the respondents use tablets for their daily job. New issues like bringing your own device [7, 8] and mobile device management [9] illustrate the impact of using mobile devices in the workplace. For field worker, who visit customers, mobile device are even more common. This change from stationary computers to mobile devices also concerns business processes. Processes, which are supported by information systems became nomadic and can now be executed anywhere and anytime. However, not only the location of the execution has changed, but the sensors of mobile devices can also deliver valuable data that affect business processes. These data can be used to directly adapt business processes to the current context that is detected by sensors. Current sensors usually measure location, acceleration, brightness and, depending on the device, other physical quantities. In addition to

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Dörndorfer, J.; Seel, C. (2017): A Meta Model Based Extension of BPMN 2.0 for Mobile Context Sensitive Business Processes and Applications, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 301-315

connecting to the mobile or wireless network, they can query data from different information systems or other machines [10]. Therefore, mobile devices are capable of measuring context and evaluating it via algorithms. Thereby, DEY defines ‘context’ as any information that can be used to characterize the situation of an entity [11]. An entity can be a person, place or object which is considered relevant to the interaction between a person and an application. Context can be used to pre-select services to reduce the information overload for a user [12].

The various possibilities of mobile devices can support the user by making decisions in a business process or when carrying out a task. FALK and LEIST [13] were able to show that mobile applications have positive impact on business processes, like cost and time reduction, as well as quality and flexibility improvements. Furthermore, applications which measure and interpret the context can automatically execute parts of the business process without the involvement of any other party. Additionally, they can adapt the process, for example skip or block [14] an activity, and influence the execution. A good example are the employment protection inspectors. From time to time they have to control the working condition of the employees, the correct montage or installation of machines and their proper functionality. In some countries like Germany these regular inspections are prescribed by law like the ‘Betriebssicherheitsverordnung’ [15]. The inspectors have to check and to document different things depending on their location, time or presence of employees. If the inspectors are in an assembly hall, they could check the machines or, if the machines are running, they could control the work clothes. If the assembly hall has security areas, they could control the security mechanisms and precautions for the employees. All these tasks are mainly depending on context information, which can easily be accessed by smart devices. They also support the task executions by showing what to control and by documenting completed checkups. All these process steps are immediately interrupted if the context switches to emergency because of an accident.

This mobile context sensitive business process gives a good impression of how context data can be used to support and ease the work of employees and increase the efficiency of business processes. However, to plan mobile context sensitive business processes a modeling language has to support context. The standard languages in the area of information systems, like Business Process Model and Notation (BPMN), Event-driven Process Chain (EPC) or the Unified Modeling Language (UML), do not support the modeling of context [16–18]. However, some approaches were made to extend the standard modeling languages to improve the configuration and flexibility of them (cf. section 2), these approaches where neither designed for mobile business processes nor mobile sensor data.

As BPMN 2.0 [19] became the de-facto standard [20] and allows to automate business processes based on execution engines, it seems reasonable to extend BPMN with adaption to mobile context. Hence, the following research question (RQ) arise:

RQ.1: *To what extend could the standard elements of the BPMN 2.0 specification be used to model contextual influences?*

RQ.2: *How could extension of the BPMN be structured to ensure an appropriate modeling of mobile context sensitive business processes?*

The remainder of this paper is structured as follows: Section 2 introduces a brief overview about existing approaches and related work in this field. In the beginning of section 3 the existing BPMN elements are analyzed for the capability to express context (**RQ.1**). Thereafter, the requirements for the extension are discussed and collected. Section 4.2 presents a meta-model based BPMN extension (**RQ.2**). Afterwards an example model is shown in order to prove the applicability of the BPMN extension. The paper ends with a conclusion and outlook to further research in context sensitive mobile applications.

2 Related Work and Research Method

The term context was defined among others [21–23] by DEY [24]. DEY'S definition is well known and accepted in the scientific community. He also declares an application as context-aware "if it uses context to provide relevant information and/or services to user, where relevancy depends on the user's task" [24].

Several approaches have been conducted to integrate context into business processes. ROSEMANN et al. [25] claim that modeling languages have to be more flexible to model context. Further they state that an increased attention on flexibility took place in the research area, which leads to a decreasing time-to-market for products [26]. Therefore, the result is a demand for higher process flexibility [27]. In particular, ROSEMANN et al. show the limitation of the actual EPC language and the lack of supporting context modeling. They also present a framework that helps to understand the different types of context and their impact on business processes. In addition, they categorize the different influence factors of a business process. However, they do not present an appropriate way to integrate the identified context in a business process. C-EPC is an extension of EPC to make it more configurable for decisions at runtime [28]. In [29] an approach to identify all variants of a business process depending on its context is presented. LA VARA et al. aim to reveal all possibilities of a business process and integrate them into one model. The outcome is a large and complex model. A way to identify and apply context on business processes is introduced in [30]. However, it is more of a theoretical framework to identify context. But the authors do not show how a context sensitive business process could be designed.

Furthermore two extensions for UML are published by AL-ALSHUHAI and SIEWE. In [31] they are extending the class diagram with additional annotations. The second paper [32] expands the activity diagram to mark context sensitive areas or sequences.

HEINRICH and SCHÖN [33] mention that business processes must consider „non-static" context events which change the process conduction, like an upcoming thunderstorm in an outdoor process. They further present an algorithm which supports automated process planning for context-aware processes, but no modelling representation in BPMN 2.0. CONFORTI et al. [34] presented an approach to cope with process risks based on sensor evaluation. Furthermore, they presented a way to model these risks and when they occur. However, they see sensors only as a source for risk evaluation, but context and its evaluation via sensors is more than only risk analyzation for business processes.

All of the presented papers do not consider how to model mobile context sensitive business processes. Therefore, this paper aims to present a new context extension for BPMN and creates a new artifact based on the design research approach by HEVNER et al. in [35]. Therefore, the meta-model of the extension will be created with Meta Object Facility (MOF) 2.0 [36]. New notation will be developed and a guideline to assist the user presented.

3 Requirements on Context Modeling of Mobile Business Processes

3.1 Analysis of the Existing BPMN Elements

To answer the **RQ.1** the BPMN 2.0 core elements will be examined in this section. They offer a few possibilities to model contextual mobile business processes. These possibilities consist of all the existing gateways (exclusive, inclusive, complex etc.) or intermediate events. Modeling context in mobile business processes using only gateways leads to a large and confusing model (cf. figure 1). Intermediate boundary events, which could be attached on activities, would be another reasonable option to model context influences. However, no event exists that really matches the description of context. For example the intermediate event *Message* "can be used to either send a Message or receive a Message" [18]. It can be used to symbolize that a context change "sends" an information, which leads to a reaction. At a first glance this looks like a promising method to model context, but a closer look reveals the problem. The event *Message* is, like other alternative events, very generic and could have several meanings. In addition, there is no possibility to describe a proper context expression. The result of using this event for depicting context influences would be a large documentation, which is counterproductive to the aims of a process visualization. Moreover, existing BPMN notation cannot sufficiently cope with non-static context [33], like changing parameters at runtime. A mix of intermediate events and gateways seems to be even worse. Confusing models with a documentation is not the idea of business process modeling. The result of the analysis is, that the existing elements of BPMN cannot be used to model context.

However, the specification of the BPMN offers a possibility to extend existing elements or add new elements to it [18]. To develop an extension of the BPMN, the requirements have to be imposed and discussed.

3.2 Requirements for the Extension

As described before, no explicit symbol or label exists which marks that an activity is influenced by context. Furthermore, not just one activity but a whole process sequence could depend on context data. In the example from section 1 an employment protection inspector has been introduced. She or he controls the working and security conditions at the workplace and inspects machines.

Figure 1 depicts a simplistic inspection process. Depending on her or his location (office building or different assembly halls) and present workers, she or he controls the first-aid kit or the security mechanisms. However, it is difficult to see that an activity or sequence depends on context information. Many decisions have to be made and modeled by gateways, which leads to large and complex models. Thus, the first requirement for the extension is an element which marks an activity or a process sequence depending on the context.

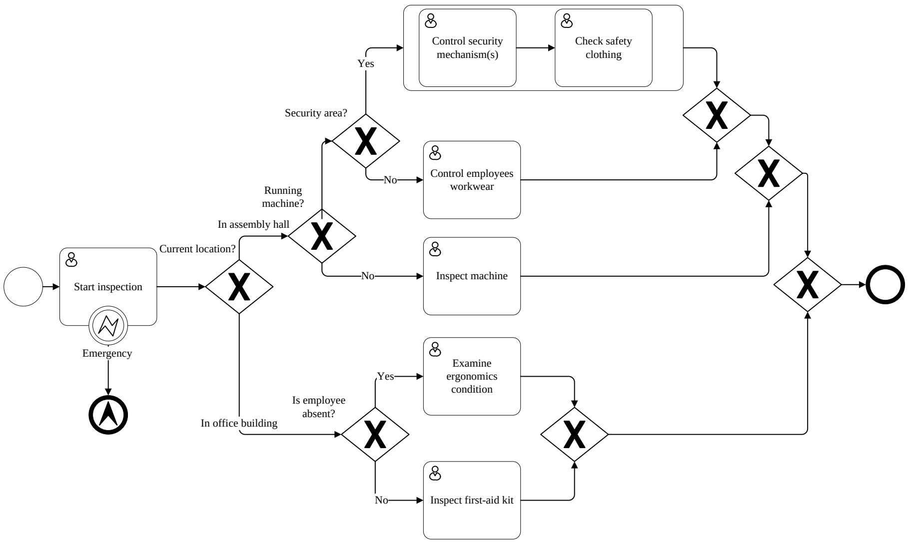

Figure 1. “Employment protection process” with BPMN 2.0 core elements

BPMN events are divided into interrupting and non-interrupting. Also a changing context can be an interrupting or non-interrupting event for an activity or sequence. For instance, if an emergency happens in the assembly hall, the inspector would take suitable measures and she or he would interrupt his or her current activity. At the moment, it is hard to model such an occurrence, because every activity in the process would have an attached exception event, like the one depicted in figure 2.

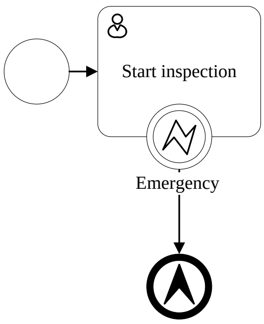

Figure 2 – Example for exception modeling in traditional BPMN 2.0

This would inflate the model unnecessarily. However, not every context change leads to an interruption of the current activity or sequence. Let us assume that a shift change happens during the first-aid kit check. Nevertheless, the context event “shift change” does not interrupt the activity “inspect the first-aid kit”. Therefore it is required that context events can be interrupting or non-interrupting. Another requirement is to express context dependencies in a short but clear way. A decision can depend on more than one context data. A textual description could lead to long sentences or even to an extra documentation file. To avoid this, a brief description method should be developed and applied.

The time to evaluate the context is important. Depending on the concrete business process, two possibilities exist. First, the context measurement is necessary at one explicit point in time. The evaluation of the context “location” only needs to be queried at the beginning of the inspection, because the location remains unchanged. In other processes the context information will be evaluated continuously. The context information “emergency” has to be queried in a tight frequency (e.g. 2 seconds) to show supportive information on the smart devices. It would be impractical to query this information only once at the beginning. Therefore, it must be possible to express the time of evaluation in the mobile business model to cope with non-static context.

In section 1 the advantages of using a standard modeling language have been discussed. To utilize these advantages the extension has to be compatible to the BPMN 2.0 standard. Thus, this is an additional requirement for the extension.

Context is measured through sensors. We define sensors not only as devices that detect and respond to a physical in- or output, like a hygrometer or a temperature sensor. It could also be a database or an application from which information could be requested or even any machine that is accessible via a network connection. In addition, a context information could be based upon different sensors. For example the context information “weather” is based on the following sensors: “temperature”, “humidity”, “condensation”, etc. Furthermore, the context information “weather” could be a “sensor” for the context “traffic”, in order to warn of snow in a traffic information system. So, context and its sensors could have interdependencies. This shows that context information is hard to model due to its complexity. Therefore, we decided to split the sensor modeling from the BPMN model and introduce an extra model. A link will be established to connect these two models. All the discussed requirements of this section are summarized in Table 1.

Table 1 - Requirements for the extension

Requirement	Description	Model
Context marker	A way to mark an activity or a sequence as context depending.	BPMN extension
Context event is interrupting / non-interrupting	A context event can be interrupting or non-interrupting.	BPMN extension

Requirement	Description	Model
Context expression language	Express a context condition in a brief way.	BPMN extension
Evaluation point	The point in time at which the context information should be evaluated.	BPMN extension
Compatibility to BPMN 2.0	The extension has to be compatible to BPMN 2.0.	BPMN extension
Sensor modeling	A possibility to model the dependencies of a context information to sensors or other context information.	Dedicated DSML for sensor modeling

4 Meta Model Based Extension

4.1 The BPMN Extensibility

A common way to extend modeling languages is a meta model extension [37]. A meta model is besides a notation and a guideline ([38] p. 36) [39] the first step to develop a complete modeling technique. A meta model is a model (M2) which describes a language (L1) to create a model (M1) of an object [40]. BPMN describes all of its elements in a class diagram, which is the meta-language for it. In addition, the BPMN specification itself describes a mechanism to extend the model to the needs of domain ([18] p. 57). The mechanism ensures the core validity and enables a way to integrate domain specific concepts. It consist mainly of four classes: Extension, ExtensionDefinition, ExtensionAttributeDefinition, ExtensionAttributeValue. These classes allow to expand existing elements through additional attributes or to enhance the BPMN meta model. To meet the compatibility requirement to BPMN 2.0 we use this well described mechanism to extend the BPMN model.

4.2 Meta Model of the Context Extension

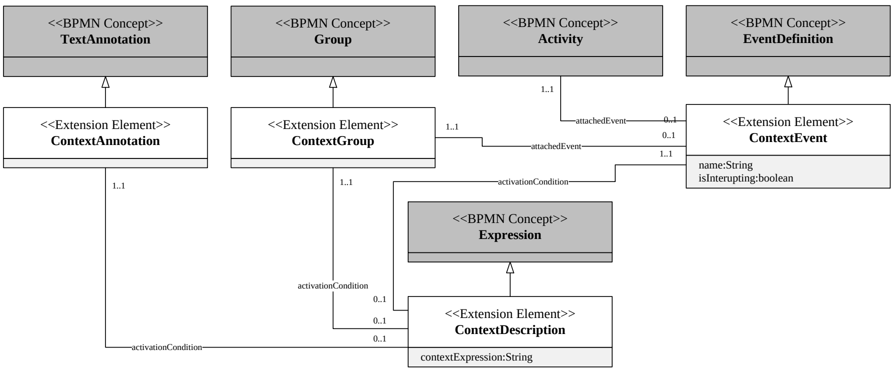

Figure 3. Meta model of Context4BPMN

Based on the in section 3.2 described requirements a meta model for Context4BPMN has been developed. The result is depicted in figure 3. Object Management Group's (OMG) standard BPMN classes are colored in grey. To mark context sensitive areas in a BPMN the Group class is extended by the *ContextGroup* class. The *ContextEvent* class creates the new context event which can be interrupting and non-interrupting as well as attached to an activity or a *ContextGroup*. Whether it is interrupting or not, is represented by the boolean variable. The *ContextDescription* class inherits from the *Expression* class to allow expressing the activation conditions of an activity or sequence. A *ContextDescription* includes the *contextExpression* to define the activation conditions, which are stored in a string. The grammar of the expression is explained in section 4.3. The *ContextDescription* could be used by the *ContextAnnotation*, *ContextMarker* and *ContextEvent*.

4.3 Syntax of the Context Extension and Example

In figure 4 the new element's graphical notations of the Context4BPMN extension are presented. The first two elements are the *Intermediate Context Events*, which add two new event types to the *Event* elements. The first element with the two solid circles and the eye is the *Interrupting Context Event*. Thereafter comes the *Non-Interrupting Context Event*. Both can be attached on *Activities* or *ContextGroups* concluded from the meta model. The *Context Annotation* is an enhancement of the *Text Annotation*. A little icon in the upper inner corner marks this new element. It can be attached to nearly every element like the "original" *Text Annotation*. The last element is the *Context Group,* which marks a activity or a sequence as context depending.

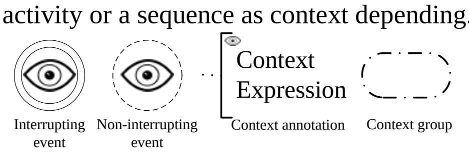

Figure 4. The new notations

```
<ContextExpression>::= [<EvaluationPoint>";"]<ContextTerm>
<ContextTerm>::= <Variable> <Comparison> <Value> |
  <ContextTerm> <LogicOperator> <ContextTerm>
<Comparison>::= "=" | "!=" | "<=" | ">=" | "<" | ">"
<LogicOperator>::= "AND" | "OR" | "XOR"
<EvaluationPoint>::= "Evaluation Point = continuous @"
  <Interval>| "Evaluation Point = " <Time>
<Time>::= -->"TimeDefintion according to RFC 5322"
<Interval>::= -->"IntegerNumber" "msec" | "sec" |"min" |
  "hours" | "days"
<Variable>::= -->"StringIdentifier in UTF-8"
<Value>::= -->"StringIdentifier in UTF-8"
```

Figure 5. EBNF Grammar for context expressions

In order to express context in a structured way that can be evaluated automatically a context expression language is developed. The context free grammar for this language has been defined in the extended Backus–Naur Form (EBNF) [41] in figure 5. To shorten some basic definitions, like integer numbers or date, we link with "-->" to standards, like the formal definition in RFC 5322 for date formats. A context expression contains a context term, which basically consists of "variable" "comparator" "value". The "variable" is the name of the context, like "location" or "status". It has to be unique in a business process and is also the link to the sensor model declaring how to measure it. Examples of the language are presented in figure 8.

4.4 Guideline for the Extension

To get a complete modeling technique a guideline for the modeler to apply the language extension is necessary ([38] p. 36) [39]. Three initial situations of mobile context sensitive modeling exists. First, a new process has to be modeled from scratch. Second, an existing process has to be remodeled as context sensitive. The last situation is when different variations of a business process depending on context variables exist and have to be merged into one business model. The first two situations differ only in the beginning, when a new business process has to define its activities, whereas an existing process has to be decomposed. Hereafter, the next steps are identical. Figure 6 and figure 7 are depicting the guideline for the different situations, which are modeled in BPMN. The guideline for the first and the second situation are an expanded version from the "procedure for context identification" by ROSEMANN et al. [25]. If a process exists, a decomposing would be necessary to get a list of activities, whereas for a new process a procedure has to be defined. At the end of both tasks a list of activities would be the outcome. The next step would be to determine context influences. The aim of this step is to identify the relevant context, which will be used in the next step to detect the context depending activities. Hereafter, a mobile context sensitive business process model could be developed with the identified context depending activities.

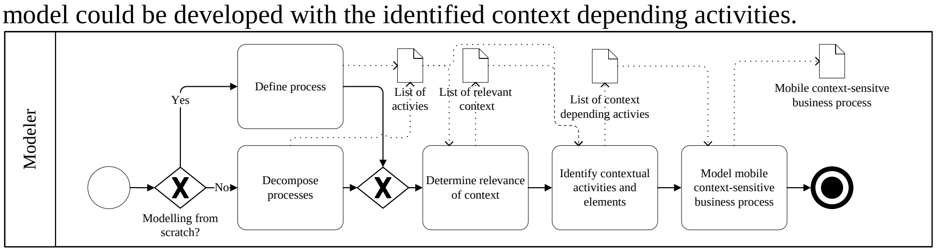

Figure 6. Guideline for initial situation one and two

If different variations of the same business process exist, the first task has to determine all variations. The output, which is a list of a variations, will be used to identify the relevant context, causing the variations. The third step is to merge all alternatives into one business model. For this task model matching algorithms can be used like the one proposed in [42]. Identical activities or sequences are context independent, whereas deviations in the models are most likely context depending. This holistic model will be used to identify the context depending activities or sequences.

These activities together with the relevant context variables will be used to model the context sensitive business process.

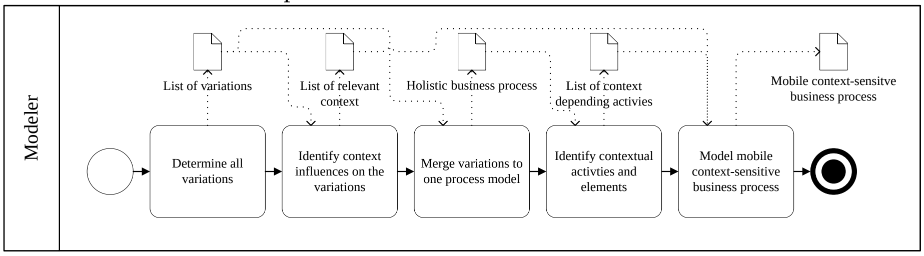

Figure 7. Guideline for the third initial situation

5 Discussion and Further Research

5.1 Requirement Examination

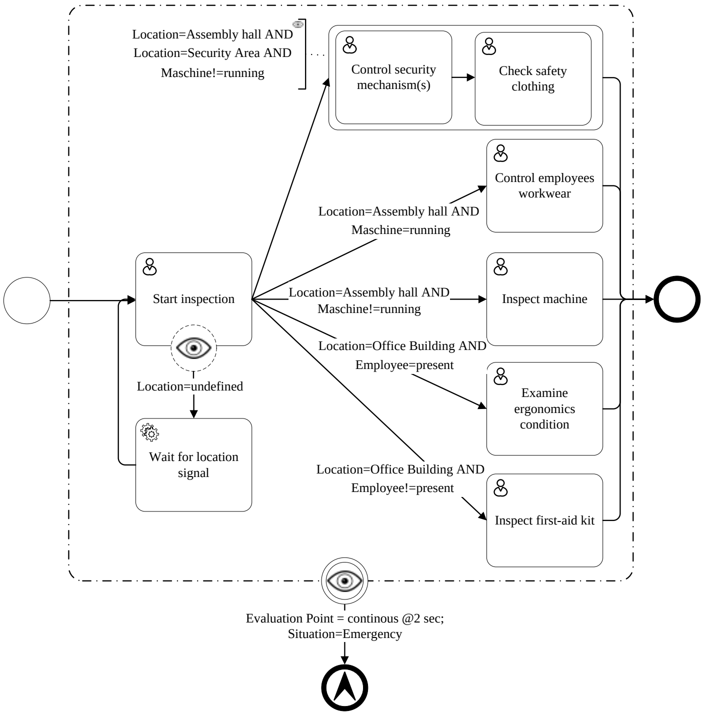

Figure 8. Inspection example depicted with the extension Context4BPMN

As stated in the beginning of this paper, it was intended to develop a possibility to model mobile context sensitive business processes. Therefore, we aimed to create an extension for BPMN to save effort and time in developing and establishing a new domain language profiting from well-known mechanisms and tool support. A brief evaluation of the created artifact as recommended by HEVNER et al. [35] will be presented. Figure 8 again depicts the example “employment protection” from section 3.2, but utilizing the new elements. The whole sequence is context depending, therefore the context group marks all depicted activities. Attached to it is an interrupting context event, which will be triggered if the situation changes from normal to emergency (non-static context). The situation could be changed at once, therefore the information is requested every 2 seconds. It would be displayed in the supporting mobile application. Further steps in the process would be defined in the catching escalation event. The “Start inspection” activity now has the non-interrupting context event attached to define the task if no location could be determined by the application.

Afterwards, one activity depending on the evaluated context will be selected. This can be seen as selecting an activity out of a pool of activities at runtime. The selection will be done by evaluating the context expression. These expressions are shown on the sequence flows and in the context annotation, attached to the brief sub-process.

Table 2 depicts the applied process steps for a certain context situation. For instance, the first row shows the process when the inspector is in the assembly hall, the machine is not running and no emergency interferes the inspection.

Table 2. Different versions of the process at runtime

Variation	Context	Applied version of the process
1	Assembly hall && machine not running && no emergency	2	Assembly hall && machine running && no emergency	3	Office building && employee present && emergency	
In section 3.2 a table with the requirements for the extension was introduced. To reconcile the requirements with the developed extension features we conducted a comparison.

Table 3. Comparison between the requirements and the features of Context4BPMN extension

Requirement	Feature	Match
Context marker	Context Group	✓
Context event is interrupting / non-interrupting	Intermediate Context Event	✓

Requirement	Feature	Match
Context expression language	Context expressions could be placed on flows and in Context Annotations	✓
Evaluation point	The Evaluation point can be stated in the context expression language	✓
Compatibility to BPMN 2.0	The extension uses the BPMN enhancement mechanism to secure the compatibility to the 2.0 version	✓
Sensor modeling	Due to lack of space for this paper the sensor model could not be presented. Only the link to it is established. Therefore, this feature is not completely described	-

As can be seen from table 3 all direct requirements to the BPMN extension are fulfilled and depicted in figure 8. A context marker is established as a context group element in the extension. Even though two intermediate context events were added, one interrupting and one non-interrupting, context expressions can now be stated on flow elements or on context annotations. It is also possible to express an evaluation time in the context expression language. A link to the sensor model is as well established. Hence, it can be claimed that all stated requirements are fulfilled.

5.2 Outlook

The main contribution of this article is to provide an extension to model mobile context sensitive business processes. It provides the possibility to model engineers to plan such processes in a precise, detailed and comprehensive way. It also enables to model the influence of context, like intermediate events on groups, which has not been available before.

There are some tasks for further research in this area: First of all, a way to model the relationships between context and sensors, furthermore, to model the interdependencies between two pieces of context information. The reason to prefer the creation of a new language instead of integrating it into a standard language like BPMN is that at firstly the model would become unnecessarily big and complex. Secondly, the inter-dependencies of context information and measuring by sensors is not a necessary part of a business process language.

Modeling a business process is just the first step in the business process lifecycle (BPL) [43]. The implementation, execution and controlling are the remaining steps in the lifecycle. Since mobile context sensitive business processes obviously need to measure context and are supported by an application on smart devices, an automated or semi-automated way to generate code from the business process would be helpful to increase the fluency between modeling and implementation phase. The logical context expressions can be used to generate decisions in the application program. Furthermore, the sensor model can be utilized to pre-generate classes and interfaces. In an additional step the use of the gathered context data from the execution of a business process will be investigated. They could be used to identify problems in the execution and therefore interesting for the controlling phase.

Systematische Identifikation von Fachkomponenten mit SOM

Sebastian Schlauderer, Martin Robel, and Thomas Friedrich

University of Bamberg, Chair of Industrial Information Systems, Bamberg, Germany
{sebastian.schlauderer, martin.robel, thomas.friedrich}@uni-bamberg.de

Abstract. Aufgrund der stetig wachsenden Herausforderungen ist es für Unternehmen heutzutage von großer Bedeutung, Informationssysteme flexibel und kostengünstig anpassen zu können. Hierfür ist es jedoch unabdingbar, dass die Software-Bausteine eines Systems entsprechend systematisch abgeleitet und gestaltet werden. Die Business-Component-Identification-Methode (BCI-Methode) verspricht vor dem Hintergrund der Komponentenorientierung die Identifikation geeigneter Software-Bausteine zu gewährleisten. Ein Vorteil dieser Methode ist es, dass sie unabhängig von der Art der zugrundeliegenden konzeptionellen Modelle angewandt werden kann. Da die Qualität der Modelle jedoch die Güte der gefundenen Lösung maßgeblich determiniert, ist es indes fraglich, welche Modellarten sich besonders gut eignen. Die Methodik des Semantischen Objektmodells (SOM) bietet einen ganzheitlichen und etablierten Ansatz zur systematischen Beschreibung des Fachkonzepts. Im Rahmen des Artikels wird daher untersucht, inwiefern die Kombination von BCI- und SOM-Methodik zu validen Ergebnissen führt. Hierfür wird insbesondere untersucht, welche Modelle betrachtet werden müssen und welche Beziehungen zu unterscheiden sind.

Keywords: Komponentenorientierung, SOM-Methodik, BCI-Methode

1 Motivation

Die Entwicklung von Informationssystemen steht heutzutage vor einer Vielzahl teils konterkarierender Herausforderungen. Einerseits ist es notwendig, auf sich ändernde Markbedingungen schnell reagieren zu können und flexibel Funktionalität hinzufügen zu können [1]. Andererseits wächst der Kostendruck auf die Entwicklungsabteilungen [1]. Vor diesem Hintergrund verspricht die modulare Entwicklung von Informationssystemen eine Vielzahl an Vorteilen [2], [3]. Durch die Strukturierung von Informationssystemen in einzelne, lose gekoppelte Bausteine wird es ermöglicht, Informationssysteme flexibel anzupassen oder zu erweitern. Durch die Wiederverwendung dieser Bausteine, auch Fachkomponenten genannt [4], können weiterhin Entwicklungszeiten und Entwicklungskosten drastisch gekürzt werden [5]. Im Vergleich zur reinen Objektorientierung kann durch das Zusammenfassen mehrerer Objekte zu einer Fachkompo-

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Schlauderer, S.; Robel, M.; Friedrich, T. (2017): Systematische Identifikation von Fachkomponenten mit SOM, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 316-330

nente das Problem fragiler Basisklassen eingegrenzt werden und gleichermaßen sichergestellt werden, dass Vererbungsstrukturen das Geheimnisprinzip nicht durchbrechen [6].

Aufgrund der erwarteten Vorteile wurde eine Vielzahl an Methoden und Werkzeugen sowohl in der wissenschaftlichen Literatur als auch in der Praxis vorgeschlagen, welche die Konzeption, die Implementierung sowie die Assemblierung von Fachkomponenten zum Ziel haben [2], [6-9]. Insbesondere die Frage, wie ein Informationssystem möglichst effizient in Fachkomponenten partitioniert werden kann, ist von zentraler Bedeutung, da hierdurch die Anpassbarkeit des Systems sowie die Wiederverwendbarkeit der Fachkomponenten determiniert wird [10]. Einerseits kann die Wiederverwendbarkeit der Fachkomponenten erhöht werden, indem möglichst feingranulare Dienste zusammengefasst werden, die eine sehr spezifische Funktionalität anbieten [6]. Andererseits wird hierdurch jedoch die Anzahl an Fachkomponenten erhöht, was deren Assemblierung in einem Informationssystem erschwert [6].

Um diesen konfliktären Zielen gerecht zu werden, wurde unter anderem die sogenannte Business-Component-Identification-Methode (BCI-Methode) vorgeschlagen, die auf Basis von konzeptionellen Modellen eine heuristische Optimierung der Problemstellung vorsieht [11]. Ein Vorteil der Methode verspricht insbesondere zu sein, dass sie unabhängig von der Art der zugrundeliegenden Modelle verwendet werden kann. Die als Ausgangsbasis verwendeten konzeptionellen Modelle determinieren damit jedoch auch maßgeblich die Qualität der gefundenen Lösung. Dies wirft die zentrale Frage auf, welche Modelle und Notationen sich für die Komponentenfindung besonders gut eignen. Mit Blick auf die Etablierung komplexer, innovativer Geschäftslösungen als soziotechnische Systeme im Rahmen des Business Engineering [12] wächst die Bedeutung einer ganzheitlichen Betrachtung der Modellierung auf der strategischen, konzeptionellen sowie technischen Ebene. Das Semantische Objektmodell (SOM) stellt einen solchen ganzheitlichen Modellierungsansatz dar [13-16]. Die Unternehmensarchitektur des SOM-Ansatzes differenziert die drei Modellebenen Unternehmensplan, Geschäftsprozessmodell und Ressourcenmodell, welche jeweils aus einer struktur- sowie verhaltensorientierten Sichtweise in Form textueller Beschreibungen bzw. semi-formal durch Diagramme beschrieben werden [16]. Während das Vorgehensmodell die Schritte zur Erstellung der einzelnen Artefakte festlegt, stellen Metamodelle die Integration der Sichten sicher. Die konsequente Verfeinerung des Unternehmensplans hin zum Ressourcenmodell in einem Top-Down-Ansatz ermöglicht die Erstellung eines hochwertigen und vor allem hinsichtlich der Anforderungen vollständigen Fachkonzepts, das als Ausgangsbasis wesentlich zum Erfolg der Komponentenfindung beiträgt. Während der SOM-Ansatz also eine etablierte Methodik bereitstellt um das Fachkonzept detailliert zu beschreiben, unterstützt die BCI-Methode die Transformation von Fach- zu Systemkonzept. Trotz dieser vermeintlich symbiotischen Beziehung wurde das Zusammenspiel beider Methoden bisher nicht wissenschaftlich untersucht, weswegen sich insbesondere folgende Forschungsfragen ergeben:

1. Inwiefern eignet sich die SOM-Methodik zur Unterstützung der Modularisierung von Informationssystemen mithilfe der BCI-Methode?
2. Welche SOM-Modelle tragen konkret zur Erlangung valider Ergebnisse bei?

3. Welche Beziehungsformen lassen sich in den SOM-Modellen differenzieren und wie lassen sich diese bei entsprechender Eignung auf die BCI-Methode abbilden?

Zur Beantwortung der Forschungsfragen wird in Abschnitt 2 zunächst der theoretische Grundstock gelegt. Im Rahmen von Abschnitt 3 wird ein Fallbeispiel eingeführt, das die Anwendung der BCI-Methode auf Basis der verschiedenen SOM-Modelle demonstriert. Die Ergebnisse dieser prototypischen Anwendung werden anschließend in Abschnitt 4 diskutiert. Abschließend wird in Abschnitt 5 der Artikel kritisch zusammengefasst und ein Ausblick für weitere Untersuchungen gegeben.

2 Theoretische Grundlagen

In den folgenden Teilabschnitten werden grundlegende Begriffe komponentenbasierter Systeme, der BCI-Methode sowie der Modelle des SOM-Ansatzes erläutert.

2.1 Komponentenbasierte Systeme

Ein generelles Modell komponentenbasierter Anwendungssysteme wird im Common Business Component Model (COBCOM) erläutert [17]. Neben der Architektur komponentenbasierter Systeme wird hier zudem der Lebenszyklus von Fachkomponenten skizziert. Im Allgemeinen basieren komponentenbasierte Informationssysteme auf einer dreistufigen Client/Server-Architektur. Neben zusätzlichen technischen Anpassungen, die etwa der Vermittlung zwischen Dienstgebern und Dienstnehmern dienen, bspw. mithilfe sogenannter Object Request Broker, ist der zentrale Unterschied die weitere Differenzierung der Verarbeitungslogik [17]. Hierfür wird die betriebliche Funktionalität weiter in sogenannte Fachkomponenten aufgespalten.

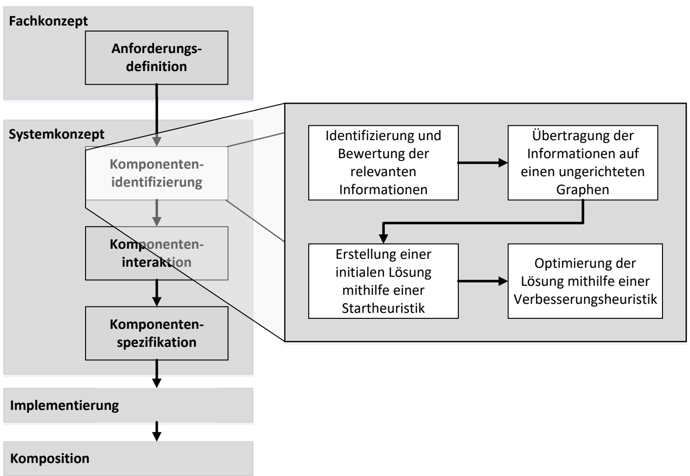

Abbildung 1. Entwicklungsprozess komponentenbasierter Systeme (links) [8] und Ablaufschritte der BCI-Methode (rechts)

Definition 1 [Fachkomponente]: „Eine Fachkomponente ist eine Komponente, die eine bestimmte Menge von Diensten einer betrieblichen Anwendungsdomäne anbietet" [4]. Fraglich ist jedoch, welche Menge an betrieblichen Diensten in einer Fachkomponente zusammengefasst wird. Der Entwicklungsprozess komponentenbasierter Systeme sieht daher auch einen eigenen Schritt zur Identifikation von Fachkomponenten vor (Abbildung 1). Es gilt den Identifikationsprozess so zu gestalten, dass die Anzahl an Schnittstellen zwischen den Fachkomponenten minimiert wird, während die Kohäsion innerhalb der Komponenten maximiert wird [6], [18]. Da die beiden Ziele jedoch konfliktär sind ist die Lösung so zu gestalten, dass beide berücksichtigt werden. Hierfür soll zunächst ein grundsätzliches Verständnis für die beiden Ziele geschaffen werden.
Definition 2 [Kopplung und Kohäsion]: Kopplung beschreibt das Ausmaß, in dem die Elemente innerhalb einer Fachkomponente mit Elementen außerhalb zusammenhängen. Kohäsion beschreibt das Ausmaß, in dem die Elemente innerhalb einer Fachkomponente in Wechselbeziehung zueinanderstehen. Die Kohäsion kann dabei als Kopplung innerhalb einer Komponente verstanden und gemessen werden [19], [20].

2.2 Methoden zur Identifikation von Fachkomponenten

Bei der Partitionierung eines Informationssystems und der Aufteilung der Dienste auf einzelne Fachkomponenten handelt es sich um ein NP-vollständiges Problem [21]. Zur Lösung dieses Problems wurden in der Literatur diverse Methoden vorgeschlagen und diskutiert [11], [22]. Viele dieser Ansätze schlagen allerdings nur grobe Richtlinen vor [23-27] und sind daher sehr stark abhänging von der Erfahrung des Anwenders. Im Vergleich dazu gibt die BCI-Methode dem Anwender zwar Freiheiten in der Gewichtung der verschiedenen Beziehungen, gibt jedoch auch ein systemgestütztes und einheitliches Vorgehen vor. Weiterhin gibt es diverse Methoden die auf Matrix Analysen basieren [28-30]. Während diese Ansätze zwar leicht anzuwenden sind, können mit ihnen nur zwei Dimensionen untersucht werden, wohingegen die BCI-Methode grundsätzlich beliebig viele Dimensionen berücksichtigt. Abschließend gibt es auch Ansätze, für die kein Tool-Support identifiert werden konnte, so dass diese Ansätze im Rahmen des Beitrages nicht anzuwenden waren [31], [32]. Folglich wurde auf die BCI-Methodik zurückgegriffen. Die Methode geht im Wesentlichen in vier Schritten vor (siehe Abbildung 1): Im ersten Schritt muss der Systemarchitekt entscheiden, welche Informationen aus den konzeptionellen Modellen gewonnen werden können und diese bzgl. ihrer Relevanz bewerten. Typischerweise handelt es sich bei den konzeptionellen Modellen um Geschäftsprozessmodelle, Datenmodelle oder um Funktionsdekompositionsmodelle. In diesem Schritt ist es anschließend notwendig, die verschiedenen Beziehungsarten zu unterscheiden und bezüglich ihrer Relevanz zu bewerten. Hiermit ist dem Systemarchitekten die Möglichkeit gegeben festzulegen, welche Beziehungsarten möglichst innerhalb der Fachkomponenten verlaufen sollen. Es handelt sich dabei um den zentralen Schritt, mit welchem der Systemarchitekt das spätere Ergebnis beeinflussen kann. Im zweiten Schritt werden alle als relevant identifizierten Informationen auf einen ungerichteten Graphen übertragen, wobei alle Elemente als Knoten und alle Beziehungen zwischen ihnen als Kanten abgebildet werden. Im dritten Schritt wird zunächst eine Startlösung generiert. Hierfür wird bspw. mithilfe der „Start-Partition-Greedy"-

Heuristik [11] eine Liste erstellt, welche alle Beziehungen bzgl. ihrer Relevanz sortiert. Am Ende dieses Schrittes steht eine initiale Aufteilung von Elementen zu Fachkomponenten. Im vierten Schritt soll diese Aufteilung optimiert werden, d.h. es soll die Kopplung minimiert und die Kohäsion maximiert werden. Hierfür ist es zunächst notwendig, die beiden Maßzahlen mathematisch zu definieren (Formel 1 und 2):

$$Cou(p) = \frac{1}{2}\sum_{i=1}^{k}\sum_{u\in C_i}\sum_{v\notin C_i} w_{(u,v)} \tag{1}$$

$$Coh(p) = \frac{1}{2}\sum_{i=1}^{k}\sum_{u\in C_i}\sum_{v\in C_i, v\neq u} w_{(u,v)} \tag{2}$$

Die Anzahl an Komponenten, die in der initialen Lösung gefunden wurden, wird durch die Variable *k* beschrieben. $w_{(u,v)}$ steht für das Gewicht, welches die Relevanz zwischen den beiden Elementen u und v ausdrückt. Im Rahmen des „Kernighan-Lin"-Algorithmus wird anschließend eine Optimierung der gefundenen Startlösung vorgenommen [33]. Einerseits wird die Summe der Gewichte der Beziehungen minimiert, die zwischen verschiedenen Fachkomponenten verlaufen (Formel 3 - links). Andererseits wird die Summe der Gewichte der Beziehungen maximiert, die innerhalb der Fachkomponenten verlaufen (Formel 3 - rechts). Unter der Nebenbedingung, dass die in der Startlösung gefundene Anzahl an Komponenten konstant bleibt, lässt es sich mathematisch nachweisen, dass die beiden Ziele mathematisch äquivalent sind [11].

$$min_p\ \frac{1}{2}\sum_{i=1}^{k}\sum_{u\in C_i}\sum_{v\notin C_i} w_{(u,v)} \iff max_p\ \frac{1}{2}\sum_{i=1}^{k}\sum_{u\in C_i}\sum_{v\in C_i, v\neq u} w_{(u,v)} \tag{3}$$

2.3 Modelle des SOM-Ansatzes

Das Semantische Objektmodell (SOM) stellt einen objekt- und geschäftsprozessorientierten Ansatz zur Modellierung betrieblicher Systeme dar und unterscheidet bis auf die Ebene des Unternehmensplans jeweils unterschiedliche Arten von Diagrammen zur Beschreibung von Struktur und Verhalten [15], [16]. Auf Ebene der Geschäftsprozesse bildet die Verknüpfung von betrieblichen Objekten durch Transaktionen im Interaktionsschema (IAS) die Struktur, die Verbindung von Aufgaben (Vorgangstypen) über Ereignisbeziehungen im Vorgangs-Ereignis-Schema (VES) das Verhalten ab. Analog beschreibt das konzeptuelle Objektschema (KOS) auf Ebene des Ressourcenmodells die Struktur des zu spezifizierenden Anwendungssystems durch konzeptuelle Objekttypen (KOT) sowie deren Interaktions-, Generalisierungs- und Aggregationsbeziehungen. Interaktionsbeziehungen zwischen Vorgangsobjekttypen (VOT) spezifizieren schließlich das Verhalten im Vorgangsobjektschema (VOS). Durch Integration der verschiedenen Modelle über die Sichten und Ebenen hinweg lässt sich sicherstellen, dass keine relevanten Informationen bei der Modellierung verloren gehen. Vielmehr findet eine Verfeinerung von einer abstrakten hin zu einer spezielleren Betrachtung auf Anwendugssystemebene statt. Das Vorgehensmodell sichert mit der Vorgabe von Zerlegungsregeln sowie der Integration der Sichten über ein Metamodell explizit die Konsistenz, Vollständigkeit und in der Folge die für die Anwendung der BCI-Methodik entscheidende Qualität des Fachkonzepts.

3 Komponentenfindung auf Basis des SOM-Ansatzes

Aufbauend auf den theoretischen Grundlagen wird nachfolgend die BCI-Methode auf Basis eines praxisnahen Fallbeispiels in SOM dargestellt. Der Fokus liegt dabei auf der Identifizierung und Bewertung relevanter Informationen aus den SOM-Modellen.

3.1 Einführung Fallsbeispiel OnlineCars

Das folgende Fallbeispiel stellt vereinfacht die Vermietung und Auftragsabwicklung von Elektrofahrzeugen über ein Internetportal (OnlineCars) dar. Mithilfe der SOM-Methodik wurden schrittweise die Schemata der einzelnen Ebenen erstellt.

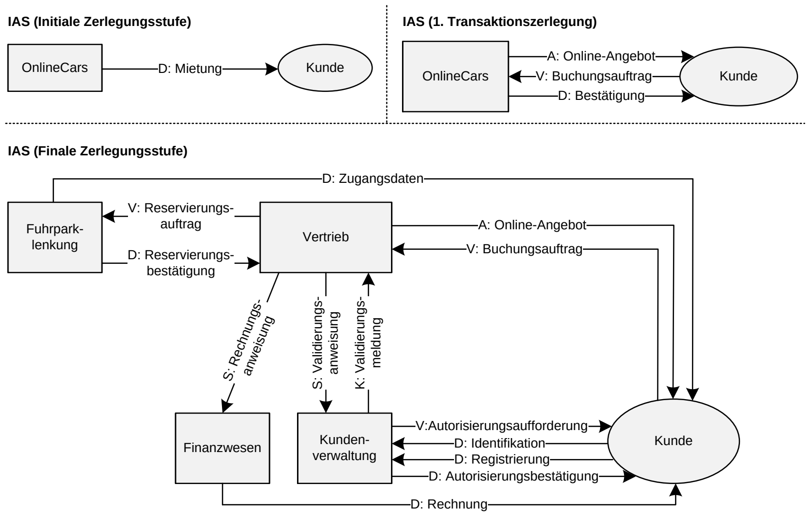

Abbildung 2. IAS des Fallbeispiels

Auf Geschäftprozessebene wird der Verleihservice in Abbildung 2 strukturorientiert in Form mehrerer Interaktionsschemata (IAS) dargestellt. Ausgehend vom initialen IAS wurden sukzessive Objekt- und Transaktionszerlegungen gemäß den Zerlegungsregeln des SOM-Ansatzes durchgeführt [16]. Während der Vertrieb dem Finanzwesen und der Kundenverwaltung hierarchisch übergeordnet ist, erfolgt die Koordination zwischen Vertrieb und Fuhrparklenkung sowie zwischen Vertrieb und dem Umweltobjekt Kunde auf Basis des Verhandlungsprinzips. Der Verleihservice erstellt als Leistung bei Vorliegen eines Buchungsauftrags neben der Autorisierungsbestätigung und der Rechnung auch die Zugangsdaten und übergibt diese dem Kunden. Die Leistungen werden nach Beauftragung bzw. Anweisung des Vertriebs von unterschiedlichen Objekten erbracht. Der Kunde übermittelt als Leistung aufgrund einer Autorisierungsaufforderung seine Registrierungs- bzw. Identifikationsdaten. In Ergänzung zum IAS beschreibt der Ausschnitt des VES in Abbildung 3 das Verhalten der betrieblichen Objekte im Geschäftsprozess. Der Empfang eines Buchungsauftrags durch den Vertrieb löst bspw. über ein objektinternes Ereignis die Sendung eines Validierungsauftrags an die Kundenverwaltung aus.

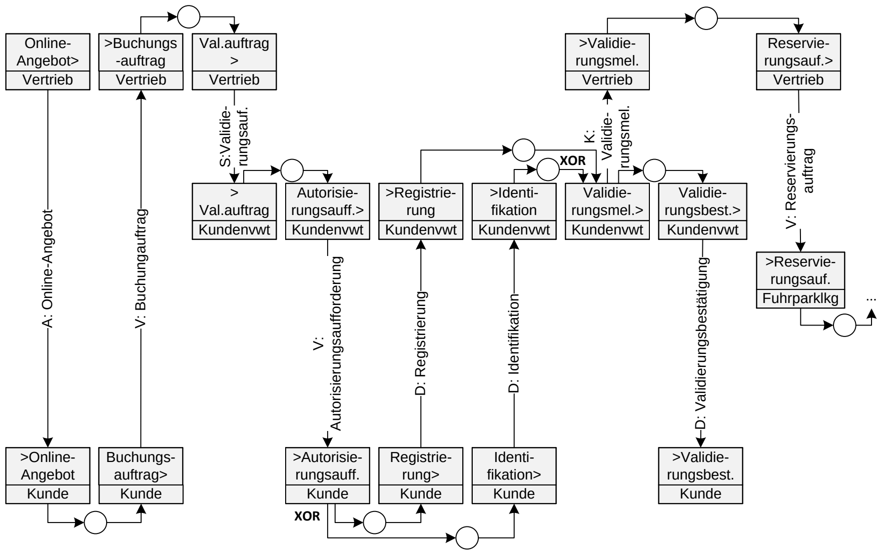

Abbildung 3. Ausschnitt VES des Fallbeispiels (finale Zerlegungsstufe)

Die Ableitung der Anwendungssystemspezifikation auf Basis der Geschäftsprozessmodelle IAS/VES in Form des KOS aus Struktursicht und des VOS aus Verhaltenssicht schließt die Modellierung des Anwendungsfalls ab. Abbildung 4 stellt das initiale und das konsolidierte KOS dar. Entsprechend des SOM-Ansatzes werden bei der Konsolidierung diejenigen KOTs entfernt, die mit nicht-automatisierten Aufgaben und Transaktionen korrespondieren [16]. Zudem werden KOTs, die sich in ihren Attributen und/oder Operatoren weitestgehend decken aus Redundanzgründen zusammengefasst. Im Fallbeispiel entstehen dabei die KOTs Autorisierung (*Validierungsauftrag*, *Autorisierungsaufforderung*) und Reservierung (*Reserverierungsauftrag* und *-bestätigung*). Es wurden keine KOTs entfernt, da sämtliche Aufgaben bzw. Transaktionen von dem spezifizierten Anwendungssystem unterstützt werden sollen. Zusätzlich werden im konsolidierten KOS die Beziehungsarten Interaktion (interacts_with), Aggregation (is_part_of) und Generalisierung (is_a) berücksichtigt.

Das für jedes betriebliche Objekt erstellte VOS wird in einer integrierten Darstellung in Abbildung 5 zusammengeführt. Analog zum KOS werden im VOS diejenigen VOTs entfernt, deren zugehörige Aufgaben nicht automatisiert werden. Ebenso werden VOTs zusammengefasst, deren Aufgaben aus Gründen der semantischen Integrität stets gemeinsam durchzuführen sind. Aus Gründen der Übersichtlichkeit wurden für das KOS und VOS des Fallbeispiels keine weitere Spezifikation, wie bspw. Zuordnung von Operatoren oder Definition von Nachrichten, vorgenommen. Die erzeugten Modelle auf der Geschäftsprozessebene (IAS/VES) sowie auf der Ebene der Anwendungssystemspezifikation (KOS/VOS) bilden die Grundlage für die Identifikation der relevanten Informationen im nächsten Abschnitt.

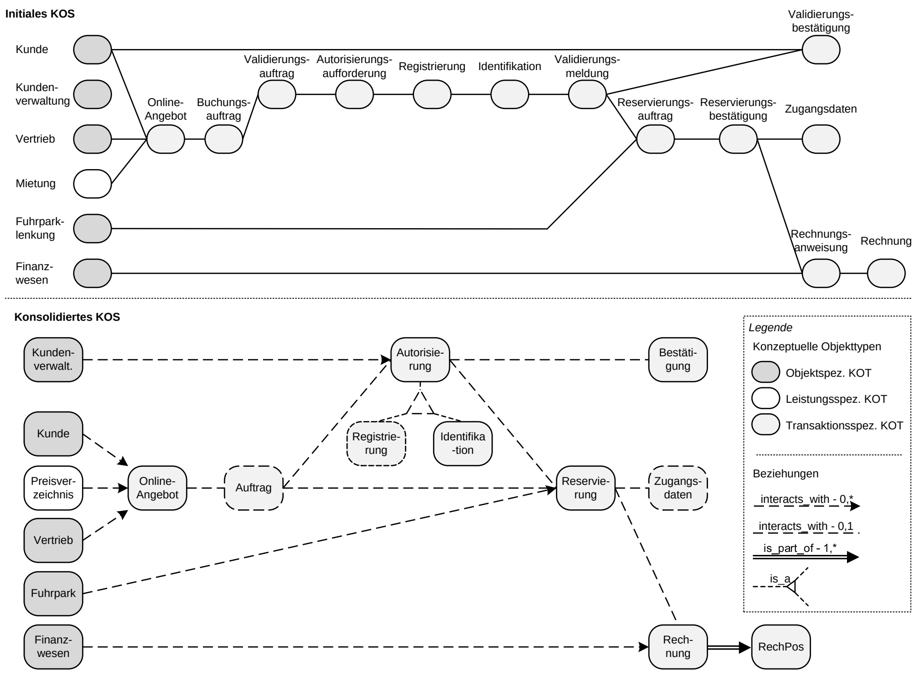

Abbildung 4. Initiales und konsolidiertes KOS des Fallbeispiels

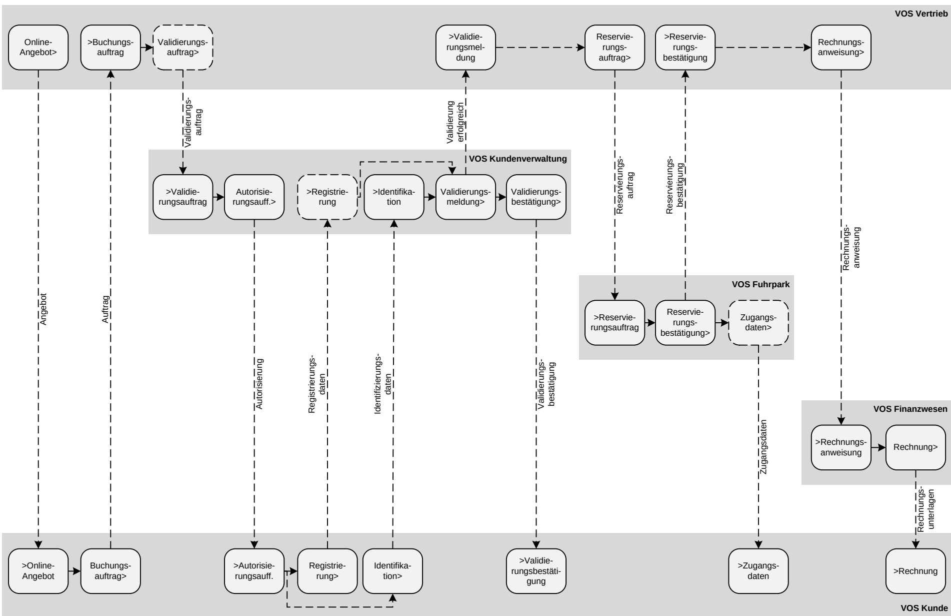

Abbildung 5. Konsolidiertes VOS des Fallbeispiels

3.2 Identifizierung und Bewertung der relevanten Informationen

Die Ergebnisse der Modellierung des Anwendungsfalls verdeutlichen bereits die Herausforderung bei der Entscheidung, welche Informationen bei der BCI-Methode zu berücksichtigen sind. Zum einen beziehen sich die Modelle des SOM-Ansatzes auf unterschiedliche Ebenen. Zum anderen wird innerhalb einer Ebene zwischen struktur- und verhaltensorientierten Modellen unterschieden. Zudem bauen die Modelle konsequent aufeinander auf und beschreiben damit ähnliche Sachverhalte.

Im Unterschied zu IAS und VES beinhalten KOS und VOS ausschließlich automatisierbare Elemente, wodurch Komponenten hervorgebracht werden können, die sich auch tatsächlich realisieren lassen. Gleichwohl entsteht aufgrund der Ableitung von KOS und VOS aus IAS und VES kein Informationsverlust, vielmehr wird eine Verfeinerung und Ergänzung hin zur Anwendungsspezifikation vorgenommen [16]. KOS und VOS bilden somit das Fachkonzept als Ausgangsbasis für die Komponentenfindung. In der systematischen Ausrichtung auf das Anwendungssystem als automatisierter Teil des betrieblichen Systems kann somit eine der Stärken von SOM ausgenutzt werden.

In einem weiteren Schritt werden die in KOS/VOS enthaltenen Beziehungen im Hinblick auf ihre Relevanz bewertet. Aufgrund der engen Kopplung von KOTs werden die Aggregations- und Generalisierungsbeziehungen im KOS relevanter eingestuft als Interaktionsbeziehungen zwischen KOTs. Zumindest theoretisch ließen sich zudem objektspezifische, leistungsspezifische und transaktionsspezifische KOTs differenzieren. Allerdings lässt sich nur schwer eine logische Begründung für die Einstufung der Relevanz geben. Interaktionsbeziehungen zwischen KOTs werden nicht berücksichtigt. Die Interaktionsbeziehungen im VOS lassen sich in Anlehnung an das VES nach objektinternen (objektinterne Ereignisse) und objektexternen Beziehungen (Transaktionen) differenzieren. Objektinterne Beziehungen verbinden Aufgaben bzw. VOTs innerhalb eines bestimmten betrieblichen Objekts und werden für die Komponentenfindung daher relevanter angesehen als objektexterne Beziehungen, die Aufgaben bzw. VOTs unterschiedlicher betrieblicher Objekte verbinden. Optionale Beziehungen (XOR), wie sie bspw. zwischen den VOTs >*Autorisierungsaufforderung* und *Registrierung*> bzw. *Identifikation*> bestehen, wird die geringste Relevanz zugewiesen. Objektexterne Beziehungen können als Teil einer Transaktion einer bestimmten Phase (Anbahnung, Vereinbarung, Durchführung) zugeordnet werden. Die Bewertung der Relevanz der verschiedenen Phasen lässt sich auch hier schwer logisch begründen, sodass objektexterne Beziehungen ohne weitere Differenzierung aufgenommen werden.

3.3 Übertragung der identifizierten Informationen auf einen Graphen

Die relevanten Informationen aus KOS und VOS müssen vor der Anwendung von Heuristiken der BCI-Methode auf einen Graphen übertragen werden. KOTs und VOTs werden als Elemente in Form von Knoten im Graphen abgebildet. Die Beziehungen zwischen den KOTs und zwischen den VOTs werden als ungerichtete Kanten dargestellt. Die fehlende Angabe der expliziten Zuordnung zwischen KOTs und VOTs in einem der Modelle führt zunächst zur Entstehung zweier unverbundener Teilgraphen. Es ist daher zur Erzeugung eines zusammenhängenden Graphen zu klären, welche KOTs mit welchen VOTs in Beziehung stehen. Grundsätzlich ist jeder VOT einem betrieblichen Objekt zugeordnet, dessen Name mit dem Namen des zugehörigen VOS korrespondiert. Die betrieblichen Objekte korrespondieren wiederum mit den entsprechenden objektspezifischen KOTs im KOS. Zunächst werden daher die einzelnen VOTs mit den objektspezifischen KOTs verbunden. Im Fallbeispiel korrespondiert bspw. der VOT *Online-Angebot>* mit dem VOS *Vertrieb*. Das VOS *Vertrieb* korrespondiert wiederum mit dem betrieblichen Objekt Vertrieb und dem objektspezifischen KOT *Vertrieb*. Es lässt sich damit eine Beziehung zwischen dem VOT *Online-Angebot>* und dem KOT *Vertrieb* herstellen. Aufgrund der im KOS durchgeführten Konsolidierung besteht jedoch die Möglichkeit, dass KOTs umbenannt oder mit anderen KOTs zusammengefasst wurden. Auf Grundlage der vorgenommenen Konsolidierungsschritte kann so bspw. der VOT *Rechnungsanweisung>* dem KOT *Rechnung*, welcher durch die Zusammenfassung der KOTs *Rechnungsanweisung* und *Rechnung* entstanden ist, zugeordnet werden. Nach der Verbindung der VOTs mit den KOTS veranschaulicht der in Abbildung 6 dargestellte Graph das Ergebnis der Übertragung der Objekte und Beziehungen.

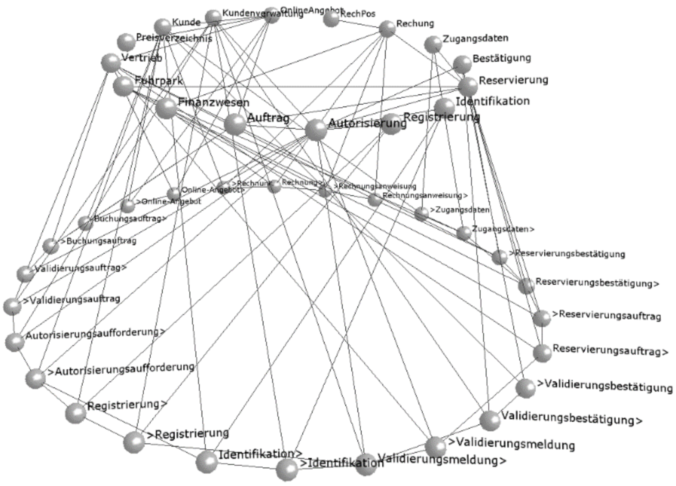

Abbildung 6. Graph der BCI-Methode

4 Ergebnisse des Fallbeispiels

Das Ergebnis der Komponentenfindung ist in Abbildung 7 als optimale Partitionierung des Graphen hinsichtlich der angewandten Heuristiken dargestellt. Die Aufteilung der KOTs und VOTs auf die verschiedenen Komponenten wurde durch die Anwendung der Start-Partition-Greedy-Startheuristik in Verbindung mit der Kernighan-Lin-Verbesserungsheuristik erreicht. Grundlage der Anwendung der Heuristiken bildet die Gewichtung der Beziehungen im Graphen. Dabei besteht die Herausforderung darin, die in Abschnitt 3.2 beschriebene unterschiedliche Relevanz der jeweiligen Beziehungen als konkrete numerische Gewichte abzubilden. Analog zur Festlegung der Relevanz der Beziehungen bestehen auch hier Freiheitsgrade für den Systemarchitekten. Um eine möglichst optimale Lösung zu generieren, wurden verschiedene Gewichtungen unter Beachtung der Relevanz der Beziehungen mithilfe eines Software-Tools (BCI-3D) getestet und die Ergebnisse hinsichtlich ihrer Eignung diskutiert. Die dem Ergebnis zugrundeliegenden Gewichtungen können Abbildung 7 entnommen werden.

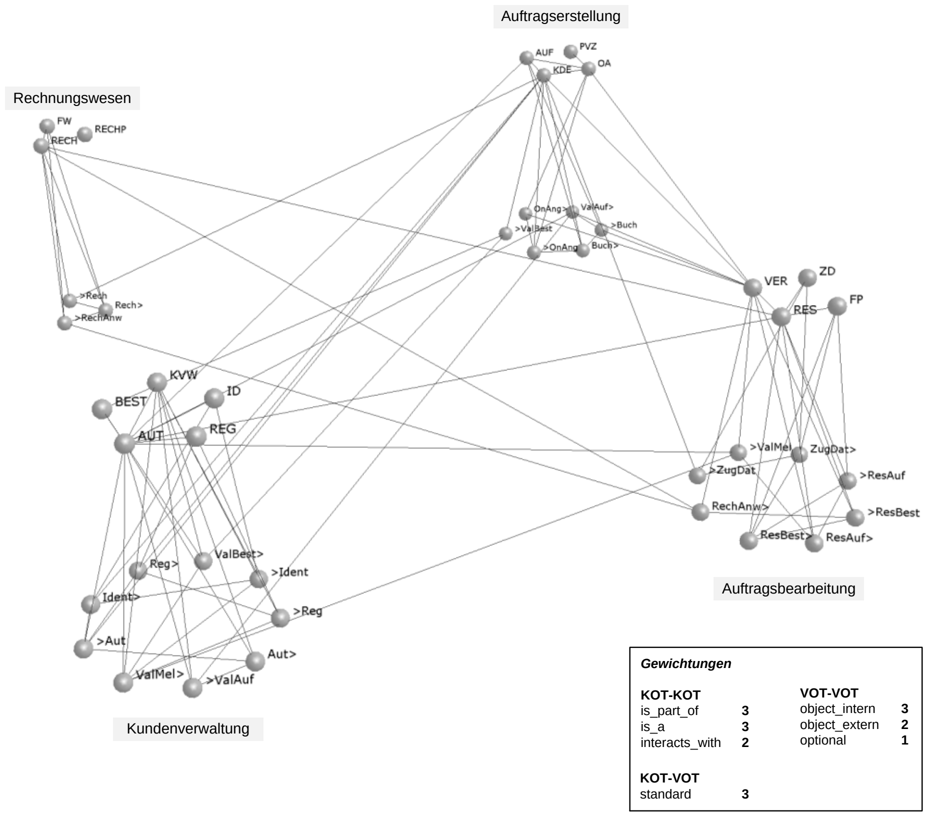

Abbildung 7. Optimierte Partitionierung des Graphen

Sofern keine Abstufungen aufgrund einer Rangfolge vorgesehen sind, wurde ein Standardgewicht von 3 gewählt. Folglich erhalten bspw. die den objektinternen Beziehungen untergeordneten objektexternen Beziehungen eine geringere Gewichtung von 2. Dem schließen sich die optionalen Beziehungen mit einem Gewicht von 1 an. Insgesamt wurden mit der vorgeschlagenen Gewichtung vier verschiedene Komponenten identifiziert. Jede Komponente fasst im Sinne der Erzielung der maximalen Kohäsion zusammenhängende KOTs und VOTs zusammen und wird in Bezug auf die Gemeinsamkeiten der bereitgestellten Dienste mit einem entsprechenden Namen versehen. Die Komponente *Auftragserstellung* veröffentlicht das Angebot an Fahrzeugen und erstellt die Buchungsaufträge der Kunden. Die Verwaltung der Kunden sowie deren Autorisierung durch Identifikation und Registrierung ist Aufgabe der Komponente *Kundenver-*

waltung. Die Reservierung von Fahrzeugen aus dem Fuhrpark, die Bestätigung der Reservierung sowie die Übermittlung der Zugangsdaten wird von der Komponente *Auftragsbearbeitung* angeboten. Schließlich stellt die Komponente *Rechnungswesen* die Funktionalität für die buchhalterische Erfassung des Auftrags und die Erstellung der Rechnungsdokumente bereit. Die verbleibenden Beziehungen zwischen den Komponenten realisieren in Form von Schnittstellen die Kopplung der Komponenten. Betrachtet man die Kosten der Partitionierung, so konnten diese nach Anwendung der Kernighan-Lin-Heuristik von $\mathrm{C(P)} = 101$ der Startlösung auf $\mathrm{C(P)} = 70$ reduziert werden. Konkret ergibt dies ein Kopplungsverhältnis von $\overline{\mathrm{Cou(P)}} \approx 0.20$ sowie entsprechend ein Kohäsionsverhältnis von $\overline{\mathrm{Coh(P)}} \approx 0.80$. Im Vergleich zur Startlösung konnte damit im Sinne einer Optimierung der Partitionierung das Kopplungsverhältnis um 0.09 verringert und das Kohäsionsverhältnis um 0.09 erhöht werden. Konkret bedeutet dies, dass die Zahl der Verbindungen zwischen den Komponenten im Vergleich zur Startlösung nochmals reduziert werden konnte.

5 Zusammenfassung und Ausblick

Im vorliegenden Beitrag wurde aufgezeigt, wie eine Komponentenfindung nach der BCI-Methode auf Basis des SOM-Ansatzes durchgeführt werden kann. Zunächst wurden hierfür die Grundlagen der Komponentenfindung, die Vorgehensweise der BCI-Methode sowie die Modelle des SOM-Ansatzes erläutert. Anschließend wurde die Anwendung der BCI-Methode auf Basis des SOM-Ansatzes anhand eines praxisnahen Fallbeispiels dargestellt. Die Ergebnisse des Fallbeispiels zeigen, wie ausgehend von den verschiedenen Modellen des SOM-Ansatzes ein Anwendungssystem in eine möglichst optimale Menge an Fachkomponenten unterteilt werden kann. In Bezug auf die in diesem Beitrag adressierten Forschungsfragen lassen sich folgende Rückschlüsse ziehen. Der objekt- und prozessorientierte SOM-Ansatz stellt mit seinen verschiedenen, aufeinander aufbauenden Modellen eine geeignete Ausgangsbasis für die Komponentenfindung dar. Für die Komponentenfindung eignen sich hierbei insbesondere die Modelle auf der Ebene der Anwendungssystemspezifikation, da diese die von einem Anwendungssystem zu unterstützenden Informationen beinhalten. Im Hinblick auf die Unterscheidung und Übertragung der für die Komponentenfindung relevanten Beziehungen bietet der SOM-Ansatz verschiedene Möglichkeiten. Für das Fallbespiel wurden bspw. die verschiedenen Beziehungsarten innerhalb des KOS als unterschiedlich relevant für die Komponentenfindung angesehen. Ebenso wurden die Interaktionsbeziehungen innerhalb des VOS weiter in objektinterne, objektexterne und optionale Beziehungen differenziert und in dieser Reihenfolge mit einer absteigenden Relevanz für die Komponentenfindung versehen. Durch die Trennung von strukturorientierten und verhaltensorientierten Modellsichten innerhalb des SOM-Ansatzes ergibt sich bei der Übertragung der relevanten Informationen auf einen Graphen die Problematik, dass hierbei zwei nicht miteinander verbundene Teilgraphen entstehen. Um dieser Problematik entgegenzuwirken, wurde innerhalb des Beitrags eine Möglichkeit aufgezeigt, wie beide Teilgraphen auf Grundlage der Informationen aus KOS und VOS zu einem gemeinsamen Graphen zusammengeführt werden können. Durch das Erstellen einer initialen Lösung mittels einer Startheuristik und der Optimierung dieser Lösung mittels einer Verbesserungsheuristik konnte eine möglichst optimale Aufteilung von vier Fachkomponenten ermittelt werden. Jede Fachkomponente wird dabei von einer Menge aus KOTs und VOTs repräsentiert, die gegenüber den KOTs und VOTs der anderen Fachkomponenten eine maximale Kohäsion und eine minimale Kopplung aufweisen.

Aus den Ergebnissen und Limitationen des Beitrags ergeben sich sowohl für die Forschung als auch für die Praxis mehrere Implikationen. Innerhalb des Beitrags wurde ein einzelnes, vereinfachtes Fallbeispiel betrachtet, bei welchem aus Gründen der Einfachheit und Übersichtlichkeit keine weiterführende Spezifikation der SOM-Modelle auf der Ebene der Anwendungsspezifikation vorgenommen wurde. Aus Sicht der Praxis bezieht sich der Nutzen vor allem auf die Möglichkeit, systematisch Komponenten auf Grundlage eines objektorientierten Ansatzes wie SOM identifizieren zu können. Mithilfe des im Beitrag vorgestellten Vorgehens wird erstmals eine methodische Grobstruktur bereitgestellt, die erläutert in welchen Schritten SOM-Modelle zur Komponentenfindung mit der BCI-Methode eingesetzt werden können. Weiterhin kann in zukünftigen praxisnahen Forschungsarbeiten die Unterscheidung der Beziehungen sowie die Gewichtungen der Beziehungsarten diskutiert werden, um eine konsolidierte Unterscheidung der Beziehungen zu erreichen. Auf Basis eines solchen konsolidierten Ergebnisses kann ein Systemarchitekt weitaus leichter Anpassungen entsprechend seiner persönlichen Präferenzen vornehmen oder auch die Sensitivität der Ergebnisse prüfen. Zudem kann mithilfe des verwendeten Tools, das die BCI-Methode umsetzt, der Ansatz auch in größeren und industrienahen Projekten verwendet werden. Insbesondere bei solchen Projekten verspricht die vorgestellte Methode mithilfe des Tools eine Vielzahl an Vorteilen gegenüber einer manuellen Systemaufteilung mit sich zu bringen.

Aus Sicht der Forschung könnte bspw. die Übertragung des Vorgehens auf weitere, komplexere Fallbeispiele einen Mehrwert dahingehend bieten, die Eignung der im Beitrag ausgewählten Beziehungen inkl. deren Relevanz zu überprüfen. In diesem Zusammenhang könnte es ebenfalls von Interesse sein, weitere Differenzierungen der Beziehungsarten zu diskutieren und diese hinsichtlich ihrer Praktikabilität zu untersuchen. Potenzial besteht im Besonderen mit Blick auf die Zusammenführung von KOS und VOS bei der Berücksichtigung der Zuordnung von Operatoren zu einzelnen VOTs sowie bei der Definition von Nachrichtenbeziehungen als Erweiterung der Anwendungsspezifikation in SOM. Grundsätzlich ist die Integration der Modellierungssichten über ein Metamodell eine der Stärken des SOM-Ansatzes. Im Zusammenspiel mit der Vorgabe definierter Zerlegungsregeln in Form eines Vorgehenesmodells kann die Konsistenz sowie die Vollständigkeit des Fachkonzepts sichergestellt werden. Die systematische Ausrichtung auf das Anwendungssystem als automatisierter Teil ist weiterhin kongruent zu den Zielen der BCI-Methode. Inwiefern Anwender hierdurch zu hochwertigeren Fachkonzepten gelangen, und damit im Rahmen der BCI-Methode bessere Ergebnissen bzgl. Kohäsion und Kopplung erzielen, müsste jedoch in zukünftigen Forschungsarbeiten empirisch geprüft werden. Weiterhin können als Resultat solcher Diskussionen SOM-Modelle auch in anderen Komponentenfindungsverfahren verwendet werden, die ebenfalls zwischen den diskutierten Beziehungen unterscheiden müssen.

Ein Merkmal zur Reduktion der Abhängigkeiten bei der Komponentenorientierung bildet die Erhöhung des Abstraktionsniveaus bei der Entwicklung, da Komponenten in

Bezug zum Klassenkonzept der Objektorientierung mehr Funktionalität kapseln und dadurch abstraktere Entwurfseinheiten darstellen [34], [35]. Hinsichtlich der Gemeinsamkeit zwischen Klassen und Komponenten durch die Kapselung von Funktionalität konnte im vorliegenden Beitrag aufgezeigt werden, wie sich systematisch mithilfe der BCI-Methode Elemente des objektorientierten SOM-Ansatzes zu semantisch sinnvollen, abstrakteren Einheiten in Form von Komponenten zusammenfassen lassen. Die Ergebnisse des SOM-Ansatzes stellen dabei mit der bereits vorhandenen Abgrenzung einzelner Objektklassen eine sehr gute Ausgangsbasis für den Ausbau der Anwendungsspezifikation hin zu einem komponentenbasierten System dar. Während die SOM-Modelle einen bewährten Ansatz liefern, um das Fachkonzept detailliert zu beschreiben, kann darauf aufbauend die BCI-Methode verwendet werden, um das Systemkonzept abzuleiten. Die BCI-Methode liefert eine systematische Unterstützung für den Übergang vom Fach- zum Systemkonzept durch die Identifikation geeigneter Fachkomponenten, ist hierbei jedoch auf hochwertige Modelle im Fachkonzept angewiesen. Insofern konnte im vorliegenden Beitrag gezeigt werden, dass sich die beiden Ansätze ideal ergänzen und weiteren Boden für zukünftige Forschungsarbeiten liefern.

Abstract. In most economic sectors organizations face rapid environmental changes like regulations. Such changes can force them to adjust both their organizational and operational structure. For instance, in the energy utility sector numerous developments moved German Public Utilities (PUs) towards a liberalized market. Nowadays PUs have to stay competitive while managing a heterogeneous information technology (IT) landscape. We address this demand for aligning business and IT by combining the holistic perspective of Enterprise Architecture Management (EAM) with the characteristic of reference modeling to reuse knowledge in a problem domain. Therefore, we utilize configurative reference modeling within Design Science Research (DSR). The artefact at hand is a method for developing a Reference Enterprise Architecture (R-EA), which is applied in the problem domain of PUs. Our contributions are the (i) adaptation of Configurative Reference Modelling (CRM) to develop a R-EA and (ii) a procedure how to elicit knowledge for R-EA development method.

1 Introduction

After the directives by the Council of the European Union from 1996 [1] and 2003 [2], Europe's energy utility industry has faced significant structural market changes in terms of market liberalization and renewable energy sources [3]. A PU is defined a natural or legal entity that supplies energy, operates an energy grid or holds power if disposition on these grids [4]. In Germany, PUs suddenly faced many challenges after the government passed the German Energy Act [4]. They do not only imply organizational or operational changes for PUs but also business opportunities for third parties to intensify competition in a prior monopolistic market. Nowadays PUs face the need to integrate new technologies resulting in heterogeneous IT landscapes. For instance, flexible demand-side management by the integration of Smart Grid technologies becomes necessary due to the volatility and uncertainty of renewable energy resources like wind or solar energy [5]. Moreover, the installation of new smart and real-time metering systems requires the reorganization of PUs' metering data management [6, 7]. This requires adaption of the PU's business models and the reengineering of existing and the establishment of new business processes [3]. Furthermore, integrating new technologies like smart metering systems has an impact on the PUs' IT architecture [7]. A survey with 53 respondents from German PUs' management level revealed that organizations currently lack in fulfilling this requirement of effective Business-IT alignment, although they assess it vital to cope with the challenged stated above [8].

In order to tackle these different challenges sketched above, it is not sufficient to focus on single aspects or initiatives. Rather, a holistic approach is needed such as EAM that creates a holistic perspective on the organization and is capable of revealing relationships between the strategy of an organization, business processes, responsible roles, applications and information infrastructures [9]. Implementing an EAM initiative would allow PUs to locate environmental changes within their organization in order to reveal necessary Business-IT alignment actions. Despite this potential, recent information systems research (ISR) activities hardly addresses EAM aspects, since it primarily focuses on Smart Grid technologies or the market itself [10], [11, 12]. They do not create holistic models or methods tailored to the PUs' situation in particular. Still, some show the multi-dimensional consequences and opportunities that challenges like smart metering cause for PUs [13]. Although practitioners agree on the potential of EAM discussed above, they consider implementing such initiatives from scratch as too resource-consuming [8]. To address this issue, we suggest the construction of a reference model as a useful approach to support PUs in benefiting from the EAM discipline. Such a model would enable organizations to reuse knowledge and reduce the effort of creating an individual model, e.g. a concrete model of an enterprise architecture [14].

In order to support the construction of such a model, we devise a method to develop a Reference Enterprise Architecture (R-EA) that is based on established literature found in the ISR sub-disciplines of reference modeling and EAM. In more detail, we adapt a configurational reference modeling method [15] in the frame of a Design Science Research approach [16]. The resulting artefact, the R-EA method, is focused on data elicitation as well as on representational aspects. The work is structured as follows:

After discussing reference modeling approaches and related work in section 2, our application of configurative reference modeling within DSR is presented in section 3. In section 4 we present the R-EA method. The method's evaluation and application in a Use Case is presented in sections 5 and 6 before concluding our work on section 7.

2 Background

As depicted earlier, practitioners agree with us that EAM would support PUs to overcome the stated market challenges [8]. This is in line with current research, since it is agreed that establishing EAM within organizations through architectural thinking increases manageability and flexibility as well as consistency [17]. EAM is a management discipline to understand, plan, develop, control and adjust organizational structures. Therefore different perspectives are developed resulting in a holistic view, which captures the current state as well as a target state of the organization [9]. These perspectives are manifold and a plethora of frameworks exist how to structure and develop such an EAM initiative [18]. In our work we use the TOGAF framework [19] as it is widely accepted among practitioners and comes with an detailed modeling language specification ArchiMate [20] as well as an open source modeling tool Archi[1].

In our work, we leverage the principles of the TOGAF framework in our method for reference model construction, the R-EA method. This means that concrete reference models constructed using our method should conform to the principles and structure of the TOGAF framework. In order to provide more background connected to the development of the R-EA method which is at the core of the paper at hand, we discuss general reference modeling approaches in the next Section 2.1. After this, we discus related work and define our work's problem statement in Section 2.2.

2.1 Utilizing Reference Modeling Approaches

A reference model can be defined as "every model […] which can be used in supporting the construction of another model can be seen in this sense as a reference model" [14], p.491). This notion emphasizes a use-oriented perspective. However, in order to be reusable, other authors such as [21] argue that also other characteristics such as the universality and recommendation have to be considered while developing a reference model. This is in line with our aim of developing a reference model that is intended for reuse. With regard to reuse, [15] identify a dilemma in reference modelling among the general validity of the model during construction and the effort of adjusting the model during its application. Their approach suggests to solve this conflict by developing *configurative reference models*, which define rules to determine model adjustments during application. This approach integrates the application aspects into the construction phase of reference modelling. We adopt this technique since the configuration of the presented R-EA would allow a certain PU to tailor the R-EA to its individual structure and thus avoiding to develop a model from scratch or adapting an

[1] See http://www.archimatetool.com.

extensive model that may be a resource consuming and tedious task. In the main part, this configurational aspect is discussed in more detail.

Regarding the overall approach of reference modelling, older works see reference model construction and application as an integrated process (e.g. [22, 23]). This is in contrast with more recent works differentiating between a phase of model *construction* and model *application* (e.g. [14]). We stick to the former distinction and present a method for the construction of a R-EA. This implies that the application of the models that can be created with this method is part of our future work.

In order to develop a reference modelling method, it is important to distinguish between two generic strategies of reference model development. While the deductive developed models emerge by deriving from generally accepted knowledge, the inductive approach abstracts from individual models to agree on a common understanding within the reference model [24]. As a part of our work on the R-EA, we propose an initial approach how to combine these two strategies into a hybrid reference modeling development method [25]. This is made transparent in Section 4.1.

Regarding these considerations, we understand the R-EA method developed in the research underlying the paper at hand as a method which supports the development of reference models that ease the implementation of EAM initiatives at German PUs. The models created using the R-EA method should be reusable, universal and should give recommendations towards the PUs on how to structure their organizations depending on certain market roles.

2.2 Related Work and Problem Statement

Only few research activities can be identified that relates to our purpose of a R-EA development method. As a starting point to develop a R-EA in the financial industry, [26] propose a working definition on enterprise reference architectures corresponding to the authors' term R-EA. They describe an R-EA as "… a generic EA for a class of enterprises, that is a coherent whole of EA design principles, methods and models which are used as foundation in the design and realization of the concrete EA that consists of three coherent partial architectures: the business architecture, the application architecture and the technology architecture" [26]. Further, [27] developed a reference requirements set in the e-government domain, which serves as a starting point for certain EAM initiatives in this domain. The approach utilizes the motivation extension of TOGAF and ArchiMate and aims to develop a complete R-EA for the e-government domain. Despite these works do identify the need for a method, neither of them addresses methodical aspects.

Most literature in the utility domain address the context of environmental sustainability, but lacks in investigating the implications for PUs' IS and its role in the current developments [28]. There has been little research activity directly addressing EAM as a means to face the challenges in the utility industry. Most research focuses on parts of EAM's scope only. [29] identified 11 reference models for information systems development in utility industry and proposed a catalogue for reference models in order to agree on a common terminology. Other topics addressed are Smart Grids [10, 11], Smart Metering Systems [6], load management and demand response [30] or dynamic tariff models [31]. All these research activities address issues PUs nowadays have to consider not only in their business but also in their information systems. The stated literature investigates this at a relatively detailed level.

We point out that current literature lacks a methodical approach for developing R-EAs. Other R-EA related research in domains such as public administration or the financial industry do not clarify how to elicit necessary knowledge for a R-EA in general nor how a R-EA should be structured. Based on these considerations this work addresses the following problem statement.

Problem Statement. We identify the need for a R-EA development method that guides data elicitation and representation of the model. The problem is addressed by two separate research questions (RQs):

RQ1: How should a R-EA method support the elicitation of the necessary domain knowledge for developing the R-EA?

RQ2: How could a R-EA method support the model structure development and the R-EA model evaluation?

3 Methodological Considerations

We selected the Design Science Research (DSR) paradigm as our research design since it supports the development of artefacts as a contribution to tackle real-world problems. At the same time, it facilitates deriving conclusions relevant for research [16]. This decision is also taken by other authors who developed reference models in diverse areas such as Master Data Management [32] or Supply Chain Management [33]. This is no surprise since DSR is essentially a problem-solving paradigm that seeks to improve the reality, in which enterprises act, by creating and analyzing innovative IT artefacts such as models, methods and prototypes [16]. Consequently, the DSR paradigm is highly relevant for method development. Our work refers to the DSR approach proposed by [34]. In this model, a regulative cycle is defined comprising the phases of *(I) problem investigation, (II) solution design, (III) design validation* and *(IV) solution implementation*, which are traversed iteratively. We applied the DSR regulative cycle as presented in Figure 1. In phase (I) we conducted an online survey, that revealed the need for a R-EA method in the certain problem domain of PUs [8]. We further analyzed literature towards methodical approaches of R-EA development and derived our problem statement as discussed in sections 1 and 2. Within (II) we adapted the method for configurative reference modeling [15] to the concepts of EAM. Therefore, we extended the CRM method with specifics of TOGAF. This resulted in an additional procedure for data collection and guidelines for structuring a developed R-EA, which are explained in section 4. In phase (III) the method was validated using Technical Action Research [35] by applying the R-EA method in the PU problem domain described above. This is illustrated in section 6. The phase (IV) is out of the scope of this paper and will be subject of our future work.

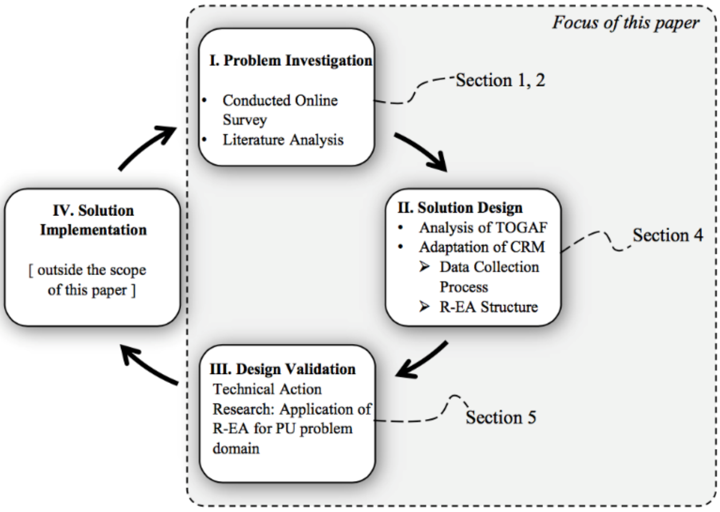

Figure 1. Applied DSR Regulative Cycle according to [34]

4 Method for R-EA development

We developed the R-EA development method based on the CRM method proposed by [36] and adapted towards the specifics of EAM. CRM comprises the five phases for reference modeling. In (1) the project's objective is defined. Therefore, the scope of the R-EA has to be clarified by identifying the problem domain and the class of organizations that are addressed by the R-EA. Also requirements towards the R-EA are set. An example of the R-EA problem domain could be the integration of smart metering systems at PUs. During phase (2) the modeling approach needs to be defined. For R-EA development one need to define what EAM framework (e.g. TOGAF) and modeling language (e.g. ArchiMate) to use. Further, the configurational aspects of the R-EA are defined. These two phases set up phase (III) were the actual reference modeling is conducted. The data is collected and the R-EA is modeled. The R-EA is refined by evaluating it in phase (IV). In the end, the R-EA is released to the market. Figure 2 illustrates that our R-EA method extends CRM in phases (3) and (4). We assess the CRM to be not comprehensive enough regarding data collection and model structure for R-EA model development. Phase (5) is out of the scope of this paper.

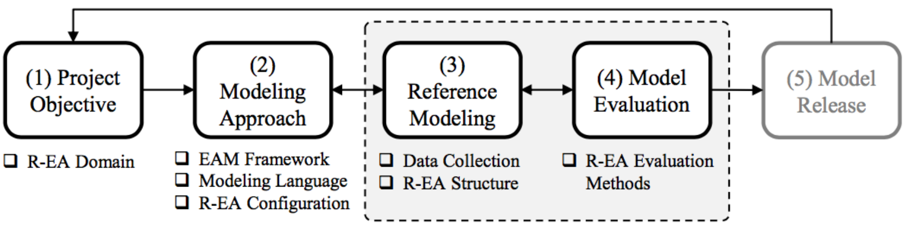

Figure 2. Basic R-EA development method applying CRM [36]

4.1 R-EA Method: A Procedure for Data Collection during R-EA Development

As described above we extend the reference modeling task CRM's phase (3) in order to comply with specifics of EAM. Therefore, we add a procedure model to phase (3), which proposes how to elicit the relevant data in order to perform R-EA development later in this phase. The procedure comprises three steps shown in Figure 3. Each step uses several data collection methods and produces an output in the form of a R-EA model version. Section 4.2 explains how to define the R-EA's elements and structure is defined.

Our R-EA method uses a hybrid approach of deductive (Step A) and inductive (Step B) reference modeling before abstract the data to final R-EA (Step C). In *Step (A)* an initial R-EA is developed using deductive collection methods. In order to ensure objective findings we propose to use methodological triangulation according to [37]. For instance, the data sources could include an analysis of domain-specific literature, expert interviews with practitioners of the domain as well as a survey addressing representatives of the prior defined organization class. The analysis of this data produces an **initial R-EA**, following a structural guideline described in section 4.2.

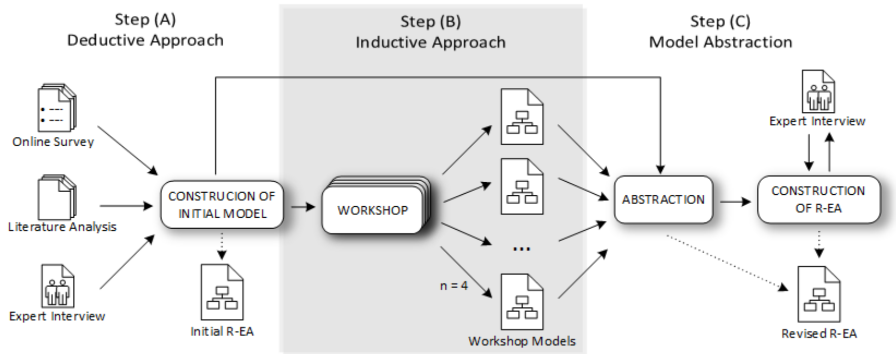

Figure 3. Development Process of the R-EA

Step (B) defines to conduct inductive reference modeling by collecting concrete enterprise architectures of representative organizations from the problem domain. The organizations' current state and challenges are captured with focus on the defined R-EA problem domain. To do so the R-EA method suggests to conduct workshops at the representative organizations'. A concrete workshop design is proposed in [38]. The workshop, its preparation and post-processing is in line with the first three stages of preparation, collection and preprocessing for inductive reference modeling from [39]. The workshop has to collect data from different perspectives on the R-EA's problem domain. These perspectives depend on the EAM framework that was chosen in (II) of CRM. When using TOGAF, elements from business, data, application and technology layer have to be considered [19]. Therefore, we recommend to conduct several small workshops at each organization. They differ in their focus and participants from the particular organization. In order to enable effective data collection, each workshops should be conducted following the guidelines of participative enterprise modeling [40].

There are several roles participating in a workshop. The research team consists of the modeling facilitator and minute takers. While the modeling facilitator moderates, asks questions and illustrates the talking points, minute takers keep record of the discussion. The participants from the organization, i.e. the domain experts, depend strongly on the focus of the respective workshop. For instance, identifying the business areas of a PU that are influenced by the integration of smart metering systems requires domain experts to be from the management level. In contrast, collecting information regarding concrete business processes or data models for smart meter installation rather requires process owners or specialists as participants. Thus, the workshops have to be planned wisely and a concrete agenda needs to be communicated to the organization. After condensing the collected data and cross-checking it with the participants, an individual **workshop model** is developed for each organization using ArchiMate. These have to be comparable and, thus, must comply with the modeling conventions defined by the researchers. This is discussed in section 4.2.

In *Step (C)*, the actual R-EA is developed based on the initial R-EA and the workshop models. It is then validated by dint of expert interviews resulting in a **revised R-EA**. For abstracting to the R-EA, reference modeling research identifies clustering as a means to derive a reference model, which requires the comparability of the individual models [39]. This is also applicable towards the R-EA. Still, research only addresses the comparability of process models in this regard and lacks methodical aspects for comparing individual EA models. In this last step of model abstraction, it is vital that the initial and all workshop models are comparable with each other, since they are more complex than process models. Therefore, the next section explicates how to agree on a structure for the R-EA development.

4.2 R-EA Method: Definition of R-EA Structure

As depicted above it is essential to model comparable individual EA models. Therefore, we suggest how to define a concrete R-EA structure that guides the development of each model (i.e. initial R-EA, workshop model and revised R-EA). Therefore, it is important to understand how an EA model is structured. First, a meta model defines what elements are used to model the EA model, e.g. the TOGAF meta-model [19]. Second, different types of relationships are defined how these elements are related among each other, e.g. a certain role *is assigned to* a business process. Third, viewpoints are used as projections on parts of the EA model to visualize a certain purpose of the model, e.g. to see what business processes are using a certain software component [20]. We understand a sound R-EA structure to consider all of these three aspects in order to guarantee comparability of the individual models.

The definition of a R-EA structure is influenced by *(a) the problem domain* and intention of the R-EA identified during (I) of CRM, *(b) the meta model* of the chosen EAM framework as well as its modeling language and *(c) the data available* for conducting the R-EA method. We suggest the following actions to follow in order to develop a R-EA structure. Keeping the problem domain of the R-EA method application in mind, the meta model of the choses EAM framework has to be analyzed. It has to be clarified what EA layers to cover, what concrete EA elements as well as what relationship types to use. This results in a modified meta model. Afterwards, a list of viewpoints has to be defined that explicates what elements and relationships are projected in what viewpoint for what purpose. When using the TOGAF framework, the ArchiMate specification provides a profound documentation of the meta-model and defines standard viewpoints [20]. Although the R-EA structure should be agreed on before modeling the initial R-EA model, data quality and data availability during data collection in steps (A) and (B) from Figure 3 will influence the R-EA structure. Thus, it may be modified during the R-EA development.

4.3 R-EA Method: Evaluation of the R-EA

Next to the construction perspective on R-EA development, our R-EA method provides a procedure how to evaluate the developed R-EA. The procedure is illustrated by Figure 4. Next to the data collection the workshops can be used to validate and refine the initial R-EA model. After conducting the model abstraction step, the resulting R-EA needs to be further validated. The R-EA method addresses this by conducting another expert interview. We recommend to interview specialists for evaluating detailed parts of the R-EA. In order to assess the R-EA's overall validity managers or business consultants should be interviewed. On the one hand, the interviewees should be familiar with EA models. On the other hand, they should not have been played a part in the R-EA construction.

The R-EA can be interpreted as a set of statements formulated in a modelling language. It can be evaluated first according to whether they are built properly (e.g. adhering to the syntactical and grammatical rules) and second to their content (e.g. semantical meaningfulness, truthful, understandable). Thus, we suggest the evaluation activities to distinguish between construction- and content-centric aspects. The construction-centric perspective concentrates on whether modeling conventions of the chosen EAM framework were followed and design decisions for the R-EA structure are appropriate towards the R-EA problem domain. Addressing the content-centric perspective it has to be assesses whether the R-EA is valid regarding semantic aspects (e.g. conciseness, consistency, completeness) and pragmatic aspects (e.g. appropriateness). During the workshops and interviews, the participants should be confronted with the model and judge it according to these aspects.

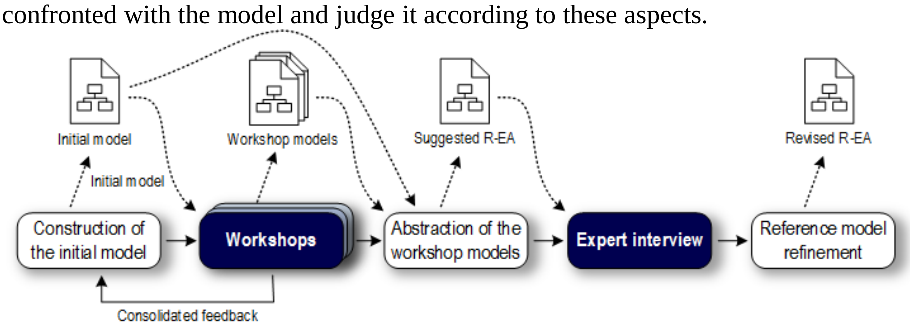

Figure 4. Procedure for Evaluating the R-EA

5 Validation of the R-EA Method

As visualized in Figure 1 we applied technical action research (TAR) for design validation of our R-EA development method [35]. After developing a first version of the method, we applied it to a problem domain. Before summarizing the method application in section 6, we discuss the setting of TAR application and want to make the R-EA method's evolution more transparent.

The R-EA method was applied in order to develop a R-EA that identifies the consequences of the market liberalization and the emerge of renewable energy sources for PU organizations. We worked together with a vendor of an enterprise resource planning (ERP) system in the energy sector, with whom we together conducted the workshops at four German PUs. During the R-EA method application (i.e. during the definition of the R-EA structure, after each workshop and during the modeling of the R-EA model) as well as after the method application we conducted interviews with the experts of the ERP system vendor addressing benefits and drawbacks of the R-EA method. According to [34] we were able to assess the method's internal validity and try to make first conclusions regarding its external validity. This relates to the observational evaluation method for DSR [16].

The method presented in section 4 represents the latest version of the R-EA method. During its application in the PU problem domain, necessary modifications of the method were identified and incorporated later on. Referring to Figure 3, the conduction of expert interviews was added in Step (A) in the first place. With the help of the vendor's expert knowledge of the industry, the initial R-EA model gain in quality and was then enriched with information from the other sources. Secondly, Step (B) was enhanced in terms of the workshop design. After we defined a strict workshop agenda, the experts noticed that the workshops need to be more flexible regarding the independence of the participants' availability. Third, in Step (C) we added the evaluation loop by conducting another expert interview in order to evaluate the final R-EA model towards construction- and content-centric aspects. Fourth, the importance of a sound definition of the R-EA structure became clear during the modeling activities in Step (B). This led to a more precise process how to structure the R-EA (see section 4.2).

According to [41] the evaluation of our artefact is primarily of formative nature. The application of the R-EA had a significant impact on the method's structure. A final expert interview with the project partner assessed the R-EA method as internal valid as defined in [34]. The developed R-EA met the partner's expectations and was used in subsequent meetings with their clients, i.e. PUs. In order to make a credible statement regarding external validity, the R-EA method needs to be applied in another problem domain. We currently apply it in a project located in the finance sector and first results indicate that the method is applicable to a different context.

6 Applying the R-EA Method to the Problem Domain of PUs

As described above the R-EA method was applied to the use case of the PUs current situation. The application was conducted together with a project partner, an ERP system vendor specialized on PUs. In Phase (I) (see Figure 1) of CRM the problem objective was to develop a R-EA that identifies the consequences of the market liberalization and the emerge of renewable energy sources for PU organizations. The class of addressed organization were PUs in Germany. The national restriction was due to the fact, that we only had positive feedback from PUs located in Germany. In (II) we agreed on using the TOGAF framework in line with the modeling language ArchiMate. The models were created with the open source tool Archi, which has full ArchiMate support. During studying the initial literature, it became clear that the business models of German PUs strongly depend on the market role they take. Thus, we derived that the R-EA will be configurable by the market role a certain PU takes. In (III) Step (A) we conducted an online survey [8], expert interviews with specialists from the partner, and analyzed domain-specific literature. This resulted in an initial R-EA, which was validated again with the partner's experts. In (III) Step (B) we designed the workshop agenda for collecting the data at four PUs. Each workshop was conducted on two days and comprised of five different workshops slots, using a top-down approach. In the first slot PU's participants were managers and department chiefs (i.e. IT department, corporate development). The focus was to identify the PU's organizational structure, its market roles as well as their business-to-customer and business-to-business relationships. For the remaining four slots, it was decided to pick four domain-specific business processes (namely customer acquisition, meter data collection, consumption-based billing and house connection) and discuss each of them with the respective process owners of the particular PU. While the first slot focused on TOGAF's business layer, the latter four collected more detailed information also for the data and application layer.

In parallel to (III) Step (A) and (B) we developed a R-EA structure and defined modeling conventions according to section 4.2. After the analysis of the data from Step (A) we modified the TOGAF meta-model by concentrating on the most vital EA elements like business actor, function, application component or data object. Due to the problem domain, we excluded all elements from the technology layer. On the basis of this modified meta-model we identified four viewpoints to model each EA model for the R-EA development: *business function, actor cooperation, service realization (for each of the four business processes) and application structure viewpoint* [20]. Three project members modeled the workshop models. Following the defined R-EA structure, it was possible to minimize the different individual modeling intentions, that occurred in the beginning. During project internal modeling workshops, we further agreed on name conventions for the same phenomena.

In (III) Step (C) the R-EA was derived by analyzing the initial R-EA and the four workshop models. During internal modeling workshops we identified similarities regarding element types, their names and relationships with other elements for each viewpoint. This was conducted manually and thus assessed as very time-intense. Figure 5 visualizes an extract of the final R-EA, the service realization viewpoint of *"contract closing"*. A PU provides this service to the consumer during the customer acquisition business process. The model shows which processes (e.g. customer registration), IT systems (e.g. CRM software), business objects (e.g. Core Data of the consumer), additional services (e.g. Checkout former Supplier) and business events (e.g. form arrives) are related to the realization of closing a new contract with a consumer. It thus also reveals the interplay between TOGAF's business, data and application layer.

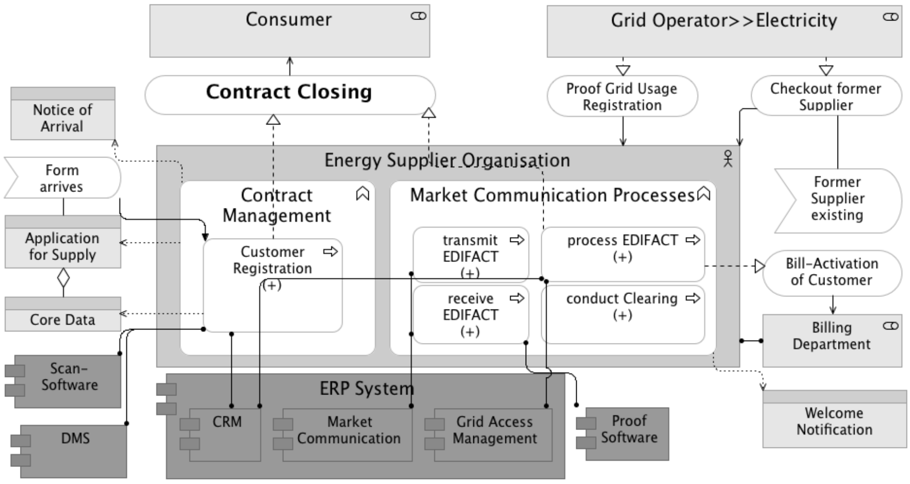

Figure 5. Extract of Service Realization Viewpoint for the Business Process Contract Closing

7 Discussion and Conclusion

Our work proposes a method for reference enterprise architecture (R-EA) development within a design science research (DSR) framework [16]. Therefore, the artefact builds on the configurative reference modeling (CRM) method [36] and extends it. Using technical actions research (TAR) [35], we apply the R-EA method in the problem domain of the energy industry and discuss the method's evolution. Our first contribution is the *(i) adaption of Configurative Reference Modelling to develop a R-EA*. We extend the CRM method and apply it for the R-EA development. Further, we suggest *(ii) a procedure how to elicit knowledge for R-EA development method*. These contributions answer RQ1. Thus, an approach for data collection is developed. We present a workshop design using participative modelling [40]. Next to knowledge elicitation the R-EA method extends CRM by providing an approach for defining a R-EA structure as well as an evaluation design of the resulting R-EA model (both addressing RQ2).

After one iteration of the regulative cycle [34], the R-EA method was assessed internally valid as the developed R-EA met the partner's expectations and was used in subsequent meetings with their clients, i.e. PUs. In terms of external validity resp. sensitivity analysis, we cannot make a credible statement so far, since the R-EA method needs to be applied to other problem domains. Currently, we apply it in a project located in the finance sector and first results indicate that the method is applicable to a different context.

Next to the validation results, there are several limitations of the R-EA method we want to point out. Although we stick to TAR by [35], the validation design holds a bias risk, since we as the method designers also applied it for validation. For future work, we should rather act as observers when applying the method in another use case. This leads to the limitation that we assess, that the method holds too much implicit knowledge for its application. This will be addressed by using a method conceptualization (e.g. [42]) and developing a method handbook. Further, the current version of the R-EA method mainly focuses eliciting the current state of practice in the problem domain, e.g. how PUs work at the moment in the changing market. Expanding this focus to future requirements of the problem domain would incorporate a *to-be* R-EA model. According to the experts this would raise the value of a resulting R-EA model. Moreover, the configuration aspect of the R-EA method needs to be investigated in more detail. This would enable to broaden the R-EA method's focus towards the application of a developed R-EA model a certain organization. Finally, also economic aspects of R-EA application have to be investigated.

Enterprise Modeling Support for SOA Migration

Sybren de Kinderen and Monika Kaczmarek-Heß

Information Systems and Enterprise Modelling, University of Duisburg-Essen, Essen, Germany
{sybren.dekinderen,monika.kaczmarek}@uni-due.de

Abstract. The migration to a Service Oriented Architecture (SOA) is a complex undertaking in terms of aligning business and IT concerns as well as analysis of technical aspects. Conceptual modeling can be helpful for supporting SOA migration by (1) bridging the gap between business and IT concerns, and (2) analyzing the as-is and to-be IT infrastructures. We contribute language requirements derived from SOA migration literature, and extend an IT infrastructure Modeling Language, ITML, to support SOA migration. We illustrate the extended ITML with a documented SOA migration case.

Keywords: enterprise modeling, service-orientation, SOA migration

1 Introduction

Since its emergence and subsequent mainstream acceptance during the early 2000s [1, p. 75], adopting a Service Oriented Architecture (SOA) remains an important concern for many organizations [2, 3]. Service orientation (ideally) fosters organizational flexibility and agility by promoting (1) re-use of the functionality offered by services [5], (2) modifiability of (IT) functionality, which is realized by loose coupling [6, p. 64].

Successfully migrating an organization towards service orientation has however proven challenging [7, 8]. Conceptual modeling has the potential to play an important role in supporting SOA migration, in particular to foster (1) communication between business experts and IT experts [10], so as to ensure that IT functionality is driven by business concerns and vice versa; (2) to perform an in-depth analysis of the as-is and to-be IT elements [9, 11] so as to, e.g., identify functionality of legacy systems in need of wrapping [11]. Although various modeling languages exist that allow for expressing service orientation from various angles (cf. [12–14]), these languages often on purpose forgo the level of detail that is required in analysis of an IT infrastructure for the needs of SOA.

In order to address this gap, we focus on the following question: *What should be the scope and characteristics of a modeling language able to support SOA migration projects?* To address it, we first identify a set of requirements based on the analysis of SOA migration literature and of characteristics of SOA migration projects and then, extend an already existing modeling language, namely ITML [4], to account for missing aspects. The proposed extensions have been evaluated against the requirements and with an extensively documented SOA example.

2 Modeling Support for SOA Migration: Requirements

'Migration' is usually understood as moving an existing operational system to a new technological or computing platform, while retaining the data and functionalities of the moved system (cf. [15]). SOA migration projects requires knowing at least the as-is and to-be states of the IT infrastructure and how these support business concerns (cf. [9, 11]).

Table 1. Requirements on a conceptual modeling language supporting SOA migration

RQ	*Requirement and Candidate Concepts*
	I Requirements For As-Is Models
1	The modeling language should allow for expressing IT landscape elements. Candidate concepts: Database, Database management system, Middleware, Server
2	The modeling language should allow for expressing the dependencies between IT landscape elements. Candidate concepts: uses, provides, runs on
3	The modeling language should account for non-functional properties of legacy systems. Candidate concepts: mission criticality, source code availability, impl. lang., code complexity
	II Requirements For To-Be Models
4	A modeling language should provide dedicated concepts that allow to model a service and its relevant types. Candidate concepts: Service, WebService, Interface
5	The modeling language should allow for relating a service to its underlying implementation, in accordance with the migration strategy. Candidate concepts: Wrapper, provides, runs on, uses
6	The modeling language should account for quality attributes of service oriented concepts. Candidate concepts: various QoS characteristics
	Overall Requirements
7	The modeling language should allow for expressing dependencies between the IT landscape and the organization action system. Candidate concepts: supports, context of use

The as-is state usually encompasses information about legacy systems. Legacy systems are systems that are usually hard to modify and expensive to maintain. However, at the same time these systems are often mission-critical and thus, must be operational at all times [9]. The to-be state reflects the service oriented design of the architecture. As understanding the as-is and to-be states is important for carrying out the migration, the aim of the modeling language should be to: (1) provide knowledge on the current state of the IT infrastructure with the focus on legacy systems (cf. RQ1 & RQ3) and (2) express the to-be state of the service orientation and reflect the changes that should be performed following the selected migration strategy (cf. RQ4).

For the as-is and to-be state IT infrastructure, we are interested in expressing the observable functionality of IT infrastructure elements, which translates into the requirements: *IT infrastructure elements* (RQ1) and their *interdependencies* (RQ2).

Furthermore, for any meaningful analysis of the possible behavior of IT infrastructure elements we need to analyze non-functional attributes [11] (RQ3).

Concerning the to-be IT landscape, the language should provide (rudimentary) expressiveness for service orientation. This entails to (1) express services and related subtypes, in addition to their quality attributes, through the language (RQ4), as well as to (2) relate these services to elements of the IT infrastructure (RQ5). The latter relation is important for the aim of the language: to analyze how an IT infrastructure should be changed to realize the functionality offered by a service.

In addition, SOA migration should be considered from both an IT infrastructure and a business perspective (cf. RQ7). Business processes largely drive what is implemented in terms of IT support [8, 16], and vice versa.

3 Extended ITML

We now briefly illustrate SOA extensions of our language, called the extended IT Modeling Language (ITML), which is based on [4]. For illustration purposes, in Fig. 1 we modeled a to-be SOA of the ACME insurance company [6, pp. 541–578]. We focus on three features of extended ITML, illustrated by the labels 1-3 (cf. Fig. 1).

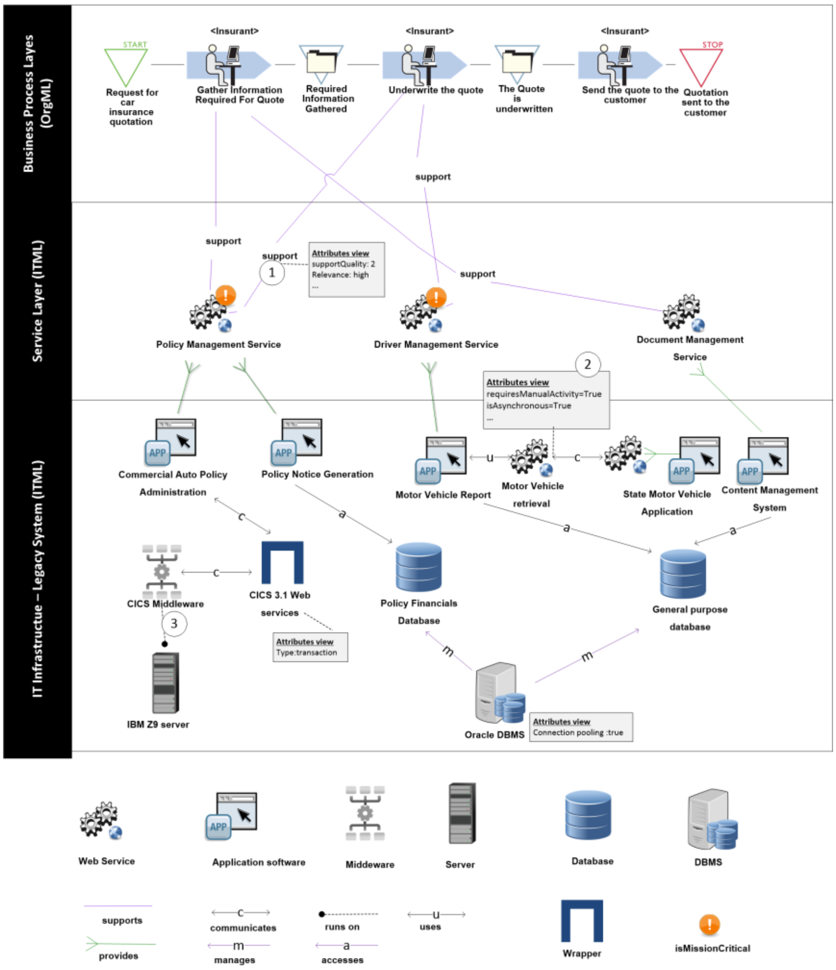

Figure 1 ACME insurance's desired service orientation, modeled in ITML

Extended ITML allows for (1) expressing, when used in tandem with the other MEMO languages [17], how IT functionality supports business processes (cf. RQ7). E.g., the web services “policy management service” and “driver management service” both support – Label 1 – the business process “underwrite the quote” (with *relevance:high*), (2) expressing non-functional attributes (RQ3&RQ6), such as – Label 2 – the necessity of a web service to support asynchronous communication, as well as a wrapper supporting bi-directional communication, and (3) inventorying relevant IT infrastructure assets and their relations (cf. RQ1&RQ2&RQ5), such as – Label 3 - the desire to keep using legacy bulk transaction processing functionality via a wrapper.

Development and Test of a Semi-structured Explorative Survey Methodology to Analyze Appropriate Learning Methods for Technology-related Training across the Phases of Technology Use

Diana Renner[1] and Sven Laumer[1]

[1] University of Bamberg, Department of Information Systems and Services, Bamberg, Germany
{diana.renner,sven.laumer}@uni-bamberg.de

Abstract. Training is regarded as an indicator for organizations' performance. To analyze appropriate learning methods for technology-related training across the phases of technology use we develop a semi-structured, explorative survey methodology. The methodology is tested with a sample of 53 healthcare professionals from China, France and the USA. Based on that, lessons learnt are concluded that confirm the usefulness of the methodology for research and practice. In addition, further improvements and enlargements of the methodology are illustrated in this paper as basis for further research.

Keywords: blended learning, training needs analysis, healthcare, technology, technology use

1 Introduction

"*Extremely powerful*" and "*cost-effective-investment*" [1, p. 147] – these two quotes relate to the characteristics of training. In the context of corporate education, training is regarded as an indicator for increasing the organization's performance [1-2]. Thus, studies focused on the investigation of pre-training, training and post-training activities [3]. From a general training research perspective, we know that the training processes start with the analysis of training needs followed by the design and delivery of trainings and ends with the evaluation and transfer of it [4]. The starting process is often referred to a training needs analysis (TNA) and concentrates on the assessment and analysis of data to determine training needs for an organization [5]. Necessary skills and knowledge that need to be acquired by the workforce are analyzed to ensure the organization's performance [2].

The appropriateness of learning methods for the delivery of knowledge and skills is not analyzed in the current practice of TNA. This confirms the request for research of Santhanam et al. [3] regarding how to match appropriate learning methods with characteristics of the trainee to ensure positive learning outcomes. The achievement of this match represents a challenge especially for blended learning concepts. These

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Renner, D.; Laumer, S. (2017): Development and Test of a Semi-structured Explorative Survey Methodology to Analyze Appropriate Learning Methods for Technology-related Training across the Phases of Technology Use, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 350-364

concepts are characterized through the combination of traditional learning methods such as classroom training and online learning methods such as web-based trainings [6]. During the last years, blended learning is increasingly used in organizations for training delivery [7] and requires a decision whether rather online or offline learning methods for the delivery of knowledge and skills should be used.

Furthermore, when a new technology is implemented the knowledge and skills which need to be trained are defined by the project management or general management [8]. The analyzed training needs are often short-term and task-oriented; however, the use of technology covers multiple years and is long-term oriented. Therefore, several phases of technology use are differentiated [9], which indicate that across all phases of technology use training needs arise and trainings are delivered; however, the respective needs for each phase are different [10].

Next to the skills and knowledge needed to be trained, the environment of the learner as well as his/her motivation is important to result in a good performance [11]. Therefore, we can assume that if the individual feels the training method as appropriate, his/her motivation increases and leads in conclusion to a better performance. Technology-related training should address the training needs of the individual for the relevant phase of technology use with regards to relevant knowledge and skills but also consider the appropriateness of learning methods based on the characteristics of the individual trainee such as working environment, training time, etc.

This aspect is not covered in the current state of TNA such that no methodological approach exists that focuses on the analysis of appropriate learning methods for technology-related training across different phases of technology use. Especially the appropriateness of blended learning for technology-related training and thus the appropriate interplay of traditional learning and online learning methods over a longer timeframe and in particular across the different phases of technology use remain unknown. Therefore, we address this gap and focus on the following research question:

> *How to analyze appropriate blended learning methods for technology-related training across the phases of technology use?*

To answer this research question, we develop a semi-structured, explorative survey methodology based on TNA research. We applied this methodology within a study in the healthcare sector and interviewed 53 subjects from ten institutions located in China, USA and France. Within our paper we will introduce the semi-structured, explorative survey methodology in detail and discuss the lessons learnt from its initial use with 53 employees. Therefore, we follow the schema of Gregor and Hevner [12] but focus on the design of the artifact and its first application in practice within this paper. The conducted evaluation investigates the usefulness and comprehensibility of the methodology for practical application, as it is important in a first step to develop a methodology that is accepted by learners [11]. It is shown that the positive evaluation of a learning method by the learner him/herself leads to a positive increase of his/her learning outcome [13]. In a second step, the designed artifact needs further be evaluated according to design science guidelines [12], [14], [15] to demonstrate that by using the suggested methodology to select an appropriate mix of learning methods for technology-related training across the phases of technology use will improve the learning outcomes. However, this part of the evaluation is not part of this paper.

We structure the paper as followed. We focus in the theoretical background on TNA and provide an overview about the state-of-the art. In addition, we explain the concept blended learning and the different phases of technology use. Then the development and evaluation of the methodology follow. Based on our first application, we will present our lessons learnt and how we adjusted the methodology. Implications for theory and practice will be provided in the discussion followed by future research and the limitations of the paper.

2 Research background

We introduce the TNA as start point of training processes in the following. In addition, an overview about current research of TNA is illustrated. Afterwards, blended learning and the phases of technology use are explained.

2.1 Training needs analysis

In general, a training need analysis is defined as *"process of gathering, assessing and analyzing data to determine the training needs for an organization"* [5, pp. 393-394]. The goal of the TNA is the identification of training needs as well as the design and development of ways and resources to address and satisfy the needs by the most possible cost-effective and efficient manner. Based on an organization's current and desired performance levels, data will be collected and interpreted by using methodical investigations and analyses [1-2]. The TNA consists of the organizational analysis, the task and knowledge, skill, and ability analysis and the person analysis. The organizational analysis focuses on the short- and long-term goals of the organization as well as on the trends that might affect these goals. The task and knowledge, skill, and ability (KSA) analysis concentrates on the analysis of the job that needs to be performed by the trainees upon completion of the training program. The third part of the TNA, the person analysis, investigates how a specific employee is carrying out the tasks of his/her job [16]. The data collection of the TNA can be done through different methods such as surveys/questionnaires, interviews, observations etc. [8]. The collected data will be interpreted and provide the basis for further activities such as training delivery.

The results of our literature analysis[1] indicate that only the task and KSA analysis are conducted within TNA reported in the literature [17-19]. Moreover, apart from Waldman et el. [20] who use interviews and survey in their studies, the other identified research studies mainly use surveys as method for performing the TNA.

[1] To get an overview about past research we screened the databases of the IS senior basket of eight and relevant journals of human resources and the organizational context (journal rated A+ and A) as well as general economics (A+)). We used the vhb-journal ranking (http://vhbonline.org/VHB4you/jourqual/vhb-jourqual-3/) as orientation. We used "training needs", "training needs analysis" and "training needs assessment" as search terms.

The literature review of Moore and Dutton [21] states that the implementation of TNA is not done in the way as it is suggested by training theorists. Although the literature review is long time ago, less research focuses on TNA in the following years such that their conclusion is still valid. Ford and Noe [18] identify in their study high impact of the position of managers in the organization and small impact of individual characteristics such as the attitude towards the utility of training on the self-assessment of training needs by managers. Phang et al. [19] develop a TNA module to support employees in their selection of the right training modules based on their analysis of training needs. The current state of the TNA research indicates that TNA covers a small part in the research field of training processes [4]. The analysis of training needs concentrates on skills and tasks of jobs and in conclusion, on relevant training content. In addition, the analysis has no temporal focus such as milestones or phases of use. Hence, we can conclude from prior research that there is a gap in the literature that focuses on how to analyze the appropriateness of learning methods and especially the mix of online and traditional methods across the different phases of technology use. Therefore, we will focus on this gap in this paper by proposing a TNA method with a focus on blended learning methods such that we introduce in the following blended learning and the phases of technology use.

2.2 Blended learning

In general, learning methods can be classified in traditional learning methods and online learning or electronic training methods [11]. Both methods are characterized through their benefits and drawbacks. Traditional learning methods have a high degree of interactivity which in contrary is often related to high costs. The benefits for the employees of being out of their daily working routine e.g. for a classroom training and having the instructor directly available for comments and questions are connected to missing working time and possible costs for traveling [7]. Online learning methods that are also known as e-learning offer the employees flexibility regarding the aspect when and where to learn and how much to learn. The instruction is often asynchronous as online learning methods are delivered by a CD-ROM, the internet or the intranet. Instruction can also take place synchronous e.g. in form of a virtual classroom training or remote training [22]. The use of a learning management system (LMS) enables to provide learning material without time and place-restrictions. LMS integrate features such as online discussion forums for the exchange of the learners or further tools such as simulation which can be used for training issues [23]. Moreover, it enables the organization to track the learning outcomes and progress of its employees [7], [22]. This aspect is often related to negative aspects of online learning such as the high front-up costs for the organization. In addition, employees often complain about the lack of interaction that might result in demotivation and feel isolated from the other learners [7]. The implementation of blended learning – which reflects the approach of combining traditional and online learning methods – tries to avoid the negative aspects and benefit from the positive aspects of both learning methods [6-7].

The results of studies indicate that the blended learning approach leads to better learning outcomes compared to only traditional learning [24] or online learning [25]. Learning outcomes can be differentiated into affective, cognitive and skill-based outcomes [26]. Previous research shows that blended learning has a positive influence on affective outcomes such as the satisfaction of the learner or cognitive outcomes such as the effective knowledge transfer [24]. In addition, past studies in the blended learning context mainly focus on comparisons between blended learning and traditional learning concepts or online learning concepts. Potential predictors for course outcomes are examined [27]. In the healthcare IS research contextual factors which have impact on the relationship between blended learning and positive learning outcomes are investigated. The studies of Buyl and Nyssen [28] and Lopez-Campos et al. [29] examine that based on the user group different blended learning concepts are necessary to ensure positive learning outcomes. In addition, culture as contextual factor is examined by the Sánchez-Mendiola et al. [30]. They confirmed that the concept of blended learning is especially successful in developing countries. In conclusion, there is no research which uses blended learning concretely in the context of technology-related training. In addition, no research focuses on the contextual factor time such that designing blended learning concepts over a longer timeframe. We use the examined contextual factors as basis for the development of appropriate blended learning concepts as they are important in the context of technology use [10] as it will be discussed in the following and hence, also for designing a blended learning concept for technology-related training.

2.3 The different phases of technology use

In general, the phases of technology use cover six phases of a technology in connection to its diffusion within the user groups [31]. The first phase, *pre-implementation*, can be defined as the period before the new technology is available for use in an organization [31] . This phase includes the process of defining, creating, and obtaining the tools, documentation, procedures, facilities, and any other physical and informational resources which are done before the implementation of the technology takes place [32]. From a training perspective the focus of the first phase is especially on making the users ready for the implementation phase. In the *implementation* phase, which is the period when the new technology has been implemented and employees are starting to use it to the point when the technology is routinely used in the daily working [33], employees get in touch with the new technology and start using it. Therefore, users need to be supported in using the technology during the implementation phase. Follow-up challenges need to be addressed in the following *follow-up* phase. Finally, in the post-implementation period, which is the period when the technology is becoming or has become part of the organization and employees use it in a routine way [34], the use of the technology itself or of specific features need to be refreshed, new employees need to be trained in using the technology or new features need to be introduced and learned when small changes or updates of the technology are implemented [32]. As a result, we differentiate between three further phases *refresh*, *new hire* and *new feature*. In summary, there are six phases of technology use which can be distinguished as illustrated by Figure 1 (left side). All the phases result in different training requirements. We will use these six different phases as a basis to reveal the appropriateness of traditional and online training methods in each phase.

3 Development of methodology

Summarizing the findings of our research background we conclude that there is no methodology covering the analysis of the appropriateness of learning methods in general and for blended learning in particular. In addition, we found no methodology that analyzes appropriate methods for technology-related training across the phases of technology use. To develop the required methodology, we use a design science research approach and followed the guidelines of Hevner et al. [14] and Gregor and Hevner [12] to design our methodology artifact.

The need for the design of an artifact results from a business problem located in the healthcare sector. The company produces healthcare technology and related services such as training in order to use the technology effectively and efficiently in the daily working routine. The job group of healthcare professionals is characterized through a high specialization in their job and a wide array of tasks performed by the group each working day [35]. The tasks are related to different skills and knowledge, expertise and former education implicates differences with regards to the use of for example healthcare information systems by nurses and physicians. The high responsibility related to the job of healthcare professionals results in a high training priority of the healthcare workforce to ensure the appropriateness of treatments and, in conclusion, the patients' health. Therefore, the use of technology is crucial in the healthcare context. As the job responsibilities and tasks vary between nurses, physicians, technicians etc., healthcare information systems are customized to cover the specialized need of the different user groups [36]. Conversely, this means that the customization of training to meet the training needs of different groups can be assumed. As a result technology-related training is of high importance for the healthcare technology company. To solve the business problem and to be able to work out concrete planning of training delivery over a longer period as well as possible investments for tools and infrastructure, the management requires a methodology for analyzing technology-related training needs which focuses on how to deliver technology-related training. The content delivered by the trainings (with regards to tasks and related knowledge and skills which need to be learned by the healthcare professionals) is well-defined. As the knowledge base of IS research [14] includes currently no methodologies facing this business need (see section 2), the development of an artifact is necessary. To get the full picture of the IS research framework we supplement the analysis of the knowledge base by the investigation of the environment in which the designed artifact should be applied. With the help of the analysis we want to get an overview about the current state-of-the art and to draw conclusions for the design of the artifact. Therefore, we analyze in the first step all relevant information from customers of the healthcare technology company with regards to methods used to analyze training needs. This provides us a first overview about the current methods used for technology-related training, issues and improvements. In the second step, we examine internally which training methods are currently used or in planning for technology-related training by conducting a survey with product managers who are responsible for the creation and implementation of training strategies. In the third step, we analyze the training offerings of further healthcare technology companies. Based on the three-step-analysis, we conclude that often the management of healthcare professionals is asked about training needs and related issues and not the end user of the technology. The feedback indicates that training needs exists also after the implementation of the technology for refreshing knowledge, extending expertise or the training of new employees. For training delivery, product managers mainly decide to use traditional learning methods such as on-site training, which takes place directly at the institution of healthcare professionals when the implementation of the technology takes place. On-site training is sometimes combined with web-based training or delivered by CD/DVD dependent of the infrastructure of the institutions. The training delivery focuses on the phases *implementation* and *follow-up*. Besides, healthcare professionals feel "over surveyed", as they commented to be too much contacted for surveys for all different cases and they indicated that they only want to participate in surveys they evaluate as positively for themselves.

Hence, based on this analysis, we designed a methodology that enables to analyze appropriate learning methods for technology-related training across the phases of technology use. A first evaluation of the artifact will be done. The evaluation focuses on the acceptance of the new methodology by learners as our analysis indicates that healthcare professionals feel "over surveyed" and that they only want to participate in surveys they evaluate as positively for themselves.

4 Semi-structured, explorative survey methodology

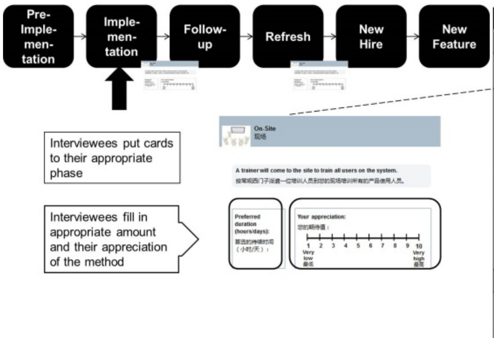
To assess the appropriate mix of traditional and online learning methods that addresses the training needs of individuals for the relevant phase of technology use we design a new methodology artifact. The proposed semi-structured, explorative survey methodology consists of two parts.

The first part focuses on general information with regards to the job, training and product experience of the interviewees. The interviewees are asked how they would classify their user role (*regular user* who uses the basics of the technology, *expert users* who are key users and have deep knowledge, and *head* users who are in a management role and often formerly worked as expert user). This enables the interviewer to get a first profile of the healthcare professional.

The second part focuses on the appropriateness of different training methods across the different phases of technology use. Therefore, we provided a list of different training methods and tools that can be used in the learning process (see Figure 1). We differentiated between traditional and online training methods and described each method in detail. This classification is based on Blanchard et al. [11]. In addition, we introduce the six phases of technology use as described in section 2. The data collection focuses on evaluating the appropriateness of different learning methods and on the amount and appreciation of the learning method. We regard the appropriateness of a training method or tool as suitable and compatible for individual subject to solve his/her issue of training needs for the phase of technology use [17]. The amount of the training method is simply the amount of time that the individual likes to spend with the training method or tool such as hours or days and is important for the planning of training [3], [17]. The appreciation considers *"a meaningful response associated with mixed emotion"* [37, p. 398] of the subject with regards to the training method or tool. Therefore, the relative value of the method or tool for the individual is in focus which covers also an important affective measure in training research [3], [17].

To **collect the data**, we suggest using a Din A1 poster and cards as additional guideline. The poster shows an overview about the six phases of technology use (see Figure 1). With the help of the cards the different learning methods are shortly explained (see the overview in Figure 1) and the amount of the training method or tool can be filled in as well as the appreciation of the individual regarding the training method or tool can be specified. For additional suggestions of training methods by interviewees empty cards are provided which can be filled out by the interviewees as well. The procedure of the data collection is suggested as follows: (1) The interviewer explains the different phases of technology use to the interviewee; (2) the interviewer explains the cards to the interviewee; (3) the interviewee choses his/her appropriate learning methods and tools for each of the phases of technology use and put the cards to the relevant phase, (4) the interviewee filled out the cards and specified the amount of training as well as the appreciation of the training method on a scale from 1 (very low) up to 10 (very high) in detail, (5) each interviewee is asked for a justification, why s/he has laid down the learning method to one of the phases of technology use, why the specified amount of the learning method is needed and why the learning method is more or less appreciated. We suggest to record the survey and that the interviewer should take notes. Figure 1 illustrates the procedure of this interactive part.

For **analyzing the data** we suggest that on the one hand one should evaluate the notes taken by the interviewer. For better comparison, the notes are structured according to comments to the phases of technology use, training methods, amount or appreciation and further comments. In addition, for clarifying or analyzing some aspects in detail, the recorded tapes can be used. On the other hand, the cards chosen by the subjects are evaluated. Thus, one regards the appropriateness of learning methods in relation to the phases of technology use in general. Therefore, one examines the overall number of cards laid down by each interviewee to all phases of technology use. In addition, one counts the cards put down to each phase of technology use. This provides a first overview about the interviewees' appropriateness of some training methods for different phases. Moreover, it shows the extent of training needs for each phase. If the interviewees wrote down additional notes on cards one can listen again to the tape to have a full understanding as the interviewee often provide more information regarding his/her notes by explaining it to the interviewer and/or translator. Furthermore, one can analyze descriptive data by the percentage of traditional learning and online learning methods in general and in detail for each of the six phases. In addition, one can investigate the percentage of tools chosen for supporting the traditional and online learning methods. The amount of training methods can be evaluated by one in the first step per hour; in the second step one can calculate the mean of each training method for each of the six phases of technology use. The appreciation of the training methods can be evaluated in general by analyzing the mean of the training method independent of the phases of technology use and in addition separated for each phase of technology use.



Method	Explanation
Traditional learning	
On-site	A trainer will come to the site to train all users on the system.
Classroom training	System users from different facilities are trained at a training center (e.g. of a vendor) to get more routine or more expertise on the system.
Clinical workshop	System users from different facilities meet at a renowned site/hospital to be trained by an advanced system user for more expertise.
Symposium	During a scientific conference, attendees can participate at various sessions around all modalities.
Consulting	A specialist will come to consult the staff of the site on different topics e.g. image quality or utilization.
Train the trainer	Course at a training center (e.g. of a vendor) that focuses on didactical skills for the internal training of customers.
Online learning	
Virtual classroom	Online meeting space for real-time learning activities with a trainer and participants from other sites/hospitals.
Web-based training	Interactive learning program on the user's computer with internet and browser access, no trainer.
CD/DVD	Interactive learning program on the user's computer, no trainer.
Podcasts	Audio or movie that can be played on mobile devices or computer (e.g. a clinical speaker informs users about best practice of improving image quality).
Remote training	Interactive one-on-one course with a remote trainer. Via remote access training can be directly conducted on the system.
Remote assistance	To receive immediate hotline/online application support in case a user gets lost during an examination.

Tool	Explanation
Online discussion forum	A forum that is accessible for system users for questions and exchange (best practice). Experts take care of the forum.
Online help	Online help provides topic-oriented, referenced information on the software. It is intended as user assistance.
Mobile simulator	An online information portal (e.g. of a vendor) that offers e.g. scan simulation. Different protocols and functionalities can be tested.

Figure 1. Proceeding of interactive part and overview about learning methods and tools for supporting

Hence, the proposed methodology is characterized as interactive. The interviewee is involved directly by a task of selecting appropriate traditional and online learning methods. The interviewer can provide guidance to the interviewee if s/he has questions. In addition, the interviewer can directly ask the interviewee why s/he has selected this learning method and why this amount is needed as well as why the method is more or less appreciated by the interviewee. This results in the detailed explanation of the appropriateness of training methods across the phases of technology use. To test the appropriateness of the methodology we evaluated it in a study in the healthcare context as it will be described next.

5 Evaluation of semi-structured, explorative survey methodology

To evaluate the usefulness, the practicality and comprehensibility of the designed methodology we conduct a study. The objective of the evaluation is the first presentation of the methodology and its practical application. A full evaluation of the design artifact has to be done according to the guidelines of design science research in future research to concretely demonstrate the utility, validity, quality and efficacy of the artifact [12], [14], [15]. The study includes three large Chinese hospitals, three large French hospitals and one large diagnostic imaging center in France as well as three large hospitals in the USA. The contact to the institutions was established by the healthcare technology company that highlighted the need for developing a new methodology for assessing the appropriateness of training methods.

In total, 53 Healthcare professionals were interviewed using the newly developed methodology and welcomed to provide feedback to the methodology. The average age of interviewees is 38.5 years (seven subjects provide no data about their age). 24 were female and 29 were male interviewees. An overview about our sample is illustrated in Table 1. The interviews took between 45-60 minutes. We select our interview partners in dependency of the technology they use. We ensure that that all interview partners work in radiography departments such that they use technology systems like angiography or x-ray (AX), low complexity of technology, computed tomography (CT), medium complexity, and magnetic resonance imaging (MRI), high complexity. Moreover, we select our interview partners according to three user roles: regular user, expert user and head.

Table 1. Overview of interviewees

		User role		
		Regular	Expert	Head
Technology	AX	CN (2); FR (0); USA (0)	CN (2); FR (3); USA (0)	CN (2); FR (1); USA (0)
	CT	CN (1); FR (1); USA (5)	CN (2); FR (6); USA (5)	CN (1); FR (1); USA (5)
	MRI	CN (1); FR (0); USA (1)	CN (2); FR (0); USA (0)	CN (2); FR (1); USA (1)
CN: China; FR: France; brackets cover number of interviewees				

For collecting our data we interviewed each professional first using the proposed method and afterwards we asked them about their evaluation of the interview conducted. For the second part, we asked questions such as *"What is your opinion about the methodology?" "How would you rate the usefulness of the method?" "Would you use the methodology in the future?"*

In addition, we observed the subjects while conducting the method. We analyzed their reactions regarding the proceeding, their tasks and if the method and its proceeding and outcome were understandable. We made additional notes if the interviewees asked questions regarding the method. We classified the notes taken by the interviewees according to questions about the proceeding in general, the comprehensibility of the method, improvements for the method and further notes.

We coded the feedback based on the transcripts of the second part of the interview and we coded the emotions of the interviewees by conducting the methodology as well as the reaction of the interviewees for providing feedback. We classified the emotions in positive (e.g. excited, satisfied), negative (e.g. bored, distracted) and neutral. Hence, we identified incidents that the interviewed healthcare professionals rather evaluate positively or negatively. Furthermore, we presented our methodology and the results of the first application to the management of the healthcare technology company. Based on the feedback and the analysis of the interviews we deduced lessons learnt from the first application for further adjustments of the methodology which will be explained in the next section.

6 Lessons learnt from first application

As a result of the demonstration and first evaluation of our designed artifact [14] we conclude four lessons learnt addressing the practical applicability of the methodology:

Lesson learnt 1: Interactivity takes time but it is worth. We estimated for conducting the survey - including all parts - 30 to 40 minutes. Whereas the first part about questions regarding the experience of interviewees was done efficiently, the second part took time because of the explanation of the additional material such as the poster and the different cards. In China and France where the interviewers were accompanied by a translator, it takes more time for translations even when the interviewees clarified for example their understanding of the training methods or tools to ensure the correctness of their selected cards. In some cases, the interviewees did not finish the survey despite lack of time.

In general, the feedback of the interviewees to the semi-structured, explorative survey methodology was positive. The interviewees felt satisfied as the methodology enables them to plan their ideal blended learning concept for learning a new technology. One American interviewee said: "*We had some time ago the implementation of a new technology. So I could reflect about the training we had and if something was missing and could be improved the next time.*" (male, 41, expert user CT). In contrary to the French and U.S. interviewees, the reactions of Chinese interviewees were more characterized through shyness and restraint. Therefore, more guidance from the interviewer and the translator was necessary. The feedback to the survey was also positive. As a result, the methodology is in general well applicable for practical use but should be adjusted regarding the aspect planning. Enough time for the performance should be calculated and also communicated to the interviewees in advance to ensure that the interviewees have enough time to complete the survey.

Lessons learnt 2: Adaption of the different phases of technology use and the methods based on the context of technology. We applied the survey methodology in the healthcare context. Therefore, other training methods can be more appropriate in other business contexts. In addition, the phases of technology use can be different based on the characteristics and use of the technology. In our study, 52 of the interviewees agreed with the six phases of technology use. Only one Chinese interviewee provided feedback that she would add another phase named "improve clinical experience" after the sixth phase. This phase is *"for improving the clinical expertise of the user and to extent the clinical knowledge"* she explained (female, 39, MRI expert user). With regards to the training methods, additional methods to the cards provided were suggested by the interviewees. Four interviewees from France proposed for example the "visit of another institution" as another training method to the *pre-implementation* phase. We can summarize that independent of the technology the interviewees are using; further methods and tools may be appropriated additional to the setting of our methodology. Therefore, the possibility for additional proposals by the interviewees should be included in the survey methodology.

Lessons learnt 3: Estimation of training amount as challenge. In the methodology we ask the interviewees also for the appropriate amount of the selected method/tool. Based on our first experience in using the survey methodology, we can conclude that this aspect is difficult to specify for the interviewees especially the amount for spending time with the tools. Therefore, we focus on guiding the interviewees to conclude what works best and how our methodology might be improved. As a result, the interviewees took additional notes to the appropriate amount they like to spend with the tool or method. The American MRI head user selected the tool mobile simulator for the pre-implementation phase of technology use but added *"it would be good to have the mobile simulator around three months in the pre- and post-install phase available to support internal training"* (male, 41). The additional information provided by the interviewees facilitates on the one hand the planning of training and the possibility to customize training according to special needs. On the other hand, comparisons between countries, for example, are difficult.

Lessons learnt 4: Expanding the horizon – for business and research. The semi-structured, explorative survey methodology and a summary about important results were also presented to the management of the healthcare technology company. With regards to the survey methodology the feedback of the management was positive to solve the business problem and for practical application. One manager commented *"A really interesting and especially innovative approach. […] This enables us to work on the customization of training needs […] and enlarge our training offerings after the installation of the systems"* (female, mid 30s). The current training strategy of the healthcare provider concentrates on the phases *pre-implementation, implementation and follow-up*. To cover all six phases of technology use for analyzing appropriate training methods of the healthcare professionals provides new insights for the management. In addition, the extent of data collection is desirable such that further factors are included in the methodology. Thus, the management asked to consider the willingness-to-pay in the survey. A manager said "*So we can see if this factor [willingness-to-pay] impacts the training and the appreciation"* (male, mid 40s). As the methodological approach appears as appropriate for the practical use, it can be adjusted and extended by further factors.

7 Discussion

By following the guidelines for design science research [14], a semi-structured, explorative survey methodology is designed. The designed methodology artifact provides an answer to the research question of how to analyze appropriate blended learning methods for technology-related training across the phases of technology use. We test the designed methodology for its practical application and evaluate the usefulness, comprehensibility and practicability. The resulting lessons learnt based on the first evaluation confirm the usefulness of the designed methodology for practice. The six phases of technology use are well accepted by the interviewees and provide guidance for the appropriateness of blended learning methods over a longer timeframe as well as the identification of technology-related training needs.

As the methodology concentrates on the analysis of how to deliver training and the appropriateness of online and traditional learning methods we contribute to TNA research. The findings of our literature review (see section 2.1) shows that the focus of TNA is mainly on what training to deliver such as knowledge and skills. In addition, the planning is often short-term oriented. Also in technology implementation research the training of new technology is mainly concentrating on the implementation phase. Therefore, we enlarge TNA research as well as technology implementation research by integrating further aspects such as the long-term orientation of training needs and the appropriateness of traditional and online learning methods across the phases of technology use. The concept of TNA provides the basis for analyzing training needs with regards to the appropriateness of learning methods. In addition, the six phases of technology use were integrated into the semi-structured, explorative survey methodology. The designed methodology addresses the research request of Santhanam et al. [3] regarding the match of training methods with individual needs and characteristics. Consequently, the results provide implications for the training design such that the appropriate amount of training is considered within the conceptualization of a training method. Further contextual factors such as characteristics of the target group (e.g. user groups, culture) [28-30] can be addressed in the training design to ensure positive learning outcomes. Thus, future research can apply the methodology to develop and validate theoretical models about the appropriateness of learning methods in different contexts. In summary, we contribute with our semi-structured explorative survey methodology as a basis for further investigations of factors influencing the relation between learning methods especially of blended learning and learning outcomes.

Next to the theoretical implications, the application of the semi-structured, explorative survey methodology results in implications for practice. The interactive methodology is easy to implement for practical use. Based on the positive feedback gathered by the interviewees from different countries as well as from the management of the healthcare technology company, the methodology facilitates to reflect about past training methods used for the implementation of new technology.

As the semi-structured, explorative survey methodology is applied for the first time within the study, there are limitations regarding the validity and reliability. In addition, a complete evaluation following the requirements of design science research is necessary in future research as within this paper only a first application of the designed method was done that focused on the acceptance of the methodology by learners. For approving these factors further studies are necessary. Additional impact factors such as the working environment can be examined in-depth. Furthermore, the usefulness of the methodology itself for other contexts should be investigated. This enables in addition, the comparison of the appropriateness of blended learning contexts based on different contexts, technologies and users. Therefore, in future research, the methodology should be applied by conducting further studies. Based on the lessons learnt and resulting adjustments the methodology should be investigated in other countries or healthcare technologies to ensure further validation. In addition, the methodology can be extended by further factors such as willingness-to-pay.

About Well-considered Decisions, Favorable Alternatives and Sudden Ideas: A Qualitative Research to Identify Beliefs that Influence Women to Study Information Systems in Germany

Caroline Oehlhorn, Sven Laumer, and Christian Maier

University of Bamberg, Germany
{caroline.oehlhorn,sven.laumer,christian.maier}@uni-bamberg.de

Abstract. Our research reveals motivational beliefs that influenced the decision to study information systems of female students in Germany. We apply a qualitative methodology in form of narrative interviews and interviewed 21 female students at a German university. On the basis of the theory of planned behavior, our results expose that a range of different beliefs exist which influenced the women's decision. We are able to expand the results of previous studies to the German context regarding especially normative beliefs, alternate choices or prior experiences dealing with information technology. In addition, we also uncover a couple of new beliefs that had not been revealed before.

Keywords: Women and IT, IS enrollments, study subject selection, theory of planned behavior.

1 Introduction

Recent articles coined the phrase *War for Internet Talent* [1] reflecting that the competition of well-educated information systems (IS) professionals reached a new level. Among others, recent statistics reveal that organizations cannot fill their information technology (IT) vacancies [2]. In line with that, top managers consider the education of IS professionals as one of the major issues [3]. As particularly women are underrepresented in the IT profession, institutions established plenty of women-specific programs, such as *Mädchen und Technik* (German for 'Girls and Technology') or *Girls Day*, to motivate women to study IS. Such programs were necessary as women and men base their decision on different aspects [4, 5].

From a theoretical perspective, the reasons why women focus a career within the field of IT are a well-discussed topic within IS research so far [6, 7]. Nevertheless, there exists also a wide range of reasons that seem to prevent women from doing so [8–13]. Respectively to the choice of studying IS, these include nonexistent interest, missing familiarity with IS or the perception of insufficient computer skills [10].

On closer consideration of the situation in Germany, we notice a slight increase regarding the number of enrollments in IS study programs of young women. Since

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Oehlhorn, C.; Laumer, S.; Maier, C. (2017): About Well-considered Decisions, Favorable Alternatives and Sudden Ideas: A Qualitative Research to Identify Beliefs that Influence Women to Study Information Systems in Germany, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 365-379

1998, the number of German women studying IS has been quintupled until today, whereas the percentage of women increased slowly from 12.8% to 17.8% [14].

A further increase in this context is desired by both, business and society. To sustainably support this process, it might not be enough to solely implement measures, but also investigating possible causes. As a first step into this direction, we want to detect the women's reasons that motivate them to matriculate into IS study programs. Only few research aims to identify motivational factors for studying IS, although previous research calls up to explore this topic in detail [15]. We, therefore, propose the following research question:

Which beliefs motivate women in Germany to study information systems?

In order to answer this research question properly, we conducted narrative interviews with 21 female students from a German university that offers two IS bachelor and three IS master degree programs. As the decision to study IS is usually planned and consciously made, our research orientates towards the theory of planned behavior (TPB). The structure of our paper is as follows: firstly, we explain the theoretical background focusing TPB and previous research related to IS studies. Next, we illustrate the applied methodology in section three and present our results in section four. The results are discussed in section five followed by a short conclusion.

2 Theoretical Background

As we want to elaborate the motivations that drive women to decide for studies in the field information systems today, the status quo of related existing literature will be presented first. The decision to study a certain subject is a planned and conscious decision [16–18]. Therefore, we refer to TPB as the theoretical foundation to explain the conscious decision studying IS. In the following subsections, we reveal theoretical essentials about TPB and decisions for academic studies among students seen from an IS-related perspective.

2.1 Theory of Planned Behavior

TPB is a frequently used theory within leading IS research [19, 20] that explains human behavior connecting beliefs and behavior. According to TPB, a person's behavior and previous intentions can be predicted by personal and environmental factors named attitude towards this certain behavior, subjective norm and perceived behavior control (PBC) [18]. TPB proposes that behavior is influenced by behavioral intention, which is influenced by the subjective norm regarding this behavior, the attitude toward this behavior, and perceived behavioral control (PBC) in turn. Subjective norm is related to social pressures a person is confronted with when deciding whether to perform a certain behavior or not. The attitude toward this behavior is defined as the person's propensity toward the behavior in relation to the expected consequences. PBC is seen as the person's perception of the difficulty of performing this behavior. TPB is useful to address our research question as it predicts intentions and behaviors very accurately [21].

In its expanded version that we apply to our research, the three influential factors within the TPB model are based on antecedent beliefs: behavioral beliefs affect the attitude, normative beliefs affect subjective norm, and control beliefs influence PBC [18]. Behavioral beliefs are individual beliefs of a person that address the related consequences of a certain behavior. Normative beliefs reflect beliefs of other people from the social environment that a person perceives regarding this particular behavior and control beliefs balance factors that influence the individual's feasibility of performing this behavior.

Referring to previous research that focuses on individual beliefs to explain behavioral choices concerning career issues [5, 10, 17, 22], we consider TPB as a proper theoretical base to examine our research question.

2.2 Previous Research

Previous research reveals a range of different factors that influence US students to study IS as major or to pursue an IT profession [23, 24]. Among others, certain factors show a significant impact on students' motivation to study IS: general interest, job-related and experiential beliefs, content-related and control beliefs, social impact and attitude in general [5, 8, 17, 23, 25–27]. Nonetheless, these results are limited in two ways. First, a comprehensive study that explains why women start studying IS does not exist yet as previous research only focusses particular beliefs. And second, previous research concentrated solely on US students [5, 10, 17]. However, these results cannot be applied for the decision of women who plan to study in Germany. While students in the US are more likely motivated to study out of reasons regarding wealth (to earn a high salary) and social status [28], students in Germany do so with regard to their perceived talents and personal development [29]. In addition, the educational systems of Germany and other European countries vary significantly from those in the US: students in the US start their academic studies attending some general and preparatory courses before choosing their major, students in Germany decide for their discipline of study before registering at a university in turn.

In this context, research also shows that these motivational factors differ by gender [4, 5]. Men, for example, are more motivated due to factors in the work itself. Women, by contrast, are more attracted by factors around the job such as job security or flexible working hours. As the demand for more women in the IT profession is still unabated, research also looks at the reasons why women are less attracted by the field of IS [8–13], suggests and analyzes countermeasures [12, 30]. As already mentioned, previous literature predominantly investigated the situation at numerous US universities, where the context differs due to the fact that the US university system distinguished from the German system. Furthermore, students in the US intend to study majors with regard to their expected wealth (to earn more money) and social status [28]. By contrast, students in Germany more likely focus on their perceived talents and personal development [29]. It is hitherto unresolved if the same factors that affect the decision towards study majors in the US are fully transferable for the decision of study subjects in Germany.

3 Methodology

We use a qualitative methodology by conducting interviews in the special form of narratives with 21 female students from a German university to reveal crucial beliefs based on TPB.

We chose narratives as a qualitative methodology for our research since narratives in their original form – a series of events in a specific order [31] – approximate the process that we aim to retrieve from the interviewees. The narrative approach[1] intends to conduct open-ended interviews that focus on the interviewees' previous experiences. As these experiences are mandatory to tell a story in the form of narratives, we focus on female students who have already decided to study IS. Some demographic information about the interviewees is depicted in Table 1. This procedure ensures that the interviewees possess the necessary experience to answer our interview questions. Furthermore, the narrative approach has been successfully applied to IS research to uncover and survey qualitative data at an early stage of research [32].

Initially, the call for participation was posted within the university's internal e-learning system and on the faculty's Facebook page in July 2016. Those students who answered the call for participation were invited to the chair's laboratory to take the interview. The interviews were recorded anonymously on tape with the agreement of each participant. According to the procedure of narratives, the interview started with some preliminary remarks that aim to encourage the participants to tell about their motivations, experiences, and thoughts before they decided to study IS. During their report, the interviewees were not interrupted to not interfere their process of self-reflection. When the interviewees finished, the interviewers asked additional questions to enlarge upon certain points if required.

All interviews were conducted during the month of July and lasted between 10 and 25 minutes. Afterwards, the interviews were transcribed verbatim and coded following qualitative coding procedures by using both descriptive and interpretative coding techniques [33].

In the first step, we searched for mentioned beliefs that obviously influenced the decision to study IS within the transcripts. For this purpose, we used a coding scheme that we adjusted to already proved beliefs of TPB obtained from thematically related literature [5, 10, 17]. Further lines and paragraphs, which did not match any existing beliefs withal, were separately coded and shown. Next, each of these newly identified beliefs was examined in its individual case. We searched for similarities and coherencies between those beliefs and grouped them into common categories referring to existing literature wherever possible. These categories were then associated with the three respective factors of TPB (behavioral, normative and control beliefs). To ensure an unambiguous assignment of the indicated beliefs and group categorization, coding was first done by all authors separately, and together at a later point in time.

[1] For more information about performing narrative approaches see [32].

Table 1. The interviewees' demographics

Participant	*Age*	*Study semester, intended degree*	*Participant*	*Age*	*Study semester, intended degree*
P 1	25	3, master	P 12	23	7, bachelor
P 2	26	4, master	P 13	25	7, bachelor
P 3	22	6, bachelor	P 14	22	1, bachelor

P 11	21	1, bachelor			

4 Results

The outcomes of the interviews are shown in this section clustered by the different beliefs according to TPB (see Figure 2). As TPB is not tied to this issue, we examine this context aiming to reveal why women study IS (behavior). This is influenced by the intention to study IS which is affected by subjective norm, the attitude toward studying IS and the PBC toward studying IS in turn. By analyzing the conducted interviews, we want to point out which beliefs act as main drivers for these.
In each section, we give examples of statements that were narrated during the interviews. As we are not able to present all statements in this section, we included a comprehensive table (Table 2) in the appendix.

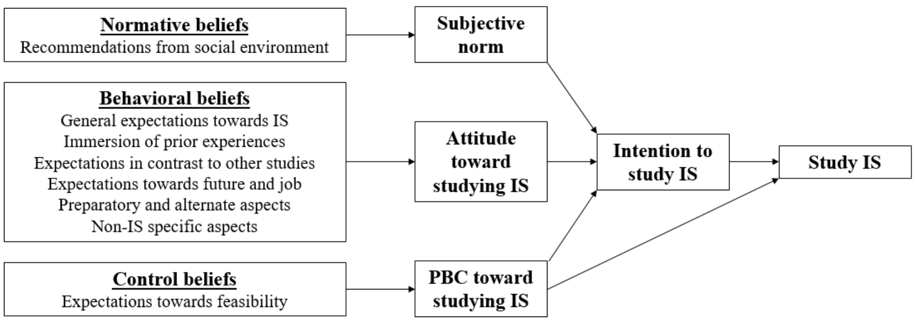

Figure 1. Results clustered by normative, behavioral and control beliefs based on TPB [18]

4.1 Normative Beliefs

As described in section 2.1, persons form normative beliefs based on the beliefs of other people from their social environment [18]. Following previous research [5, 17], we interpret those beliefs as normative beliefs when the influence of another person, who for example studies the same subject or gives recommendations, on the own behavior is recognizable. We especially notice normative beliefs in form of recommendations from the interviewees' social environment that called the students' attention towards IS or motivated them to enroll in IS studies. The mentioned social environment includes family members, friends, and persons in the university environment such as enrolled students, professors or members of the student council. Among all statements, we recognize that **recommendations from family members and friends** occurred predominantly.

As I said, I started with business administration, but this was some kind of temporary solution. Later, I met a friend at the university who studied information systems and she really raved about her studies with all the trimmings. So, I just went to one professor to get more information, and hereinafter, I decided to study the same. [P7]

I spoke to my brother who studies mechatronics where informatics is also included. He showed and explained me a lot and I was able to try some stuff. That was kind of funny. [P9]

4.2 Behavioral Beliefs

Behavioral beliefs are a person's individual beliefs that refer to the consequences of a particular behavior [18]. We expound those beliefs as behavioral beliefs when these are connected to aspects which can be seen as consequences of the decision for IS studies. The quantity of statements that belong to the category of behavioral beliefs was enormous and substantially widespread. We therefore clustered those into several subcategories that rely on different expectations or consequences related to an enrollment in IS study programs: expectations towards the study subject in general, in contrast to other study programs, or towards the own future and job possibilities as well as immersions of prior experiences with IT, IS studies as an alternative or preparatory study program, but also beliefs that cannot be related directly to the study subject.

General Expectations Towards IS. Previous research indicates that students fuel different expectations that can be related to the study subject itself such as the study contents or the composition of scientific fields [5, 10]. The interviewees within our research mentioned that they initially had different expectations on their enrollment in IS studies. They looked forward to the widespread range of topics, the composition of courses or the interdisciplinary field of the study subject for example. Others aimed to satisfy their genuine interest about IT, wished "to learn IT" or viewed the studies as a possibility of further education or even as an experiment.

Information systems is exciting related to its possible applications. I wanted to accept a new challenge after graduation from school and within information systems, I saw the best possibilities to improve myself. [P5]

Information systems offers a multifarious topic area, human-computer interaction, programming, media informatics for example. Hence, I thought, maybe I did not know all the different areas, and I wanted to try out if this is something for me. [P19]

I neither had economy at school nor informatics. But I was always a fan of: 'Let's do something new.' (...) I was really uneducated at the technical level as I never had a connection to it. But I was always interested. (...) I even had difficulties dropping subjects in school, and in this context, information systems is interesting as it combines two very different disciplines. [P8]

Immersion of Prior Experiences. Gaining first experiences, for example in form of introducing practices or even internships, in a certain subject has an evident influence on the career choice of young people [34]. Consequently, a couple of students already had first experiences with IT. They wanted to expand or deepen their knowledge with enrolling in IS studies. Other interviewees report that they had ease or fun learning IT at school.

I lived in the Silicon Valley as an au pair girl and had the perfect insight into this world and these themes in a way and I was deeply interested in this. Back home, I found this study program and it immediately appealed to me. [P21]

I actually had not that many expectations, because I did not know at all what is going to happen. All I knew, was that these two subjects (N.B.: Economy and computer science) are fun, and I hoped that it would still be fun. [P10]

I already had information systems and economy in school, and this was really fun to me. Information systems at school was more theory-loaded, I mean, we never did programming. We rather did modeling and this was quite cool. [P18]

Expectations in Contrast to Other Studies. Today, students are able to decide between a multitude of different study programs. Some programs are attended by plenty of students and can be described as almost overcrowded, whether other programs are allocated to niche areas with a manageable number of students. In this context, prior research shows findings revealing that students also decide for IS studies because they expect different circumstances from doing so in contrast to other study programs [5]. Within our research, the interviewees frequently mentioned statements that covered comparisons of IS with other study subjects such as business administration or informatics. Those comparisons referred to beliefs that other study programs are overrun with students or are not enough challenging (especially business administration) and in turn, some other studies would be too difficult for them to complete (especially informatics).

It's the whole direction of information systems, also how it is acknowledged within the economy and what I'm able to do with it. Because… When I think about this *bachelor in business administration, I have to say, I never liked it. Let us just put it in this way: this is just mainstream.* [P14]

Well, I first studied business administration (...). On the one hand, a lot of people study business administration. (...) IT is an issue where many people think it is all about programming and you have to do a lot of math and this is kind of scaring. But I think information systems shows that IT is so much more than just programming in the meantime. (…) *We just knew, that we would have more possibilities…and that enterprises would come up to us. And that the supervision is so much different with the result that I think I personally would be able to learn more.* [P13]

I ended up with information systems because I was searching for a study program that also included some IT components. But after I made some inquiries, I knew that computer science is really IT-loaded und you have to do lots of programming sometimes. Programming at school was not that much fun and therefore, I wanted something that also included some components of business administration. [P18]

Expectations Towards Future and Job. The choice of a study program is often a career decision at once. Students do not only choose their study subject for the next years, but set a path in the direction of career. Thus, students predominantly have different expectations towards their future career or certain jobs in mind when they think about enrolling in a study program [5, 17]. This corresponds to our results as the most often mentioned statements (see Table 2) of the interviewees refer to beliefs that are linked to their personal future. This shows that the students had already their lives after their studies in mind before they enrolled. Some already had specific perceptions how IS studies would affect their career or which (job) opportunities would be offered to them in the future.

You just have a positive feeling, if you can say: 'Well, cool, even if I go through with this, I'll get a job and because this is a thematically widespread study program, I would also be able to choose completely free what I am going to do.' [P11]

My cousin works as an IT business engineer and I just asked him what he is doing there. He just said in a platitudinous way: 'Well, I am sitting between a computer scientist and a business economist, and I explain to the computer scientist what the business economist wants to have.' That sounded pretty cool, especially because informatics was really easy for me to learn at school. [P1]

Preparatory and Alternate Aspects. Not all students are able to study their preferred study program from the start. Some programs require excellent grades at school or existing knowledge for example. And equally, some jobs are only allocated to candidates when they studied a certain subject in advance. So, students also consider study programs with respect to their existing and target-aimed opportunities [35]. In other cases, the interviewees told that they chose IS studies with regard to further purposes. Some students preferred other study programs and IS was just an alternative choice. For others, studying IS is a preparatory measure as it presents a mandatory qualification for specific master studies or desired careers that they already had in mind.

I initially planned to study medical engineering, but these programs only start in winter semesters. So, I examined possibilities at my hometown's university if there is something offered that would be preparatory for this. I found information systems and planned to do this for one semester with the opportunity to change later. [P16]

When studying IS, we have also the possibility to dabble in other areas and that was really interesting for me, because I was always interested in psychological studies. But my graduation grade was not good enough to enroll in psychology. So, this was also a nice opportunity to try psychology tentatively. [P19]

Since I was 15 years old, I know that I want to work in the gaming industry. There are people who do the programming, and there are people who do the management. And that is what I want to do. But to end up in this industry, you need a sort of special master, in gaming or something like that. And for doing a gaming master, you need a bachelor in computer science or just information systems. [P17]

Non-IS Specific Aspects. Whereas most beliefs can be associated with the study program itself, some interviewees also argued reasons that show no direct connection to IS studies. For example, some students were searching for study programs in a specific city or chose IS due to admission requirements. A couple of interviewees also reported that enrolling in IS was some kind of spontaneous or intuitive decision.

So at that time, I decided to study information systems kind of spontaneously. I always wanted to do something with business and first, I considered math or business mathematics. But it did not really appeal to me and I considered information systems in the short term instead. (…) I knew that I liked math und everyone told me, if I liked math, I should orient towards a technical direction and so, the decision resulted in information systems. [P12]

As I absolutely wanted to study in this city, and this study subject was a new offer at the university, I just applied there. In addition, the university over there sent off promises really early and that is why I did not apply elsewhere. [P1]

4.3 Control Beliefs

Fundamental research indicates control beliefs as factors that weigh a person's own feasibility of performing a behavior [18]. Prior research also understands the students' perceived feasibility of accomplishing a study subject as a control belief [17]. **Expectations towards the feasibility** of IS studies were often mentioned by the interviewees which is why we interpret those as control beliefs. Some students justified their choice based on good grades at school, existing knowledge or thorough information about the study program. In contrast to that, other interviewees believed that any study subject would be connected to obstacles anyway or they were going to learn everything during their studies and would not need any preparatory knowledge.

I really had no plan what to study. This sounds kind of haughtily, but I had good marks in all subjects at school. So, regarding my marks, it did not matter and it was not recognizable that anything was particularly suitable for me. [P6]

At that time, I completely reoriented and searched for mathematical study subjects, because math always suited more to me than languages, although I always had fun with that. (...) I thought that, in the worst case, I could not lose anything, because I also study business and I would have the opportunity to switch to economics or business administration. [P11]

I had no previous knowledge or anything. Except for one year at school, we did nothing in this area. Just some Word, but nothing 'IT-like'. That is why did not want to purely do computer science. Then, I found information systems that contains an imaginable scope of IT that would be possible for me. [P4]

When considering only the name, you can draw conclusions, if you are able to handle it or not. So, I informed a bit using the homepage and looked, if this would be feasible or if it would be lots of programming. [P2]

5 Discussion

Our research aim was to identify beliefs that motivate German women to start an IS study program. Existing literature shows that there is a wide range of different reasons why students-to-be choose IS or not, and how these differ by gender [5, 8, 17, 24]. However, these studies expose this phenomenon focusing only on US universities. As our research aims to uncover the beliefs of German students, we conducted narrative interviews with 21 female participants from a German university that offers several IS study programs. The completion of our research allows us to give a number of theoretical contributions and practical implications. Additionally, possible limitations of the current study are explained.

5.1 Theoretical contributions

First, we identified several beliefs that led to an enrollment in IS studies by interviewing 21 female students. After identification we defined each belief and grouped them into preceded categories with respect to previous literature (see Table 2). We integrated these categories in the three comprehensive beliefs according to TPB [18] referring to existing research within this issue [5, 10, 17, 23, 25, 27]. Our results show that the interviewees decided for IS studies based on recommendations from the social environment (normative beliefs), their perceived feasibility of the subject (control beliefs) and several behavioral beliefs such expectations towards the subject itself, towards future and job opportunities and in contrast to other study programs or immersions of prior experiences.

Second, we also contribute by confirming that the consideration of beliefs is a proper theoretical base for revealing intentions and behavior of women towards studying IS as previous literature has already shown before [5, 8]. To dissociate from those, which address solely the US university system, we conducted our research at a German university to examine the situation in Germany. Our results correspond with a couple of the already validated beliefs from previous research [5], such as job availability, aptitude, genuine interest and recommendations from the social environment. But we also see categorical differences such as formed normative beliefs out of recommendations, the students' personal and social image being an IS student [5] or negative beliefs concerning their performance in form of anxiety or low computer self-efficacy [8]. As a result, we also obtain the insight that cultural conditions might influence the women's decision to study IS which should be investigated in future research.

Third, we disclosed some other factors that influenced the interviewees' decision, which had not been considered by previous literature in this context before [5, 8, 12, 13, 17]. One is the existence of prior experiences in the field of IT: some students mentioned that they already had IT subjects at school or other impressions, such as internships or insights in IT enterprises, and that these were determinative for their decision for IS studies. Furthermore, the pure interest in the field of IS was part of many students´ decision making. Hereby, they mentioned that they had to exert their selves no matter which study programs they would choose or that they would be able to change their subject if they do not like it as already achieved grades could also be credited in other study programs such as business administration. Hereby, a certain serenity becomes apparent that further motivates the students to try IS studies, although some concerns regarding this behavior might exist.

5.2 Practical implications

We can also provide practical implications for universities, employers and other institutions that aim to attract women for an IT career. Our study results unveil that many interviewees perceived an IS study program as feasible after they sought adequate information. Several sources for information were mentioned including statements of IS students, online reports, brochures and others. As a consequence, institutions need to highlight possible job opportunities within the IT field, different fields of application and other benefits that would be offered to women if they decide to study IS.

On a final note, we would like to make all girls, who are interested in an IS study program, aware that none of the interviewees did regret her decision yet, even if there had been little concerns in advance. By reciting one student, who said *'Actually, it was a gut decision. I did not know for what I let myself in but in the end… well, it just seems to be the right thing'* [P6], we would like to note that a certain (and wise) degree of serenity is not wrong when facing important decisions, especially if these affect the own future. Sometimes it is just about trying something new or succumb to the own interest.

5.3 Limitations

The research on hand is subject to several limitations. Firstly, our study was only conducted at one university in Germany as our research's focus is on the choice of the study subject, not the study location. Nonetheless, we cannot ensure that our results are completely transferable to other universities. We also abandoned to interview participants who decided against an IS study program due to the choice of our methodological approach in form of narratives as it is explained in detail in the third section. In addition, we interviewed only female students as this is done by leading research focusing women issues within the IS field [7, 36].

6 Conclusion

We aimed to answer the research question: "Which beliefs motivate female students in Germany to study information systems?" with our research by applying a qualitative methodology in form of narrative interviews with 21 female students. Our results show that a range of different beliefs influenced the women's decision to study IS. Those exhibit several similarities and differences toward previous studies that have already been conducted at universities in the US.

…beliefs that obstacles will occur in every study program	8, 19	2
…extensive information about IS studies	2, 5, 15, 18	4
…opportunities to change the subject/credit previous grades	5, 7, 9, 11, 13, 14, 20	7
…good grades at school	6, 17	2

When Life Gives You Lemons: How rating scales affect user activity and frustration in collaborative evaluation processes

Thomas Wagenknecht[1], Jan Crommelinck[1], Timm Teubner[2], and Christof Weinhardt[2]

Abstract. Initiators of open innovation processes involving customers or employees often face vast amounts of idea proposals. These proposals vary greatly in terms of quality, which is why organizers often engage the users themselves in the evaluation process. Building on the concept of information overload, we evaluate the effects of three distinct rating scales on users' activity and frustration measures. On the basis of an open innovation campaign for employees of a public-private institution in Germany, we systematically compare the novel "bag of lemons" method with conventional Likert scales and up-down-voting schemes. Our results demonstrate that the "bag of lemons"-approach yields higher levels of user activity, but is also perceived as significantly more frustrating. We find this effect to be fully mediated by perceived information overload, which points to potential avenues for the design of stimulating yet tolerably complex Information Systems for open innovation and rating techniques.

Keywords open innovation, rating scales, information overload, participation

1 Introduction

From strategic planning to product innovation, small and large firms as well as other organizations are involving their employees and stakeholders to propose novel ideas through digital platforms [1–3]. These processes are sometimes strictly limited to participation within the company or part of a larger open innovation campaign, including customers, suppliers, and other interested parties [4, 5]. Regardless of their target group, these platforms all have in common that users face vast amounts of proposals of varying quality, but only a few can or even should be implemented [2, 6]. Hence, there is a strong need for group decision support systems (GDSS) that enable users to filter ideas appropriately [7], i.e., that achieve high accuracy in identifying the best ideas and avoid to expose users to the adverse effects of information overload, including frustration and disengagement [8, 9].

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Wagenknecht, T.; Crommelinck, J.; Teubner, T.; Weinhardt, C. (2017): When Life Gives You Lemons: How rating scales affect user activity and frustration in collaborative evaluation processes, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 380-394

Accordingly, there exists a myriad of filtering techniques. On the one hand, these include complex approaches such as prediction markets [10, 11], or automated methods like text mining that initially require a lot of human oversight and implementation capacity [12]. On the other hand, approaches like voting and user ratings are easier to implement and widespread on various online platforms. For instance, many social media and community platforms offer simple up- and down-voting (e.g., Reddit, Quora, Stackoverflow, etc.) or up-voting only (e.g., Facebook and Yammer in the form of "Likes"). Other platforms use Likert scales, often in form of star-ratings (e.g., Amazon, Airbnb, etc.). Yet, these methods face inherent shortcomings, including biased distributions [13], limited accuracy due to oversimplification, a possible disconnect between the goals of process organizers and raters, as well as reduced user satisfaction [14–16]. In this vein, the video platform YouTube dropped its Likert scale rating system in 2009 as users mostly rated content as either very bad or very good – rarely using any measures in the middle of the 5-point scale. Since then, the platform switched to up- and down-voting [17].

Seeking to address some of the shortcomings of existing approaches, Klein and Garcia [7] proposed a novel method. Their so-called "bag of lemons" (BOL) approach lets users in evaluation tasks allocate a predefined amount of *lemons* to those ideas they consider to be the worst. A lemon thus represents a negative assessment and a user can allocate multiple, indeed up to all of her lemons to one single idea. This way, the crowd is assumed to flag bad ideas, supposedly identifying a (remaining) set of high quality ideas. In fact, the BOL method outperformed Likert scales in terms of time for task completion and accuracy [7]. To follow up on these first auspicious insights, this paper systematically assesses the characteristics of the BOL method in comparison to up-/down voting and (conventional) Likert scales. In doing so, we focus on two factors. First, as crowd-based schemes rely on the laws of large numbers and the quality of collaborative evaluations usually increases in the number of independent assessments [18], we consider *user activity* under the three mentioned rating method regimes. Second, as crowd-based approaches typically work on a voluntary basis and hence require a positive user attitude and engagement [10, 19, 20], we consider the – potentially detrimental – effects on *frustration* as a key indicator of a non-positive attitude and user disengagement [20]. Such motivational variables are widely perceived as a crucial factor for user acceptance and usage of information systems [21, 22]. In this sense, this research is motivated by the following key drivers: First of all, there exists a clear research gap as BOL represents a novel method and its role in contrast to established methods is still unclear. However, organizations increasingly seek to involve their employees, citizens, or members in decision making in order to increase content, loyalty, identification, and productivity – often using those very collaborative voting techniques [23]. In consequence, as accruing informational charges grow constantly, such methods may expose participants to excessive informational load, yielding undesired results such as frustration, disaffection, and disengagement [8].

To connect the different rating methods with our target variables, we hence base our research on two intermediate, explanatory factors. First, as the BOL method represents a novel and commonly unknown rating technique, we consider the factor of *perceived novelty*, capturing potential user deterrence by the unknown, or a lack of comprehensibility. Second, as BOL requires users to deal with a host of informational bits and pieces, *information overload* may be a concern. It was shown to yield adverse effects on employees as they are exposed to ever-growing amounts of unrestricted and unfiltered data [8, 9]. Accordingly, in this study, we pose the following overarching research questions:

RQ_1: How does the "Bag of Lemons" rating method affect user activity and frustration in a collaborative evaluation task?

RQ_2: Which role do perceived novelty and information overload play in mediating these effects?

To address our research questions, we conduct an online-based field experiment, including the collection of survey data. As part of a real world open innovation campaign, employees of a private-public institution rated the idea proposals of their peers. We systematically vary rating method, using up-/down voting, Likert scales [24] and the BOL method [7]. We investigate the ramifications for user activity, frustration [20], and task completion time, taking into account the factors perceived novelty and information overload [8]. Exceeding previous studies [7, 15, 20], users in this scenario were not forced to rate all ideas, which promises a more realistic situation and novel findings. In consequence, this study makes three main contributions to the Information Systems (IS) literature. First, we evaluate a novel, thus hardly researched method of idea evaluation (BOL) in comparison to more established methods (Likert scales, up-/down voting) in terms of the important indicators *user activity* and *frustration*, which has not or only scarcely been assessed by extant literature. By integrating these opposing factors within a joint research model, we enhance the understanding of collaborative evaluation processes in view of differentiated rating regimes [5, 25, 26]. Second, by relating these key indicators to mediating factors, we provide starting points for understanding *how* the different rating methods affect the users' perceptions and behaviors. In particular, we identify perceived information overload as a potential mediating factor at play. Third, our study provides a show case of employee-driven innovation [27] and computer-supported organizational participation [28].

This paper is organized as follows. We outline related work and the theoretical background in Section 2. Section 3 then illustrates our study design. Section 4 presents the results of our study. Lastly, we discuss our findings in view of theoretical and practical implications, limitations, and starting points for future research in Section 5.

2 Theoretical Background and Related Work

In recent years, the IS literature has begun to systematically evaluate ways to exploit the wisdom of the crowd, including a broad strand of research on open innovation processes [5, 29]. Notably, a number of studies analyzed voting and rating techniques on open innovation contests [7, 10, 15, 20, 30]. Such approaches relate to GDSS in the sense that groups evaluate proposals which were generated by the group itself, which can have important ramifications due to personal or social attachment, preoccupation, and other biases [31, 32]. With the emergence of large-scale open innovation contests, IS research revived its investigation of rating scales. Several studies in this line of research evaluated both quality and task completion time with regard to different rating techniques [15, 20, 30, 33, 34]. In this section, we describe the theoretical background of the concepts and factors that form the basis of our study. We begin with a brief introduction of open innovation contests.

2.1 Open Innovation

Adamczyk et al. [5] define open innovation contests as IT-based and time-limited competitions by individuals or organizations calling on the general public or a specific target group to propose innovative solutions. Thereby the organizers make use of the expertise, skills, and creativity of distributed crowds. Engaging employees and customers in open innovation processes can have several benefits for the organizers, including increased loyalty, brand image, and success in recruitment [35]. For an open innovation contest to be successful, previous research identified a number of factors. Organizers, for instance, need to express a sense of urgency and establish a trusted environment [14, 36]. Moreover, users might be motivated by gaining access to the knowledge of experts as well as receiving appreciation for their input by peers and organizers of the process [37]. Furthermore, extant research also established that collaborative tools drive increase the quality of results in open innovation engagements [23].

Recently, several leading IT corporations engaged both their customers and employees in open innovation contests. For instance, IBM’s “Innovation Jam” resulted in 46,000 product ideas proposed by 150,000 participants [1], while users in Dell’s ongoing “IdeaStorm” have generated more than 20,000 suggestions for product improvements thus far [6]. Open innovation contests among employees of a company are one application of employee-driven innovation [27, 28]. In the broader context of computer-supported organizational participation, these contests can be a way to actively provide employees the means to be part of the decision-making processes of their workplace, which was found to be related to increased employee commitment and productivity [28].

Considering the vast amount of ideas, it becomes more likely that an open innovation contest will produce more superior solutions than an innovation process limited to only few innovators [38]. Thus, in line with the “wisdom of the crowds” paradigm, some user-generated ideas are able to compete with expert or core inside innovators [15, 25, 39]. However, assessing these crowd proposals can be costly. Robinson and Schroeder [40] estimate that large corporations take about four hours working time and $500 just to evaluate one idea. Yet, only few ideas are really worth increased attention. Prior research established that open innovation processes tend to produce large idea collections that are highly redundant and greatly vary in terms of quality [2, 20, 33, 39], where only 10-30% of the ideas tend to be of good or high quality [33]. Put figuratively, large-scale open innovation processes create excellent needles. They do, however, also create the corresponding haystacks. The main challenge then is to identify the valuable propositions. One common solution to this problem is to engage users in the evaluation process using voting and rating techniques [7, 10, 15, 20, 30, 34].

2.2 Rating Scales, Attitudes, and Intrinsic Motivation

The usage of rating scales transforms the process of idea evaluation into a concrete task of judgment, where individuals consider a finite set of alternatives [10]. In effect, this enables the organizers of open innovation contests to reduce their costs for idea evaluation by basing decisions on aggregated user ratings.

However, the gathered data may depend on the specific rating scale. Prior research suggests that rating scales are prone to selection biases and other dysfunctionalities [7, 10, 15, 20, 30, 33, 34]. For instance, some researchers claim that rating scales often fail to properly distinguish between medium/good and excellent ideas [7, 34]. Moreover, there may occur discrepancies between the initiator's and the participants' goals and intentions. While initiators would like the participants to evaluate as many ideas as possible thoroughly, the latter are restricted both in terms of time and information available to them. Hence, organizers need to take potential factors such as non-interest, distractions, lack of knowledge, and workload into account [7, 20]. In consequence, they need to communicate clearly what, why, and how they would like their participants to do specifically.

Nonetheless, evaluation tasks are often described poorly and hence remain fuzzy. The rating scale itself hence become an important factor as participants are searching for potential cues [41]. In fact, participants tend to develop attitudes toward rating scales based on characteristics such as graphical elements and input variables [10, 19, 20]. Attitudes, in turn, can affect cognition and behavior [42]. In this context, Riedl et al. [20] found that users perceive different rating scales as more or less exciting, entertaining, satisfying, and positive, which can be explained by flow theory [43], suggesting that people can become very immersed by an activity, accompanied by high concentration on a task, while losing self-consciousness. Koufaris [44] suggested that flow states are related to increased intrinsic enjoyment and perceived control. Both constructs are also related to intrinsic motivation [45]. IS research established intrinsic motivation to be an important factor in creating favorable user perceptions, intention, and actual system use [21, 22]. In contrast, all too simple or overwhelmingly complex systems may deter users from entering such states, rendering system use a frustrating experience which is in consequence unlikely to be continued. Several potential antecedents of frustration come to mind. Given the structure of evaluation tasks with many diverse ideas, information overload is a concern which we further outline in the next paragraphs.

2.3 Information Overload

Information overload can be characterized as a state in which cognitive processing capacity is exceeded by the volume and speed of incoming stimuli that need to be processed [8]. People continuously evaluate their usage of information systems and discontinue usage when experiencing techno stress [46]. For instance, Maier et al. [47] found that users stop using social network services when experiencing, among other factors, exhausting levels of information disclosures by friends leading to information overload. Koroleva et al. [48] found similar results for Facebook and Eckhardt el. [49]

did so, asking participants in an experiment on LinkedIn to extract specific information for a job application. The phenomenon of information overload might be especially pronounced in open innovation evaluation tasks as users need to process a manifold, diverse, partly contradicting, and often novel set of ideas. Aggravatingly, the proposers usually do not follow a common schema, style, or language in describing their ideas. Comparing ideas across one another may hence be particular challenging.

Depending on the structure of the rating scale and evaluation task, perceived information load may thus differ [8]. It has, however, not been investigated with regard to rating scales in IS studies thus far. In the following, we hence describe a design allowing to relate users' perceptions of information overload to different rating methods, forming the basis of the field experiment reported in this paper.

3 Experimental Design

In this section, we outline an approach to address our research questions. Similar to Klein and Garcia [7], our study is based on an (internal) open innovation campaign at an actual private-public research center. Both the ideation as well as the evaluation phase were part of a broader participatory process at this institution [28]. The institution is legally incorporated as a foundation, disposes over a yearly budget of approximately €14 million, and employs a total of 280 people. Employees work on a variety of projects in the domains of computer science, information technology, robotics, and engineering.

Our study employs a two-staged approach. In the first stage, employees of this institution were invited to propose ideas on how to make the research center an (even better) employer via an online system. We invited all employees to this online platform. In the second stage, all employees were invited again to rate the ideas in a condensed set, using either BOL, up- and down-voting, or Likert scales.

3.1 Stage 1: Idea Generation

Employees of the institution were asked to propose ideas on how to make the center an (even better) employer. In a first phase, we received a total of 71 "raw" proposals. Before proceeding to the second stage, we eliminated hoax and proposals not compliant with the terms of use (e.g., including clear names of employees or foul language), consolidated redundant proposals, redacted grammatical and other language- and style-related issues, and in consequence, generated a condensed and workable idea corpus of 42 proposals. The proposals covered a wide range of topics, addressing organizational procedures, marketing, human resources, and many other areas. In this first stage, participants were able to propose ideas within a range of two weeks. Ideas were generally posted anonymously in order to both comply with German data protection legislation and to enable employees to speak their mind freely [50, 51].

3.2 Stage 2: Idea Evaluation

In the second stage, employees were then invited to rate their peers' proposals on another online platform. This platform was accessible for two weeks, too. Here, each employee could participate only once. Participants were prompted to assess the ideas' overall quality, which may be based on subcategories such novelty, feasibility, or value to the company [15, 20, 30, 39]. Note, however, that these sub-dimensions were not surveyed separately. In fact, idea evaluation was based on either bag of lemons, up- and down voting, or Likert scales.

Each participant was allocated to only one of the three treatment conditions (between-subjects design). All participants were presented the same 42 proposals in all treatment conditions, using a random order for each participant in order to rule out sequence effects. Following Klein and Garcia [7], participants in the BOL setting disposed over a total of eight lemons, representing ~20% of the total idea basket, which they were able to allocate to the ideas. In the up- and down-voting setting, participants could either up-vote or down-vote each idea once. This setting replicates that of platforms such as YouTube. Participants in the Likert scale setting were able to rate the ideas on 5-point Likert scales, ranging from 1 (very bad) to 5 (very good). Exceeding previous studies [7, 15, 20], participants in the Likert and up- and down-voting treatments were free to rate as many ideas as they liked, that is, there was neither a minimum nor maximum requirement. Participants were asked to complete a mandatory quiz before the actual rating task in order to ensure comprehension and hence validity.

3.3 Measures

After completing the rating process, participants were asked to conduct a brief survey. To ensure validity, previously validated scales were used and adapted to the context of this study. We assessed user attitudes towards the rating method, operationalized by the categories novelty and frustration [20, 52]. Information overload was adopted based on the items proposed by Schultz and Vandenbosch [8]. To assess user activity, we measured how many votes were casted in relation to the maximum number of votes in the respective treatment. This index ranges between 0 and 1.

Table 1. Measurement items

Construct	***Item***	***Source***
Perceived Novelty	Using the rating scale was a novel experience to me.	[20]
Frustration	Using the rating scale was a frustrating experience to me.	[20]
Information Overload	In using the rating scale, I was forced to concern myself my many idea proposals.	[8]
	In using the rating scale, I could not focus on the actual relevant idea proposals.	
	The rating scale overcharged me by too many idea proposals and too much information.	

4 Results

In total, 141 participants completed the questionnaire, representing approximately 50% of the total workforce at the institution. Altogether, 54 participants evaluated the ideas using BOL, 48 were in the Likert treatment, and 39 in the up- and down-voting treatment. In compliance with German privacy regulation, participants were able provide personal information on a voluntary basis. Thus, only part of our sample reported age (61.5%) and/or gender (71.5%). The age of the (reporting) participants ranged from 18 to 37 years (mean 28.9). Moreover, 80% of our participants were male. These characteristics did not differ significantly among the three treatments.

We first turn to the central target measures of this study, user activity and frustration. As illustrated in Figure 1, user activity was highest for the BOL method, and lowest for up-/down voting. A set of t-test confirms the significance of these differences ($t_{BOL/Likert} = 1.648$, $p=.103$; $t_{BOL/U\&D} = 4.347$, $p<.001$; $t_{Likert/U\&D} = 3.206$, $p<.001$). As a first result, we thus note that the bag of lemons rating scheme facilitates higher levels of user activity than Likert scales or up- and down voting.

Next, we consider how frustrating users perceived the different rating methods. Figure 1 shows that BOL provokes markedly higher levels of frustration than the other methods, whereas Likert and up-/down voting yield comparable levels. A set of t-test confirms this impression statistically ($t_{BOL/Likert} = 2.498$, $p=.014$; $t_{BOL/U\&D} = 2.783$, $p=.007$; $t_{Likert/U\&D} = .283$, $p=.778$). As a second result, we note that the bag of lemons rating scheme facilitates higher levels of perceived frustration than Likert scales or up- and down voting.

Besides these focal measures, we surveyed the participants in terms of how novel and how (informational) overloading they perceived the three rating methods. As can be seen in Figure 1, both for novelty and information overload, the bag of lemons method yields (marginally) significant higher levels than the other two (Novelty: $t_{BOL/Likert} = 11.033$, $p<.001$; $t_{BOL/U\&D} = 11.711$, $p<.001$; $t_{Likert/U\&D} = .983$, $p=.328$; Overload: $t_{BOL/Likert} = 1.816$, $p=.072$; $t_{BOL/U\&D} = 2.555$, $p=.013$; $t_{Likert/U\&D} = 1.0613$, $p=.292$).

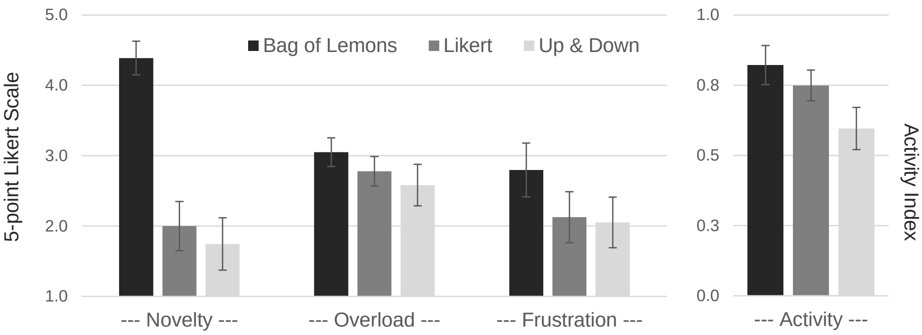

Figure 1. Overview of novelty, information overload, frustration, and activity scores (error bars indicate 95% confidence intervals)

We now turn to a structural analysis of the effects of rating scale on user activity and frustration. As we have outlined in Section 2, we hypothesize perceived novelty and information overload as potential mediators, that is, carriers and hence psychological determinants of the rating scale effects on the target measures. For doing so, we slightly simplify the analysis, comparing the bag of lemons method against both other methods simultaneously, that is, using only one binary dummy variable for "bag of lemons." Our model, along with the results, is depicted in Figure 2. We use structural equation modelling based on partial least squares (SEM-PLS) to operationalize this analysis. Specifically, SmartPLS 3.0 [53] was used due to its flexibility in terms of sample size and its lack of assumptions regarding data and residuals distribution [54]. The sample size of this study (n = 141) exceeded the minimum required to validate a model in PLS, given the present structural model [55]. Confirming the results from above, this analysis shows that the bag of lemons significantly increases the perception both of (rating scale) novelty (*b*=.743, *p*<.001) as well as information overload (*b*=.212, *p*<.010). Information overload, in turn, significantly drives frustration (*b*=.262, *p*<.010), whereas the direct path from BOL to frustration is insignificant. Thus, information overload fully mediates the method's direct impact on frustration (beyond its indirect effect via this path).

In contrast, there does not occur any mediation on user activity, neither via perceived novelty, nor via information overload – both paths are insignificant. There exists, however, a positive and significant direct effect from BOL to user activity (*b*=.390, *p*<.001).

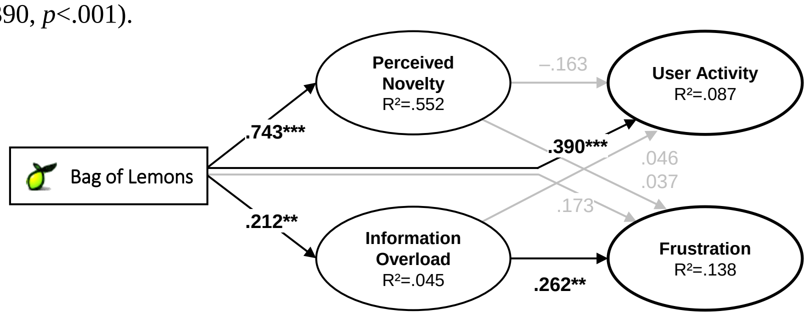

Figure 2. Structural Research model, including standardized path coefficients and R squared values (*** *p*<.001; ** *p*<.01)

Lastly, we considered the individual task completion times. Since this factor has an open-ended scale in one direction, Figure 3 depicts the main characteristics of the time distributions for the three treatment conditions in boxplot diagrams (indicating, median, as well as 25%- and 75%-quartiles). We find that the three conditions do not differ significantly in terms of completion time ($t_{BOL/Likert}$ = 1.564, *p*=.122; $t_{BOL/U\&D}$ = 1.467, *p*<.147; $t_{Likert/U\&D}$ = –.097, *p*=.923).

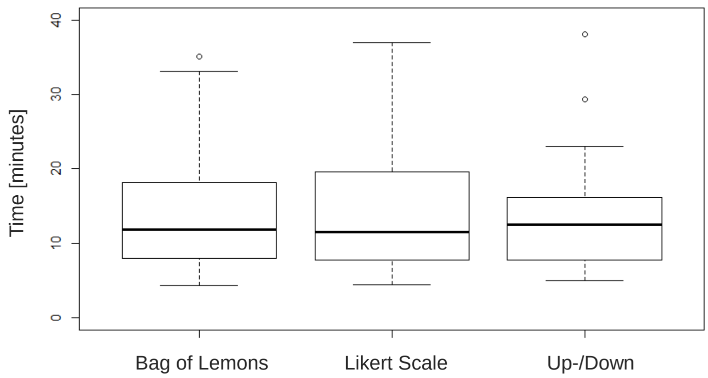

Figure 3. Boxplots of task completion times

5 Discussion and Conclusion

In this paper, we analyzed the effects of rating scales on users' activity, perceived information overload, perceived novelty, and frustration. In a field experiment in an open innovation campaign for a mid-size German research center, we assessed how BOL, up- and down-voting, and Likert scales differed in terms of these measures when employees were asked to evaluate a corpus of ideas created by their peers. All employees of the research center were invited to rate 42 proposals, being exposed to one of the above mentioned rating scales (between subjects design). Analyzing the behavioral as well as the post-evaluation survey data, we demonstrate that BOL, while stimulating activity, is also perceived as more frustrating than other rating techniques. We trace this result to the mediating factor of perceived information overload. Although participants were exposed to the same amount of information, that is, the identical corpus of 42 ideas, the bag of lemons method yielded much higher overload perceptions. We suggest that this may be due to deliberative and "pending" nature of the bag of lemons approach. While using Likert scales or up/down voting techniques, each idea can be assessed at a time, allocating lemons to a set of many ideas can be challenging since the desire to allocate a lemon late in the process may require to reassess previously rated ideas, for instance, to decide where to withdraw lemons from. This need for continuous cross-links requires to keep more ideas in mental "working memory," whereas they can be considered (and forgotten) sequentially when using the other techniques.

Coming back to our first research question of how the "Bag of Lemons" rating method affect user activity and frustration in a collaborative evaluation task, we hence can summarize that BOL increases both user activity and frustration. With regard to the second research question, that is, the role of perceived novelty and information overload in mediating these effects, we see that information overload fully mediates the effect of the BOL method on frustration, while perceived novelty does not exhibit any mediating properties. Moreover, there do not occur any cross-mediating effects, that is, from novelty to frustration or from information overload to activity.

Considering that approximately 50 percent of the employees of the institution evaluated their peers' proposals, this also hints at the high interest of employees in getting engaged in the process of participating in the decision-making processes at their workplace [28].

Theoretical and Practical Implications

This study contributes to the literature by evaluating a novel, thus hardly researched method of idea evaluation (BOL) in comparison to more established methods (Likert scales, up-/down voting). We focus on the important indicators of *user activity* and *frustration,* which has not or only scarcely been assessed by extant literature in this context. By integrating these opposing factors within a joint research model, we enhance the understanding of collaborative evaluation processes in view of differentiated rating regimes [5, 25, 26]. Next, by relating these key indicators to mediating factors, we provide starting points for understanding *how* the different rating methods affect the users' perceptions and behaviors. In particular, we identify perceived information overload as a potential mediating factor at play. Moreover, our study provides a show case of employee-driven innovation [27] and computer-supported organizational participation [28]. We confirm findings of Riedl et al. [20], who suggested that people form attitudes towards rating scales. Our findings also lend support to Klein and Garcia [7], underpinning BOL's novelty but, in contrast, do not confirm the method's superiority in terms of task completion time. Yet, we extend the authors findings by shedding light on users' perception of BOL's restraining character. Participants in our study expressed higher levels of frustration when evaluating ideas using the BOL as compared to Likert and up- and down-voting. This suggests that people might refrain from engaging in a BOL evaluation task in the future. Accordingly, practitioners should be aware of the possibly detrimental effects of BOL when designing an open innovation platform. This effect, as it is mediated by perceived information overload, may substantially be driven by the relatively high number of idea. We suggest that idea evaluation tasks with fewer ideas (e.g., 6 to 12), may yield different results.

Limitations and Future Research

Our study needs to be considered against several limitations. First, we compared the different rating methods in terms of user activity, frustration, and time, however, could not consider the evaluations' accuracy, that is, a match between the crowd's assessment versus how good the ideas actually were. This limitation points at several paths for future research, very much in the sense of prior studies [7, 20]. Future work needs to take into account accuracy, for instance by comparing the collaborative results with an expert rater panel.

Next, as we have shown in this study, BOL facilitates higher levels of (relative) user activity than other rating methods. Nonetheless, on average, Likert and up-/down votes yield a higher overall numbers of idea evaluations. Systematically varying the amounts of ideas and "lemons" to distribute could thus shed more light on the strengths and weaknesses of the BOL approach and its robustness against different set sizes.

Due to strict German data protection legislation at the workplace, we were only able to capture some demographic characteristics of our participants. Thus, the data set is somewhat incomplete and restricts us from fully taking into account potential age or gender effects. Based on the data we have, these characteristics did not differ between treatments, so that at least a treatment bias due to demographic factors could be ruled out. Another limitation relates to the fact that part of the correlation between the item-based measures may be due to common method bias as most data was collected using standard questionnaire items. User activity represents an exception; correlations here will not exhibit common method bias.

As this study finds rating scales to affect user frustration, we suggest that it is worth exploring the antecedents of scale-related techno-stress. The noteworthy differences for information overload between BOL and up- and down-voting already lend some support to this presumption.

Furthermore, our study as well as previous ones [7, 10, 15, 20, 34] asked participants to rate ideas in the absence of any indication on whether and how other users already rated proposals. Future research could thus investigate the impact of information cascades, that is, users being able to see the evaluations of other (earlier) users [56], which may significantly impact results [57]. Finally, future research should address how open innovation contests within companies shape employee commitment and overall productivity [28].

The Rise of Crowd Aggregators
- How Individual Workers Restructure Their Own Crowd -

Abstract. Crowd work has emerged as a new form of digital gainful employment whose nature is still a black box. In this paper, we focus on the crowd workers – a perspective that has been largely neglected by research. We report results from crowd worker interviews on two different platforms. Our findings illustrate that crowd aggregators as new players restructure the nature of crowd work sustainably with different effects on the behavior as well as the existing relationships of crowd workers. We contribute to prior research by developing a theoretical framework based on value chain and work aggregation theories which are applicable in this new form of digital labor. For practice, our results provide initial insights that need to be taken into account as part of the ongoing discussion on fair and decent conditions in crowd work.

Keywords: Crowdsourcing, Crowd Work, Digital Work, Division of Work.

1 Introduction

In the last few decades the nature of work and employment relations has been changed sustainably on various levels, particularly caused by the restructuring of value chains [1]. As a result, the relationships are becoming unstable and the number of self-employed people is increasing in many industries [2]. With the rise of new information and communication technologies (ICT) as well as the internet, value chain restructuring relates to digitally mediated services. Nowadays, these services increasingly take place on online labor markets where labor is exchanged for money via the internet [3]. However, in course of the online labor markets a new form of digital work has emerged, i.e. *crowd work.*

This phenomenon can be described as a distinct type of labor that is located at the intersection of digital work and gainful employment, in which an undefined mass of people (i.e., crowd worker) creates digital goods via an open call [4]. Substantial parts of the value creation take place on IT-facilitated platforms provided by intermediaries. These intermediaries usually divide the tasks into discrete subtasks, distribute them and subsequently aggregate the contributions to a final solution [5].

13th International Conference on Wirtschaftsinformatik,

Durward, D.; Blohm, I. (2017): The Rise of Crowd Aggregators - How Individual Workers Restructure Their Own Crowd -, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 395-409

Crowd work has shown a strong track record as the number of platforms and crowd workers has been growing continuously. Hence, the World Bank estimates the total crowd work market to be $4.8 billion in 2016 and up to $25 billion in 2020 [6].

Despite this rather growing importance, research on crowd work is still in its inception, in particular regarding the ones who perform the work, i.e. the crowd workers. Prior research that focused on the individual crowd worker have examined their motivations to participate in different types of projects [e.g., 7, 8], their demographical backgrounds [9], or analyzed antecedences of their task performance [10]. Furthermore, other researchers focused on characteristics of the crowd that meet specific organizational needs [11], as well as trust-related aspects [12]. Although few studies have been conducted to address the individual worker, there is a gap in understanding experiences and perceptions of crowd workers [13], in particular regarding the structure of work. Most research focused on the intermediaries and the processes of work aggregation on online labor markets [14, 15]. However, besides the ongoing value chain restructuring and its potentials, new hierarchies can be observed in online labor markets that apparently need to be analyzed out of an individual's view in order to gain a better understanding [1].

Thus, we examine aspects of restructuring and aggregation in crowd work context out of a crowd workers` perspective. For practice, it is essential to understand the continuous reshaping in crowd work in order to anticipate effects on the workforce. Furthermore, we contribute to the research fields of crowd work as well as online labor markets by describing more precisely the relationships between the involved parties and the prevailing conditions in the crowd-based value chain.

Therefore, we intend to fill the outlined research gaps regarding the perception of crowd work by addressing the following research question:

RQ: How do individual workers perceive the nature of crowd work regarding structure and aggregation?

2 Conceptual Background

2.1 Crowdsourcing and Crowd Work

The phenomenon of crowdsourcing describes a new form of outsourcing tasks, or more accurately, value creation activities and functions. According to Blohm et al. [16], the fundamental idea of crowdsourcing is that a crowdsourcer (which could be a company, an institution or a non-profit organization) proposes to an undefined group of contributors or crowd workers (individuals, formal or informal teams, other companies) the voluntary undertaking of a task presented in an open call. In this context, the ensuing interaction process unfolds over IT-based platforms. These platforms are provided by crowdsourcing intermediaries that assure the connection between the crowdsourcing companies (i.e. the crowdsourcers) and the crowd workers. Since these intermediaries provide platforms on which supply and demand of labor meet, they represent online labor markets as well as a new approach of work organization [17]. Figure [1] illustrates the traditional crowdsourcing context including the three mentioned parties.

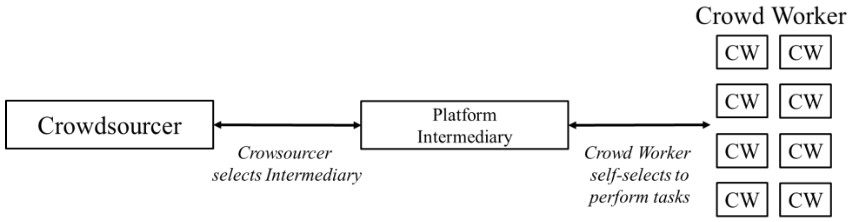

Figure 1: Roles and mediation in crowdsourcing initiatives (Source: adapted from Zogaj, Bretschneider et al. [18])

Furthermore, research has found important differences between the notions of crowdsourcing and crowd work [e.g., 4, 19]. According to Durward et al. [4] crowd work resembles a distinct type of labor that is located at the intersection of digital work and gainful employment. While crowd work is always paid, participation in crowdsourcing initiatives may have different motives and does not necessarily require financial remuneration, for example unpaid work that is done for a common good promoted by galleries, libraries, archives, or museums [e.g., 20]. Thus, out of an individual's perspective, crowd work reflects a kind of digital gainful employment that is based on crowdsourcing as organization principle. In this paper, we focus on the perception of crowd work out of an individual's view.

2.2 Value Chain Restructuring

In business studies literature, the value chain is an old-established concept that has been predominantly used by Porter [21] and describes a sequence of productive (i.e., value-added) activities leading to the delivery, consumption and maintenance of goods and services [22]. The term value chain is also used to emphasize the power relations, the vertical ties as well as sequential stages of production as well as service provision processes [23]. In this context, value chains are seen as dynamic and reconfigured on an ongoing basis [22]. However, online labor markets seem to be at the cutting edge of this new era of service chain value restructuring since they bring together buyers and sellers of digitally mediated service work [1].

Against this backdrop, crowd work is performed on online labor markets as crowd workers sell their skills and labor to crowdsourcers in order to generate various services that are mediated by the platform intermediary. In the last few decades, this service value chain restructuring has shaped the nature of work and employment sustainably [23]. In particular, the pattern of reintermediation has been shown to be a profound change in online labor markets since it refers to the disappearance of direct connections between clients and workers [1]. Against this backdrop, emerging structures, new forms of intermediation or aggregation in crowd work as a novel digital gainful employment need to be analyzed more precisely.

2.3 Work Aggregation

In general, aggregation is defined as the collecting of units or parts into a mass or whole [24]. This definition can apply to various contexts, including work and labor markets, on which work aggregators are able to break more complex projects into microtasks, distribute them to thousands of workers and subsequently aggregate the subtasks to a final solution [18]. A similar notion refers to online labor markets, in which work aggregators provide a managed service and platform usually as a layer on top of a intermediary's platform [25].

In crowd work context, there is an ideal-typical process of projects. Initially, the general task gets decomposed, described in detail and distributed to the crowd [4]. Breaking down tasks into subtasks can be provided either by the intermediary or the crowdsourcer itself. There are specific task modularization mechanism that provide functionalities that enable crowdsourcers to divide tasks into fine-grained subtasks [5]. Afterwards, the actual processing of the tasks takes place, before the solutions get selected and aggregated. Thus, this task decomposition and the reintegration are accomplished by the crowdsourcer in collaboration with the intermediary [5]. Against this backdrop, the analysis-synthesis concept comprises the decomposition of the main task into subtasks delegable to people and further the synthesis of subtasks results in order to reach the goal of the whole organization [26]. In previous research on crowd work [e.g., 5, 27, 28], work aggregation has mainly focused on the intermediaries or on the organizations as crowdsourcers.

However the perceptions and roles of the individual crowd workers regarding aggregation have been widely neglected. We assume that there are specific forms of aggregation within crowd work due to the predominant heterogeneity of potential contributors, the varying complexity of tasks and the asymmetric relationships between involved actors.

3 Research Method

3.1 Research Context and Data Collection

In order to develop our theoretical model, we analyzed the work context and perception of crowd workers on two crowdsourcing platforms – i.e., *Elance.com*[1] and *Freelancer.com.*[2] With the aim of preventing elite bias [29], we have chosen these marketplaces to overcome biases resulting from a single intermediary and due to the diversity of offered tasks as well as the various types of crowd workers. The primary data source contains of 12 semi-structured interviews since this kind of interviews are well suited in exploring attitudes, values, beliefs as well as the views of a person towards a phenomenon of interest [30]. Hence, we decided to conduct semi-structural interviews to understand the socio-technological context of crowd work out of a workers' perspective and extract their individual views regarding the nature of work.

[1] https://www.upwork.com/about/
[2] https://www.freelancer.com

In developing the interview protocol, we therefore used Kvale's [30] framework of conversational, qualitative interviewing as a template to ensure that our semi-structured interview elicit information relevant to our research question. Based on these guidelines, we designed an open-ended interview protocol that focused on the work environment and the perception of work by using the well-established constructs of the work design questionnaire (WDQ) [31]. In IS research it is essential to provide an explicit framework for guiding the participants throughout the interview to articulate and interpret their experiences [32]. Since the key topics of the interviews derived from the WDQ as our framework, we had to modify the wordings of the questions and adjust them to the study context of crowd work. The interviews took place between December 2015 and January 2016. Every single interview lasted between 60 and 90 minutes and was conducted with voice over IP (VoIP) communication via *Skype*. Since a respondent and an interviewer might be less engrossed in an interview conducted by telephone than in person [33] and anonymity is assured, we therefore aimed to prevent interviewer bias as well as social desirability and thus generating accurate information [34]. Subsequently, the interviews has been transcribed, coded and analyzed by using the analysis software package *ATLAS.ti*.

Since we aim to provide an unbiased data basis, numerous and knowledgeable respondents who view the focal phenomena from diverse perspectives, have been interviewed. Thus, we select respondents who differ regarding the duration of marketplace membership and performed jobs, (e.g., designing, or coding). As the evaluation of perception and behavior could differ concerning their previous experience, we interviewed more and less experienced crowd workers. Furthermore, we also analyzed their personal data that was available on their publicly visible user profiles. It has been found that the duration of membership (i.e., the time registered on the given platform), the amount of clients, the number of performed jobs and the average hourly rate of the crowd workers are reliable indicators of experience (see Table [1]). We interviewed six crowd workers per intermediary.

Table 1. Selection of crowd workers

Crowd worker	*Membership*	*Category*	*Jobs*	*Average Hourly Rate*	*Clients*
CW1	Nov 11	Writing	64	$ 15	37
CW2	Nov 11	Writing	21	$ 27	15

CW11	May 14	Programming	24	$ 18	21
CW12	Aug 03	Programming	16	$ 80	13

3.2 Data Analysis

We want to find out how crowd workers behave and how they organize their work on crowdsourcing platforms. Thus, according to several researchers [e.g., 35], we apply the approach of Gioia, et al. [36] to analyze our qualitative data. This methodology basically consists of two separate analysis phases. In a first iteration, the analysis follows interviewee-centric terms and concepts in an inductive fashion (1st-order analysis). Within the phase of the 1st-order analysis, a myriad of terms, codes and concepts emerged in the analysis process. Looking for similarities and relations among the many codes we reduced the number of codes to a manageable amount by relating them to concepts. We tied to focus on concepts and tentative relationships emerging from the interviews in order to develop a comprehensive compendium of 1st-order terms [36]. In this context, concepts are vaguely specified notions that capture basic qualities of a phenomenon [36]. In a second step, we organized the 1st-order concepts into 2nd-order (theory-centric) themes and distilled them into overarching theoretical dimensions. These emerging 2nd-order themes indicate concepts that might help to explain the observed phenomena. Subsequently, we distilled the 2nd-order themes even further into aggregate dimensions [36].

In sum, having the 1st-order concepts, the 2nd-order themes and the aggregate dimensions, the foundation for building a data structure is provided. Besides its visualization, the data structure represents a presentation of the process from raw data to terms and themes in conducting the analysis and thus is an essential part of demonstrating rigor in qualitative research [37]. We then formulated dynamic relationships among the 2nd-order concepts in the data structure and transformed these insights into a theoretical model [36]. The focus of building models is how to account for not only all the major emergent concepts, themes and dimensions, but also for their dynamic interrelationships [36]. Against this backdrop, we want to find out how crowd workers perceive and organize themselves in crowd work as online labor markets by following this introduced approach.

4 Results

In a first step, we therefore provide the essential groundwork for theory-building by developing the data structure. Our data structure includes 1st-order concepts that are significant to the crowd workers and 2nd-order themes that are extracted overarching themes. Finally, both iterations enabled us to assemble the aggregated dimensions.

4.1 Constitutive Elements of a Theoretical Model

Relocation of Value Creation. Our findings provide information about several aspects of activities abroad the intermediary's platform. First, certain crowd workers increasingly acquire more tasks on the platform than they can perform by their own. This is an intended action since they subsequently forward parts of the initial job to other crowd workers or even to an own platform external workforce. These persons are usually acquaintances, friends or even family members. We found evidence that certain tasks are given to siblings, partners or the own children by crowd workers: *"I'm looking for someone in order to handle the workload. I'm looking for an editor as good as I am. And my son just had started. At least I can rely on him." (CW7).*

Furthermore, these persons are to be entrusted with certain tasks regularly and thus represent a standing pool of external human resources. Identified motives for this relocation of value creation parts are trust-related aspects, reliability and more efficient interaction between the crowd workers and well-known external persons. Thus the composition of the crowd changes since external contributors get either hired by crowd workers or acquired as part of the existing crowd without necessarily register on the crowdsourcing-platform.

Second, we observed that existing boundaries between the platform-based crowd work and external activities become blurred. We observed that some crowd workers use the crowdsourcing platform only as an acquisition tool for attracting new crowdsourcers. Once the crowd workers have made the initial contact and completed first tasks, the follow-up business will be subsequently realized off-platform via different channels. In this context an interviewee stated: *"I would say that most of the business takes place offside the platform […] Most people finally use the platform in order to acquire clients." (CW3).*

In fact, the crowd workers proactive use various communication technologies like VoIP, E-mail, phone or virtual workplaces to interact bilaterally with the crowdsourcers instead of using the provided infrastructure of the platform intermediary. A major part of tasks and jobs are consciously processed beyond the platform sphere. In addition, all so-called after sales activities (e.g., customer service) for the crowdsourcers are independently managed by the crowd workers aside the platform. The aim is to develop long-term relationships to the crowdsourcers and simultaneously to save platform fees for both parties. Thus, the original idea of giving problems or tasks into the crowd and all steps of this service value creation will take place on platforms, must be critically questioned. We observed a contrary trend, in which particularly further business relationships develop beyond the platforms. Communication and information exchange as well as the actual task performance with the crowdsourcers take place in external settings of the crowd workers.

In sum, we identified two forms of value chain restructuring in crowd work. On the one hand, we observe an additional step in the crowd-based value creation since single crowd workers acquire tasks and further redistribute these tasks to external persons. One the other hand, the crowd workers are cutting out intermediation by interacting more directly with crowdsourcers and ignore the provided platform infrastructures as well as terms and conditions. This increase of disintermediation is originated from the crowd workers itself and reconfigures the existing service value chains. Hence, the value chain restructuring in crowd work is primarily based on the external relocation of certain value creation steps beyond the platform.

Emergence of New Hierarchy. In general, the decision-making process in crowd work is mutual. The crowdsourcers and the crowd workers are in certain negotiating situations, in which they exert bargaining power on each other through the platform. We observe this to be different when certain crowd workers undertake fundamental functions of the platform such as the management of tasks. Our analyses show that single crowd workers acquire larger tasks from the platform, decompose them into smaller subtasks and distribute these to other crowd workers. In this context, the single crowd worker takes over the governance and management of the subtasks. Furthermore, this mediating crowd worker predefines the conditions of the subtasks like payment, milestones and deadlines, based on the earlier agreements with the crowdsourcer. The other crowd workers, who perform the subtasks, do not have that much space to negotiate in this context since the general conditions have been set already. Thus, decisions are no longer being made bilaterally but by the mediating crowd worker. *"Then I realized that he himself was just a first intermediate step from another client." (CW08),* a hired crowd worker reported. In particular, unexperienced crowd workers who have not yet performed a lot of tasks, are implicitly dependent on these forwarded subtasks. They rely on information and specific input of the mediating crowd worker.

Furthermore, the conventional relationships between crowd workers and crowdsourcers depend on the scope and the type of tasks and thus vary considerably in crowd work. Nevertheless, we observe the relationships between the mentioned mediating crowd workers and the hired crowd workers, to be more long term oriented. The crowd workers who distribute the subtasks aim to develop long-term business relations to the task-performing crowd workers irrespective of the scope or type of task. One reason for this is a certain level of quality assurance since this closer business relationship permits a better control out of the mediating perspective. In the view of the performing crowd workers, this relation might be advantageous as well since they get tasks on a regular basis and thus a more secure income. *"They want to hire you more often and can save the fees for Elance." (CW7),* an interviewee said.

The division of labor is an essential characteristic of crowd work that varies regarding the different nature of tasks. Nevertheless, our analyses indicate that the mediating crowd worker acquires large projects and tasks on the platform, then decompose them and subsequently again broadcast the subtasks to the crowd. For example, the translation of a book chapter in English to French and German does not usually involve any division of labor. The crowd worker acting as an intermediary, however, acquires as well as decomposes the actual task of translation into several subtasks and then distributes them to other crowd workers he will hire. One crowd worker actually translates the text to French, while a second crowd worker will do the same in German. A third crowd worker subsequently proofread the translations before the mediating crowd worker will aggregate the subtasks into a final solution, submit it on the platform and thereby present it to the crowdsourcer. Since this trend is observable in various types of tasks, we can state that the division of labor tends to increase when those mediating crowd workers are present.

Therefore, with the rise of the introduced mediating actor, an additional element of the service value chain has emerged. Since dependencies between crowd workers shift and coordination as well as interaction becomes unilateral, we observed recent developments in crowd work towards more hierarchical structures.

Formation of Specialized Sub-Crowds. The single crowd workers who manage own tasks and projects apart the platform intermediary act as new intermediaries in crowd work contexts themselves. Thus they need their own standing workforce to expand and gain even more jobs. In order to achieve a competitive advantage, these mediating crowd workers, thus acquire their own specialized crowd. They proactively contacting other crowd workers based on their experience and skills to work for them. One interviewee stated: *"There are always many tasks you need certain specialists for and those are forwarded […] so when you are chef, you say that the cutting of onions is taken over by the assistant." (CW12).* The aim is to develop an own pool of expertise that is committed in the long-term by regularly forwarded tasks. Thus, these selections of workers represent sub-crowds that partially use the infrastructure of the platform but are managed by single mediating crowd workers.

Furthermore, these sub-crowds extend the own portfolio of the mediating crowd worker since new services, based on the crowd workers` skills, can be offered on the platform. Against this backdrop, the single mediating crowd worker wants his sub-crowd to be highly diverse concerning their capabilities. For example, a single crowd worker who offers the development of application programming interfaces (API) on the platform by itself begins to build up his own sub-crowd in the area of software development. Thus, the single crowd worker hires a specialist for agile software development methods and another backend developer who is proficient in different programming languages. Finally, a third crowd worker who is an engineer for the design of software products will be hired. The new intermediary manages all activities, subsequently consolidates and aggregates the single subtasks to a final solution. From a marketing point of view, the mediating crowd worker extended its own portfolio by forms of horizontal and vertical diversification.

Once the mediating crowd workers have built up their own workforce, some of them actually invest in their sub-crowds. They provide equipment (e.g., professional software to translate texts) and even share their own expertise and knowledge (e.g., by providing good own design templates). In line with this, one worker mentioned: *"So I bought him the transcription software F4 […] and he would not been able to afford the 50 Euros himself." (CW7).* Thus, the mediating workers act as some kind of mentor and develop their sub-crowds.

In sum, we outline our data structure in figure [2] which illustrates the 2nd-order themes on which we built our model of crowd work aggregators. These insights enabled us to develop a theoretical model of structures and concepts that emerged from the data. Hence, figure [2] represents first building blocks of a theory that have to be aligned and set in relation to each other in the next section.

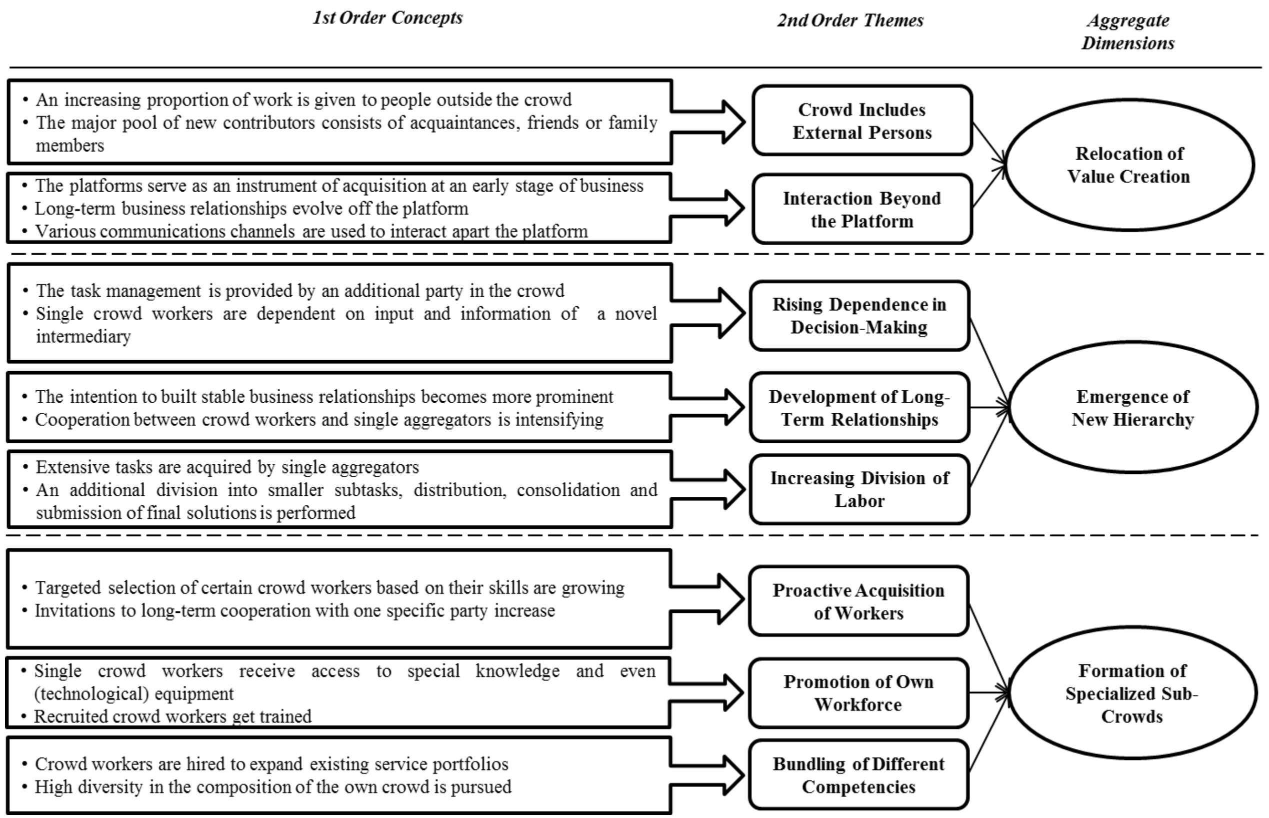

Figure 2: Data structure

4.2 The Role of Crowd Aggregators as New Elements of Value Creation

Although the data structure is essential, it is nonetheless the static picture of a dynamic phenomenon of interrelations [36]. Thus, we develop an inductive model that is grounded in the data of the crowd workers and captures the nature of crowd work in theoretical terms. Therefore, our model shows the dynamic relations amongst the emergent 2nd-order concepts which describe restructuring and reintermediation processes caused by new players in crowd work – i.e., the *crowd aggregators*.

The identified inclusion of external persons in existing service value creation processes changes the nature of crowd work sustainably. In particular, well-known persons of actual crowd workers are actively involved: *"Well, I have also invited friends and kind of activated them as a freelancer. They were previously no freelancers. And I knew what they are capable of and that they will work for that salary."(CW4).* In addition, the interactions between crowdsourcers and crowd workers increasingly take place not only via the platforms but using various channels aside. Hence, we propose that single crowd workers are responsible for this shift away from the actual platform-based crowd work towards a hybrid non-platform-based shape with external elements.

> **Proposition 1:** Crowd Aggregators consciously relocate parts of the value creation in crowd work.

Furthermore, certain crowd workers build up their own workforce by delegating prior decomposed subtasks to other crowd workers. In particular, unexperienced crowd workers are dependent on these tasks in order to gain reputation on the platform. Since the mediating worker usually unwinds repetitive tasks with the same crowd workers, this situation resembles an employer-employee-like relationship. Thus, a long-term relationship between the mediating crowd worker and the task-performing workers easily evolve. A mediating worker noted: *"In the end, I manage so to speak […] I develop myself towards project management and have my own sub-agency." (CW7*). Since the mediating crowd workers delegate and govern the work processes, we assume power asymmetries and dependencies to arise in these relationships. Hence,

> **Proposition 2:** Crowd Aggregators establish hierarchical structures in crowd work.

In addition, the aggregating crowd workers assemble a pool of other workers based on their capabilities and experience. These hired crowd workers further extent the own portfolio of the aggregator and thus represents a flexible workforce: *"I cannot program software. This is beyond my expertise. So, I hired another freelancer who is familiar with the technical details." (CW3).* Although the performing crowd workers are supervised, we found evidence indicating that the mediating crowd worker support its sub-crowd. On the one hand, the sub-crowd benefits from knowledge transfer with the aggregator and further its expertise. On the other hand, the mediating worker provides technical equipment if necessary and thus invest in the own specialized sub-crowd in order to gain reputation and generate more business itself on the crowdsourcing platform.

Proposition 3: Crowd Aggregators proactively develop own specialized sub-crowds.

This crowd aggregator represents a novel business idea in which the crowd is the core instrument of the service value chain. The aggregator is able to shape its own sub-crowd and act as a digital niche provider that guarantees efficient performance based on the specific composition of the sub-crowd. It exploits the provided infrastructure of the platform intermediary and reintermediates more specific services to the crowdsourcers. While the majority of the platform intermediaries focus solely on the pure mediation of tasks, the crowd aggregator supports the crowdsourcer during the entire procedure, particularly in larger and more complex projects. Out of the crowdsourcers view, the core competences of the crowd aggregator are coordination, decomposition and refinement of tasks as well as the final quality control of the single subtasks. Thus, the main assets of the crowd aggregator contain an efficient task assignment and successful management. In sum, we therefor denote a crowd aggregator as: *(1) An individual or a group of individuals that (2) act(s) as a novel intermediary and (3) use(s) existing platform infrastructure to build up its own specified sub-crowd.*

Figure [3] represents the core of our research results and outlines the data-to-theory connections. It illustrates the propositions (i.e., P 1-3) and their relations since it shows the two spheres (i.e., non- and platform-based), the composition as well as the involved parties of service value creation in crowd work. In addition, the model highlights the role and interrelations of crowd aggregators within crowd work context.

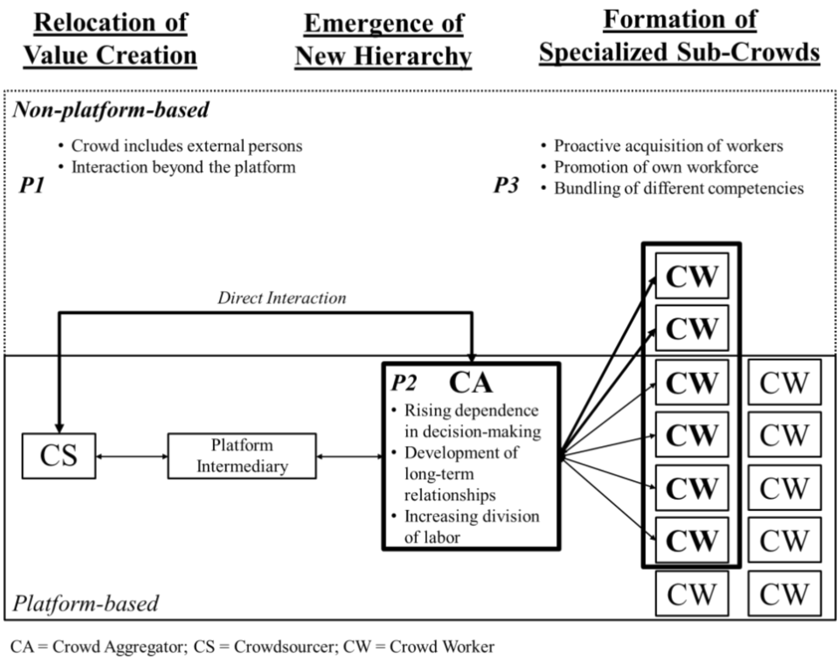

Figure 3: Model of crowd aggregators in crowd work

5 Discussion

We analyzed the nature of crowd work out of an individual's perspective. Thus, we address significant methodological shortcomings since we did not exclusively rely on online data about workers and their behavior [1]. In addition, our research contributes to literature on reintermediation that already takes place in online labor markets [e.g., 23], since we found evidence that the crowd aggregator represents more than an additional step in existing structures by illustrating their impact on structural as well as organizational level [1]. Previous research examined that crowd work describes a new system for the coordination of work that can be classified as ranking between the established forms of the two organizational principles of market and hierarchy [4]. Our findings indicate that crowd work redevelops towards hierarchical structures due to the rise of crowd aggregators. The unilateral decision-making processes, the long-term relationships between aggregator and its workers as well as the higher level of division of labor rather describe crowd work as more hierarchical. Furthermore, our findings can be explained by a lack of automated coordination mechanisms [38] in this crowd work context, since the crowd workers orchestrate the tasks themselves. Due to the missing of a higher-order coordination that provides the matching between the crowd and the offered tasks [26], crowd aggregators emerge as new coordinating elements. Our results are in line with the analysis-synthesis concept [26] since we illustrate that there is a need of certain decomposition and aggregation in crowd work.

For practice, platform intermediaries should closely monitor this development since the relocation of value creation aside the platform by the crowd aggregators may cause losses in control and income. In addition, our findings provide essential insights for the ongoing discussion about fair work conditions in the crowd. On the one hand, crowd aggregators exercise certain power over the crowd workers who are dependent on the aggregator. On the other hand, work conditions might be less precarious due to the rather long-term relationships, the constant supply of tasks and the enhanced provision of information. Nevertheless, the study has several limitations which constrain the generalizability of our results, since we developed our model gathering data from only two intermediaries. Further studies may overcome these limitations by evaluating the provided dimensions in subsequent empirical studies.

6 Conclusion

Given the lack of research on the individual in crowd work, our primary objective was to achieve a better understanding of the nature of work in the crowd. We followed a well-established methodology to conduct a qualitatively rigorous inductive study and developed a theoretical model of crowd aggregators. Our results illustrate that these crowd aggregators represent new players that restructure the workflows in crowd work on different levels and have impact on the behavior and relationships of the crowd workers. The crowd aggregators relocate activities off the platforms, reintermediate existing processes and build up an own sub-crowd. As a result, with their rise, crowd work evolves into a more hierarchical form of labor.

Abstract. Die Einführung von Smart Glasses eröffnet neue Chancen für die Gestaltung zukünftiger Arbeitsprozesse. Bisher sind diese Technologien wenig erforscht und werden nur experimentell hinsichtlich einzelner Aspekte untersucht. Zur Priorisierung zukünftiger Forschungsthemen und Identifikation relevanter Problemstellungen für den Bereich der Wirtschaftsinformatik wurden daher explorative Fallstudien mit zwei Logistikdienstleistern durchgeführt. Zur Ermittlung relevanter Einsatzszenarien wurde eine Triangulation aus Experteninterviews, Beobachtungen und Fokusgruppen gewählt und durch eine systematische Literaturrecherche ergänzt. Die 36 resultierenden Anwendungsfälle wurden mithilfe einer Umfrage priorisiert und auf Basis ihrer qualitativen Aussagen bzgl. der Herausforderungen analysiert. Die Ergebnisse des Beitrags sind (1) Einsatzszenarien für Smart Glasses in der Logistik sowie (2) daraus abgeleitete Forschungsthemen für die Wirtschaftsinformatik. Somit leistet diese Studie einen Beitrag zur Forschung im Bereich des ganzheitlichen Designs von Dienstleistungssystemen und zukünftiger Aufgaben digitaler Arbeit.

Niemöller, C.; Zobel, B.; Berkemeier, L.; Metzger, D.; Werning, S.; Adelmeyer, T.; Ickerott, I.; Thomas, O. (2017): Sind Smart Glasses die Zukunft der Digitalisierung von Arbeitsprozessen? Explorative Fallstudien zukünftiger Einsatzszenarien in der Logistik, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 410-424

1 Einleitung

Die Einführung von Smart Glasses verspricht neue Möglichkeiten zur Digitalisierung von Arbeitsprozessen. Vor allem in Situationen, in denen Mitarbeiter informationsintensive Tätigkeiten ausführen und gleichzeitig freie Hände benötigen, können Smart Glasses kontextsensitive Informationen in das Blickfeld der Nutzer einblenden und sie durch Arbeitsschritte leiten [1]. Die Logistik bietet aufgrund dieser Eigenschaften und zusätzlich starker Mitarbeiterfluktuation eine typische Anwendungsdomäne für Smart Glasses-basierte Dienstleistungssysteme.

Bisher sind diese Technologien wenig erforscht und werden nur experimentell hinsichtlich einzelner Aspekte untersucht (u.a. [2-4]). Eine systematische Literaturstudie zeigte, dass konkrete Anwendungsfälle in der Logistik bisher vor allem in praxisorientierten Fachmagazinen diskutiert werden (u.a. [5]). Dadurch bestätigt sich zum einen die betriebliche Relevanz des Themas, andererseits zeigt es die Lücke in der Forschung. Um dieser Lücke zu begegnen, wurde eine explorative Fallstudie in Kombination mit einer systematischen Literaturstudie durchgeführt, um Anwendungsfälle für die Logistik zu sammeln, abzugrenzen, zu definieren und weiteren Forschungsbedarf für die Wirtschaftsinformatik aufzuzeigen. Dabei wurden zum einen ein global agierender Logistikdienstleister mit Fokus auf die Kontraktlogistik sowie ein mittelständischer Logistiker mit Fokus auf die Fashion-Logistik ausgewählt. Zur Ermittlung relevanter Anwendungsfälle wurde eine Triangulation aus Interviews, Beobachtungen und Fokusgruppen gewählt und durch eine systematische Literaturrecherche ergänzt. Es zeigte sich, dass in der Literatur bisher vor allem klassische Themen wie Kommissionierung und Serviceunterstützung betrachtet wurden [6-8]. Die Fallstudie ergab allerdings zusätzliche Anwendungsfälle wie u.a. Workload Management, Integration der Kunden zur Direktabwicklung bspw. im Schadensmanagement (Value Added Services) oder automatisierte Prozessdokumentationen, welche bislang kaum betrachtet wurden. Zur Kategorisierung der Anwendungsfälle hinsichtlich weiterer Untersuchungen und zur Analyse ihrer Relevanz wurden die 36 ermittelten Anwendungsfälle mithilfe einer Umfrage bewertet und durch qualitative Aussagen zu möglichen Herausforderungen bei der Umsetzung ergänzt.

Die Ergebnisse des Beitrags sind Einsatzszenarien für Smart Glasses in der Logistik und eine Diskussion und Priorisierung dieser. Somit leistet dieser Artikel einen Beitrag zur Forschung im Bereich des ganzheitlichen Designs von Dienstleistungssystemen und zukünftiger Aufgaben digitaler Arbeit. Es liefert die Basis für weitere Forschung sowohl für (a) die gestaltungsorientierte Wirtschaftsinformatik, indem einzelne Szenarien mit Smart Glasses priorisiert zur Umsetzung vorgeschlagen werden und welche Herausforderungen dabei zu beachten sind (bspw. Datenschutz, technische und organisatorische Integration), als auch (b) für die verhaltensorientierte Forschung, u.a. welche Bereiche priorisiert betroffen sein werden und welche neuen Arbeitsformen sich ergeben. Der Beitrag gliedert sich wie folgt: In Abschnitt 2 wird zunächst das methodische Vorgehen begründet dargestellt. In Abschnitt 3 werden die abgeleiteten Anwendungsfälle aufgezeigt. In Abschnitt 4 werden diese hinsichtlich ihres weiteren Forschungsbedarfs diskutiert. Abschließend werden in Abschnitt 5 die Ergebnisse zusammengefasst und ein Ausblick gegeben.

2 Methodisches Vorgehen

2.1 Forschungsmethode

Um zu untersuchen, in welchen Prozessen Smart Glasses nutzbringend eingesetzt werden können, wurde eine Fallstudie im Rahmen des von Yin definierten Case Study Research Vorgehens gewählt [9]. Zwei Fälle innerhalb des Logistikbereichs werden unter der Benutzung von Replikationslogik evaluiert. Jeder Fall stützt sich auf mehrere Beweisquellen, aus denen Daten im Zeitraum der letzten 11 Monate extrahiert wurde.

Für die Fallstudie und die zu Grunde liegende Identifikation relevanter Use Cases wurden die Prozesslandschaften von zwei Logistikunternehmen untersucht. Die Auswahl der Unternehmen erfolgte auf Basis der Zielsetzung, möglichst viele unterschiedliche Prozesse mit hoher Stückzahl zwecks späterer Validierung zu untersuchen. Das ausgewählte global agierende Kontraktlogistikunternehmen (Fall A) zeichnet sich durch ein breites Spektrum an Anwendungsfällen aus dem Bereich der Lager- und Transportkonzepte aus. Diese reichen von See- und Luftfracht bis zur Lieferung per Zug und LKW mit mehr als 20 Mio. Sendungen pro Jahr. Ergänzt wird dies durch einen mittelständischen Logistikdienstleister (Fall B), der als Anbieter für Fashionlogistik vor allem als Experte im Bereich Kommissionierung und Value Added Services fungiert.

2.2 Datenerhebung und –auswertung zur Bestimmung der Use Cases

Zur Erhebung der Daten wurde eine Triangulation [10] aus (1) einer strukturierten Literaturrecherche, (2) Shadowing von Logistikprozessen, (3) Experteninterviews und (4) Diskussionen in Fokusgruppen gewählt.

Literaturrecherche. Zunächst wurde eine strukturierte Literaturrecherche durchgeführt [11, 12]. Dazu wurden folgende Datenbanken der Wirtschaftsinformatik und Wirtschaftswissenschaften (Ebscohost, ScienceDirect, AISeL, ACM, IEEE, Jstor, SpringerLink) sowie alle Journale des VHB Teilrankings der Logistik [13] analysiert. Zudem wurde die Suche auf die Datenbank WISO und Google Scholar ausgeweitet, um zusätzlich aktuelle Entwicklungen der Wirtschaft über tagesaktuelle Printmedien und sogenannte Grauliteratur abzudecken. Zur Identifikation von Use Cases in der Literatur wurde dazu die Kombination der Begriffe Datenbrille und Logistik, sowie deren englische Äquivalente, für die Suche verwendet (u.a. *"Smart Glasses" AND Logistics* und *Datenbrille AND Logistik)*. Die identifizierte Literatur wurde in Hinblick auf ihre Relevanz überprüft sowie entsprechend systematisiert und ausgewählt [12]: Einbezogen wurden Publikationen, (a) in denen Use Cases bzw. mögliche Anwendungsszenarien der Smart Glasses im logistischen Umfeld beschrieben werden und (b) in denen beispielhafte Umsetzungen von Smart Glasses Lösungen in Projekten des logistischen Umfelds erläutert werden. Ausgeschlossen wurden Publikationen (c) ohne Fokus auf die Logistikbranche, (d) mit thematischem Schwerpunkt auf „Smart Glass“ (intelligentes Fensterglas) und (e) in denen die Suchwörter ausschließlich getrennt voneinander behandelt werden. Es wurden 53 relevante Publikationen identifiziert.

Shadowing. Das Shadowing [10] diente im Rahmen der Forschungsarbeit dazu, durch Beobachtung der Arbeitsabläufe und Tätigkeiten erste potentielle Use Cases für Smart Glasses zu identifizieren. Zu diesem Zweck wurden jeweils am Standort Osnabrück eines globalen Logistikdienstleisters zunächst in einem Umschlagslager über zwei Tage alle relevanten Tätigkeiten zur Abwicklung des Stückgutgeschäfts analysiert und daraufhin in einem Distributionslager für drei Tage die Kernprozesse Wareneingang, Einlagerung, Kommissionierung und Warenausgang beobachtet. Die Erhebung wurde in Form von Feldnotizen und Prozessmodellen dokumentiert. Auf Basis der dokumentierten Prozesse wurden von den Wissenschaftlern die einzelnen Aktivitäten in Bezug auf potentielle Einsatzfelder für Smart Glasses diskutiert. Ein Use Case wurde definiert, wenn eine Aktivität durch Smart Glasses (a) entweder eine bessere Informationsbereitstellung oder (b) eine einfachere Umsetzung komplexer oder überflüssiger Arbeitsabläufe ermöglicht werden kann.

Experteninterviews. Durch Experteninterviews wird eine thematische Sondierung des Forschungsgegenstands aus einer praktischen Perspektive ermöglicht [14]. Im Rahmen der Experteninterviews wurden ein Business System Consultant sowie ein Business System Analyst mit 11 und 6 Jahren Berufserfahrung in der Position aus Fall A befragt. Beide Teilnehmer besaßen Expertise bezüglich der Informationssysteme (IS) und der Geschäftsprozesse des Logistikdienstleisters. Erste Kenntnisse über die Technologie der Smart Glasses lag insofern vor, dass die Probanden bereits Modelle wie die Google Glass selbst getestet, allerdings noch keine eigenen Implementierungen durchgeführt hatten. Der Leitfaden zur Durchführung der Experteninterviews bestand aus einer Reihe Fragen, die einen Transfer des Wissens der Experten über die logistischen Prozesse und die jeweiligen fachlichen Anforderungen auf die Technologie der Smart Glasses anregen sollten. Die Fragen waren dabei: (1) *Wie könnten Lagermitarbeiter im Umschlagslager durch Smart Glasses unterstützt werden?*, (2) *Haben Sie bereits mobile Informationssysteme im Güterumschlag im Einsatz?*, (3) *Wo würden Sie weitere Einsatzszenarien für Smart Glasses in der Logistik sehen?* und (4) *Gibt es Bereiche, Funktionen oder Tätigkeiten für die Sie den Einsatz von Smart Glasses kategorisch ausschließen würden?*.

Fokusgruppen. Die Durchführung der Fokusgruppen orientiert sich methodisch an dem von Bürki [15] und Misoch [16] beschriebenen Ansatz, indem zunächst Stimuli vorausgingen (hier Besichtigungen einzelner Läger von Fall A und B) und danach eine Gruppendiskussion durchgeführt wurde, dessen Ergebnisse von einem Protokollanten dokumentiert wurden: Es wurden vier Gruppendiskussionen an wechselnden Standorten durchgeführt. Der Kreis der Teilnehmer war überwiegend konstant, divergierte jedoch geringfügig auf Grund terminlicher Diskrepanzen und wechselnder Konsultation von externen Experten der Unternehmen A und B (u.a. Lagerleiter, Schichtleiter). Die konstanten Teilnehmer der Fokusgruppe bestanden aus (a) fünf Experten des logistischen Umfelds aus Fall A und B, (b) drei Wissenschaftlern aus dem Bereich Logistikmanagement, (c) zwei Experten aus der Software Entwicklung eines Software- und Beratungshaus und verknüpfend (d) vier Wissenschaftlern aus dem Bereich Dienstleistungsmanagement und Smart Glasses-Technologien (Leiter der Fokusgruppen-Diskussionen). Den Diskussionen gingen jeweils Stimuli in Form von Führungen durch ein Umschlags- und ein Liegewarenlager der Fälle A und B voraus.

Dies sollte als Impuls bzw. Anhaltspunkt für die Ideenfindung dienen und eine allgemeine Diskussionsgrundlage für die Teilnehmer schaffen. In den ersten drei Fokusgruppentreffen wurden jeweils mögliche Use Cases frei diskutiert, gesammelt und von Protokollanten dokumentiert. In der vierten Fokusgruppendiskussion wurden zu Beginn des Treffens die Summe der Use Cases aus der Triangulation (Literaturrecherche, Experteninterviews, Shadowing und den drei vorausgehenden Fokusgruppen) vorgestellt und anschließend weitere Use Cases ergänzt und diskutiert. Die Fokusgruppe diente neben der Sammlung von Use Cases (Fokusgruppentreffen 1-4) abschließend zur Validierung der aus den einzelnen Methoden aggregierte Liste der Anwendungsfälle. Hierzu fanden zwei weitere Fokusgruppen-Workshops statt (Fokusgruppentreffen 5-6). Dabei wurden auf Basis der aggregierten Liste aus der Triangulation (40 Use Cases) zum einen der Detailierungsgrad, die Verständlichkeit, die interne Konsistenz und die Anwendbarkeit zur Erreichung einer bereinigten und gültigen Liste der Use Cases [17] diskutiert. Dazu wurde jeder einzelne Use Case in Bezug auf Beschreibung, Akteure, Prozessphase (Wareneigang, Kommissionierung, Value Added Services etc.) und beispielhafte Instanziierungen des Use Cases diskutiert. Hierbei wurden die 40 Use Cases zu 36 Use Cases konsolidiert.

Datenauswertung. Zur Erfassung und Verdichtung der Use Cases wurde zunächst einzeln für jeden der vier Datensätze aus den vier Schritten der Triangulation die induktive Kategorienbildung nach Mayring [18] angewandt. Ein Use Case wurde definiert, wenn dieser entweder (a) eine funktionelle Unterstützung, (b) eine Umsetzung fachlicher Anforderungen der Logistik oder (c) potentielle oder erprobte Anwendungsszenarien beschreibt. Das heißt sobald eine der drei Kriterien zutraf wurde ein Use Case aufgenommen [18]. Wurde im weiteren Analyseverlauf wieder eine dazu passende Stelle gefunden, so wurde sie diesem Use Case ebenfalls zugeordnet (Subsumption), alternativ wurde ein neuer Use Case induktiv auf Basis des spezifischen Materials formuliert [18]. Eine grundsätzliche Herausforderung bei der Formulierung und Aggregation der Use Cases war das Auftreten teilweise stark divergierender Abstraktionsgrade bei der Beschreibung der Einsatzszenarien in den unterschiedlichen Methoden. Deshalb wurde, ausgehend von den Ergebnissen der vier verschiedenen methodischen Ansätze, erneut eine Kategorienbildung nach Mayring [18] angewandt, um die Use Cases schrittweise zu subsumieren. Bei der Durchführung dieser Vorgehensweise wurden genau solche Use Cases zusammengefasst, die eine möglichst hohe Homogenität bezüglich der Kurzbeschreibung und Zielführung aufwiesen. Abschließend wurden für alle Use Cases jeweils durch Domänenexperten der Fälle A und B eine Beschreibung (inkl. Akteure, Prozess und Aktivitäten) und Beispiele formuliert. Die Use Cases wurden in den Fokusgruppen-Treffen 5 und 6 validiert und konsolidiert (siehe „Fokusgruppen“) und bilden die Basis für die weitere Bewertung.

2.3 Datenerhebung und –auswertung zur Priorisierung der Use Cases

Datenerhebung. Im Rahmen der Fallstudie wurde eine personalisierte Online-Umfrage [19, 20] zur Bewertung der Use Cases durchgeführt. Die Bewertung der Use Cases wird ermittelt über den Grad der Übereinstimmung des Befragten mit einer vordefinierten Aussage. Die verwendete 7-stufige Skala umfasst die Werte 1 (Stimme gar nicht zu) bis 7 (Stimme stark zu), sowie „Nicht sinnvoll beantwortbar".

Der Fragebogen ist wie folgt strukturiert: Einleitend werden die 36 Use Cases in einer Übersicht dargestellt und als Orientierungshilfe zum Download zur Verfügung gestellt. Die Umfrage beginnt mit der Erfassung demographischer Daten, u.a. zum Arbeitsplatz und der Erfahrung im Umgang mit Smart Glasses. Anschließend erfolgt die Einschätzung der Use Cases einzeln, nach einem einheitlichen Fragenmuster. Dazu erfolgt zunächst die Beschreibung des Anwendungsfalls, unterstützt durch ein konkretes Beispiel im Logistikkontext (diese wurden jeweils durch Domänenexperten aus Fall A und B beschrieben und durch das Forschungsteam konsolidiert). Der Teilnehmer bewertet den jeweiligen Use Case im Anschluss anhand folgender vier Aussagen: (1) *Ich bewerte den Nutzen dieses Anwendungsfalls als hoch.* (2) *Ich bewerte den Innovationsgehalt dieses Anwendungsfalls als hoch.* (3) *Angenommen ich hätte Zugang zu Smart Glasses, dann würde ich sie für diesen Anwendungsfall einsetzen.* und (4) *Ich schätze den funktionalen/organisatorischen Aufwand der Einführung in meiner Organisation wie folgt ein.*

Die Bewertung dieser Aussagen ist obligatorisch für den Fortlauf der Umfrage und kann in einem freiwilligen Kommentarfeld ergänzt werden.

Definition des Fragenkatalogs. Existenziell für die Priorisierung von Umsetzungsprojekten ist die Auswahl relevanter Faktoren als Entscheidungsgrundlage [21]. Nach Jiang und Klein [27] sind für Projekte mit Technologien, deren strategische Auswirkungen langfristig bemerkbar sind, vor allem interne Einflussfaktoren (organisationale, anwenderbezogene, finanzielle, technische, und risikospezifische) entscheidend für die Projektwahl. In einem Fokusgruppen-Meeting wurden die Dimensionen zur Bewertung der Einsatzszenarien diskutiert und abschließend daraus vier Bewertungskriterien abgeleitet: (1) Organisatorischer Aufwand, (2) Nutzen, (3) Anwendungsbereitschaft und (4) Innovationsgrad. Der *organisatorische Aufwand* beschreibt den Aufwand für die Restrukturierung der Arbeitsprozesse. Für die organisationalen Ziele ist vornehmlich der *Nutzen* der Use Cases entscheidend. Die Fortschrittlichkeit der Use Cases und das damit verbundene Potenzial zur Restrukturierung werden durch den *Innovationsgrad* bewertet. Die *Anwendungsbereitschaft* der Use Cases wurde als anwenderbezogene und risikospezifische Dimension identifiziert. Die Business Use Cases repräsentieren die Anforderungen der Anwender; für eine *technische Bewertung* im Einzelnen, sind weitere Differenzierungen und Variantenbildungen in Form von System/IT-Use Cases erforderlich. Daher wurde in der Umfrage zunächst auf die Bewertung des technischen Aufwands verzichtet[1].

Beschaffenheit der Stichprobe. Die Stichprobe der Umfrage besteht aus einer bewussten Auswahl von Stakeholdern eines Smart Glasses-basierten Systems. Die Zielpopulation wurde nach dem Schneeballsystem konstituiert [20]: ausgehend von den Fokusgruppen wurde die Erhebungsgesamtheit auf betroffene Personenkreise innerhalb der beteiligten Institutionen erweitert. Es ergibt sich eine Grundgesamtheit von 31

[1] Eine Bewertung hinsichtlich des technischen Aufwands erfolgte im Nachgang durch Bildung einer Fokusgruppe aus acht IT-Experten und ist nicht Gegenstand dieses Beitrags.

Teilnehmern: 67 % Domänenexperten (10 Teilnehmer aus Fall A und 11 Teilnehmer aus Fall B), 7 % Implementierer und 26 % Wissenschaftler.

Datenauswertung. Basierend auf den mithilfe des Fragebogens erhobenen Daten wurden Datenwolken von den Kombinationen aus jeweils zwei Bewertungskriterien erstellt (Paarvergleichsmethode). Dieses Verfahren verhindert eine nachträgliche subjektive Beeinflussung der Ergebnisse (wie z.B. bei der Gewichtung oder Gruppierung von Kriterien) und erlaubt eine Fragmentierung der Gesamtfragestellung in weniger komplexe Einzelbetrachtungen [22]. Nach vorheriger Elimination nicht gültiger Werte (bspw. Auswahl „Nicht sinnvoll beantwortbar") wurde das arithmetische Mittel für jede der vier Kriterien (Nutzen, Aufwand, Anwendungsbereitschaft, Innovation) über alle Teilnehmer der Umfrage errechnet.

Für die Einteilung der Beobachtungen in einzelne Gruppen, bzw. Cluster, wurde das k-means-Verfahren als eines der populärsten Methoden des Clustering verwendet [23]. Der zugrundeliegende Algorithmus bestimmt die Zugehörigkeit der jeweiligen arithmetischen Mittelwerte zu einem Beobachtungscluster anhand der Entfernung der jeweiligen Beobachtungen zu einem der k-Clusterzentren. Dabei werden die k-Clusterzentren so verschoben, dass die kumulierten quadrierten Entfernungen aller Beobachtungen zum nächstgelegenen Clusterzentrum minimiert werden. Für die Bestimmung der optimalen Anzahl an Clusterzentren, k, wurde das Caliński-Kriterium verwendet [24].

Die qualitativen Daten wurden in ein Kategorienschema überführt, in dem gekennzeichnet wurde auf welches Statement oder welchen organisatorischen Aspekt sich der Kommentar bezieht. Die Aussagen wurden nummeriert mit A1-A9 und als Grundlage für die Ableitung von Implikationen herangezogen.

3 Use Cases für den Einsatz von Smart Glasses in der Logistik

Nach Anwendung der Methodik zur Verdichtung und Kategorisierung der Use Cases ergeben sich 36 Use Cases, welche nach ihrer jeweiligen Prozessschrittzugehörigkeit (Prozessgruppe) als auch ihrer Funktion (Funktionsgruppen) in der Fokusgruppe induktiv kategorisiert wurden. Als Prozessgruppen ergaben sich: *Management*, *Kommunikation*, *VAS*/*QS* und *phasenspezifische Use Cases* (*Wareneingang*, *Einlagerung*, *Kommissionierung*, *Warenausgang* und *Inventur)*. Ergänzend wurden folgende Funktionsgruppen definiert: *Monitoring*, *Steuerung*, *Anleitung*, *Video*, *Automatisierte Kontrolle*, *Identifizierung*, *Navigation* und *Sicherheit*. Abbildung 1 visualisiert die entstandene Landschaft aus 36 Anwendungsfällen[2] kategorisiert nach ihrer Prozess- und Funktionsgruppe.

Die Zuordnung eines Use Cases zu jeweils einer Prozessgruppe ist nicht in jedem Fall möglich, da gewisse Anwendungsfälle in mehreren Unternehmensprozessen vorkommen (n:m-Beziehung). Die Use Cases wurden daher der am nächsten stehenden Kategorie zugeordnet und mit der Fokusgruppe validiert. Für einige Gruppen ist ein Hilfs-Use Case identifiziert worden, welcher als Unterstützung für die Umsetzung der

[2] Eine detaillierte Beschreibung der 36 Use Cases kann unter https://www.imwi-data.uni-osnabrueck.de/Business-Use-Cases.pdf eingesehen werden.

anderen Business Use Cases der Gruppe dient. Diese Use Cases wurden in Abbildung 1 mit einem „H“ markiert. Es folgt eine Beschreibung der Funktionsgruppen und zur Veranschaulichung ausgewählten Use Cases (UC).

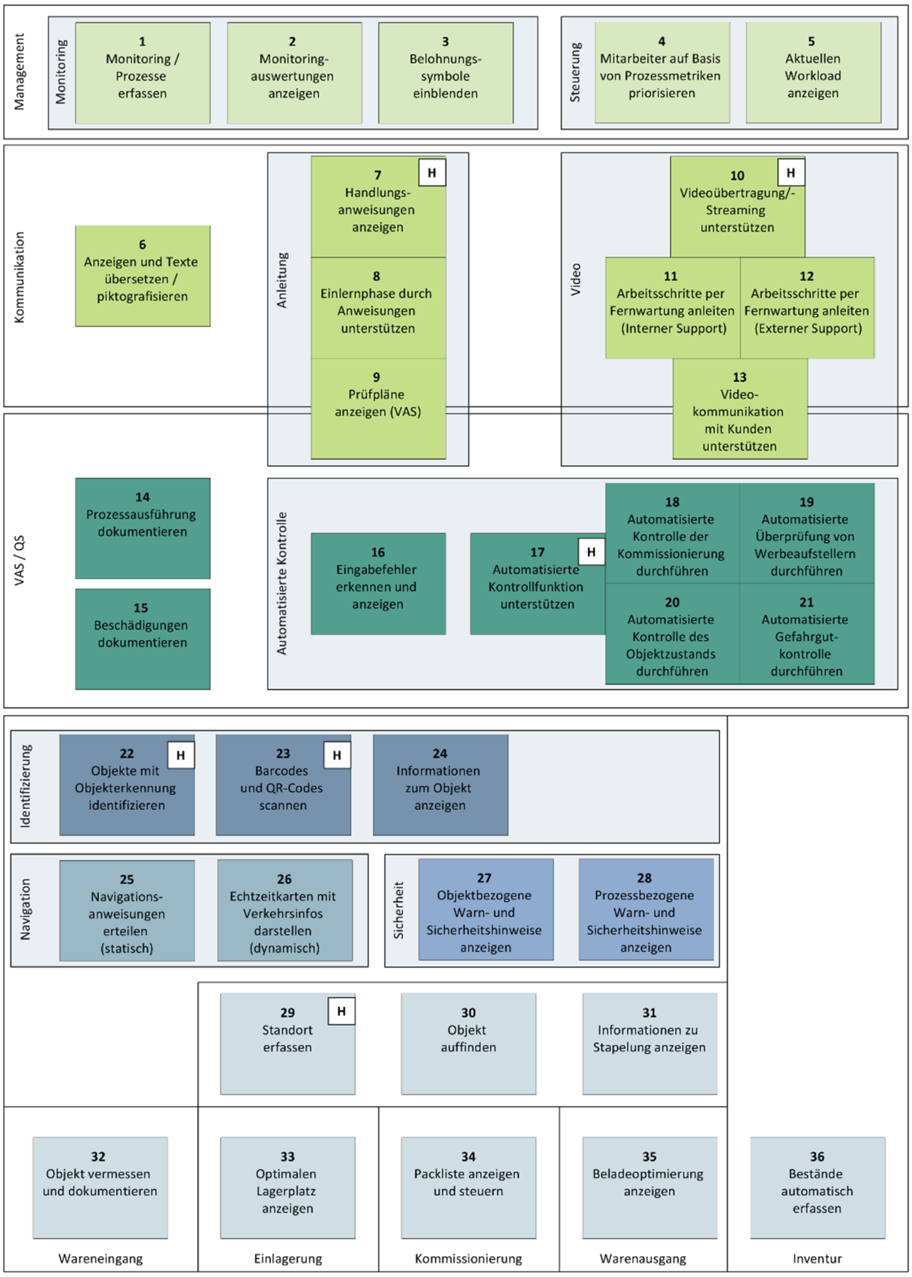

Abbildung 1. Kategorisierung der Use Cases

Management. Der Einsatz von Smart Glasses ermöglicht neue Use Cases zum *Monitoring* und *Steuern* von Mitarbeitern. Mithilfe der Smart Glasses können kontinuierlich Prozessdaten und Prozessabläufe während der Tätigkeit erfasst werden (UC1). Somit ist bspw. die Modellierung von Prozessen möglich, während der Mitarbeiter seine Tätigkeit durchführt. Mithilfe von Auswertungen (UC2) oder Belohnungssymbolen (UC3) kann dem Mitarbeiter z.B. das Erreichen einer Tagesleistung in der Kommissionierung und Prämien für weitere Leistung angezeigt werden. Auf Basis der angezeigten Auslastung (UC5) können mit Hilfe der Smart Glasses direkt einzelne Mitarbeiter gesteuert werden. Ein Schichtleiter kann bspw. kurzfristig einem Mitarbeiter auf dessen Smart Glasses eine priorisiert zugeordnete Aufgabe anzeigen (UC4).

Kommunikation. Die Funktionsgruppe *Anleitung* wird primär durch die Anforderung des Anzeigens von Handlungsanweisungen (UC7) als Hilfs-Use Case definiert. Dies kann z.B. in Form von Checklisten bei der Warenkommissionierung aber auch bei Prüfpläne für VAS-Dienstleistungen (UC9) zum Einsatz kommen. Für die Funktionalität *Video* ist im ersten Schritt eine Videoübertragung/Streaming notwendig. Ein bidirektionales Streaming ermöglicht Dritten, die Ansicht des Blickfelds des Smart Glasses-Trägers (z.B. für eine interne (UC11) oder externe (UC12) Fernwartung) zugänglich zu machen. Darüber hinaus ermöglichen die Smart Glasses eine vereinfachte Kommunikation durch die Übersetzung von Texten oder durch Piktografisierung (UC6), bspw. der Beschilderung für ausländische LKW-Fahrer.

Value Added Services (VAS) und Qualitätssicherung (QS). Der Einsatz von Smart Glasses ermöglicht eine *Automatisierte Kontrolle*. Dabei soll eine kamerabasierte Fehlererkennung und Rückmeldung an den Mitarbeiter (UC17) erfolgen, aber auch Fehler in der Eingabe erkannt und gemeldet werden (UC16). Besonders für die Qualitätssicherung sind eine Dokumentation, bspw. der nach den Service Level Agreements vereinbarten Prozessausführung, aus Sicht des Benutzers (UC14) als auch die Dokumentation von Beschädigungen mittels Kamera und Weiterleitung an das Schadensmanagement (UC15) potenzielle Einsatzszenarien.

Phasenspezifische Use Cases. Die Funktionsgruppe *Identifizierung* stellt eine Ansammlung von Schlüsselfunktionen dar. Hierzu gehören die Erkennung von Objekten anhand gespeicherter Merkmale (UC22), wie Farbe, Größe und Geometrie, als auch die Identifizierung mittels Bar- und QR-Code (UC23) sowie die Anzeige von Information zu den erkannten Objekten (UC24). Zur *Navigation* der Mitarbeiter bieten die Smart Glasses Möglichkeiten, zum einen statische Navigationsanweisungen, z.B. durch die Anzeige von Karten der Läger und Anweisungen zu erteilen (UC25), sowie eine dynamische Navigation (UC26) anhand von Echtzeitkarten mit Verkehrsinformationen anzuzeigen. Mithilfe der dynamischen Navigation könnten bspw. in einem Umschlagslager andere Staplerfahrer angezeigt werden, um Unfälle zu vermeiden. Einsatzszenarien im Bereich *Sicherheit* sind die Anzeige von objektbezogenen Warn- und Sicherheitshinweise (UC27), z.B. die Bruchgefahr von einzelnen Artikeln, wie auch prozessbezogene Sicherheitshinweise (UC28) bei z.B. dem Erreichen der maximal erlaubten Arbeitszeit. In beiden Fällen können akustische, optische oder haptische Signale für die Warnmeldung verwendet werden. Neben den funktionszugehörigen Use Cases stellt besonders der Anwendungsfall der systemunterstützen Standort-Erfassung (UC29) einen zentralen Hilfs-Use-Case dar. Weiterführend gibt es Use Cases, welche sich lediglich anhand von Standard-Lager-Prozessen, wie dem Wareneingang und der Kommissionierung kategorisieren lassen. Dazu gehört die Objektvermessung mittels Bilderkennung und spätere Dokumentation (UC32) aber auch die Packlisten Darstellung und Steuerung (UC34), welche die Verwaltung und die Abwicklung von Kommissionier-Aufträgen ermöglichen.

4 Implikationen für die Forschung

4.1 Analyse der Use Cases

Zur Priorisierung erster Use Cases zur Umsetzung und Ermittlung damit verbundener Forschungsbereiche für die Wirtschaftsinformatik wurden mithilfe der Paarvergleichsmethodik des Clustering (vgl. 2.3) erste Use Cases ausgewählt. Im Rahmen der Fokusgruppenworkshops haben die Vertreter aus Wissenschaft und Industrie den Kriterienvergleich von *Nutzen und Innovation* als Grundlage zur Identifikation besonders relevanter und forschungsorientierter Use Cases mit Innovationscharakter selektiert (siehe Abbildung 2).

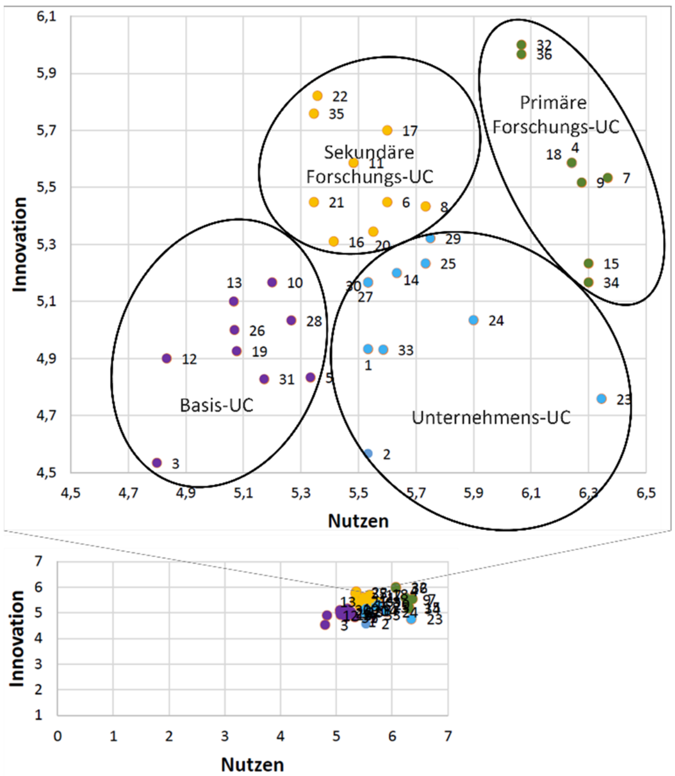

Abbildung 2. Kriterienvergleich Innovation zu Nutzen

Bei Betrachtung von Innovationsgehalt und Nutzen (vgl. Abbildung 2) ergeben sich vier Cluster: Use Cases mit vergleichsweise mittlerem Nutzen und mittlerem Innovationsgehalt (*Basis-UC*) sowie mit vergleichsweise hohen Nutzen aber nur mittlerem Innovationsgehalt (*Unternehmens-UC)* sowie mit einem vergleichsweise hohem Innovationsgehalt und mittlerem Nutzen (*Sekundäre-Forschungs-UC*). Die *Primären-Forschungs-UC* sind durch einen hoch bewerteten Nutzen und einen mittleren bis sehr hohen Innovationsgrad höchst relevant. Auf Basis dieser Auswertung ergeben sich acht Use Cases, die zunächst für weitere Forschungsaktivitäten priorisiert werden. Die quantitative Analyse wird durch eine Auswertung der qualitativen Daten aus den Kommentarfeldern der Umfrage vervollständigt. Eine Übersicht der priorisierten Use Cases (A0) und den zugehörigen qualitativen Aussagen wird in Tabelle 1 gegeben (Aussagen A1-A9). Die Reihenfolge der Use Cases folgt der Häufigkeit der Nennung in den relevanten Clustern.

Tabelle 1. Priorisierte forschungsrelevante Use Cases (A0) und qualitative Aussagen (A1-A9)

Use Case	*Anmerkungen*	*Nr.*
(4) Mitarbeiter auf Basis von Prozessmetriken priorisieren	Erhöhte Anforderung an vorgelagerte Systeme (ERP, LVS, PPS, MES)	A1
	Rechtliche Bedenken (Betriebsrat, Datenschutz)	A2
	Prozessveränderung nach Umsetzung	A3
(7) Handlungsanweisungen anzeigen	Erhöhte Anforderung an vorgelagerte Systeme (ERP, LVS, PPS, MES)	A1
	Neue Anforderung von zu pflegenden Daten	A4
(9) Prüfpläne anzeigen (VAS)	Analog Potential für weitere Value Added Service (VAS) Prozesse eruieren	A5
	Integration dynamischer Prozessveränderungen erforderlich	A3
(15) Beschädigungen dokumentieren	Erhöhter Aufwand bei technischer Umsetzung	A6
(32) Objekte vermessen und dokumentieren	Technische Umsetzung nicht trivial je nach Objektgröße	A6
(36) Bestände automatisch erfassen	Heute vorhandenes Potential der Bilderkennung ist zu prüfen	A6
	Technische Umsetzung ist aufwändig	A6
	Hohe Anforderung an die verbaute Technik in den Smart Glasses	A6
	Realer Nutzen abhängig vom Objekt und der Umgebung - ggfs. nur für ausgewählte Warengruppen möglich	A7
(18) Automatisierte Kontrolle der Kommissionierung	Organisatorischer Aufwand (Einmaliger Aufwand für Lagerfachkennzeichnung)	A8
(34) Packliste anzeigen und steuern	Realer Nutzen abhängig vom Objekt und der Umgebung	A7
	Erhöhte Anforderung an vorgelagerte Systeme (ERP, LVS, PPS, MES)	A1
	Smart Glasses als Visualisierungswerkzeug	A9

Als Validierung und Ergänzung wurden die im Rahmen der Umfrage erfassten Kommentare ausgewertet. In drei Fällen (UC 15, UC 32, UC 36) wurde die *technische Umsetzung* als nicht trivial angesehen sowie bei drei Anwendungsfällen (UC 4, UC 7, UC 34) eine erhöhte Komplexität bzgl. der *IT-Architektur* und Anbindungen an vorgelagerte Systeme (ERP, LVS, PPS, MES) gesehen. Weiteren Forschungsbedarf gibt es, den qualitativen Kommentaren der Umfrage folgend, vor allem in Bezug auf *Datenschutz* und *organisatorischer Integration* (u.a. Prozesse und Datenhaltung).

4.2 Diskussion

Die in der Fallstudie ermittelten Ergebnisse bzgl. einer Priorisierung der Umsetzung einzelner Use Cases sowie weiterer Forschungsthemen bieten Implikationen für die Wirtschaftsinformatik. (A0) Für die Forschung besonders interessante Use Cases (hoher Innovationsgrad bei gleichzeitig hohem Nutzen) können Tabelle 1 entnommen werden. Zur Umsetzung dieser Use Cases sind laut gestaltungsorientierter Forschung zunächst die Meta-Anforderungen für die konkreten Einsatzszenarien und Design-Prinzipien zu spezifizieren [25, 26]. Die systematische Literaturrecherche zeigte, dass bisher eine geringe Literaturbasis für Smart Glasses-basierte Dienstleistungssysteme besteht. Daher stellt sich im Besonderen die Frage *Auf welchen Bereichen der Knowledge Base kann zur Gestaltung der Design Prinzipien von Smart Glasses-Systemen für die Logistik aufgebaut werden?* Die Use Cases und deren qualitative Anmerkungen zeigen, dass vor allem (A1, A3) Prozessorientierung und (A9) Visualisierung als wichtige Themen erachtet werden, sodass Analogien aus diesen Bereichen bspw. aus dem Wearable Computing Design (u.a. [27-29]) und der Untersuchung von mobilen prozessorientierten Assistenzsystemen aus der Dienstleistungsforschung (u.a. [30-32]) herangezogen werden können. Analysen der technischen Funktionen von Smart Glasses [1] (A6) können darüber hinaus Implikationen für die Design Prinzipien sowie Integrationsfragestellungen geben.

Bezüglich der Integration in die IT-Architektur (A1, A6) ergeben sich Fragen aus den technischen Eigenschaften der Smart Glasses, bspw. in Bezug zu den Sensoren, und wie diese in die Schnittstellen der bestehenden Architektur integriert werden können. Die Unternehmensarchitektur und die Geschäftsprozesse betreffend stellen sich u.a. folgende Fragestellungen, die sich auch in den qualitativen Aussagen widerspiegelten: *Welche Veränderungen ergeben sich in den Geschäftsprozessen durch die Umsetzung der Use Cases?* (A3) Bzw. *Ergeben sich durch den Einsatz von Smart Glasses neue Arbeitsmuster und –arbeitsformen?* (A3) Bspw. durch den Use Case „Bestände automatisch erfassen“ (UC36) können interne Inventurprozesse neugestaltet bzw. komplett durch eine kontinuierliche Erfassung der Prozesse ersetzt werden. Gleiches gilt für den Use Case „Beschädigungen dokumentieren“ (UC15). Hier zeigte das Shadowing, dass bisher ein aufwendiger Retourenprozess ablief, mit nachträglichem Erfassen von Schäden und dem Zeitpunkt des Eintritts. Durch die Smart Glasses kann bei jedem Prozessschritt (bspw. Wareneingang, Umschlag, Auslagerung) kontinuierlich ein Foto des Objektes zur einfacheren Dokumentation erstellt werden. Hier ergeben sich weiterführende Anforderungen an das Datenmanagement (A4). Ein großer Forschungsbereich, der sich aus den diskutierten Einführungen ergibt, ist der Datenschutz (A2). Hinsichtlich der Berücksichtigung in der Systementwicklung ergibt sich zunächst die Forschungsfrage: *Welche datenschutzrechtlichen Anforderungen an Smart Glasses bestehen und wie kann ein datenschutzkonformes System gestaltet werden?* In der Literatur wird die isolierte Betrachtung von Datenschutzaspekten bei der Entwicklung von Privacy-invasiven Systemen (so auch Smart Glasses) kritisiert und die Integration einer Anwenderevaluation in die Systemkonstruktion gefordert [33]. Somit stellt sich in Bezug auf die konkrete Entwicklung eines Prototyps weitergehend die Forschungsfrage, wie Maßnahmen der Informationsprivatheit in die Systementwicklung integriert werden können. Zur Begegnung der geäußerten Bedenken hinsichtlich des Betriebsrats (A2) ist, einhergehend mit dem Datenschutz, die Akzeptanzfrage zu betrachten. Es ist zu untersuchen, ob in der Literatur bekannte Modelle den erweiterten Funktionsumfang neuer IKT erfassen [34] oder, ob die Integration neuer Einflussgrößen erforderlich ist (vgl. [35]). Die Akzeptanz betreffend können ggf. Analogien aus dem Wearable System Engineering herangezogen werden, bspw. zur Verbesserung von Arbeitsschutz und Ergonomie [36]. Abschließend wurde in der Studie die Frage nach Übertragungspotenzialen auf weitere Szenarien (A5, A7, A8) angemerkt. Dies impliziert für die weitere Forschung, dass einzelne Use Cases kontinuierlich sowohl summativ als auch formativ während der Gestaltung und Implementierung zu evaluieren sind, wie es auch aktuell in der gestaltungsorientierten Forschung diskutiert wird [37, 38].

5 Fazit

Bisher gibt es wenig wissenschaftliche Literatur bzgl. des Designs und der Implementierung Smart Glasses-basierter Dienstleistungssysteme, obwohl vor allem in der Logistik ein Einsatzgebiet und weiterer Forschungsbedarf in praxisorientierter Fachliteratur gesehen wird. Daher wurden eine explorative Fallstudie in Kombination mit einer systematischen Literaturstudie durchgeführt, um Use Cases für Smart Glasses in der Logistik zu identifizieren und aufzeigen, welche Use Cases priorisiert betrachtet werden sollten sowie welche Implikationen für zukünftige Forschung bestehen. In der Literatur wurden bisher vor allem Use Cases im Bereich Kommissionierung und Wartung bspw. der Stapler gesehen. Die Fallstudie eröffnete weitere Use Cases wie die Dokumentation von Beschädigungen oder die automatische Erfassung von Beständen (Inventur). Somit zeigte die explorative Fallstudie, dass Smart Glasses Einsatzpotenzial haben, um zukünftig Arbeitsprozesse zu digitalisieren. Forschungsbedarf und somit Aufgaben dieser Digitalisierung werden vor allem in Bezug auf die technische Machbarkeit und Integration in die Gesamtarchitektur gesehen, sowie im Bereich Datenschutz und organisatorischer Eingliederung bspw. durch Anpassung entsprechender Prozesse und des Datenmanagements. Forschungsbereiche der Wirtschaftsinformatik, die bei der Gestaltung des Einsatzes von Smart Glasses einbezogen werden sollten, sind somit u.a. Dienstleistungsmanagement und -engineering, Informationsprivatheit und Datenschutz aber auch Interface-Design, Unternehmensarchitekturmanagement und Geschäftsprozessmanagement. Somit leistet dieses Paper einen Beitrag zur Forschung im Bereich des ganzheitlichen Designs von Dienstleistungssystemen und zukünftiger Aufgaben digitaler Arbeit. Es liefert die Basis für weitere Forschung sowohl für (a) die gestaltungsorientierte Wirtschaftsinformatik, indem einzelne Szenarien mit Smart Glasses priorisiert zur Umsetzung vorgeschlagen werden und welche Herausforderungen dabei zu beachten sind, als auch (b) für die verhaltensorientierte Forschung, u.a. welche Bereiche priorisiert betroffen sein werden und welche Fragestellungen sich bspw. hinsichtlich Akzeptanz und neuer Arbeitsformen ergeben.

6 Danksagung

Dieser Beitrag ist Teil des Projekts *Glasshouse*, welches vom Bundesministerium für Bildung und Forschung (BMBF) unter dem FKZ. 01FJ15062 gefördert wird.

Abstract. A company's ability to change increasingly depends on the ability to change its IT, something referred to as "IT-agility" here. High IT-agility can contribute to increased business agility and thus create a competitive advantage. In this paper we focus on the IT application systems landscape, a resource of significant importance for the IT-agility and competitiveness of a company. To manage IT-agility it must be measurable. In our research, a goal hierarchy and a derived performance measurement (key figure) system was developed to measure and actively manage the agility of IT application systems landscapes. This measurement model is scalable from the measurement of individual domains to the entire IT application landscape. It has demonstrated its practicality in the context of several case studies.

Keywords: IT-Agility, IT Application Systems Landscape, Competitive Advantage, IT Controlling, IT Management.

1 Introduction

The business of companies and thus their business processes and products are changing over time. These changes almost always have an impact on the company's IT in the sense that IT systems need to be adapted. Surveys in recent years among IT managers as well as scientific contributions show that a key requirement for the IT organization is the ability to adapt to the needs of the professional business [5] [6].

Moreover, IT penetration of the core business processes in companies in recent decades has increased continuously. This will be even truer with digital transformation of industries gaining pace. Thus, the change ability of enterprises increasingly depends on the ability to change the IT [4] [21]. In business, we see that some companies are dealing better than others with the continuous need of change in their information systems (IS). Hence, we would like to understand, and ultimately measure and manage this ability of IT. To come up with a sound suggestion for these issues that we will refer to under the label of IT-agility is the central theme of our paper.

2 Related Work – Literature Review

Based on a very recent and detailed literature review by Termer [33, p.24-30] the use of the “agility” term in information systems research will now be highlighted. By citation analysis, Termer identifies five major sources [p.24-25], amongst 57 relevant contributions, which dominate the definition of the term agility in the actual research literature: [9] [12] [25] [30] [22]. He also reveals that indeed a manifold of sources are used, so that overall a fragmented definition is apparent. It should be noted that in this analysis contributions dealing with agility in the limited context of software development are excluded. Also, papers using the term agility without defining it were excluded from further analysis. Moreover, research on the term “flexibility” is viewed as related, but not identical to “agility”.

Agility is understood by Sambamurthy et al. as an ability to recognize and use market potential rapidly and unexpectedly for competitors [30, p. 245]. This ability has two components: to probe the market (exploration) and to exploit the market (market arbitrage). Furthermore, agility is divided into three dimensions: customer agility, partner agility and operational agility. Even though IT in all three areas is assigned a supportive role, it is not part of the agility consideration [30, p. 246]. IT and the competence of using it are seen as the initiator and enabler for corporate actions, which are conducted in the three mentioned agility domains.

According to Overby [25, p. 121], who also sees IT in an enabling role for business, the capability of (enterprise) agility results in two significant basic skills: on the one hand the ability to notice changes in the corporate environment (sensing), and on the other hand the ability to conduct certain actions in a suitable way regarding these changes (responding). The sensing skill is here explicitly assigned to the tasks of anticipation and the prediction of environmental changes. The ability of responding includes moreover the essential pace to conduct the chosen action [16, p.127-128].

The definition of agility according to Goldman et al. [12] results from a production theoretic view. The term agile describes the ability of producers to be successful in changing, fragmented markets. Some constitutive features are specified: agility is dynamic and unlimited, context–specific, agile companies offensively embrace changes, and agility is offensive, as it creates chances for profit and growth. Termer argues [33, p. 31] that these characteristics overlap with features of flexibility, as described in the research literature. Flexibility refers to the capability of a corporation to be able to move rapidly from one known task to the next one. Here it is important that the appropriate situation is known beforehand and therefore the corresponding tasks to overcome this situation should also be defined in advance [12]. A corresponding questionnaire for the capturing of agility proves to be imprecise and subjective [16, p.127-128].

In the definition according to Dove [9] the ability of responding is especially emphasized: “We look at agility as deriving from both the physical ability to act (response ability) and the intellectual ability to find appropriate things to act on (knowledge management). Agility is expressed as the ability to manage and apply knowledge effectively so that an organization has the potential to thrive in a continuously changing and unpredictable business environment.” [9, p.9]. Hence two essential features of agility are emphasized: on the one hand the ability to act and on the other hand the ability to identify the right things for acting on. Basically the tasks of knowledge management are linked therewith [9, p.9-16]. Products, processes, practices and people are the primary action fields for agility [9, p.83, 163-180]. Dove reveals basic approaches, which contribute to better response ability. These include the abilities to reuse, reconfigure and rescale, which are used for different production scenarios [9, p. 33, 38, 42 and 61], as well as the standardization of interfaces to enable the use of a loosely coupled resource pool [9, p.41].

While considering agility, the aspects of proactive [9, p. 92-99] and reactive changes are incorporated [9, p. 100-107]. Proactive changes are made possible by means of innovation or by taking up the leading position in a division. Its trigger is therefore within the company. Dove refers to reactive changes as the foundation of survivability of a company and as the basis for opportunistic behavior. Reactive actions are always evoked by (external) events, which require such a reaction.

In the definition of agility according to Seo and La Paz the ability to notice signals from the internal and external environment (perception) and the adequate answers (responding) to these signals are placed into the center of the considerations [32, p. 136]. In this process, an organization is subjected to a perpetually changing cycle to which it adapts better and better, and thus ensures survival in a dynamic environment. Possible negative aspects in dealing with agility are predominantly discussed in this literature source [32, p.137–138). For instance, correct information from the environment has to be admitted, which furthermore needs to be made available for an adequate evaluation, so that the decision makers can make a decision on the basis of relevant information. Likewise it must be possible that actions can be implemented in a reasonable timeframe. Information systems have to be capable of this speed without claiming a high management effort. These negative aspects can be mitigated by standardization and outsourcing as well as by a suitable organization and culture.

Termer [33, p.28-30] concludes that none of the references identified in his extensive literature review actually designed a tool that would help companies identify the level of IT-agility attained, or follow the effectiveness of measures to increase IT-agility over time. The only exception, according to Termer, are the works of the research group of Nissen [22] [23] [24] [29], where a key figure system for the measurement of IT-agility was developed and tested in several practical case studies. The present article actually continues the development of this key figure system.

Termer, in his PhD-thesis [33] defines IT-agility from a behavioral point of view, stating that “agile behavior, also agility, is understood to mean the self-motivated, purpose-oriented activities of an organization which aims at the aggressive design of the environment” [33, p.46, translated]. IT-agility here is influenced by three main aspects of company IT: the technical infrastructure, the IT-staff, and the organizational structure, including IT-processes [33, p.49].

For the practical analysis of IT-agility, Termer recommends, drawing a parallel to air combat maneuvers, “to define appropriate actions (maneuvers) and to keep corresponding expectations of their implementation. The concrete execution of the actions could be documented and evaluated (…).” [p. 225, translated] While we view this behavioral definition of IT-agility as interesting from a scientific perspective, it must be said that this understanding is not very helpful from a practical point of view, as we cannot define maneuvers with a company IT in real life. Therefore, our own considerations of IT-agility, which are given in the next section, draw on the abilities and characteristics of the IT to define, measure, and manage the level of IT-agility.

Finally, we want to add the definition of IT-agility as suggested by the influential paper of Conboy [8, p.340] in the context of information systems development (ISD), which is a more limited scope than the one we address in our paper. Conboy states that agility is "the continual readiness of an ISD method to rapidly or inherently create change, proactively or reactively embrace change, and learn from change while contributing to perceived customer value (economy, quality, and simplicity), through its collective components and relationships with its environment." As one can see, there is some similarity to components in the previous definitions, particularly by Dove [9] and Termer [33]. Agility is seen as having reactive as well as proactive parts, ultimately thriving for customer value. We shall use these common aspects in our own conceptualization of IT-agility.

3 Conceptualization of IT-Agility

Our conceptualization of IT-agility is based on the underlying theoretical rationale of the resource-based view of strategic management (RBV). The RBV [1] [27] [37] places the heterogeneous equipment of companies with internal resources as a source of competitive advantage in the center. It is argued that not the sole possession of these resources is the cause of the success of a company, but additionally appropriate employee skills and management skills are needed who know to take advantage of the potential of resources. This will be reflected in our three pillars of IT-agility.

For the characterization of (strategically relevant) resources, various properties were defined in the academic discourse. According to the VRIS-framework of Barney, a resource is valuable, rare (or even unique), inimitable and non-substitutable, i.e. cannot be replaced by other equivalents [1, p 105]. Other authors have varied these properties and added in particular the usability and immobility aspects [35].

Applying the principles of RBV on the subject field of IT, the mere possession of IT does not lead to competitive advantage. Carr has described this situation very strikingly, in which he referred to IT as a commodity without strategic relevance [7]. This can be explained by his narrow viewing angle to pure technique. But strategic value of IT can be achieved through its effective and efficient use. The value contribution of IT to business then becomes a multi-facetted concept, where IT-agility is one component, next to others such as service orientation or enabling compliance [34]. Moreover, the target role of IT as an innovation engine for the company has been stressed in publications recently [17], fueling the understanding that IT is not a mere reactive enabler, but should also have a proactive function in the company.

In our conceptualization, a high IT-agility can be a strategic asset for companies, particularly in turbulent environments, and with many IT-based products or processes. Overall IT-agility is the result of agility in its three constituting parts ("pillars of IT-agility"), which we draw from the RBV and previous research in [22] [23] [24] [29]

[33]: 1. IT-infrastructure, in particular the architecture of the IT application systems landscape, 2. IT-organization / IT-processes, and 3. IT-staff / IT-management. This contribution deals only with the first of these three pillars.

Looking at the IT infrastructure of enterprises, it can be said that not all of its components are equally sources of competitive advantage. In particular, hardware and standard software are not strategically relevant. However, if the entire IT application systems landscape is considered, the criteria of the resource-based approach can be met, as was shown in [24]. Thus it can be stated that with the provision of an agile IT application systems landscape a strategic resource can be created that allows for a sustainable competitive advantage.

The elements of the IT application systems landscape are the application systems (applications and associated data), their interfaces as well as the domains and functions of a company. The architecture of the IT application systems landscape (short: application landscape) describes the application systems, their relationships and structure based on business-related criteria (domains and functions). The (nonexistent) IT architecture of obsolete application landscapes prevent easy maintenance and results in a low ability to change. This is supported by many literature sources, e.g. [11] [19] [28], which view IT application landscapes that have over many years grown uncontrolled as a main cause of the lack of IT-agility in companies. Moreover, there is a common believe that the architecture of the IT application systems landscape represents in fact a key differentiator between highly agile and less agile companies [10] [31] [23].

When dealing with change two archetypal forms can be distinguished: reactive and proactive. Many contributions in the IS literature define a passive coping with change as reactive, whereas an active, internally driven change intention is defined as proactive. When it comes to the type of change required in IT, one can basically distinguish capacitive and functional aspects. Capacitive requirements relate to scalability, i.e. the ability of IT to respond to growing business volumes, or performance, i.e. provide a constant response time even with changing demand volumes. Functional requirements relate to features, products, and processes of IT.

In the literature on agility there are some components of a definition that frequently appear: strategic thinking, identification of opportunities that create business value, proactive (innovative) and reactive (quick response) components, embracing change. We include the aforementioned considerations in our definition of IT-agility:

IT-agility is the ability of a company's IT to respond very quickly (preferably in real time) to changing capacity demands and changing functional requirements, as well as to use the potential of information technology in such a way that the business scope of action of the company is extended or even redesigned.

To manage IT-agility it must be measurable. Today no method is available that measures IT-agility and especially the agility of the IT architecture based on observable factors. Based on this situation, the following research question is derived:

How can the agility of the IT application systems landscape, as an important part of the IT-agility of a company, be measured and actively managed, based on objectively observable characteristics?

In the following, the development of a corresponding measurement instrument is outlined.

4 Method

4.1 Design Science Approach

The design science research (DSR) approach as a methodological framework seems well suited to answer the research question described. On the one hand the lack of measures of IT-agility and, more specifically, the agility of IT application systems landscapes is a relevant issue that comes from business practice. On the other hand, the development of a key figure system for measuring the agility of application landscapes is a design activity [15]. The specific sequence of the research activities in our investigation follows the popular DSR Methodology Process Model of Peffers et al [26]. From a scientific perspective, our contribution is the developed hierarchy of goals (and associated key figures) as a comprehensive model to explain the relationships between architecture principles and the agility of IT systems landscapes. The corresponding key figure system is the tool for measuring and actively managing IT-agility. In the following, we describe essential components and results of the iterative design process, which is grounded in a structured literature review, expert interviews and case studies. We report on results from the last design cycle.

4.2 Development of a Goal Hierarchy

First, the relevant parameters were determined for the design of the performance measurement system, i.e. those properties of IT application system landscapes that have an impact on the IT-agility. This was done through a structured literature review following Webster and Watson [36], not detailed here for reasons of space. The full description can be found in [29]. It revealed 29 relevant papers from which design input could be derived for measuring the agility of IT application systems landscapes, describing objectives in the context of IT flexibility and IT-agility, to be achieved with suitable measures. The goal network in Figure 1 shows the goals that were repeatedly mentioned. Bold relations are dominant. These are discussed frequently in the literature and have been further confirmed in a series of semi-structured interviews with 18 experts in the field. Suggestions obtained therefrom were incorporated into the final design of the goal hierarchy and associated indicators. In the semi-structured expert-interviews we followed [3] and questioned both IT top managers as well as IT architects. Moreover, in order to complete the picture, and also to get an external IT view, managers from the business were included that have a strong link to IT. Finally, some IT-related business consultants were also interviewed.

Along the dominant goal relations a goal hierarchy is constructed starting from the top goal. The goals connected by relations are adopted in the goal hierarchy. In addition, goals are further sharpened or detailed (Figure 2). Very few elements from the literature have not been incorporated, since they do not satisfy one or more of the required quality criteria. An example is the goal of high parameterization of the application landscape, meaning the ability of an application system to implement a business change without programming. For this goal the necessary data can in practice not be collected with reasonable effort, as was revealed in both the expert interviews and several practical case studies [24] [29].

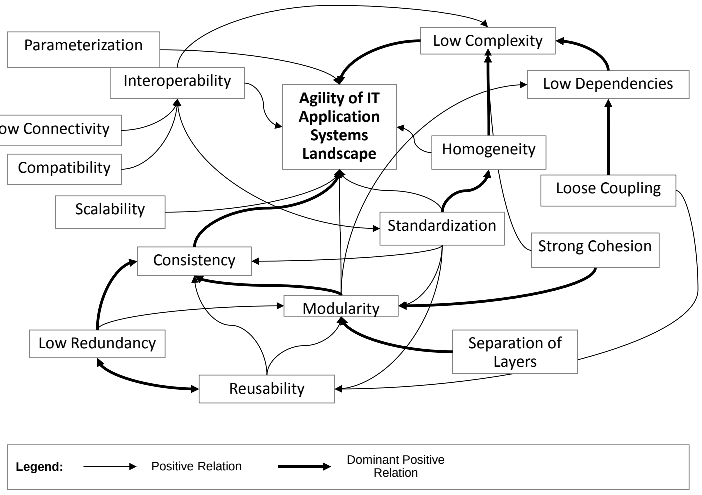

Figure 1. Goal relations from the analyzed literature

The goal hierarchy consists of five levels. On the first level is the overall goal "high agility of the IT application systems landscape." This is divided into the goals "high functional agility" and "high capacitive agility". The process is continued to the fifth level containing nine elementary goals, briefly characterized below.

Low Connectivity: The entire IT application systems landscape is regarded as a network of connected application systems. Low connectivity requires that in an application landscape as few application systems are interdependent as sensible.

Adequate Coupling: Adequate coupling requires that domains are internally closely and externally loosely coupled.

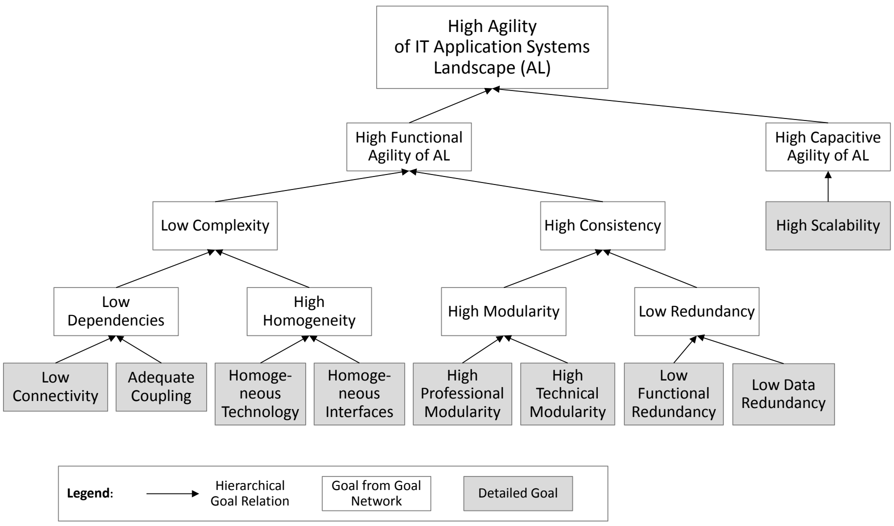

Figure 2. Goal hierarchy for the agility of an IT application systems landscape

Homogeneous Technology: The uniform application of few, dominant technologies facilitates the portability and compatibility of application systems. Functions can be easily re-used, which enables changes and contributes to IT-agility.

Homogeneous Interfaces: Uniform interface technologies reduce complexity. Data can easily be exchanged between applications.

High Professional Modularity: The structure of the application landscape of the company should be based on the company's business (processes and organization). The more two business processes, business functions or departments are linked together, the closer should be coupled the supporting application systems.

High Technical Modularity: Each application system should have a clear unambiguous technical purpose. Engels et al. differentiate four categories [11]: interaction components, process components, function components, inventory. High technical modularity requires that each system of the IT application landscape can be assigned to precisely one of the four established software categories.

Low Functional Redundancy: Ideally, a professional function is implemented only at a single point in the application landscape. If this function is used elsewhere, the existing implementation should be re-used. Multiple efforts for the implementation and for ongoing maintenance can thus be avoided.

Low Data Redundancy: Databases should be managed each by a single application system and all applications that require these data need to access the respective application system. Low redundancy of data is only required at the logical level.

High Scalability: Both the ability of the application system for parallel execution of processing steps as well as the capability of the technical infrastructure to scale horizontally should be evaluated jointly. The structure of the application landscape has only a supportive indirect influence on scalability. The direct factors affecting scalability can be found in the architecture of individual applications as well as in the nature of the technical infrastructure.

5 Artifact Description

5.1 Key Figure System

In order to manage the development of an IT application systems landscape towards a high agility, the attainment of the goals set out must be made measurable. To this end, we follow the approach suggested by Kütz [18]. For the documentation key figures profiles are used. Table 1 gives an example. The full key figure system is depicted in Figure 3.

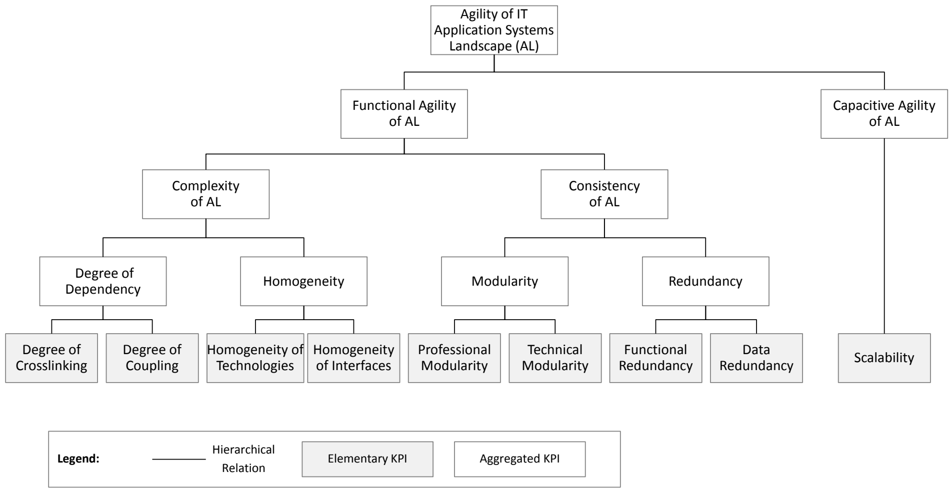

Figure 3. Key figure system to measure the agility of an IT application systems landscape

Table 1. Example of a key figure profile

KPI	
Technical Modularity ($MODU_{TECH}$)	
Supported goal	References
High technical modularity	[14, 15]
Question	
How well can the application systems of the IT application systems landscape be assigned to a unique technical software category?	
Description	
Technical modularity measures how well the application systems can be assigned to software categories. Software categories characterize different tasks (e.g. interaction, function or inventory) of application systems. Each application system should, ideally, be assigned a unique software category.The technical modularity sets the number of software category overruns of application systems in relation to the number of all application systems of the application landscape. The fewer overruns exist, the higher the value of the measure.	
Calculation	Standardization
$MODU_{TECH} = \frac{\sum(\mathrm{SK(a)} - 1)}{\mathrm{ELEM(AL)}}$	5 – $\mathrm{MODU_{TECH}} < 0.2$ 4 – $0.25 > \mathrm{MODU_{TECH}} \geq 0.2$ 3 – $0.35 > \mathrm{MODU_{TECH}} \geq 0.25$ 2 – $0.5 > \mathrm{MODU_{TECH}} \geq 0.35$ 1 – $MODU_{\mathrm{TECH}} \geq 0.5$
Data	
SK(a) = number of software categories application system „a“ can be assigned to ELEM(AL) = number of application systems in the entire application landscape	

A company needs to set target values, in accordance with the importance of IT-agility and after consideration of other strategic goals, and track the achievement of these target values. The performance measurement system can be used not only for measuring entire application landscapes, but also for parts of it. For clarity, the figures are, however, always defined for the whole IT application systems landscape. If, for example, the KPIs should be used for the measurement of individual domains, the concept of the application landscape must be replaced with the appropriate domain name. The potential user base of the performance measurement system is the top leadership circle of the IT organization as well as the enterprise architects of a company.

Below the elementary KPIs are briefly described. The indicators and thresholds in standardization were presented as part of the iterative design process in the expert interviews and used in several case studies, and have been intensively discussed.

Degree of Crosslinking: With the degree of crosslinking, the degree of internal dependencies of the application landscape under consideration is measured. The actually existing links between the application systems are set in proportion to the maximum possible number of links. The degree of crosslinking measures the complexity of the application landscape based on the connections between the application systems. The more application systems are connected together, the higher are the dependencies, and thus also the complexity of the application environment.

Degree of Coupling: The application systems or sub-domains contained in a domain should be more closely linked than the domains are connected to each other. Interfaces of a domain can be measured by the "coupling ratio", weighted by the number of application systems. The coupling ratio for a domain determines the ratio between the number of interfaces within a domain and the number of application systems contained therein. The average coupling ratio of the domains is assessed in relation to the coupling ratio of the entire application landscape. The greater this ratio, the stronger the domains are linked internally and the higher the degree of coupling.

Homogeneity of Technologies (Applications): The homogeneity of application systems technology measures the complexity that arises because different technologies are used in parallel in the application landscape. In addition to the number of different technologies also their distribution in the IT application systems landscape is measured. A high number of used technologies results in low technology homogeneity and thus leads to a high complexity of the application landscape.

Homogeneity of Technologies (Interfaces): The technology homogeneity of interfaces measures the complexity that arises when different interface technologies are used in parallel. In addition to the number of different interface technologies also their distribution in the application landscape is measured.

Professional Modularity: The professional modularity is the measure of the unambiguous assignment of application systems to domains. It sets the number of domain overruns of application systems in relation to the number of all application systems of the application landscape. The fewer domain overruns, the higher the value.

Technical Modularity: for details see Table 1

Functional Redundancy: The functional redundancy measures how many business functions have been implemented several times (and to what extent) in different applications. For this, the sum of all redundancies of functions in the application landscape is set in proportion to the total number of IT-supported functions.

Data Redundancy: The data redundancy measures how many data are maintained multiple times in different application systems and to what extent. For this, the sum of all redundancies of data stores in the IT application systems landscape is assessed in relation to the total number of data stores.

Scalability: This KPI measures the proportion of the application landscape, which is designed scalable. For this purpose, the proportion of the application systems is measured, where scalability was explicitly specified as a non-functional requirement in the implementation. This is then multiplied by the ratio of scalable infrastructure (hardware) components. The interviewed experts considered this KPI useful, but noted that the necessary data are rarely available in the required quality and completeness in practice. This has also been confirmed in the case studies conducted.

5.2 Aggregation of Key Figure Values

The hierarchical aggregation runs along the described goal hierarchy. Since the assessment of all key figures is carried out in an identical manner and standardized to the value range [1 ... 5], the calculation is made simple. The lowest level consists of the already explained elementary KPIs. The aggregate indicators in the levels above are always put together by the same aggregation rule, a weighted additive aggregation of subordinated key figures.

The weighting factors of the indicators have values between 0 and 1, and their sum in an aggregation is always equal to 1. As a result, the lower-level KPIs can be weighted relative to one another, and the result is always on a scale between the values 1 and 5. Through the weighting factors, companies can set priorities, if they consider parts of the goal hierarchy to be particularly desirable. For a benchmarking of various companies or parts of the same company, however, the weighting factors must be kept constant, otherwise the comparability of the results is not given

6 Discussion

The motivation of our research and the problem to be solved is the lack of instruments to measure and actively manage the IT-agility (not only) in the field of the IT application systems landscape. This problem is of considerable practical importance across industries, since the IT-agility can be seen as an integral part of the value contribution of IT in an enterprise [34]. Our research makes contributions on the scientific as well as the practical side of this problem.

From a scientific point of view, our contribution is the developed hierarchy of goals (and associated key figures) While we acknowledge that agility as a research topic has been treated in a sizable number of contributions in the literature, the agility of the IT architecture is rarely discussed [14]. To our knowledge, we provide the first comprehensive model to explain the relationships between architecture principles and the agility of IT application systems landscapes.

The applicability and usefulness of the key figure system was tested in several case studies in practice. Here, the approach followed recommendations of Yin [38] and Benbasat et al. [2]. In selecting the companies studied emphasis was placed on finding relatively different companies in order to examine a wide range of possible scenarios for the key figure system. For reasons of space, the case studies cannot be presented here. However, details can be found in [29]. In order to ensure the validity and reliability, different data sources were used in the companies, such as architecture data bases, architecture graphs, architecture concepts and interviews with enterprise architects. In addition, a database has been set up for each case study that includes, separated from the raw data, a comprehensible analysis and calculation of key figures.

In our work, case studies and expert interviews were combined to evaluate the performance measurement system. This combination of evaluation methods is frequently used in application-oriented work when no similar model exists [20]. It turned out that through the developed indicators the agility of the IT application systems landscape can be measured and controlled over time, thus making a substantial practical contribution.

We now compare our approach with the DSR guidelines as provided by Hevner [15, p.83]. Guideline 1 (Design as Artifact): A key figure system is an artifact in the sense of Hevner. Guideline 2 (Problem Relevance): The measurement and management of IT-agility are issues of substantial relevance that add to the value contribution of IT in practice. Guideline 3 (Design Evaluation): Although, because of a lack of space, the evaluation had to be largely omitted from this paper, the goal hierarchy and associated key figure system have undergone substantial evaluation through expert interviews and practical case studies. Guideline 4 (Research Contribution): The key figure system and the goal hierarchy provide scientists with a new basis for the concept of IT-agility in the IT architecture of organizations. Guideline 5 (Research Rigor): We used a mixed-method approach combining a structured literature review with semi-structured expert interviews and practical case studies. All methods were designed after established methodology references as mentioned in the text. Guideline 6 (Design as a Search Process): Our research required several design cycles to come up with the final artifacts as presented here. The research on IT-agility in our group is an ongoing process since 2008. Guideline 7 (Communication of Research): This paper is our attempt to communicate the current results to the scientific community.

7 Conclusions

IT-agility is attributed a strong value proposition to corporate success, however, the required level of IT-agility is seldom achieved in companies. According to our expert interviews, the demand for IT-agility is considered particularly high in companies with a strong IT penetration, complex and diverse products with short product life cycles, a strong end customer orientation and dynamic competitive environments. Based on design principles and with appropriate measuring instruments the IT-agility can be improved in practice.

In our research, a goal hierarchy and a derived performance measurement (key figure) system was developed to measure and actively manage the agility of IT application systems landscapes. This measurement model is scalable from the measurement of individual domains to the entire IT application landscape.

The key figure system was developed with a focus on the part of the application landscape that supports the core business processes of a company. In particular in the field of Business Intelligence, which often accounts for a significant portion of IT budgets, questions concerning the applicability of the suggested KPIs to the field of analytical applications may be of interest. Also interesting is whether the performance measurement system can be applied to enterprise networks (value chains).

Methodically, it would be desirable to quantitatively evaluate the key figure system. For this purpose, however, a large number of participating companies is necessary. A large-scale quantitative survey would also enable the validation of the proposed standardization (normalization of indicator results).

Also, the question of the cost of the build-up of IT-agility is not yet considered. Only when this has been clarified, together with the demand question (How much IT-agility is actually needed?), a statement about the optimum level of IT-agility in a company can be made.

While in this contribution the IT architecture was the focus, appropriate considerations are also required with respect to the other pillars of IT-agility, namely the IT organization and IT processes as well as IT staff and management. This represents a current focus of our research with the ultimate goal to make IT-agility measurable and manageable in all fields of action.

Abstract. Digitalization heralds a new era of enterprise IT. It challenges CIOs to find a balance between renovating legacy IT and seizing the opportunities of digital technologies to keep up with competitors and start-ups. This requires organizations to operate two software development modes simultaneously: the traditional and the agile mode. Despite substantial research on both modes, little is known about whether to implement distinct software development projects traditionally or agile. As a first step to addressing this gap, we propose a quantitative decision model that compares the cost and risk profiles of both modes associated with the implementation of a distinct project. The decision model integrates qualitative and quantitative characteristics of the project in focus and of the traditional and the agile mode. As for evaluation, we implemented the decision model as a software prototype and validated its behavior using sample projects as well as a sensitivity analysis.

Keywords: Software Development, IS/IT Management, Agile Methods, Decision Model.

1 Introduction

Digitalization is transforming many industries [1]. Digital technologies enable innovative business models and provide novel revenue opportunities. In their yearly CIO Survey, Gartner [2] relate digitalization to the third era of enterprise information technology (IT). While the first era refers to the initial implementation of corporate information systems, the second era focused on improving reliability and stability. Currently, new technological trends are shaping the third era in a way most CIOs are not prepared for [2]. There is a tension between "doing IT right […], doing IT safely […] and working the plan" and "doing IT fast, […] doing IT innovatively […] and adapting" [2].

Although the third era of enterprise IT requires different architectures, processes, and governance, it mostly impacts software development (SD) [1]. To tackle the challenges related to the tension mentioned above, researchers and industry experts suggest operating multiple SD modes within a company [1, 3]. The two most common modes are the traditional (TSD) and the agile SD mode (ASD) [2]. TSD is about upfront planning and maximizing control, ASD about risk-taking and dealing with uncertainty to

Afflerbach, P.; Kratzer, S.; Röglinger, M.; Stelzl, S. (2017): Analyzing the Trade-Off between Traditional and Agile Software Development - A Cost/Risk Perspective, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 439-453

create innovation at a high pace [4]. Both research and industry call for operating TSD and ASD in parallel. Thus, there is a shift from talking about why and how to do agile toward finding an appropriate trade-off between TSD and ASD.

Most approaches that support deciding about the appropriate SD mode for a distinct SD project (SDP) rely on qualitative analysis [3, 5]. Although there is research on quantifying the characteristics of both modes, there are, to the best of our knowledge, no approaches that quantitatively analyze the decision between TSD and ASD with respect to the implementation of a distinct SDP [6]. Thus, we investigate the following research question: *How can organizations decide whether to implement a distinct SDP in TSD or ASD mode regarding a cost/risk perspective?*

As a first step to answering this question, we adopted the design science research (DSR) paradigm and propose a quantitative decision model, taking a cost/risk perspective [7]. Our model incorporates characteristics inherent to the SDP in focus as well as characteristics specific to TSD and ASD mode. Mapping project characteristics to the cost/risk profiles of both SD modes, our decision model addresses the TSD/ASD trade-off for a distinct SDP. Thereby, our model does not strive for exact estimations of an SDP's business value. Rather, it aims to compare the economic effects associated with both SD modes. We thus take a tactical perspective on the TSD/ASD trade-off instead of a budget planning and cost estimation perspective.

Following the DSR reference process [8], we first provide theoretical background on both SD modes as well as on cost, benefit, and risk management for SDPs. We also derive design objectives that characterize proper solutions to our research problem (*objectives of a solution*). We then introduce the design specification of our decision model (*design and development*), before we report on our evaluation activities so far (*evaluation*). We conclude by summarizing key results, reviewing our limitations, and suggesting topics for further steps to answer this research question.

2 Theoretical Background and Design Objectives

2.1 Traditional and Agile Software Development

SD involves activities grouped into four phases, i.e., specification, design, implementation, and testing [9]. Although all SD methods follow these phases, they differ in how and how often these phases are traversed. TSD mode is sequential or iterative, while ASD is evolutionary or iterative and incremental [10]. The philosophy of TSD is plan- and process-driven as well as formal and tool-oriented [11, 12]. Aitken and Ilango [3] list methods for TSD mode. Methods related to TSD mode rely on the upfront planning of requirements, documentation, and long development cycles [11, 13]. This makes TSD mode beneficial for projects whose scope and features are known upfront. Defects or changes in scope or requirements, however, result in expensive iterations of previous phases [9]. To outline the characteristics of TSD, we use the waterfall model, which sequentially traverses the four SD phases without any iteration or repetition [14].

Due to long development cycles and rising demand for more flexible methods, ASD mode evolved in the 1990s. In 2001, experienced software practitioners issued the Agile Manifesto [15]. The idea behind ASD is the prioritization of individuals and interactions over processes and tools, working software over comprehensive documentation, customer collaboration over contract negotiation, and responding to change over following a plan [15]. Dybå and Dingsøyr [13] as well as Lee and Xia [10] provide an overview of methods related to ASD mode. A well-known ASD method is SCRUM. The essential part of SCRUM is a sprint, an iteration that may last from one day to four weeks. After each sprint, there is a working software artifact ready to be released. ASD methods are primarily characterized as being able to react to changes in requirements and to encourage developers' creativity and autonomous work. As a disadvantage, ASD heavily relies on trustful relationships among customers, developers, and managers as well as a high amount of self-reliance of all participants. Furthermore, ASD often faces problems in a highly regulated and plan-driven environment [3]. Aitken and Ilango [3], Conboy [11], as well as Nerur et al. [12] compare TSD and ASD mode according to mode-specific characteristics.

The argumentation above revealed structural differences between TSD and ASD when implementing an SDP. These differences make the two modes differently suitable for specific projects. Thus, decisions about the appropriate SD mode must account for these differences. Against this background, we define the following design objective:

(DO.1) *Differences of TSD and ASD:* The decision on the appropriate SD mode must account for structural differences of TSD and ASD mode.

2.2 Costs and Risk in Software Development Projects

The dynamic environment in the third era of enterprise IT challenges managers to choose among different SDPs and to decide in which mode to implement these SDPs. In the last decade, researchers and practitioners proposed success criteria and frameworks for project valuation [16]. Techniques that help quantify an IS/IT project's value fit into five categories: net present value (NPV) methods, rate of return methods, ratio methods, payback methods, and accounting methods [17]. The cost-benefit analysis, a representative of the ratio methods, has evolved into the most popular approach to the valuation of IT projects [18]. With this popular approach, the qualitative and quantitative benefits of a distinct project are compared to implementation and operating costs. Finally, a project has a positive business value, if benefits exceed costs. Besides benefits and costs, risk evolved into a third recognized dimension of cost-benefit analysis [19]. As an SDP's largest benefits realize at run time of the related software product, they are out of our decision model's scope [20].

The estimation of an SDP's implementation costs is a well-covered topic in software engineering [6]. Thus, many software cost estimation models are available. These models can be grouped into five categories, i.e., model-based, expert-based, learning-oriented, regression-based, dynamics-based, and composite approaches. Model-based approaches propose algorithms that are specifically developed for the SDP context [9]. COCOMO is a model- and regression-based algorithmic approach for estimating the costs of projects conducted in TSD mode based on input parameters such as project size, scaling factors, and effort multipliers [21]. As a widely recognized approach to software cost estimation, we use the improved version COCOMO II in our decision model for projects executed in TSD mode. There are also cost estimation models for projects conducted in ASD mode. Cao et al. [22] suggest dynamics-based methods that can be adjusted to changing requirements. Yang et al. [23] as well as Benediktsson et al. [24] modify COCOMO II for ASD mode, adjusting the number and length of iterations as well as by incorporating additional efforts. As COCOMO II and the extensions proposed by Benediktsson et al. [24] use the same input parameters, their recommendations are comparable. Thus, we rely on these approaches to consistently compare the costs for implementing an SDP in TSD and ASD mode.

In general, risk is an uncertain event or condition that, if it occurs, has a positive or negative effect on a project objective [20]. In our study, we focus on IT project risks, as we investigate SDPs from a stand-alone perspective and focus on the implementation phase. Studies about IT project risk are provided by Schmidt et al. [25], Boehm [26], Bannerman [20]. Referring to these studies, the most important risks are the following ones: lack of top management support, misunderstanding of requirements, changes in requirements, lack of user involvement, and lack of adequate project staff. We aggregate these risks into three risk types that represent the major impacts of the above-mentioned risk factors on an SDP, i.e., the risk of requirement changes, the risk of delay, and the risk of defect. In our model, we adjust an SDP's implementation costs by risky costs originating from the risk types just introduced [27].

The preceding reasoning underscores the relevance of an integrated cost/risk-perspective when deciding about the appropriate SD mode for a distinct SDP. An integrated perspective is not only necessary as for economic factors, but also when it comes to the comparison of both SD modes. We define the following design objective:

(DO.2) *Integrated economic valuation:* The decision on the appropriate SD mode requires considering economic dimensions (e.g., costs and risks) in an integrated manner. This decision requires ensuring the comparability of both modes.

3 Design Specification

Our decision model systemizes and combines factors relevant for determining the appropriate SD mode for a distinct SDP. Thus, our unit of analysis is the implementation of a distinct SDP. In our basic setting, the management has already strategically decided to implement the SDP, i.e., the benefits outweigh costs and risk independent from the chosen SD mode. Only the decision about the appropriate SD mode is open. We assume that the organization has the capabilities and expertise to conduct the SDP in focus in both modes (Assumption 1). In our decision model, this operative decision is based on the costs and the risks associated with TSD and ASD mode. Although researchers point to qualitative factors beyond a cost/risk perspective, we focus on their economic impacts and model them implicitly via the costs and risks effects of the SDP in focus [28]. As stated, we abstract from benefits as they materialize at run time. For the same reason, we focus on those costs and risks that accrue during the SDP's implementation.

The decision about the appropriate SD mode involves two major challenges. First and inherent to almost all economic decisions, the decision requires resolving trade-offs. In our TSD/ASD trade-off, the advantages and drawbacks of TSD mode face those related to ASD mode. Second, the decision is multi-dimensional. In order to address the TSD/ASD trade-off, the involved decision-makers must integrate quantitative and qualitative factors. We address these challenges by integrating these factors and evaluating their effects economically from a cost/risk perspective.

3.1 General Setting

We first introduce the general setting of our model and outline the TSD/ASD trade-off. We also define the model's objective function. From an economic perspective, we can break down the TSD/ASD trade-off into differences regarding the cost/risk profiles of an SDP in both SD modes. There are projects for which the cost/risk profiles dovetail, with the TSD/ASD trade-off clearly tending to one side. We refer to such SDPs as TSD- or ASD-type projects. TSD is the preferable SD mode if the cost and risk advantages of TSD exceed those of ASD – and vice versa. There are also projects whose profile cannot be unambiguously assigned to either type.

To facilitate a structured presentation of the decision model, we first consider costs and risks separately, before integrating them. The deterministic base costs C are defined as those costs associated with the SDP's implementation. We model the base costs by using the cost estimation models COCOMO II by Boehm et al. [21] for TSD mode and the extensions of Benediktsson et al. [24] for ASD mode. Furthermore, we define the risk R as additional costs taking the risks of defects, requirement changes, and delays into account. Basically, there are two reasons why we chose COCOMO II for modeling base costs: First, COCOMO is popular and well-known among researchers and practitioners, which is why it increases the comprehensibility of our model [9]. Second, COCOMO II and the extension by Benediktsson et al. [24] ensure comparability as both methods use identical input parameters. In fact, our aim is to offer decision support on the comparison of TSD and ASD for a distinct SDP, and not to estimate costs as accurately as possible.

To evaluate the SDP's costs and risk depending on the chosen SD mode, we use the certainty equivalent method. The certainty equivalent method is an acknowledged approach for corporate decision-making in risky situations [29]. It has also proven to be useful for decision-making in IS/IT projects as well as in IS/IT project portfolio management [16, 30]. The certainty equivalent represents the certain amount of money that creates the same subjective utility for the involved decision-makers as the corresponding risky situation [27]. Applying the certainty equivalent enables comparing the deterministic base costs C and the risky additional costs R. For decision-makers with a constant absolute risk aversion α, measured via the absolute Arrow-Pratt measure, and for a normally distributed risk with expected value μ_R and variance σ_R^2, the certainty equivalent of a distinct SDP for a chosen SD mode is given by Eq. (1) [31]. As the certainty equivalent can be structurally decomposed into the expected costs and a risk premium, we refer to the certainty equivalent as risk-adjusted costs to outline both decisive components. On this foundation, we use the difference between the risk-adjusted costs that accrue when implementing the SDP in TSD or in ASD mode as our objective function, which is shown in Eq. (2).

$$\Phi = \mathbb{E}[-(C+R)] - \frac{\alpha}{2} \cdot VAR[-(C+R)] = -C - \mu_R - \frac{\alpha}{2} \cdot \sigma_R^2, \qquad \alpha \in \mathbb{R}^+ \tag{1}$$

$$\Delta\Phi = \Phi^{\text{TSD}} - \Phi^{\text{ASD}} \tag{2}$$

In case $\Delta\Phi > 0$, the SDP should be implemented in TSD mode, and vice versa. Below, we analyze the costs, their components, and the corresponding parameters. After that, we provide more details on the risk component.

3.2 Cost Perspective

First, we focus on the base costs of an SDP. The base costs for implementing an SDP depend on the chosen SD mode, because TSD and ASD mode feature different cost structures [3]. In TSD mode, the SDP is organized in a long phase which is processed sequentially in a single iteration. In contrast, ASD mode is organized and processed in several smaller iterations, so-called sprints. As mentioned above for modeling the base costs we use COCOMO II by Boehm et al. [21] for TSD mode and its extension from Benediktsson et al. [24] for ASD mode.

The base model of COCOMO II describes the SDP's effort in TSD mode in of person-months by taking the project size to the power of a scaling exponent E (Eq. 3). The number of person-months multiplied with the staff costs leads to the base costs. The variable size is measured in thousand source lines of code (KSLOC). Other measurement units for size (e.g., function points) are applicable as well. The constant A is an effort coefficient for productivity and the parameters $EM_1, \dots, EM_{16}$ are effort multipliers that represent factors like product complexity, programmer capability, or platform volatility. The factor a thus adjusts the effort regarding productivity. The scaling exponent, which indicates economies $(E < 1)$ or diseconomies of scale $(E > 1)$, comprise a constant B and scale factors $SF_1, \dots, SF_5$ accounting, for example, for development flexibility, team cohesion, and process maturity. If all scale factors are rated "very high" and B is calibrated as COCOMO II suggests, E equals at least 0.91, implying economies of scale. Economies of scale can hardly be realized in SDPs. In almost every possible parameterization of COCOMO II, the cost function exhibits an exponent between 1.0 and its maximum 1.226, indicating diseconomies of scale. This is as communication and integration overheads increase over-proportionally with the project size. Eq. (3) represents the base model for TSD mode Boehm et al. [21].

$$PM_{\text{TSD}} = a \cdot size^E \qquad \text{with } E = B + 0.01 \cdot \sum_{j=1}^{5} SF_j \text{ and } a = A \cdot \prod_{i=1}^{16} EM_i \tag{3}$$

Benediktsson et al. [24] adjust the base model of COCOMO II for ASD mode. They divide the project size into sprints, a transformation that causes an initial effort for defining the breakdown structure. Moreover, sprints are interpreted as sub-projects. Consequently, Benediktsson et al. [24] apply the exponent E to the sprint sizes and sum up the resulting efforts, arguing that smaller sprints require less overhead and planning compared to the single large phase in TSD mode. In reality, the overall project length may vary between the different SD modes. However, there is no evidence that one mode is dominating the other. Therefore, and for reasons of comparability, we assume the project length to be identical for TSD and ASD mode (Assumption 2). Our model setup would allow for length discounts in favor of ASD by subtracting a certain number of sprints from the length calculated for project implementation in TSD mode. Such a parameter, however, would be subject to extreme estimation inaccuracies and increase the complexity of our decision model. Furthermore, sprints can differ in size and content, which depends very much on the SDP at hand. We assume that all sprints take a constant amount of time (e.g. two weeks, four weeks) in case the SDP is implemented in ASD mode (Assumption 3). Thus, we divide the project length calculated for TSD mode into n equi-length sprints in ASD mode and apply the approach of Benediktsson et al. [24] [32]. Eq. (4) shows the base model for implementing the SDP in ASD mode as an adaption of the TSD mode estimation.

In Eq. (4), the parameter d_n models the overhead of the total effort required to define the breakdown structure. It depends on the total number of sprints [24]. Thereby, d_n is calibrated by a linear interpolation between the relative effort for defining one sprint e and for defining the largest number of sprints f (Eq. 5). The parameter c represents the overhead costs per sprint and accounts for the additional overhead within single sprints. The number of sprints n is gained from the calculation of the project length in COCOMO II multiplied with the number of sprints per month. The exponent F consists of similar components as its counterpart for TSD mode. The constants G (called C in COCOMO II) and D are obtained by calibrations based on former projects [21].

$$PM_{\text{ASD}} = d_n \cdot a \cdot size^E + n \cdot a \cdot \left(\frac{size}{n} \cdot (1 + c)\right)^E \tag{4}$$

with $n = G \cdot (PM_{\text{TSD}})^F \cdot sprints\ per\ month$ and $F = D + 0.02 \cdot 0.01 \cdot \sum_{j=1}^{5} SF_j$ and

$$d_n = (f - e) \cdot \frac{n-1}{n-N} + e \tag{5}$$

Figure 1 illustrates the cost/size relationships for projects implemented in TSD and ASD mode. Costs are measured in Monetary Units [MU], size in KSLOC. Since SDPs typically exhibit diseconomies of scale, we apply an exponent larger than 1 [21].

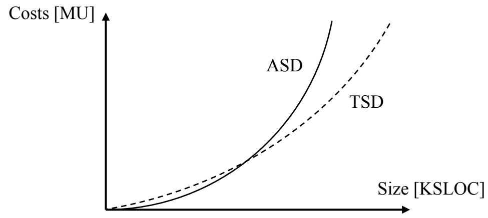

Figure 1. Costs of an SDP with diseconomies of scale depending on size

For $E \neq 1$, the two cost curves cross each other at a distinct intersection point. For small projects, ASD mode appears more favorable. This is as the initial effort required for creating a small number of sprints in ASD mode is small compared to the initial overhead for planning in TSD mode. Thus, TSD mode needs a minimum project size to justify the initial overhead. From a pure cost perspective, TSD mode is becoming more preferable with an increasing project size. This is as the initial overhead is distributed over the project length. For large projects, the initial overhead for ASD mode is becoming relatively expensive as planning and managing sprints is getting complex [33].

3.3 Risk Perspective

In our analysis, we focus on three risk types, i.e., the risk of defect, risk of requirement changes, and risk of delay. Defects, changes in requirements, and delays can happen several times during implementation of an SDP. We model each risk type as a normally distributed variable with expected additional costs and a variance per sprint (Assumption 4) [27, 30]. Typically, the expected value μ per risk type is denoted in percent of the corresponding total costs C depending on TSD or ASD mode. Furthermore, the variance σ^2 of each risk type is measured in percent of the expected value.

We add this risk perspective to our decision model in order to incorporate the specific characteristics of TSD and ASD mode. The risk of defect covers the risk of having major defects in the software product due to developer mistakes [25, 26]. Boehm and Turner [34] model this risk based on an SDP's criticality. A large project size combined with a lack of upfront planning and inexperienced developers, for example, can cause such defects. A defect typically results in negative economic effects, which we model by expected additional costs resulting from a defect μ_{DEF} and their variance σ^2_{DEF}. Since there is a detailed ex-ante planning in TSD mode, the expected additional costs and their variance are typically smaller as compared to ASD mode [12]. The risk of requirement changes, which Boehm and Turner [34] call the dynamism of a project, addresses change requests during project implementation. Due to regular releases, frequent stakeholder feedback as well as an environment geared toward refactoring and backlog refinement, the expected additional costs for requirement changes μ_{CHG} and their variance σ^2_{CHG} are generally lower in ASD mode than in TSD mode [10]. The risk of delay addresses the risk of missing a deadline or not being fast enough regarding time-to-market. This risk is particularly high if the software product exhibits a short time-to-market. Delays result in expected additional costs μ_{DEL} and variance σ^2_{DEL} from losing market share to competitors or from financial penalties due to missed deadlines. ASD mode can better mitigate the risk of delay as running software increments can be released more flexibly [5]. Thus, expected additional costs and the variance are generally higher in TSD mode.

In order to aggregate the three risk types, we must consider dependencies. There can be intra- and inter-temporal dependencies among the risk types. For example, in case of a major defect, the chance for a delay in the same period is higher than usual. We account for these dependencies between two risk types based on the Bravais-Pearson correlation coefficient ρ [35]. As an SDP lasts multiple periods or sprints, the risk types may also influence themselves over time. For example, if a major delay occurs, the chance for a greater delay in the following periods could be higher. Further, the risk of defect may tend to increase throughout the project in TSD mode. This drift that increases costs of defects over project time could be modeled via martingales. Alternatively, we could use individual distributions for every sprint, which would lead to more parameters and a more complex model. In our decision model, we therefore abstract from such auto-correlated structures, assuming that the distribution of each risk type is identical over all periods (Assumption 5). This assumption leads to an underestimation of the costs of defects in TSD mode. In general, assuming inter-temporal independence underestimates the overall risk exposure. However, as the risk is underestimated in both SD modes and as we compare both SD modes regarding the implementation of a concrete SDP, this has not effect on the recommendations of our decision model. On this assumption, we can sum up the expected additional costs and variances of the three risk types per sprint t to derive the total expected additional costs μ_R and their variance σ_R^2. The result is shown in Eq. (6) and (7).

$$\mu_R = \sum_{t=1}^{n} \left(\mu_{t,\mathrm{DEF}} + \mu_{t,\mathrm{CHG}} + \mu_{t,\mathrm{DEL}}\right) = n \cdot \left(\mu_{\mathrm{DEF}} + \mu_{\mathrm{CHG}} + \mu_{\mathrm{DEL}}\right) \tag{6}$$

$$\sigma_R^2 = \sum_{t=1}^{n} \sum_{i} \sum_{j} \sigma_{t,i}\, \sigma_{t,j} \rho_{i,j} = n \cdot \sum_{i} \sum_{j} \sigma_i\, \sigma_j \rho_{i,j} \tag{7}$$

with $i, j \in \{\mathrm{DEF}, \mathrm{CHG}, \mathrm{DEL}\}$

On this foundation, the objective function from Eq. (2) can be rewritten as shown in Eq. (8). Thereby, C_{Dev} represents the costs for a software developer.

$$\Delta\Phi = -C_{\mathrm{Dev}} \cdot a \left(size^E - d_n \cdot size^E + n \cdot \left(\frac{size}{n} \cdot (1 + c) \right)^E \right) - \Delta\mu_R - \frac{\alpha}{2} \cdot \Delta\sigma_R^2 \tag{8}$$

4 Evaluation

To validate our decision model, we implemented its design specification as a software prototype [36]. The prototype enabled conducting sample calculations and a sensitivity analysis. As for our calculations, we consider two fictional sample SDPs specified in Table 1. This setting does of course not account for all possible projects. We chose the parameters such that one project favors each mode. The input parameters for the base costs are identical for both projects, but the risk parameters differ. Depending on the specific cost/risk profile, we have a TSD-type project with a high exposure to defects and an ASD-type project with a high exposure to requirement changes and delays. One example for such a TSD-type project is the implementation of a new core system within a bank. An example for the ASD-type project is the development of a new payment application for smartphones. For the TSD-type project, the expected additional costs of defect and the related variance are quite large, while the other risks are rather small. For the ASD-type project, it is the vice versa. Additionally, the risks of the TSD- and the ASD-type project vary according to the risk profiles of both SD modes. We keep the size flexible to enable a comparison between costs and risks for both SD modes with respect to different project sizes.

Table 2 shows the correlation coefficients of the risk types for both modes, which we use for our calculations. For both modes, the risk of defect is positively correlated with the risk of delay. As TSD is not as adaptive and flexible as ASD, a defect in TSD has a larger impact on the risk of delay compared to ASD. For TSD, a change of requirements increases the risk of delay, as heavy planning does not allow for changes. ASD mode can cope much better with changed requirements. As a consequence, the risk of requirement changes and risk of delay are uncorrelated in ASD mode.

Table 1. Specification of a TSD-type and an ASD-type sample project

Base costs input parameters				Risks TSD-type project			Risks ASD-type project		
a	2.94	SF_5	6.24		TSD mode	ASD mode		TSD mode	ASD mode
B	0.91	EM_i	1						
G	3.67	C_{Dev}	5,000 MU	μ_{DEF}	1.5 %	4 %	μ_{DEF}	1 %	2 %
D	0.28	c	0.15	μ_{CHG}	1.25 %	0.5 %	μ_{CHG}	2.5 %	1.5 %
SF_1	3.72	e	0.05	μ_{DEL}	1.25 %	0.5 %	μ_{DEL}	2.5 %	1.5 %
SF_2	3.04	f	0.4	σ_{DEF}	5 %	30 %	σ_{DEF}	5 %	15 %
SF_3	4.24	Sprints	2 per mo.	σ_{CHG}	15 %	10 %	σ_{CHG}	22.5 %	10 %
SF_4	4.38	$Size$	$size$	σ_{DEL}	15 %	10 %	σ_{DEL}	22.5 %	10 %

Table 2. Sample correlations between risk types for TSD and ASD mode

TSD mode				ASD mode			
$\rho_{i,j}$	DEF	CHG	DEL	$\rho_{i,j}$	DEF	CHG	DEL
DEF	1	0	0.5	DEF	1	0	0.25
CHG	0	1	0.5	CHG	0	1	0
DEL	0.5	0.5	1	DEL	0.25	0	1

We first analyze the ASD-type project from Table 1 and choose a constant absolute risk aversion $\alpha = 0.0002$. This is reasonable according to Bamberg and Spremann [37]. Figure 2 (left chart) illustrates the results, where we show different deltas between TSD and ASD mode in terms of costs, risk, and risk-adjusted costs while varying the project size between 0 and 300 KSLOC. The dotted line depicts the delta in terms of costs, the dashed line depicts the delta in terms of risk, and the continuous line depicts the delta in terms of risk-adjusted costs.

As outlined, the cost advantage for ASD is only given for small projects. The initial effort required for accomplishing a small number of sprints in ASD mode is relatively small compared to the overhead of upfront planning in TSD mode. With larger project sizes, the initial planning effort in TSD mode increases less than the overhead for planning larger amounts of sprints in ASD mode. Thus, TSD has a cost advantage for larger project sizes. This finding in our sample calculation complies with extant knowledge. Researchers have argued that TSD mode is more favorable for large projects in general [38]. From a risk perspective, ASD is the preferable SD mode for all investigated project sizes between 0 and 300 KSLOC. The risk advantage for ASD always exceeds the cost advantage for TSD mode. Therefore, ASD is the appropriate mode for the sample project at hand. For decision-makers with a lower level of risk aversion (α), the delta between TSD and ASD in terms of risk-adjusted costs is depicted by the continuous grey line in Figure 2 (left chart). In this case, ASD is not favorable for all project sizes. In case of more risk-seeking decision-makers, the cost advantage for TSD exceed the risk advantage for ASD for large project sizes. This example illustrates that deciding on the SD mode is similar to balancing the certain cost advantage of TSD against the risk advantage of ASD. Economically speaking, decision-makers charge a risk premium for requirements changes on the safe cost advantage for TSD mode.

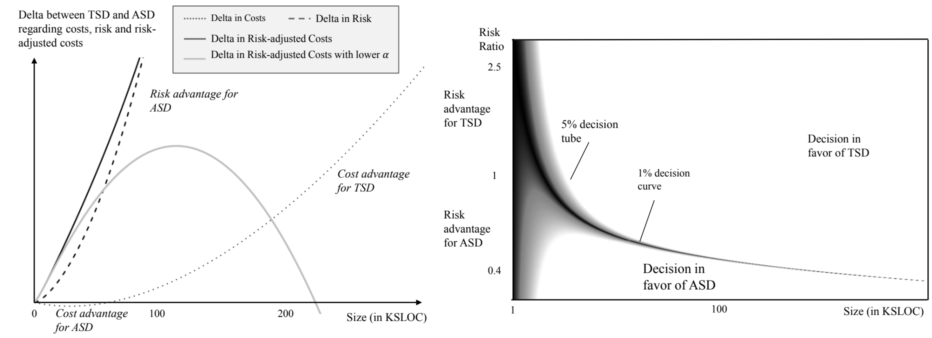

Figure 2. Calculation for the ASD-type sample project and grey-scale plot of relative delta

Next, we analyze the TSD-type project from Table 2. Table 1 shows the correlation coefficients of the risk types for both modes, which we use for our calculations. For both modes, the risk of defect is positively correlated with the risk of delay. As TSD is not as adaptive and flexible as ASD, a defect in TSD has a larger impact on the risk of delay compared to ASD. For TSD, a change of requirements increases the risk of delay, as heavy planning does not allow for changes. ASD mode can cope much better with changed requirements. As a consequence, the risk of requirements changes and risk of delay are uncorrelated in ASD mode. The cost advantages of TSD and ASD are the same as for ASD-type project, as the input parameters for the base costs are independent of the SD mode. Further, the risk advantage of TSD is positive for all project sizes, making TSD the preferable mode for nearly all project sizes. With the above examples, we demonstrated the suitability of our decision model by conducting sample calculations for a TSD- and an ASD-type sample project.

To demonstrate the robustness of our decision model, we now analyze the delta in risk-adjusted costs between both SD modes by varying the size and risk structure of a given project using a sensitivity analysis. When setting up the sensitivity analysis, two features must be considered: First, to stay comparable with an increasing project size, we rely on the relative delta in risk-adjusted costs, i.e., we divide the absolute delta in risk-adjusted costs by the absolute risk-adjusted costs of the respective SD mode. We do not consider the absolute risk-adjusted costs delta, which gets biased with an increasing project size. Second, as we only have a single dimension for describing the risk structure, we divide the risk of defect, which is typical for TSD-type projects, by the sum of the risk of requirement changes and delay, which are more typical for ASD-type projects. Thereby, we get a risk ratio that indicates a risk profile in favor of ASD for values from the interval $[0,1[$ and in favor of TSD for values from $]1,\infty[$. As a result, we get a three-dimensional analysis with project size and risk ratio on the horizontal and vertical axis, and the delta in relative risk-adjusted costs as a grey-scale plot. The delta in relative risk-adjusted costs is depicted on a grey-scale with bright indicating a high delta and dark indicating a low delta. The dark area shows settings where decision-makers are indifferent, whereas the bright areas illustrate robust decisions in favor of either TSD or ASD. We start with the TSD-type project from Table 1. We then reduce the risk of defect successively, while equivalently increasing the risk of requirement changes and delay until we end up with the ASD-type project from Table 1. This way, we get comparable projects regarding costs and a balanced risk profile half way between both projects (i.e., risk ratio = 1). The black area and line in Figure 2 (right chart) shows the decision curve, i.e., the area of indifference between both SD modes. Along the decision curve, the relative delta in the risk-adjusted costs is less than one percent. The grey decision tube around the black line depicts the delta values that are less than five percent of the respective risk-adjusted costs. Within this tube, the decision is not profound, but slightly tends to one of both modes. Decision-makers have to be careful regarding decisions within the five percent decision tube, as estimation errors may strongly influence the decision. For small projects, the decision is mainly influenced by the risk advantage of TSD or ASD depending on the SD mode, since the cost advantage of ASD is negligibly small. The black area indicates that our decision model is indifferent for small projects as it strongly depends on the risk distribution of the project at hand and the SD modes. However, this indifference is plausible, as the decision on the appropriate SD mode for a small SDP does not carry as much weight in terms of total costs as for large SDPs. The managerial implication is that decision makers should focus on finding the appropriate mode for larger SDPs, since for small projects the cost and risk difference is negligibly small. With an increasing project size, the costs are strongly in favor of TSD mode, leading to a steep decrease of the decision curve. The decision curve then converges towards the horizontal axis, indicating a larger area for unambiguous decisions in favor of TSD for very large projects. This is due to the cost advantage of TSD. That is, it can be reasonable from a cost/risk perspective to implement an SDP in TSD despite a risk advantage for ASD mode. For strongly ASD-type SDPs, i.e., projects with a very strong risk of requirement changes and delays, however, ASD is appropriate. The managerial implication of this finding is that decision makers should carefully evaluate the project's risk in both modes, since it could reverse a strong cost advantage for large projects. Although the graph in Figure 2 indicates otherwise, there is no reason to believe that the majority of projects should be conducted in TSD mode. First, SDPs in practice are not equally distributed over the size and risk dimensions. Second, we analyzed only one particular sample SDP in Figure 2. In a practical setting, our model primarily serves as decision support. Decision-makers should nevertheless carefully evaluate the outcome by taking their experience and other models into account.

5 Conclusion

In this study, we investigated how organizations can decide whether to implement a distinct SDP in TSD or ASD mode. Building on the characteristics of the SDP in focus and the characteristics of both SD modes, we proposed a decision model that analyzes the costs and risks associated with the implementation of a distinct SDP. Our model builds on the cost estimation method COCOMO II for TSD mode and the extensions proposed by Benediktsson et al. [24] for ASD mode to achieve comparability between both SD modes. To extend a purely cost-based view, the model accounts for three major risk types related to the implementation of an SDP, i.e., risk of defect, requirement changes, and delay. Besides these risk types, the decision model incorporates sprint length and overhead costs as characteristics of TSD and ASD mode. Our contribution is twofold. First, we bring the two cost estimation approaches together. Second, we extend the solely cost based view by a risk perspective. As for evaluation, we applied the decision model to sample projects with different input parameters. We also conducted a sensitivity analysis based on a software prototype to validate the decision model's suitability and robustness. The sensitivity analysis corroborated that the decision model yields plausible results. Overall, we contribute to the prescriptive knowledge on software development with a decision model as concrete artifact and its instantiation as a software prototype.

Our decision model is beset with limitations. First, we assume the risk types to be independent over time and normally distributed. Thus, the decision model underestimates risks associated with implementing an SDP. Risks may also increase or decrease over time, e.g., the expected additional costs for a change in requirements may increase over time if the project is executed in TSD mode. Research on inter-temporal dependencies of SD risks is required to implement these effects into our decision model. Future research should explore the risk structure of SDPs. Second, the decision model focuses on costs and risks that accrue during SDP implementation. Considering an SDP's business value also requires integrating benefits. In ASD mode, design and run time can no longer be separated as benefits accrue after each sprint. In TSD mode, however, benefits only realize after the SDP has been fully completed. Thus, we recommend that further research extends the decision model toward a cost-benefit analysis that includes benefits and a runtime perspective. Third, we focused on individual SDPs, ignoring the portfolio perspective. Future research should investigate how project dependencies influence the TSD/ASD trade-off. Fourth, as a first step, we demonstrated and analyzed the decision model via sample projects and a sensitivity analysis. Thus, the decision model would benefit from naturalistic evaluation, e.g., real-world case studies.

Abstract. Agile Methoden sind seit einigen Jahren in der Softwareentwicklung etabliert und erfahren vor dem Hintergrund digitaler Transformationsprojekte aktuell eine sehr hohe Aufmerksamkeit. Gleichzeitig erscheinen der Zusammenhang zwischen dem gewählten Agilitätsgrad eines Softwareentwicklungsprojekts und seinem Erfolg sowie die moderierende Rolle der Unternehmenskultur weitestgehend ungeklärt. An dieser Stelle setzt unsere Forschung an, indem sie die Erfolgswirkung von Agilität in Softwareprojekten quantitativ-empirisch untersucht und dabei die spezifische Kultur des jeweiligen Unternehmens berücksichtigt. Hierzu wurden mit Hilfe eines Fragebogens insgesamt 108 verwertbare Antworten von IT-Projektmitarbeitern gesammelt und mit dem Ansatz Partial Least Squares in einer Mehrgruppenanalyse statistisch ausgewertet. Die Ergebnisse zeigen, dass einerseits ein höherer Agilitätsgrad zu einem höheren Projekterfolg führt, diese Wirkung andererseits aber von der Unternehmenskultur beeinflusst wird. Entsprechend erweitern unsere Forschungsergebnisse die Wissensbasis in diesem Bereich und liefern wertvolle Erkenntnisse für die Praxis der Softwareentwicklung.

Keywords: Agile Softwareentwicklung, Projekterfolg, Unternehmenskultur

1 Einleitung

Nach nunmehr 15 Jahren seit dem Verfassen des agilen Manifests sind agile Methoden im Bereich der Softwareentwicklung fest etabliert [1]. Vor dem Hintergrund von Digitalisierungsaktivitäten in zahlreichen Unternehmen erfahren diese Methoden derzeit eine hohe Popularität. Trotzdem werfen agile Methoden und deren zugrundeliegenden Werte und Prinzipien nach wie vor Fragestellungen auf, die einer Beantwortung bedürfen, um ein klares Bild dieser Vorgehensweise zu erhalten und eine entsprechende adäquate Anwendung zu ermöglichen. Dies konstatiert auch Hunt [2] als einer der Autoren des Manifests beim Rückblick auf die Entwicklungen in diesem Bereich. Seiner Beobachtung nach sei der Grundgedanke der agilen

Haase, M.; Jöhnk, J.; Lipowsky, S.; Urbach, N. (2017): Der Einfluss des Agilitätsgrads auf den Erfolg von Softwareentwicklungsprojekten unter Berücksichtigung der Unternehmenskultur, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 454-468

Softwareentwicklung verloren gegangen und Agilität werde oftmals auf die reine Anwendung von entsprechenden Methoden und Techniken beschränkt. Wie verschiedene Beobachtungen zeigen, werden agile Methoden in Unternehmenskontexten nicht selten unreflektiert eingeführt, ohne deren Eignung im Vorfeld zu prüfen [3]. Nicht immer scheinen agile Methoden vorteilhafter gegenüber den klassischen, plangetriebenen Ansätzen zu sein, auch wenn die gegenwärtigen Diskussionen dies teilweise suggerieren. Neben spezifischen Projekteigenschaften stellt vor allem die vorherrschende Unternehmenskultur einen wichtigen Einflussfaktor dar, der grundlegend beachtet werden sollte [4, 5].

Eine weitere Beobachtung sind die dauerhaft niedrigen Erfolgsquoten von IT-Projekten. So wird durch zahlreiche Studien, trotz der weitläufigen Kritik aufgrund variierender Erfolgsdefinitionen sowie fehlender Kontext- und Projektinformationen, doch deutlich, dass der Erfolg von IT-Projekten im Allgemeinen als vergleichsweise niedrig angesehen werden kann [6]. So wurde beispielweise im Jahr 2014 im Rahmen des jährlichen *Chaos Report* der Standish Group, eine Erfolgsquote von nur 16,2% aller IT-Projekte festgestellt [7]. Über Erfolg oder Misserfolg von Projekten entscheidet unter anderem eine adäquate Auswahl und Anwendung der Projekt-Vorgehensweise. Deren Erfolg ist wiederum von der Kompatibilität zur jeweiligen Unternehmenskultur abhängig [8].

Entsprechend erscheint eine genauere Untersuchung des Zusammenhangs von der gewählten Projekt-Vorgehensweise und dem Erfolg eines IT-Projekts unter Berücksichtigung der gegebenen Unternehmenskultur als wertvoll für ein besseres Verständnis im IT-Projektmanagement. Mit spezifischen Fokus auf agile Praktiken und Softwareentwicklungsprojekte möchten wir mit diesem Forschungspapier der Beantwortung der folgenden Forschungsfrage nachgehen: *Welchen Einfluss hat der Agilitätsgrad der eingesetzten Vorgehensweise auf den Erfolg eines Softwareentwicklungsprojekts unter Berücksichtigung der Unternehmenskultur?*

Zur Beantwortung dieser Forschungsfrage haben wir ein quantitativ-empirisches Forschungsdesign gewählt. Auf Basis früherer Forschungsarbeiten leiten wir zunächst ein konzeptionelles Forschungsmodell ab, welches wir im Anschluss mittels gewonnener Daten aus einer Umfrage unter IT-Projektmitarbeitern analysieren. Als statistischen Ansatz zur Auswertung des empirischen Datenmaterials und zur Validierung des Forschungsmodells setzten wir den varianzbasierten Ansatz Partial Least Squares (PLS) ein.

2 Theoretische Entwicklung

2.1 Agile Softwareentwicklung

Mit dem Entstehen von verschiedenen Softwareentwicklungsmethoden in den 90er Jahren wurde der Grundstein für die agile Vorgehensweise in der Softwareentwicklung gelegt. So existieren aktuell gängige agile Methoden wie *Scrum* oder *Extreme Programming* (XP) bereits seit diesem Zeitraum [1, 9]. Die Entstehung resultierte aus der Überzeugung heraus, dass sich bisherige, plangetriebene Vorgehensweisen wie die Wasserfallmethode nicht mehr für die wachsende Dynamik im

Softwareentwicklungsbereich eignen [10]. Durch diese bewusste Abgrenzung wurde im Jahr 2001 das agile Manifest verfasst, um die Kernelemente der entstandenen Methoden aufzunehmen und damit die Basis der neuen agilen Vorgehensweise zu schaffen [11]. Seit diesem Zeitpunkt hielt die agile Softwareentwicklung Einzug in Praxis und Wissenschaft und gilt heute als eine der zentralen Vorgehensweisen [12].

Obwohl mittlerweile verschiedenste Definitionen der agilen Softwareentwicklung existieren, wird das agile Manifest nach wie vor am Häufigsten zur Charakterisierung herangezogen [13]. Diese Definition besteht dabei aus vier Werten und zwölf Prinzipien, worauf sich wiederum konkrete agile Methoden wie *Scrum* sowie entsprechend genutzte Praktiken begründen [11]. Die vier Werte stellen die Leitsätze der agilen Vorgehensweise dar. Dabei werden in erster Linie der Mensch und dessen Rolle im Softwareentwicklungsprozess in den Vordergrund gestellt. Besonders die enge Interaktion innerhalb des Entwicklungsteams sowie die Kollaboration mit dem Auftraggeber sind dabei essentiell. Außerdem wird die frühzeitige Auslieferung von Software-Funktionalitäten in möglichst kurzen Abständen angestrebt. Um dabei die kontinuierliche Aufnahme und Bearbeitung von neuen oder geänderten Anforderungen zu gewährleisten, wird eine schnelle Reaktionsfähigkeit während des gesamten Softwareentwicklungsprozesses vorausgesetzt. Dafür werden weiterhin eine kontinuierliche Informationsverfügbarkeit sowie ein kompetentes und eigenverantwortliches Team gefordert [14]. Die zwölf Prinzipien dienen wiederum als Operationalisierung, deren Berücksichtigung die Erfüllung der agilen Werte ermöglicht. Zusammenfassend wird dabei die Zufriedenstellung des Auftraggebers durch die Auslieferung qualitativer Software fokussiert. Darüber hinaus werden besonders Fähigkeiten der Selbstorganisation sowie der Anpassung bei Unsicherheiten aller Beteiligten hervorgehoben. Auch die kontinuierliche Verbesserung und Weiterentwicklung der Arbeitsweise während der Softwareentwicklung sowie direkte Kommunikationsflüsse werden angestrebt [15].

2.2 Projekterfolg

Der Projekterfolg wird seit langem immer wieder von der Forschung aufgegriffen, wobei die Anfänge bis in die 70er Jahre zurückreichen [16]. Dennoch konstatiert Prabhakar [17], dass weder in der Praxis noch in der Wissenschaft eine allgemeingültige Definition für den Erfolg von Projekten existiert. Diese Heterogenität schlägt sich auch auf die Erhebung des Projekterfolgs nieder, da je nach Erfolgsdefinitionen die Zielerreichung von IT-Projekten stark schwankt [6]. Trotz oder gerade aufgrund der verschiedenen beteiligten Stakeholder ist eine adäquate Abbildung des Projekterfolgs jedoch unerlässlich [18].

Traditionell wird der Projekterfolg anhand des *Iron Triangle*, dem Projektmanagementdreieck, dargestellt. Die Zielerreichung wird dabei in den Dimensionen Zeit, Kosten und Anforderungen gemessen [19]. Die Erreichung der geplanten Anforderungen ist im Vergleich zu den anderen beiden Dimensionen nicht klar abgrenzbar und wird häufig auch als Qualität, Leistung, Spezifikationen sowie Umfang bezeichnet [20]. Insbesondere im Hinblick auf die unterschiedlichen Perspektiven der beteiligten Stakeholder stellen diese drei Projekterfolgsdimensionen eine vereinfachte Abbildung des multidimensionalen Konstrukts dar und werden demnach oft als unzureichend kritisiert [u.a. 19]. Zudem wird mittels dieser Bestandteile nur die kurzfristige Sicht auf den Projekterfolg dargestellt, wobei längerfristige Auswirkungen durch das Projekt außen vor bleiben [21].

Daher existiert in der Literatur neben den dominierenden traditionellen Erfolgskriterien eine Vielzahl von weiteren Erfolgsbestandteilen und alternativen Projekterfolgsdefinitionen [20]. Dazu zählen die Zufriedenheit der beteiligten Stakeholder (Auftraggeber, Projektmitarbeiter und Nutzer), Steigerungen der Effektivität und Effizienz sowie der Beitrag zum Unternehmenserfolg [19, 20]. Dabei wird häufig zwischen Produkt- und Prozesserfolg unterschieden [18]. Der Prozesserfolg kann auch als Projektmanagementerfolg bezeichnet werden und umfasst die traditionellen Dimensionen des *Iron Triangle* [22]. Die Prozesseffizienz, welche das Verhältnis aus Zielerreichung und Aufwand beschreibt, wird jedoch teilweise als eigenständige Erfolgskomponente angesehen. Dies resultiert daraus, dass ein Projekt zwar hoch effizient durchgeführt werden kann und dennoch nicht die gesteckten Ziele erreicht, da diese bspw. von Anfang an unrealistisch waren [20]. Zum Produkterfolg wird dagegen die Erreichung der strategischen Unternehmensziele des Auftraggebers, des verfolgten Projektzwecks sowie die Bedürfnisse beteiligter Personengruppen gezählt [23]. Die Zufriedenheit der beteiligten Stakeholder kann entweder als Bestandteil oder aber auch losgelöst von den beiden Kategorien angesehen werden [23, 24]. Diese Überschneidungen der Kategorien sind neben verschiedenen Begriffsabgrenzungen insbesondere auf die Interdependenzen zwischen den einzelnen Projekterfolgsbestandteilen zurückzuführen. So ist bspw. die Erreichung von geplanten Anforderungen für das eigentliche Projektziel, die Erfüllung der Stakeholderbedürfnisse, zuständig. Dies bedingt wiederum die Zufriedenheit aller Beteiligten [25]. Auf Grundlage der diskutierten Literatur haben wir Projekterfolg im Rahmen dieser Arbeit als multidimensionales Konstrukt mit den Bestandteilen Prozesserfolg (Zielerreichung in Zeit, Kosten und Anforderungen; Prozesseffizienz) und Produkterfolg (Ergebnisqualität; Stakeholderzufriedenheit) definiert.

Seit den Anfängen der agilen Vorgehensweise werden die dazugehörigen Methoden zur Softwareentwicklung mit Erfolg assoziiert. Andere, plangetriebene Methoden seien demnach nicht mehr zeitgemäß und müssten innerhalb der Softwareentwicklung von Methoden anderer Vorgehensweisen abgelöst werden [26]. Wissenschaftliche Nachweise über die generelle Vorteilhaftigkeit der agilen Softwareentwicklung wurden bisher jedoch nur spärlich erbracht [27]. Trotzdem existieren verschiedene Veröffentlichungen, die Anhaltspunkte für die Vorteilhaftigkeit liefern. Dazu zählt die empirische Untersuchung von Serrador und Pinto [28]. Sie stellen fest, dass je agiler Projekte bewertet wurden, desto höher waren die Zufriedenheit der Beteiligten sowie die übergreifende Effizienz des Projekts. Weiterhin stellen Bermejo et al. [29] fest, dass die Einhaltung agiler Prinzipien einen positiven Einfluss auf den Erfolg der Softwareentwicklungsprojekte hat. Weiterhin liefern Praxisstudien Anhaltspunkte für einen positiven Einfluss der agilen Vorgehensweise auf den Erfolg von Softwareentwicklungsprojekten. So stellt der bereits erwähnte bekannte *Chaos Report* des Jahres 2014 dar, dass sowohl die kontinuierliche Auslieferung von Software als auch ein iteratives Vorgehen, zwei wesentliche Merkmale der agilen

Softwareentwicklung, sowie die verbundene Komplexitätsreduktion der Projekte die bisherige geringe Erfolgsquote anheben können [7]. Entsprechend formulieren wir unsere erste Hypothese:

H1: Ein höherer Agilitätsgrad führt zu höheren Erfolgsquoten von Softwareentwicklungsprojekten.

2.3 Unternehmenskultur

Im Kontext des Unternehmens wird die Kultur in der Fachliteratur vermehrt über kognitive Aspekte wie Überzeugungen, Werte und Annahmen definiert [30]. Schein [31] definiert Unternehmenskultur als Muster gemeinsamer Annahmen einer Gruppe, die Probleme äußerer Anpassung und innerer Integration so erfolgreich lösten, dass sie als gültig begriffen und an neue Mitglieder weitergegeben werden. Nach seinem Modell der drei Kulturebenen beinhaltet die unterste Ebene die als selbstverständlich angenommenen Grundannahmen, auf denen die beiden oberen Ebenen basieren. Diese oftmals unbewussten Annahmen umfassen bspw. Überzeugungen, Auffassungen, Gefühle und Gedanken. Darauf aufbauend folgt die Ebene der Normen und Werte, welche zum Teil bereits wahrnehmbar ist. Diese Ebene liefert den Mitgliedern einer Kultur Verhaltensrichtlinien für bestimmte Situationen, sowie Strategien, Ziele und Philosophien. Die oberste Ebene ist die der sichtbaren Artefakte und Symbole. Dazu zählen bspw. gemeinsame Verhaltensweisen, Sprache und Rituale sowie organisationale Prozesse und Strukturen.

Werte sind dabei für das im Folgenden beschriebene Untersuchungsmodell besonders relevant. Diese repräsentieren Präferenzen von gewissen Situationen gegenüber anderen, die implizit erlernt und als selbstverständlich wahrgenommen werden. Sie liefern Aufschluss über Verhaltensweisen, Prinzipien und Eigenschaften, die in einer Kultur als wertvoll angesehen werden [32]. Nach Schein [31] können die Mitglieder über Werte diskutieren und diese akzeptieren – womit sie zur Grundlage der Kultur werden – oder ablehnen. Durch Reduzierung der Kulturdefinition auf wenige Elemente wird ein direkter Vergleich zwischen Kulturtypen ermöglicht [33]. Demnach erfüllt die verwendete Kulturdefinition von Schein bzw. das zugrundeliegende Modell den eigentlichen Zweck der vorliegenden Arbeit.

Unternehmenskultur ist immer eine Koexistenz verschiedener (Sub-) Kulturen [34]. Dabei unterschieden sich diese bspw. je Hierarchiestufe, je Abteilung oder sogar je Team [35]. Weiterhin können sich die Subkulturen aufgrund von Aufgaben, Rollen oder spezifischen Machtstrukturen voneinander unterscheiden [36]. Die jeweiligen Mitglieder sind nicht an eine Subkultur gebunden, sondern können gleichzeitig mehreren angehören [33]. Trotz der unterschiedlichen Perspektiven und Werte existieren oft verbindende Charakteristika, die alle Subkulturen des Unternehmens gemeinsam haben. Dazu zählt bspw. die geteilte Ansicht über die Identität des Unternehmens [37]. Für den empirischen Teil dieser Untersuchung wird die jeweilige Kultur des entsprechenden Projektumfeldes untersucht.

Die Unternehmenskultur stellt im IT-Kontext einen wesentlichen Forschungsgegenstand dar [38]. Besonders in der Softwareentwicklung scheint eine geeignete Unternehmenskultur von hoher Relevanz zu sein. So stellt Ahimbisibwe [39] fest, dass die Unternehmenskultur ein kritischer Erfolgsfaktor von Softwareentwicklungsprojekten ist. Besonders im spezifischen Kontext der agilen Softwareentwicklung nimmt die Unternehmenskultur eine zentrale Rolle ein. Im Gegensatz zur Arbeit von Chow und Cao [40], in der kulturelle Aspekte als nicht erfolgskritisch für den Einsatz agiler Methoden identifiziert wurden, weisen viele Autoren auf die Relevanz einer geeigneten Kultur hin. So stellen Strode et al. [5] eine Verbindung zwischen der Nutzung agiler Methoden und kulturellen Merkmalen, wie bspw. Zusammenarbeit und Loyalität her. Auch Cohen [41] beschreibt die Agilität primär als ein kulturelles Thema. Demnach kann ein Unternehmen nicht agil sein, wenn die entsprechende Unternehmenskultur nicht vorliegt. Weiterhin führt Nerur [4] die Unternehmenskultur und verbundene Faktoren wie bspw. Führungsstil und Teamwork als Schlüsselelemente zur Einführung agiler Methoden auf. Weitere Autoren weisen auf notwendige Charakteristika einer agilen Unternehmenskultur hin. So kommen Siakas und Siakas [32] zu dem Schluss, dass die Werte Anpassungsfähigkeit, Kollaboration im Team und mit Kunden sowie eine möglichst schnelle Auslieferung von Software durch die Unternehmenskultur gefördert werden sollte. Da verschiedene Kulturtypen mit unterschiedlichen Merkmalsausprägungen existieren, sollten sich diese demnach auch unterschiedlich gut für den Einsatz agiler Softwareentwicklung eignen [42, 43]. Entsprechend formulieren wir unsere zweite Hypothese:

H2: Die Unternehmenskultur hat einen moderierenden Einfluss auf den Zusammenhang zwischen Agilitätsgrad und Erfolg von Softwareentwicklungsprojekten.

3 Untersuchungsmethodik

Für die empirische Untersuchung der aufgestellten Hypothesen wurde ein quantitativ-empirischer Forschungsansatz gewählt. Konkret haben wir ein Fragebogen-basiertes Vorgehen zur Validierung angewendet. Die gewählte Analyseeinheit des Forschungsvorhabens ist dabei stets ein konkretes Projekt. Der Fragebogen richtet sich an IT-Projektmitarbeiter mit verschiedenen Rollen und Aufgabenbereichen.

3.1 Konstruktoperationalisierung

Für die Konstruktoperationalisierung haben wir – soweit möglich – auf etablierte Messmodelle zurückgegriffen. Aufgrund der vergleichsweise hohen Neuartigkeit der verwendeten Konstrukte mussten jedoch einige Operationalisierungen neu entwickelt werden. Eine Übersicht der verwendeten Messmodelle ist Tabelle 1 zu entnehmen.

Da im Rahmen dieser Forschungsarbeit das agile Manifest als Definition zugrunde gelegt wurde, ist vor allem die Erfüllung der zwölf Prinzipien für einen hohen Agilitätsgrad im Projekt essentiell [11]. Entsprechend haben wir den Agilitätsgrad als formatives Second-Order-Konstrukt mit zwölf Higher-Order-Konstrukten (HOC) modelliert. Jedes HOC, welches entsprechend ein agiles Prinzip repräsentiert, wurde anhand von jeweils zwei Indikatoren, welche die entsprechenden Lower-Order-Konstrukte (LOC) darstellen, gemessen [44]. Der jeweils erste Indikator spiegelt dabei das eigentliche Prinzip des agilen Manifests wieder, das zweite eine spezifische Konkretisierung des jeweiligen Prinzips auf Basis von Praktiken etablierter agiler Methoden.

Für die Projekterfolgsmessung konnten wir das Messinstrument an Forschungsarbeiten mit ähnlichen Forschungszielen anlehnen. Für die Erstellung des Messinstruments wurde daher zwischen Gesamterfolg, Prozesserfolg (Termintreue, Budgettreue, Zielerreichung, Prozesseffizienz) sowie Produkterfolg (Ergebnisqualität, Zufriedenheit des Projektteams, Kundenzufriedenheit) unterschieden. Dabei bestätigen die Arbeiten von Bermejo et al. [29] sowie Serrador und Pinto [28] die Anwendbarkeit der Erfolgsdimensionen Termintreue, Budgeteinhaltung, funktionale Zielerreichung und Prozesseffizienz. Die Indikatoren der Ergebnisqualität sowie der Zufriedenheit relevanter Stakeholder wurden Baccarini [23] entlehnt, wobei auch die aktuelle Forschung im agilen Umfeld diese Erfolgskriterien aufgreift [28, 29].

Zur Messung der vorherrschenden Unternehmenskultur haben wir auf das Competing Value Model (CVM) von Cameron und Quinn [35] aufgesetzt. Dieses theoretische Modell zählt zu den am häufigsten genutzten Modellen in der Unternehmenskulturforschung [45]. Zur Operationalisierung des CVM haben wir das darauf basierende Organizational Culture Assessment Instrument (OCAI) eingesetzt. Mit diesem Instrument lassen sich über sechs Dimensionen komplexe Kulturprofile des Unternehmens ableiten. Diese sechs Dimensionen umfassen dominante Charakteristika des Unternehmens sowie Führungsstile und Umgang mit Mitarbeitern. Weiterhin werden sowohl die strategische Ausrichtung und Erfolgskriterien als auch die vorhandene Bindungskraft im Unternehmen analysiert [35]. Jede der sechs Dimensionen wurde anhand von jeweils vier etablierten Indikatoren gemessen.

Tabelle 1. Konstruktoperationalisierung

Konstrukt	**Operationalisierung**	**Anzahl Indikatoren**	**Quelle(n)**
Agilitätsgrad	Zwölf Prinzipien des Agilen Manifests sowie jeweils eine Konkretisierung	24	[11, 46]
Projekterfolg	Gesamterfolg, Termintreue, Budgettreue, Zielerreichung, Prozesseffizienz, Ergebnisqualität, Zufriedenheit des Projektteams, Kundenzufriedenheit	8	[23, 28, 29]
Unternehmens-kultur	Arbeitsumfeld, Führung, Umgang mit Mitarbeitern, Bindungskraft, Strategische Ausrichtung, Erfolgskriterien	24	[35]

3.2 Datenerhebung

Zur Erhebung empirischer Daten haben wir eine Umfrage durchgeführt. Der eingesetzte Fragebogen umfasste die drei Hauptbereiche Agilitätsgrad, Projekterfolg und Unternehmenskultur. Darüber hinaus wurden weitere projekt- und personenbezogene Daten erhoben. Die Bewertung der Indikatoren zur Messung des

Agilitätsgrads und des Projekterfolgs erfolgte über fünfstufige Likert-Skalen. Zur Messung der Unternehmenskultur wurden ipsative Skalen genutzt. Dieser vergleichsweise untypische Skalentyp umfasst die Aufteilung einer festgelegten Punktzahl auf eine feste Anzahl an vordefinierten Antworten. Im Rahmen des OCAI wird dabei eine Aufteilung von 100 Punkten auf vier Antwortmöglichkeiten vorgegeben. Vor der eigentlichen Datenerhebung wurde der Fragebogen einer ausführlichen Prüfung unterzogen. Zum Pre-test des neuentwickelten Messinstruments für den Agilitätsgrad wurde ein Card-Sorting-Verfahren genutzt, welches u.a. von Kankanhalli et al. [47] vorgeschlagen wird. Dieses wurde mit drei Experten aus dem Softwareentwicklungsumfeld durchgeführt. Des Weiteren wurde ein Pilottest des Fragebogens mit vier weiteren Personen durchgeführt. In Einzelgesprächen wurden Anmerkungen erhoben und der Fragebogen entsprechend angepasst.

Die eigentliche Datenerhebung fand im Zeitraum vom Februar bis Mai 2016 statt. Auf verschiedenen Kanälen wurde die Umfrage unter Teilnehmern von Software-Entwicklungsprojekten beworben: auf den sozialen Netzwerk-Plattformen XING, LinkedIn und Twitter, im persönlichen Netzwerk bei Kunden und Mitarbeiter einer IT-Beratung sowie über den Newsletter einer Projektmanagementgesellschaft. Die Ansprache erfolgte vor allem über E-Mails sowie über die persönliche Kontaktaufnahme. Ziel war es, Projektbeteiligte unterschiedlicher Rollen (Projektleiter, Product Owner, Scrum Master, Entwickler etc.) zu erreichen und jeweils ein Projekt bewerten zu lassen. Eine Einschränkung auf eine spezifische Rolle wurde nicht vorgenommen. Die Begründung hierfür war, dass es je nach Unternehmen verschiedene Rollenbezeichnungen mit unterschiedlichen Aufgaben gibt und eine Abgrenzung die Stichprobe ungewollt in traditionelle bzw. agile Richtung verschoben hätte. In der vorliegenden Untersuchung wollten wir jedoch bewusst das gesamte Projektspektrum betrachten.

Die deskriptive Auswertung der Umfragedaten ergab, dass verschiedene Projektbeteiligte an der Befragung teilgenommen haben. Unter den 108 vollständigen Rückläufern sind die Antworten von 32 Projektmanagern, 31 Softwareentwicklern, eine geringere Anzahl agiler Rollen (13 Scrum Master und acht Product Owner) sowie 24 Teilnehmer andere Rollen. In Bezug auf die Projektcharakteristika ergab die Auswertung der Umfragedaten, dass Projekte aus der Bank- und Versicherungsbranche mit 70% klar dominieren. Weitere 10% der untersuchten Projekte stammen aus der Energieversorgungsbranche. Ebenfalls in der Stichprobe enthalten sind u.a. Projekte aus den Bereichen Forschung und Entwicklung, Informations- und Kommunikationstechnologie, Medien sowie Handel. Insgesamt konnten Mitarbeiter aus einer Vielzahl verschiedener Projekte gewonnen werden.

4 Analyse und Ergebnisse

Zur statistischen Analyse der gewonnenen Daten haben wir den varianzbasierten PLS-Ansatz und das Softwarepaket SmartPLS in der Version 3.0 genutzt. Unser konzeptionelles Modell wurde sowohl mit der gesamten Stichprobe als auch unterteilt nach dominierenden Kulturausprägungen analysiert. Da in der Stichprobe zwei

Kulturtypen nur vereinzelt dominierend vorlagen, wurden zwei Untersuchungsgruppen gebildet, die jeweils zwei Kulturtypen enthalten. In der Mehrgruppenanalyse repräsentiert Gruppe A den Stichprobenteil (n=55), in dem die Kulturtypen *Clan Culture* und *Adhocracy Culture* dominieren, während Gruppe B den Stichprobenanteil (n=53) umfasst, in dem *Hierarchy Culture* und *Market Culture* die dominierenden Kulturtypen darstellen. Bei dieser Einteilung wurden vor allem die Merkmale der einzelnen Kulturtypen beachtet. So beinhaltet Gruppe A Kulturtypen, die sich besonders durch Flexibilität und Dynamik auszeichnen, während die Kulturtypen in Gruppe B vorwiegend durch Stabilität und Kontinuität geprägt sind [42, 43].

4.1 Untersuchung der Messmodelle

Der erste Schritt der empirischen Analyse ist die Validierung der Messmodelle, welche wir sowohl formativ (Agilitätsgrad) als auch reflektiv (Projekterfolg) modelliert haben.

Für das zweidimensionale, formative Messmodell des Agilitätsgrads haben wir auf beiden Ebenen die Pfadkoeffizienten in Form der Pfadgewichte herangezogen, für die in der Fachliteratur Mindestwerte von 0,1 bzw. 0,2 gefordert werden [48]. Weiterhin wurde die Signifikanz dieser Pfadgewichte untersucht [49]. Auf der *LOC*-Ebene erreichten vorwiegend die Indikatoren, die direkt aus dem jeweiligen agilen Prinzip abgeleitet wurden, höhere Werte. In Verbindung mit der *HOC*-Ebene konnte weiterhin ein durchgängig signifikanter Einfluss auf den Agilitätsgrad ausgehend von sechs agilen Prinzipien ermittelt werden. Trotz teilweise fehlender Signifikanzen und schwacher oder negativer Pfadgewichte, haben wir das Messmodell – wie von mehreren Autoren empfohlen [u.a. 44] – aufgrund von inhaltlichen Überlegungen nicht nachträglich verändert. Besonders im Hinblick auf die zwölf agilen Prinzipien würde die Elimination einzelner Indikatoren bedeuten, dass eine anerkannte Definition nur teilweise durch das Untersuchungsmodell abgebildet werden würde. Für die Analyse wurde außerdem die Korrelation zwischen den Indikatoren mittels des Varianzinflationsfaktors (VIF) bewertet, um Multikollinearität zwischen den formativen Indikatoren auszuschließen. Dabei lagen alle Werte des Messmodells innerhalb des empfohlenen Wertebereiches von VIF<5 [44].

Das Konstrukt des Projekterfolges haben wir reflektiv modelliert. Zur Validierung wurden die Faktorladungen der einzelnen Indikatoren herangezogen, welche einen Mindestwert von $\lambda_i>0,7$ annehmen sollten [49]. Im Grundmodell erreichten sieben von acht Faktorladungen diesen Mindestwert. Lediglich ein Indikator lag mit $\lambda=0,697$ nur minimal – und damit vertretbar – darunter. Auch die in der Literatur geforderten Werte der Gütekriterien der Konstruktreliabilität ($0,6<\rho_c<1$), welche die interne Konsistenz durch Korrelation der Indikatoren bewertet, sowie die Konvergenzvalidität (0,5<AVE<1), die den erklärbaren Varianzanteil bemisst, wurden erfüllt [44].

Die Analysen der beiden kulturspezifischen Gruppen weisen Abweichungen vor allem innerhalb des Messmodells des Agilitätsgrads auf. Dabei wurden erforderliche Mindestwerte der Pfadgewichte sowie der verbundenen Signifikanzniveaus teilweise nicht erreicht. Dies ist u.a. durch die starke Verkleinerung der Stichprobe bei gleichbleibender Indikatoranzahl zu begründen, sollte bei der Interpretation der Ergebnisse aber dennoch berücksichtigt werden.

4.2 Untersuchung des Strukturmodells

Der zweite Schritt der empirischen Analyse stellt die Validierung des Strukturmodells dar. Ein wichtiges Gütekriterium sind dabei ebenfalls die Pfadkoeffizienten mit den oben beschriebenen Schwellenwerten [48]. Bei der Analyse der Gesamtstichprobe konnten sowohl die Höhe als auch die Signifikanz des Pfadkoeffizienten bestätigt werden. Ein weiteres Gütekriterium ist das Bestimmtheitsmaß (R^2), welches den Varianzanteil der endogenen Variablen, der durch die exogene Variable verursacht wird, wiedergibt. Der R^2-Wert von 0,54 für die abhängige Variable Projekterfolg ist als mittelhoch anzusehen [50]. Weiterhin wurde die Prognoserelevanz (Q^2) des Strukturmodells herangezogen, welche angibt inwieweit die empirischen Daten durch das Untersuchungsmodell besser rekonstruiert werden können, als über den Mittelwert. Der erreichte Q^2-Wert von 0,28 erfüllt den geforderten Mindestwert von $Q^2>0$ [50].

Die beiden kulturspezifischen Gruppen weisen ähnlich gute Werte für die Höhe und Signifikanz der Pfadkoeffizienten auf. Der signifikante Einfluss des Agilitätsgrads auf den Projekterfolg ist dabei für Gruppe A mit einem Wert von 0,86 am stärksten. Die Unterschiede zwischen den einzelnen Strukturmodellen werden aber vor allem bei der Betrachtung des Bestimmtheitsmaßes deutlich. Hierbei ist für Gruppe A ein Wert von $R^2=0{,}73$ feststellbar und ist damit als substanziell anzusehen. Bei Gruppe B verhält sich dieses Gütekriterium mit einem Wert $R^2=0{,}57$ ähnlich zur Gesamtstichprobe. Die weiterhin betrachtete Prognoserelevanz wird auch in den beiden kulturspezifischen Gruppen erfüllt, weist allerdings keine nennenswerten Unterschiede auf. Abbildung 1 fasst die Ergebnisse der Analyse auf Basis der Gesamtstichprobe sowie der beiden Untergruppen zusammen.

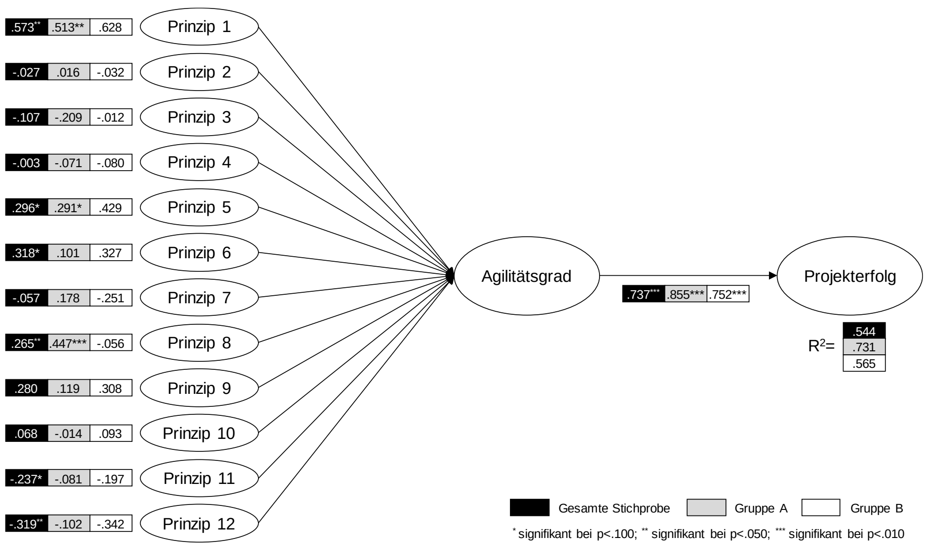

Abbildung 1. Empirische Validierung des Forschungsmodells

5 Diskussion der Ergebnisse

Die Ergebnisse der empirischen Validierung zeigen einen positiven Zusammenhang zwischen dem Agilitätsgrad und dem Projekterfolg, sowohl für die Gesamtichprobe als auch für die unterschiedlichen Kulturtypen. Dabei ist deutlich erkennbar, dass der Einfluss des Agilitätsgrads auf den Projeterfolg in der Gruppe A höher ist als in der Gruppe B. Dieses Ergebnis ist dahingehend zu interpretieren, dass bei einem höheren Agilitätsgrad eines Projektes, das in *Clan*- bzw. *Adhocracy Culture* durchgeführt wurde, auch der Projekterfolg höher ist. Das gleiche gilt zwar auch für Projekte in Unternehmen, in denen *Hierarchy Culture* und *Market Culture* die dominierenden Kulturtypen darstellen. Hier ist jedoch der Zusammenhang weniger stark ausgeprägt. Entsprechend unterstützt die empirische Untersuchung sowohl den hypothetisierten positiven Zusammenhang zwischen Agilitätsgrad und Projekterfolg von Softwareentwicklungsprojekten sowie den Einfluss der vorherrschenden Unternehmenskultur. Damit können beide zuvor aufgestellten Hypothesen bestätigt werden.

Aus den Ergebnissen ergeben sich verschiedene Implikationen für Wissenschaft und Praxis. Grundsätzlich kann auf Basis der analysierten Daten die Vorteilhaftigkeit einer agilen Vorgehensweise in Softwareentwicklungsprojekten festgestellt werden. Selbst über verschiedene Unternehmenskulturtypen hinweg waren positive Effekte auf den Projekterfolg erkennbar. Zusätzlich haben wir festgestellt, dass sich diese positiven Effekte zwischen den verschiedenen betrachteten Unternehmenskulturen hinsichtlich ihrer Stärke unterscheiden. Dieser Zusammenhang kann in Kombination mit weiterführenden Überlegungen und Analysen zur Bewertung der Vorteilhaftigkeit einer agilen Softwareentwicklung für den spezifischen Unternehmenskontext herangezogen werden. Eine Entscheidung für die agile Softwareentwicklung sollte allerdings von verschiedenen Faktoren abhängig gemacht werden. So wurde bereits im Grundlagenteil auf die Komplexität der Unternehmenskultur aufmerksam gemacht. Dabei bildet das genutzte *OCAI* nur einen Teil Unternehmenskultur ab. So können möglicherweise Faktoren, die nicht in dieser Analyse betrachtet wurden, einen negativen Einfluss auf die Nutzung der agilen Softwareentwicklung haben. Darüber hinaus ist auch Wandel hin zu einem anderen Kulturtyp ein langwieriger Prozess, der nicht unterschätzt werden sollte [35]. Demnach sollte grundsätzlich vorerst die jeweilige Unternehmenssituation betrachtet werden. Hierbei können bspw. weiterführende Kulturtests eingesetzt werden [51]. Der Erfolg agiler Softwareentwicklung ist nicht nur von der Unternehmenskultur abhängig. Demnach werden weitere erfolgskritische Rahmenbedingungen für eine erfolgreiche Einführung der agilen Softwareentwicklung in Betracht gezogen [4]. Ein Indiz dafür liefert auch die deskriptive Analyse unserer Daten. Hierbei wurden sehr viele Mischformen zwischen agilen und traditionellen Softwareentwicklungsmethoden festgestellt, was möglicherweise auch auf Barrieren für eine vollständige Agilitätsausprägung innerhalb der Unternehmen zurückzuführen ist. Weiterhin können auch die agilen Prinzipien selber ein Hindernis darstellen. So ist bspw. denkbar, dass ein iteratives Vorgehen weitreichende prozessuale Anpassungen nach sich zieht. Demnach sollte auch hier vorerst die Unternehmenssituation auf Eignung analysiert werden.

Trotz des nachgewiesenen Wirkungszusammenhangs sind die Limitationen unseres Forschungsvorhabens zu berücksichtigen. Im Rahmen der quantitativen Erhebung können verschiedene Verzerrungen aufgetreten sein, die es zu berücksichtigen gilt. Besonders der Social Desirablitiy Bias, der Verzerrungen aufgrund von sozialer Erwünschtheit umfasst, könnte die Ergebnisse beeinflusst haben [52]. So wird die agile Softwareentwicklung in der Fachliteratur nicht selten als generell vorteilhaft gegenüber der traditionellen Softwareentwicklung dargestellt [26]. Dadurch ist es grundsätzlich denkbar, dass die Umfrageteilnehmer dazu tendierten, Aussagen, die für die agile Softwareentwicklung sprachen, besser zu bewerten. Auch die Erhebung der Unternehmenskultur kann grundsätzlich durch diese Verzerrung betroffen sein. So ist eine hierarchische Kultur möglicherweise negativ behaftet [35]. Dies konnte allerdings nicht durch die Datenanalyse bestätigt werden, da dieser Kulturtyp am häufigsten dominierte. Weiterhin denkbar ist, dass auch Aussagen hinsichtlich des Projekterfolges verzerrt bewertet wurden [25]. Grundsätzlich konnten zwar auch sehr geringe Werte für den Projekterfolg ermittelt werden, diese bildeten allerdings die Ausnahme. Gleichzeitig war auch erkennbar, dass sehr hoch bewertete Projekterfolge ausblieben. Auch in Verbindung mit den Kulturtypen könnte eine Verzerrung aufgetreten sein, Demnach ist es denkbar, dass in Gruppe A agile Projekte als erfolgreicher bewertet wurden. Im Rahmen der Limitationsbetrachtung sollte auch die Datenanalyse berücksichtigt werden. Hierbei sind besonders die Bestandteile des Messmodells des Agilitätsgrads zu beachten. So konnten im Rahmen der Analyse die geforderten Werte für Signifikanz und Pfadgewichte teilweise nicht erfüllt werden. Eine Veränderung des Messmodells des formativen Konstrukts haben wir aus inhaltlichen Erwägungen dennoch abgelehnt. Grundsätzlich ist es deshalb möglich, dass auch die Zusammenhänge im Strukturmodell von diesen Effekten beeinflusst worden sind. Weiterhin ist anzumerken, dass für die kulturspezifische Betrachtung nur vergleichsweise kleine Stichproben genutzt werden konnten, was die Ergebnisse ebenfalls beeinflusst haben könnte.

6 Zusammenfassung und Fazit

Ziel der vorliegenden Forschungsarbeit war die empirische Untersuchung des Wirkungszusammenhangs vom Agilitätsgrad eines Softwareprojekts auf den Projekterfolg. Weiterhin sollte der moderierende Einfluss der vorherrschenden Unternehmenskultur berücksichtigt werden. Dazu haben wir ein deduktives Forschungsmodell durch eine Umfrage unter IT-Projektmitarbeitern validiert. Als statistischen Ansatz zur Auswertung des empirischen Datenmaterials haben wir die Strukturgleichungsmodellierungsmethode Partial Least Squares eingesetzt.

Die zu Beginn dieses Artikels dargestellte Forschungsfrage konnte durch den gewählten Forschungsansatz beantwortet werden. So zeigt sich, dass eine agile Softwareentwicklung besonders in einer geeigneten Unternehmenskultur erfolgreich ist. Aber auch unabhängig davon ist ein positiver Zusammenhang zwischen Agilitätsgrad und Projekterfolg feststellbar. Trotz der gewonnenen Erkenntnisse ist das Forschungsfeld nicht erschöpft. Vielmehr ergeben sich verschiedene

Anknüpfungspunkte für zukünftige Untersuchungen. Dabei weisen grundsätzlich alle drei Konstrukte verschiedene anerkannte Definitionen und Messmöglichkeiten auf. Besonders die Konzeption der Agilität sollte zukünftig wiederholt aufgegriffen werden, da das aktuell verwendete Messmodell Schwächen aufweist. So könnte bspw. die ebenfalls weit verbreitete Definition von Conboy [13, 53] zugrunde gelegt werden. Darüber hinaus stellt auch die kontextspezifische Interaktion zwischen Unternehmenskultur und agiler Vorgehensweise ein zukünftiges Forschungsfeld dar, um die Auswirkungen auf den Projekterfolg detailliert zu begründen [54]. Ein Vergleich der bisherigen mit zukünftigen Forschungsergebnissen kann dabei dazu beitragen, die Zusammenhänge der drei Konstrukte besser zu verstehen. Weiterhin sollte in weiteren Forschungsvorhaben die Stichprobengröße in Bezug auf die einzelnen Kulturtypen ausgeweitet werden. Dabei kann eine weitere Datensammlung und -analyse weiterhin zur Untersuchung von potenziellen Verzerrungsmöglichkeiten genutzt werden.

Abstract. Große Investitionen in Informationstechnologie (IT) sind oftmals langfristig geplante Investitionsvorhaben, die sich über einen längeren Zeitraum erstrecken und dadurch Investitionsauszahlungen in mehreren Perioden erfordern. Bei deren Planung und Budgetierung muss daher ein mehrperiodiger Planungshorizont inklusive relevanter finanzieller Rahmenbedingungen und Risiken berücksichtigt werden. Dadurch können Höhe und Zeitpunkt der Investitionsauszahlungen über mehrere Perioden hinweg optimal bestimmt und der erhoffte Wertbeitrag des Investitionsvorhabens abgesichert bzw. ggf. sogar gesteigert werden. Dies gilt insbesondere für Unternehmen, deren verfügbare finanzielle Eigen- und Fremdmittel stark begrenzt bzw. besonders unsicher sind. Deshalb sollten bei der Planung von langfristigen IT-Investitionen sowohl aktuelle, als auch zukünftig drohende finanzielle Beschränkungen berücksichtigt werden. Dies erfordert einen Disziplinen-übergreifenden Ansatz, der Erkenntnisse aus Finanzmanagement und IT-Management verbindet. In diesem Beitrag wird daher ein Optimierungsmodell entwickelt, bei dem relevante finanziellen Rahmenbedingungen bei der Planung eines IT-Investitionsvorhabens berücksichtigt werden, wodurch dessen Wertbeitrag gesteigert werden kann.

Keywords: IT-Investition; IT-Management; Investitionsbewertung; Investitionsstrategie

1 Einleitung und Motivation

IT-Investitionen sind durch die zunehmende Durchdringung von Unternehmen mit IT und die rapide fortschreitende Digitalisierung ein entscheidender Wettbewerbsfaktor für Unternehmen. Sie leisten einen wichtigen Beitrag zum langfristigen wirtschaftlichen Erfolg eines Unternehmens. Gleichzeitig können Unternehmen allerdings gezwungen sein, aufgrund finanzieller Beschränkungen geplante Budgets für langfristige IT-Investitionen zu reduzieren (vgl. bspw. [15], [26], [35]). Dadurch kann ein Unternehmen die Rückflüsse aus dem jeweiligen Investitionsvorhaben nicht bzw. nicht in geplanter Höhe realisieren, wodurch der dazugehörige Wertbeitrag erheblich reduziert wird oder sogar ein negativer Wertbeitrag resultieren kann. Die finanzielle

Pfosser, S. (2017): Bewertung und Planung von IT-Investitionen unter Berücksichtigung finanzieller Beschränkungen, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 469-483

Situation eines Unternehmens spielt daher auch für das Management von IT-Investitionen eine entscheidende Rolle. Folglich ist eine Disziplinen-übergreifende Integration von IT-Investitions- und Finanzmanagement notwendig, um IT-spezifische und finanzielle Aspekte integriert berücksichtigen zu können [30]. Eine Kombination etablierter Ansätze verschiedener Disziplinen bietet die Möglichkeit neue Lösungen für unternehmerische Fragestellungen zu entwickeln – selbst ohne eine grundlegende Weiterentwicklung der Ansätze. Gleichzeitig stellen wird eine wertvolle Grundlage geschaffen für weiterführende Arbeiten wie bspw. empirische Studien oder exemplarische Anwendungen und Weiterentwicklungen auf Basis von realen Daten.

Zur Bewertung der ökonomischen Potentiale von IT-Investitionen existieren zahlreiche, überwiegend empirische, Arbeiten (bspw. [4], [27], [38], [40]), die den Zusammenhang zwischen IT-Investitionen und unternehmerischem Erfolg untersuchen. Daneben existiert in der Literatur eine weitere Forschungsrichtung, in der auf Basis quantitativer bzw. finanzwirtschaftlicher Ansätze Methoden für eine risikointegrierte Bewertung von IT-Investitionen entwickelt und analysiert werden. Zur Berücksichtigung von IT-spezifischen Risiken erweitert bspw. [39] den allgemeinen Kapitalkostensatz um einen spezifischen IT-Risikozuschlag (WACC zu WACIT). [42] vermindern hingegen den stochastischen Kapitalwert der IT-Investitionen um einen IT-spezifischen Risikoabschlag. [41] und [21] betrachten in ihrer Arbeit insbesondere das Risiko durch stochastische Abhängigkeiten der IT-Investitionen.

In dieser Arbeit werden Ansätze des Investitions- und Finanzmanagements zur Berücksichtigung finanzieller Beschränkungen ([2], [13]) auf den Kontext der IT-Investitionsplanung übertragen und um eine entsprechende Risikobetrachtung erweitert. Dabei ist es nicht originäres Ziel diese Ansätze weiter zu entwickeln. Vielmehr sollen bestehenden Ansätze auf eine Problemstellung in einem anderen Kontext übertragen und entsprechend angepasst werden, um neue Lösungsmöglichkeiten zu entwickeln. Dadurch ist es möglich, finanzielle Rahmenbedingungen bei der Bewertung und Planung von langfristigen IT-Investitionen zu berücksichtigen. Mit Hilfe des entwickelten Optimierungsmodells kann gezeigt werden, dass der erwartete Wertbeitrag abgesichert bzw. sogar erhöht werden kann, wenn auf finanzielle Beschränkungen mit einer Liquiditäts- bzw. Budgetreserve – welche in der Finanz- bzw. Investitionsliteratur als probates Mittel anerkannt ist ([5], [18]) – reagiert wird. Um die Auswirkungen einer solchen Reserve auf den Wertbeitrag des IT-Investitionsvorhabens zu quantifizieren, wird dieser *mit* und *ohne* Reserve ermittelt und werden beide Alternativen miteinander verglichen.

Dazu wird ein Modell zur Planung von IT-Investitionen entwickelt, mit dessen Hilfe für ein Unternehmen die in Bezug auf Investitionszeitpunkt und Höhe optimalen Auszahlungen in das IT-Investitionsvorhaben unter Berücksichtigung finanzieller Rahmenbedingungen bestimmt werden können. Da es sich um einen integrierten Ansatz handelt, der IT-Investitions- und Finanzmanagement verbindet, wird die zur Entwicklung des Modells relevante Literatur an den jeweiligen Stellen herangezogen, sodass die Literatureinbettung im Modellteil und nicht wie zumeist üblich in einem gesonderten Literaturkapitel erfolgt.

Danach werden grundlegende Einflüsse zentraler Faktoren auf den Wertbeitrag des Investitionsvorhabens diskutiert und auf Basis eines Fallbeispiels analysiert. Zuletzt werden die Ergebnisse und Limitationen des Beitrags zusammengefasst und ein Ausblick auf weiterführende Forschungsfragen und praxisrelevante Implikationen gegeben.

2 Modell und relevante Literatur

Zunächst werden die Annahmen für die Bewertung des IT-Investitionsvorhabens anhand der relevanten Literatur vorgestellt und darauf aufbauend für das betrachtete Unternehmen die optimalen Investitionsauszahlungen (bzgl. Zeitpunkt und Höhe) zur Erreichung des maximalen Wertbeitrags (WB) ermittelt. Um den Einfluss der finanziellen Rahmenbedingungen auf den WB zu verdeutlichen, wird darauffolgend der resultierende WB in deren Abhängigkeit analysiert.

2.1 Modellannahmen

Im Rahmen eines Zwei-Perioden-Modells wird ein Unternehmen betrachtet, das die für ein mehrperiodiges IT-Investitionsvorhaben verfügbaren finanziellen Eigen- und Fremdmittel mit Hilfe einer Reserve optimal auf zwei mögliche Investitionszeitpunkte aufteilen möchte (vgl. Abbildung 1).

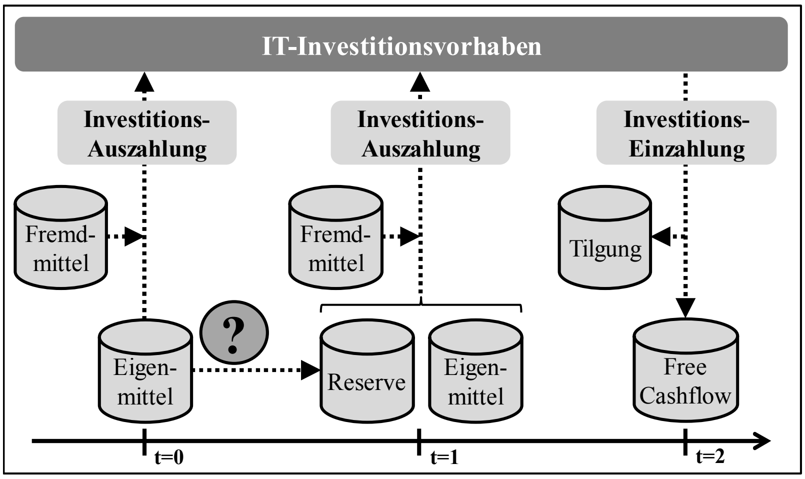

Abbildung 1. Entscheidungssituation des Modells

Annahme 1) *Das Unternehmen verfügt in den Zeitpunkten $t = 0$ und $t = 1$ über die Cashflows $\widehat{CF}_t$ aus dem bestehenden Unternehmensportfolio, die für die IT-Investitionen verwendet werden können. $\widehat{CF}_0$ ist bekannt, wohingegen $\widehat{CF}_1$ unbekannt und gemäß $\widehat{CF}_1 \sim N\left(E[\widehat{CF}_1], \sigma^2(\widehat{CF}_1)\right)$ normalverteilt ist.*

Bei der Planung mehrperiodiger IT-Investitionsvorhaben ist es nicht ausreichend, nur für den gegenwärtigen Zeitpunkt die Investitionsauszahlungen zu planen, da deren

Finanzierung über den kompletten Planungszeitraum hinweg sichergestellt sein muss. Andernfalls wir der insgesamt erwartete WB gefährdet, falls das Unternehmen zukünftige Investitionsauszahlungen nicht in ausreichender Höhe finanzieren kann.

Die Cashflows des Unternehmens stellen die Basis für die Planung der Investitionen dar. Dabei wird der zeitliche Horizont der Investitionen berücksichtigt, wobei sich Teilinvestitionen eines IT-Investitionsvorhabens in lang- und kurzfristige IT-Investitionen unterscheiden lassen (vgl. [24], [31], [43]). Dabei konkurrieren die Teilinvestitionen eines Investitionsvorhabens indirekt um begrenzte Unternehmensressourcen, wodurch sie sich gegenseitig beeinflussen und daher im Rahmen der IT-Investitionsplanung integriert betrachtet werden sollten [30].

Zur Finanzierung des Investitionsvorhabens kann das Unternehmen zusätzlich zu den Cashflows $\widehat{CF}_t$ auch Kredite aufnehmen und die für die Investition zu tätigenden Auszahlung I_t mit $t \in \{0,1\}$ dadurch erhöhen.

Annahme 2 a) *Im Zeitpunkt* t *nimmt das Unternehmen einen Kredit in Höhe von* K_t *mit* $t \in \{0,1\}$ *auf, welcher im Zeitpunkt* $t = 2$ *vollständig getilgt wird. Die mit dem risikolosen Zinssatz* r_f *anfallenden Zinsen sind zusammen mit der Tilgung im Zeitpunkt* $t = 2$ *endfällig zu zahlen.*

Insbesondere bei IT-Investitionen ist die Möglichkeit der Fremdfinanzierung allerdings oftmals stark eingeschränkt, da IT-Investitionen (bspw. die Entwicklung einer Software) i. d. R. zu einem hohen Anteil immateriell sind [22] bzw. mit Hilfe von IT-Investitionen unternehmensindividuelle, immaterielle Güter (bspw. Informationsverfügbarkeit und -qualität) geschaffen werden [10]. IT-Investitionen haben daher häufig einen spezifischen Wert für das jeweilige Unternehmen, der auch erhebliche immaterielle Investitionsbestandteile (bspw. aufgebautes Wissen) umfasst. Dieser unternehmensspezifische Wert ist durch den unternehmensspezifischen Wertanteil i. d. R. deutlich höher als ein rein anhand der Investitionsauszahlungen (I_t) feststellbarer objektiver Liquidationswert [11]. Darüber hinaus können IT-Investitionen bei einer kurzfristig notwendigen Liquidation nur mit erheblichen Preisabschlägen veräußert werden (falls überhaupt), da für ein anderes Unternehmen erneut erhebliche unternehmensspezifische Anpassungen erforderlich wären. Dadurch kann kurzfristig oftmals selbst der objektive Liquidationswert nicht erlöst werden.

Finanzielle Restriktionen dieser Art führen grundsätzlich zu einer Einschränkung der Investitionsfähigkeit eines Unternehmens [7], [12], [13]. Dies gilt insbesondere für IT-Investitionen, da deren hoher immaterieller Werteanteil die Aufnahme von Krediten zur Finanzierung der Investitionsauszahlungen erschwert [1], [20], [33]. Diese Besonderheit muss daher bei der IT-Investitionsplanung berücksichtigt werden, da dadurch die maximal finanzierbaren Investitionsauszahlungen begrenzt werden [1], [20], [33].

Annahme 2 b) *Die Höhe des Kredits* K_t *im Zeitpunkt* $t \in \{0,1\}$ *ist gemäß* $K_t \leq (1 - \gamma_{I_t}) \cdot I_t$ *beschränkt und hängt von der Höhe der Investitionsauszahlungen* I_t *des Unternehmens im jeweiligen Zeitpunkt ab. Dabei bezeichnet* $\gamma_{I_t} \in (0,1)$ *einen IT-investitionsspezifischen Illiquiditätsparameter.*

Der Illiquiditätsparameter γ_{I_t} bildet die beschränkte Fremdfinanzierungsmöglichkeit von IT-Investitionen ab. Die Höhe des Illiquiditätsparameters ist investitionsspezifisch, wobei bspw. ein erworbener Server (als standardisierte Hardware leichter übertragbar) i. d. R. mit einem geringeren Abschlag liquidiert werden kann als eine speziell entwickelte Individualsoftware (i. d. R. nur nutzbar für das jeweilige Unternehmen).

Um die verfügbaren Mittel optimal auf die periodischen Investitionsauszahlungen allokieren zu können, muss ein Unternehmen schätzen, wie die Höhe der erreichbaren Investitionseinzahlungen (d.h. die Rückflüsse der Investitionen) von der Höhe der Investitionsauszahlungen abhängt. Dadurch kann unter Berücksichtigung der geschätzten Grenzein- bzw. -auszahlungen der Wertbeitrag des IT-Investitionsvorhabens maximiert werden. Dazu muss ein Unternehmen das ökonomische Potential, d.h. die für das Unternehmen realisierbaren Einzahlungen, des IT-Investitionsvorhabens schätzen. Dabei ist zu berücksichtigen, dass verschiedene IT-Investitionen teilweise deutlich unterschiedliche ökonomische Potenziale aufweisen, die auch vom Investitionszeitpunkt und –umfang beeinflusst werden können. So weist bspw. eine frühzeitige Investition in eine IT-Innovation i.d.R. ein sehr hohes ökonomisches Potential auf, da sich dadurch bspw. neue Geschäftsfelder und Märkte erschließen lassen. Eine Investition in eine neue Verwaltungssoftware hat dagegen i.d.R. ein niedrigeres ökonomisches Potential, da sich damit zwar Effizienzgewinne erzielen lassen, diese aber oftmals deutlich geringer sind.

Zur Schätzung des Verhältnisses von monetären und nichtmonetären Inputgrößen zu Outputgrößen skalierbarer IT-Investitionen kann bspw. eine Funktion auf Grundlage der allgemeinen Produktionstheorie [37] verwendet werden (bspw. [8], [9], [16]). Solche Produktionsfunktionen finden bei der Planung von IT-Investitionen Anwendung [3], [22], wobei der dabei angenommene Zusammenhang i. d. R. nicht linear ist. Insbesondere bei großen IT-Investitionen sinkt mit steigendem Input der marginale Output, da mit steigendem Umfang die Komplexität und der Organisationsaufwand überproportional zunehmen [6], [22] , d.h. die Einzahlungen sind oftmals durch abnehmende Grenzeinzahlungen gekennzeichnet.

Darüber hinaus lassen sich aufgrund der komplexen und vielfältigen Abhängigkeitsbeziehungen und Wechselwirkungen die Ein- und Auszahlungen von IT-Investitionen ex ante nur schwer abschätzen, weshalb diese mit einer großen Unsicherheit behaftet sind [16], [22]. Dabei tragen insbesondere die unsicheren Einzahlungen einer IT-Investition zu deren finanziellen Risiko bei [29], [34]. Zur Vermeidung von Fehlallokationen des IT-Budgets ist daher das Risiko bzw. die Unsicherheit der Einzahlungen von IT-Investitionen im Rahmen der IT-Investitionsplanung zu berücksichtigen [24].

Annahme 3) *Die im Zeitpunkt* $t = 2$ *durch die Investitionsauszahlungen für das Unternehmen ermöglichten Einzahlungsüberschüsse werden durch die Funktionen* $EZ_i(I_t) = k_i \cdot f_i(I_t)$ *mit* $k_i \sim N(E[k_i], \sigma^2(k_i))$ *mit* $i = \{0,1\}$ *abgebildet. Dabei bildet* k_i *das unsichere ökonomische Potenzial der IT-Investition ab und* $f_i(I_t)$ *sind streng monoton steigende und konkave Funktionen. Diese repräsentieren für das Unternehmen den Barwert aller in Abhängigkeit von den Investitionsauszahlungen* I_t *in der Zukunft realisierbaren Einzahlungsüberschüsse.*

Wie bereits beschrieben verringert die Unsicherheit über zukünftig verfügbare Eigen- und Fremdmittel die Investitionsfähigkeit eines Unternehmens [7], [12], [13]. Zur finanziellen Absicherung existieren verschiedene Methoden, wobei in dieser Arbeit das Vorhalten einer Reserve betrachtet wird, da viele Unternehmen bspw. nach [5], [18] hohe Summen als finanzielle Reserven vorhalten. Darüber hinaus ist bspw. eine Betrachtung von Kreditlinien im Rahmen der IT-Investitionsplanung nicht sinnvoll, da IT-Investitionen durch ihre hohe Illiquidität nur sehr eingeschränkt als Sicherheit verwendet werden können und mit Kreditlinien weitere Beschränkungen verbunden sind [12].

Annahme 4) *Das Unternehmen bildet in* $t = 0$ *eine (unverzinsliche) Reserve* $R \geq 0$, *welche in* $t = 1$ *zusätzlich für die Finanzierung der Investitionsauszahlung zur Verfügung steht.*

Das Unternehmen steht somit vor der Entscheidung, in welcher Höhe die aktuell verfügbaren finanziellen Mittel sofort investiert oder teilweise als Reserve für eine Absicherung der Investition in $t = 1$ vorgehalten werden sollen. Auf Basis der getroffenen Annahmen ergeben sich für das Unternehmen die folgenden Cashflows CF_t für $t \in \{0,1,2\}$, die die Grundlage für die Entscheidung bilden:

$$CF_0 = \widehat{CF}_0 + K_0 - I_0 - R$$

$$CF_1 = \widehat{CF}_1 + K_1 - I_1 + R$$

$$CF_2 = EZ_0(I_0) + EZ_1(\tilde{I}_1) - K_0 \cdot \left(1 + r_f\right)^2 - K_1 \cdot (1 + r_f) \tag{1}$$

Dabei bezeichnet $CF_t \geq 0$ den nachschüssig anfallenden Free Cashflow, der für Ausschüttungen an die Eigenkapitalgeber zur Verfügung steht und die Grundlage für eine objektive Bewertung der IT-Investition bildet [19].

Um den Zeitwert der Zahlungen zu berücksichtigen, wird der Wert des Investitionsvorhabens zum Bewertungszeitpunkt $t = 0$ mit Hilfe eines Discounted Cashflow-Verfahrens ermittelt [25]. Die Risiken der unsicheren Zahlungsüberschüsse können dabei mit Hilfe der Risikozuschlags- oder Risikoabschlagsmethode berücksichtigt werden, welche bei konsistenter Anwendung zu identischen Ergebnissen führen [14], [32]. Zur Bewertung mehrperiodiger Investitionen kann die Risikoabschlagsmethode verwendet werden [28], bei der ein Abzug eines Risikoabschlags von den erwarteten Free Cashflows gemäß $E[CF_t] - RA(CF_t)$ erfolgt. Der Risikoabschlag $RA(CF_t)$ wird dabei basierend auf dem Capital Asset Pricing

Model (CAPM)[1] [17] multiplikativ mit Hilfe des Marktpreises des Risikos $\lambda = \frac{E[r_M]-r_f}{\sigma^2(r_M)}$ und der Kovarianz des Zahlungsüberschusses CF_t mit der Rendite r_M des Marktportfolios[2] $Cov(CF_t, r_M)$ ermittelt [23], [36]:

$$RA(CF_t) = \lambda \cdot Cov(CF_t, r_M) \tag{2}$$

Somit kann ein risikoadjustierter WB für den Zahlungsstrom der IT-Investition als Summe der auf den Zeitpunkt $t = 0$ mit dem risikolosen Zinssatz r_f diskontierten Cashflows abzüglich der jeweiligen Risikoabschläge berechnet werden. Dabei soll der erwartete WB durch die Wahl der optimalen Höhe der Investitionsauszahlungen I_t^* mit $t \in \{0,1\}$ maximiert werden, wodurch sich das folgende Optimierungsproblem ergibt:

$$\max_{I_t} WB = \sum_{t=0}^{2} \frac{E[CF_t]-RA(CF_t)}{(1+r_f)^t} = CF_0 + \frac{E[CF_1]-\lambda\cdot Cov(CF_1,r_M)}{1+r_f} + \frac{E[CF_2]-\lambda\cdot Cov(CF_2,r_M)}{(1+r_f)^2}$$

$$CF_t \geq 0 \;\; \textit{für}\; t \in \{0,1,2\}$$

$$K_t \leq \left(1-\gamma_{I_t}\right) \cdot I_t \;\; \textit{für}\; t \in \{0,1\} \tag{3}$$

Da im Optimum der Barwert der erwarteten Grenzzahlungsüberschüsse aus dem IT-Investitionsvorhaben dem Barwert der marginalen Investitionsauszahlungen entsprechen muss, können die optimalen Investitionsauszahlungen I_t^* folgendermaßen bestimmt werden:

$$\frac{\partial WB}{\partial I_0} = 0 \Leftrightarrow \frac{E[EZ_0'(I_0^*)]-\lambda\cdot f_0'(I_0^*)\cdot Cov(k_0,r_M)}{(1+r_f)^2} = 1 \;\; \textit{für}\;\; t = 0 \tag{4}$$

$$\frac{\partial WB}{\partial I_1} = 0 \Leftrightarrow \frac{E[EZ_1'(I_1^*)]-\lambda\cdot f_1'(I_1^*)\cdot Cov(k_1,r_M)}{(1+r_f)^2} = \frac{1}{(1+r_f)} \;\; \textit{für}\;\; t = 1 \tag{5}$$

Von I_t^* abweichende Investitionsauszahlungen vermindern den Wertbeitrag, da einerseits höhere Investitionsauszahlungen $(I_t > I_t^*)$ nicht durch die hieraus zusätzlich resultierenden risikoadjustierten Zahlungsüberschüsse kompensiert werden und andererseits niedrigere Investitionsauszahlungen $(I_t < I_t^*)$ weitere, noch mögliche Steigerungen des Wertbeitrags nicht realisieren.

2.2 Analyse des Modells

Im Folgenden wird die Investitionsstrategie eines Unternehmens analysiert, das finanziellen Beschränkungen unterliegt, d.h. es kann die eigentlich optimalen Investitionsauszahlungen I_t^* auf Grund von zu niedrigen bzw. zu unsicheren Cashflows $\widehat{CF}_t$ oder zu hohen Illiquiditätsabschlägen γ_{I_t} bei der Kreditaufnahme nicht finanzieren.

---

[1] Es liegen keine Unsicherheit und intertemporalen Abhängigkeiten bzgl. der Verteilungsparameter vor, sodass eine mehrperiodige Anwendung des CAPM möglich ist.

[2] Das Marktportfolio enthält alle am Kapitalmarkt verfügbaren Vermögenswerte im Verhältnis zu ihrer Kapitalisierung.

Somit kann das Unternehmen selbst bei Verwendung aller zu den Investitionszeitpunkten $t \in \{0,1\}$ verfügbaren Mittel nur die geringeren *Investitionsauszahlungen eines finanziell beschränkten Unternehmens* $I_t^B < I_t^*$ finanzieren. Zur Maximierung des WB kann das Unternehmen mit Hilfe einer Reserve die Investitionsauszahlungen I_t^B mit $t \in \{0,1\}$ folgendermaßen optimieren:

Einerseits wird die Investitionsauszahlung I_0^B durch die Bildung der Reserve verringert und andererseits die Investitionsauszahlung I_1^B erhöht. Folglich verringert bzw. erhöht sich der resultierende Zahlungsüberschuss der jeweiligen Teilinvestition des Investitionsvorhabens. Je nachdem, welche Veränderung die höheren Auswirkungen hat, wird durch die Einzahlung in eine Reserve der insgesamt aus dem Investitionsvorhaben resultierende Wertbeitrag negativ oder positiv beeinflusst. Zur Maximierung muss daher die optimale Höhe der Reserve R^* bestimmt werden.

Das Unternehmen wird in beiden Investitionszeitpunkten alle verfügbaren Mittel investieren, weil die Investition höhere Grenzein- als -auseinzahlungen erwarten lässt, da $I_t^B < I_t^*$ für $t \in \{0,1\}$. Zusätzlich werden die Investitionen mit so hohen Krediten wie möglich finanziert um die Investitionsauszahlungen zu erhöhen. Somit ergibt sich I_0^B mit Hilfe von Annahme 2b) und Formel (1) folgendermaßen:

$$I_0^B = \frac{\widehat{CF}_0 - R}{\gamma_{I_0}} \tag{6}$$

Sie ist von der Höhe der verfügbaren finanziellen Mittel sowie von der Höhe der gebildeten Reserve abhängig. Analog dazu ist in $t = 1$ die Höhe der Investitionsauszahlung I_1^B ebenfalls von der Höhe der risikoadjustierten finanziellen Mittel und der Höhe der in diesem Zeitpunkt aufgelösten Reserve gemäß

$$I_1^B = \frac{E[\widehat{CF}_1] - \lambda \cdot Cov(\widehat{CF}_1, r_M) + R}{\gamma_{I_1}} \tag{7}$$

abhängig. Da in beiden Investitionszeitpunkten alle verfügbaren finanziellen Mittel investiert werden ($CF_0 = CF_1 = 0$), ist nur der resultierende Cashflow des Zeitpunkts $t = 2$ für die Bestimmung der optimalen Höhe der Investitionsauszahlungen relevant. Das Optimierungsproblem des Unternehmens lässt sich damit nach

$$\max_{I_t} WB^B = \frac{E[k_0] \cdot f_0(I_0^B) - \lambda \cdot f_0(I_0^B) \cdot Cov(k_0, r_M)}{(1+r_f)^2} + \frac{E[k_1] \cdot f_1(I_1^B) - \lambda \cdot f_1(I_1^B) \cdot Cov(k_1, r_M)}{(1+r_f)^2}$$

$$- \frac{(1-\gamma_{I_0}) \cdot (I_0^B) \cdot (1+r_f)^2}{(1+r_f)^2} - \frac{(1-\gamma_{I_1}) \cdot (I_1^B) \cdot (1+r_f)}{(1+r_f)^2} \tag{8}$$

als Summe der risikoadjustierten Barwerte der erwarteten Zahlungsüberschüsse aus dem IT-Investitionsvorhaben abzüglich der Barwerte der Tilgung der aufgenommenen Kredite (inklusive Zinsen) abbilden.

Wie bereits erläutert hat die Reserve für das Unternehmen sowohl erhöhende, als auch verringernde Auswirkungen auf den Wertbeitrag. Daher werden so viele Mittel in die Reserve eingestellt, bis die marginale Erhöhung des WB (durch die höhere Investitionsauszahlung in $t = 1$) der marginalen Verringerung des Wertbeitrags (durch die geringere Investitionsauszahlung in $t = 0$) entspricht. Diese optimale Höhe der finanziellen Reserve R^* kann mit Hilfe der folgenden Bedingung bestimmt werden:

$$\left[E[k_0] \cdot f_0'(I_0^B) - \lambda \cdot f_0'(I_0^B) \cdot Cov(k_0, r_M) - \left(1 - \gamma_{I_0}\right) \cdot \left(1 + r_f\right)^2\right] \cdot \left(\frac{1}{\gamma_{I_0}}\right)$$

$$= \left[E[k_1] \cdot f_1'(I_1^B) - \lambda \cdot f_1'(I_1^B) \cdot Cov(k_1, r_M) - \left(1 - \gamma_{I_1}\right) \cdot \left(1 + r_f\right)\right] \cdot \left(\frac{1}{\gamma_{I_1}}\right) \Leftrightarrow$$

$$\Leftrightarrow \left[E[k_0] \cdot f_0'\left(\frac{\widehat{CF}_0 - R^*}{\gamma_{I_0}}\right) - \lambda \cdot f_0'\left(\frac{\widehat{CF}_0 - R^*}{\gamma_{I_0}}\right) \cdot Cov(k_0, r_M) - \left(1 - \gamma_{I_0}\right) \cdot \left(1 + r_f\right)^2\right] \cdot \left(\frac{1}{\gamma_{I_0}}\right)$$

$$= \begin{bmatrix} E[k_1] \cdot f_1'\left(\frac{E[\widehat{CF}_1] + R^* - \lambda \cdot Cov(\widehat{CF}_1, r_M)}{\gamma_{I_1}}\right) \\ -\lambda \cdot f_1'\left(\frac{E[\widehat{CF}_1] + R^* - \lambda \cdot Cov(\widehat{CF}_1, r_M)}{\gamma_{I_1}}\right) \cdot Cov(k_1, r_M) - \left(1 - \gamma_{I_1}\right) \cdot \left(1 + r_f\right) \end{bmatrix} \cdot \left(\frac{1}{\gamma_{I_1}}\right) \tag{9}$$

Unter Berücksichtigung der marginalen Erhöhung bzw. Verringerung des WB kann ein finanziell beschränktes Unternehmen durch optimale Wahl der Höhe der finanziellen Reserve R^* den resultierenden WB maximieren. Diese Möglichkeit zur Maximierung besteht allerdings nur für ein Unternehmen, welches finanzielle Beschränkungen bereits bei der IT-Investitionsplanung berücksichtigt.

Um die Auswirkung der Reserve auf den WB zu quantifizieren, wird für ein finanziell beschränktes Unternehmen der WB mit optimaler Höhe der Reserve $WB_{R^*}^B$ (d.h. unter Berücksichtigung der finanziellen Beschränkungen im Rahmen der IT-Investitionsplanung) mit dem WB ohne Reserve $WB_{R=0}^B$ verglichen. Somit kann eine Wertbeitragssteigerung WBS_{R^*} als Differenz der beiden Wertbeiträge definiert werden:

$$WBS_{R^*} = WB_{R^*}^B - WB_{R=0}^B \geq 0 \tag{10}$$

Im Folgenden wird das Modell auf Basis einer exemplarische Anwendung analysiert, um die Effekte geänderter finanzieller Beschränkungen zu quantifizieren.

3 Exemplarische Anwendung des Modells

Die folgende exemplarische Anwendung hat zum Ziel, zentrale Wirkungszusammenhänge des Modells mit Hilfe von Sensitivitätsanalysen zu verdeutlichen. Dabei werden auch die für ein Unternehmen relevanten ökonomischen Auswirkungen einer Reserve veranschaulicht. Für die exemplarische Anwendung werden zunächst die optimalen Investitionsauszahlungen ermittelt – ohne und mit Berücksichtigung der finanziellen Situation des Unternehmens – und anschließend mittels der Sensitivitätsanalysen der Einfluss relevanter Parameter auf den resultierenden WB bzw. die mögliche WBS_{R^*} analysiert.

Da eine Evaluierung des Modells auf Basis von Realweltdaten noch aussteht, wird im vorliegenden Beitrag als erster Schritt eine Analyse auf Basis exemplarischer Werte bzw. Funktionen vorgenommen. Dabei wird von den in Tabelle 1 aufgeführten Funktionen ausgegangen, sodass sich durch Abzug der Risikokosten von den

Einzahlungen und deren Optimierung anhand Formel (4) bzw. (5) optimale Investitionssauzahlungen I_t^* i. H. v. 55,47 bzw. 113,38 Geldeinheiten (GE) ergeben.

Tabelle 1. Einzahlungen, Risikokosten und optimale Investitionsauszahlungen

Zeitpunkt	$EZ_i(I_t)$[3]	$\lambda \cdot f_i(I_t) \cdot Cov(k_i, r_M)$	I_t^*
$t = 0$	$1 \cdot 100 \cdot ln(I_0)$	$2{,}67 \cdot 100 \cdot ln(I_0) \cdot 0{,}15$	55,47
$t = 1$	$1 \cdot 150 \cdot ln(I_1)$	$2{,}67 \cdot 150 \cdot ln(I_1) \cdot 0{,}075$	115,38

Über die zur Finanzierung der Investitionsauszahlungen verfügbaren Cashflows (d.h. Eigenmittel) liegen Schätzungen zur erwarteten Höhe und deren Risiko vor. Die eingeschränkte Kreditaufnahme ist durch den Illiquiditätsparameter γ_{I_t} abgebildet. Tabelle 2 enthält die entsprechenden Werte zur Höhe der in den Investitionszeitpunkten verfügbaren Eigen- und Fremdmittel.

Tabelle 2. Parameterwerte zur finanziellen Situation des Unternehmens

	$t = 0$	$t = 1$	$t = 2$
Bestehender Cashflow $\widehat{CF}_t$	20	20	20
Standardabweichung der Cashflows $\sigma(\widehat{CF}_t)$	-	10	15
Illiquiditätsparameter γ_{I_t}	0,5	0,9	-

Auf Basis der in den Investitionszeitpunkten beschränkten Eigen- und Fremdmittel plant das Unternehmen für den Zeitpunkt $t = 0$ mit 40 GE (vgl. Formel (6)) und für den Zeitpunkt $t = 1$ mit 15,55 GE (vgl. Formel (7)) als erwartete Mittel, die für das IT-Investitionsvorhaben zur Verfügung stehen. Mit diesen Werten, die deutlich unter den optimalen Investitionsauszahlungen liegen (vgl. Tabelle 1), kann nur ein erwarteter WB i. H. v. 497,79 GE erreicht werden (vgl. Formel (3)). Werden dagegen mit Hilfe einer Reserve verfügbare Mittel i. H. v. 9,96 GE von $t = 0$ auf $t = 1$ übertragen, so können Investitionsauszahlungen i. H. v. 20,05 GE in $t = 0$ und 26,2 GE in $t = 1$ finanziert werden, die ebenfalls deutlich unter den optimalen Investitionsauszahlungen liegen, aber einen höheren WB i. H. v. 528,07 GE (vgl. Formel (8)) ermöglichen.

Tabelle 3. Vergleich der Situation mit und ohne Reserve

	R^*	I_0^B	I_1^B	$WB_{R^*}^B$
Mit Reserve	9,96	20,05	26,2	528,07
Ohne Reserve	-	40	15,56	497,79

Ohne Reserve würde das Unternehmen in $t = 0$ einen zu hohen Betrag und in $t = 1$ einen zu niedrigen Betrag investieren. Die Reserve ermöglicht eine optimale Anpassung der Investitionsauszahlungen, wodurch eine Wertbeitragssteigerung

[3] Die Funktionen bilden den Barwert aller zukünftig anfallenden Einzahlungsüberschüsse zum Zeitpunkt $t = 2$ ab.

WBS_{R^*} i. H. v. 30,28 GE (~ 6,1%) erreicht werden kann. Um zu verdeutlichen, wie WBS_{R^*} von den finanziellen Rahmenbedingungen beeinflusst wird, werden die folgenden Sensitivitätsanalysen durchgeführt.

3.1 Analyse des Cashflows aus dem Unternehmensportfolio in $t =$

Ist in $t = 0$ ein im Vergleich zu den Startwerten des Beispiels höherer Cashflow $\widehat{CF}_0$ verfügbar, werden die höheren Mittel auf die Investitionsauszahlung in diesem Zeitpunkt und die Reserve aufgeteilt. Je höher dabei $\widehat{CF}_0$ ist, desto höher ist auch die Einstellung in die Reserve, da das Unternehmen durch die Investitionsauszahlungen in $t = 1$ höhere Grenzeinzahlungen erreichen kann. Ohne Reserve würde der höhere Zahlungsüberschuss für die Investitionsauszahlungen in $t = 0$ verwendet werden, wodurch aufgrund der niedrigeren Grenzeinzahlungen nur ein geringerer WB erzielt werden könnte. Zur Veranschaulichung sind in Abb. 2 sind WBS_{R^*} und R^* in Abhängigkeit vom $\widehat{CF}_0$ abgebildet.

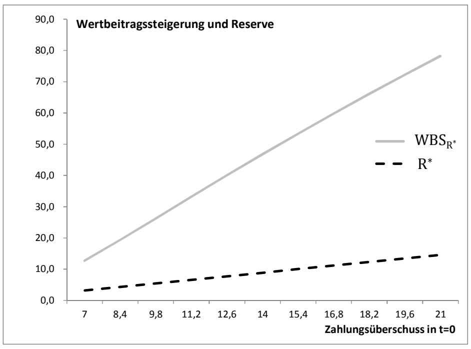

Abbildung 2. Einfluss der Höhe des Cashflows in $t = 0$

Der wertbeitragssteigernde Effekt der Reserve wird größer und eine höhere Reserve wird vorgehalten, je höher der in $t = 0$ verfügbare Cashflow $\widehat{CF}_0$ ist.

3.2 Analyse des Cashflows aus dem Unternehmensportfolio in $t = 1$

Erwartet das Unternehmen in $t = 1$ einen im Vergleich zu den Startwerten des Beispiels höheren Cashflow $\widehat{CF}_1$, kann die Höhe der Reserve verringert werden, da mehr Mittel zur Finanzierung der Investitionsauszahlung in $t = 1$ erwartet werden. Bei einem niedrigeren Cashflow $\widehat{CF}_1$ wird die Reserve dagegen erhöht, um die Investitionsfähigkeit in $t = 1$ abzusichern. Ohne Reserve kann das Unternehmen die verfügbaren Investitionsauszahlungen in $t = 1$ nicht erhöhen, obwohl eine höhere Investition vorteilhaft wäre, da sich in $t = 1$ höhere marginale Einzahlungen erreichen lassen. Die Wertbeitragssteigerung WBS_{R^*} wird daher auch überproportional größer, je niedriger der erwartete Cashflow $E[\widehat{CF}_1]$ ist (vgl. Abb. 3).

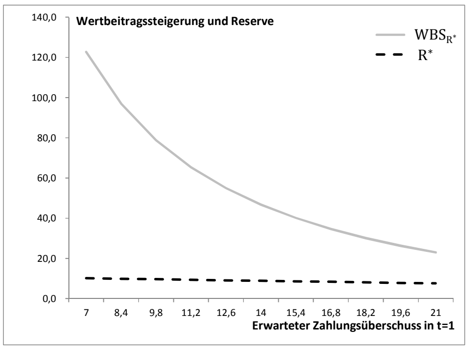

Abbildung 3. Einfluss der Höhe des erwarteten Cashflows in $t = 1$

Abb. 3 verdeutlicht, dass bei sinkendem erwarteten Cashflow $E[\widehat{CF}_1]$ durch eine Erhöhung der Reserve eine zunehmende Wertbeitragssteigerung WBS_{R^*} möglich ist.

3.3 Analyse des Risikos des Einzahlungsüberschusses in $t = 1$

Erhöht sich das Risiko des Cashflows $\widehat{CF}_1$ (d.h. $\sigma(\widehat{CF}_1)$) im Vergleich zu den Startwerten des Beispiels, sinken die verfügbaren risikoadjustierten Mittel in $t = 1$ durch die höheren Unsicherheit. Durch die Reserve kann dies bei der IT-Investitionsplanung berücksichtigt werden, sodass mehr Mittel für die Investition in $t = 1$ vorgehalten werden. Dabei steigt WBS_{R^*} wenn sich das Risiko des Cashflows $\sigma(\widehat{CF}_1)$ erhöht (vgl. Abb. 4).

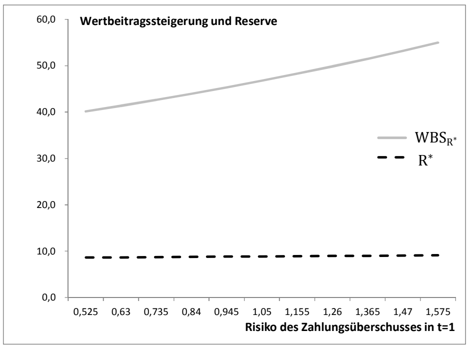

Abbildung 4. Einfluss des Risikos des Zahlungsüberschusses in $t = 1$

Insgesamt erhöht sich somit der Vorteil einer Reserve (gemessen durch WBS_{R^*}), je niedriger aktuelle und je höher zukünftige erwartete finanzielle Beschränkungen sind. Die Reserve hat somit einen hohen positiven Einfluss auf den WB von IT-Investitionen wenn ein Unternehmen gegenwärtig über hohe Mittel verfügt und davon einen Teil für Investitionen in zukünftigen Perioden vorhält, in denen die Finanzierung der geplanten Investitionsauszahlungen sehr unsicher ist.

4 Zusammenfassung und Ausblick

Durch finanzielle Beschränkungen besteht die Gefahr, dass langfristige IT-Investitionen eingeschränkt bzw. sogar kurzfristig abgebrochen werden müssen, wodurch ein Unternehmen deren geplanter WB nicht realisieren kann. Da die Relevanz von IT-Investitionen bspw. durch die voranschreitende Digitalisierung für Unternehmen verschiedenster Branchen weiter zunimmt und eine Berücksichtigung der finanziellen Rahmenbedingungen bei der Planung von solchen Investitionsvorhaben i. d. R. nicht ausreichend erfolgt, wurden in dieser Arbeit IT-Investitions- und Finanzmanagement in einen Ansatz integriert.

Mit dem entwickelten Modell können mit Hilfe einer finanziellen Reserve die negativen Auswirkungen finanzieller Beschränkungen verringert werden, da ein Unternehmen die Investitionsauszahlungen anpassen kann und dadurch der resultierende WB steigt. Zur Verdeutlichung des Einflusses der Reserve wurde die mögliche Wertbeitragssteigerung anhand eines Fallbeispiels analysiert. Dabei zeigen die durchgeführten Sensitivitätsanalysen, dass der wertbeitragssteigernde Effekt besonders deutlich ist, wenn ein Unternehmen aktuell über hohe Mittel verfügt und zukünftige Mittel geringer bzw. unsicher sind und dadurch die zukünftige Investitionsfähigkeit gefährdet ist. In diesem Fall kann durch die Reserve die langfristige Finanzierung des IT-Investitionsvorhabens abgesichert und dessen WB gesteigert werden.

Daher sollten Unternehmen bei der Budgetierung längerfristiger IT-Investitionsvorhaben nicht nur die Investitionsauszahlungen der aktuellen Periode optimieren, sondern auch zukünftige Investitionsauszahlungen berücksichtigen und deren Finanzierung absichern. Daher sollte eine Abstimmung zwischen Finanz- und IT-Abteilung erfolgen, damit die notwendigen Mittel zum richtigen Zeitpunkt zur Verfügung stehen. Dazu sollte ein langfristiges Optimierungskalkül zugrunde gelegt werden, bei dem neben IT-spezifischen Faktoren auch finanzielle Ertrags- und Risikoaspekte berücksichtigt werden. Auf dieser Basis können optimale langfristige Budgets bestimmt werden. Dabei sollte es einem IT-Projektmanager auch ermöglicht werden einen Teil des Budgets für Investitionsauszahlungen in Folgeperioden zu reservieren, ohne eine Budgetkürzung befürchten zu müssen.

Durch die getroffenen Annahmen und gewählten Parameter weist das Modell Schwächen bzw. Einschränkungen auf, die allerdings zugleich Raum für Erweiterungen im Rahmen zukünftiger Forschungsarbeiten bieten. So könnte für die Quantifizierung der Einzahlungen und Risiken Schätzverfahren entwickelt werden, die für verschiedene IT-Investitionen passende Funktionen auf Basis historischer Daten spezifizieren. Da der Fokus der Arbeit auf den finanziellen Aspekten der IT-Investitionen liegt, bleibt eine tiefergehende Analyse und Abbildung immaterieller Werte von IT-Investitionen künftiger Forschung vorbehalten. Da das auf bestehenden Ansätzen aufbaut und diese neu kombiniert, kann es keine fundamentale Weiterentwicklung dieser Ansätze leisten. Nichtsdestotrotz bietet das Modell einen Disziplinen-übergreifenden Ansatz, der im Rahmen weiterer Arbeiten empirisch validiert oder anhand eines realen Praxisbeispiels angewendet werden könnte (bspw. durch großzahlige empirische Untersuchungen oder Fallstudien).

Trotz der genannten Restriktionen kann der vorliegende Beitrag in einem ersten Schritt zeigen, dass eine Berücksichtigung finanzieller Rahmenbedingungen bei der Planung mehrperiodiger IT-Investitionen einen Beitrag zur Absicherung bzw. Erhöhung des resultierenden WB leisten kann.

Abstract. As digitalization is rewriting the rules of competition, companies need to adapt to external changes or they will be left behind. Indeed, digitalization bears a lot of economic potential and is undoubted to have tremendous impacts on the economy. Many companies already launched digital initiatives. However, most of them lack an understanding of the value digitalization can create. They often neither know the organizational value created, nor define accountability measures or specify targets. Therefore, as a first step this paper aims to provide clarity by relating digital benefits listed in literature and highlighting the underlying value drivers. Our results help companies to identify digital business value, but also lower the hurdles that prevent them from scaling up their digital effort.

Keywords: Digitalization, benefit, value driver.

1 Introduction

Digitalization is on the rise and "is rewriting the rules of competition" [1]. Those companies who are not able or willing to adapt will be left behind [1–3]. Especially the ability to handle the new challenges that come with digitalization will make the difference in future. The main differences compared to common IT usage lie in the faster speed of change, in the higher level of interconnectedness, and in the willingness of individuals to use technological devices [2]. Those phenomena already have an enormous impact on private lives and the society and will also tremendously impact business practices and success models. Hence, digitalization is considered as the fourth wave of industrialization, which will dramatically change the business world [4].

Many consultancies provide extensive studies about success stories, trends, challenges, strategies and benefits of digitalization [5–8]. The economic potential of the Internet of Things, for instance, is considered to be up to $ 1.9 trillion by 2020 [9]. And yet, the Internet of things is only one of the topics considered as digitalization. Cloud computing, big data, social networks, and many other novelties unfold even more prosperous properties. Many companies set up digital initiatives in order to benefit from the supposed fruits of digitalization. A study among 500 company executives by KPMG showed that about 43% of companies already conducted changes in their business

13th International Conference on Wirtschaftsinformatik,

Neumeier, A.; Wolf, T.; Oesterle, S. (2017): The Manifold Fruits of Digitalization - Determining the Literal Value Behind, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 484-498

model and that about 60% already made adjustments towards digital in their product and service portfolios and their administrative processes [6]. However, companies mostly lack a deeper understanding of the value digitalization can create within their organization and therefore are mostly not able to determine the gain their digital initiatives actually shall deliver. According to a survey among 850 C-level executives by Gottlieb and Willmott [10], only 7% of the respondents consider their organization to understand the exact value from digitalization. Furthermore, over 60% admit that their companies do neither have accountability measures nor specified targets for digital initiatives [10]. This emphasizes the necessity for shading light to manifold supposed fruits of digitalization.

Therefore, the goal of our research endeavor is to identify the value of digitalization within an organization. Therefore, we need to clarify the main value drivers of digitalization that can be used as a starting point for developing measures for the value of digitalization. Thus, we state the following research question:

What are the benefits and which aspects can be considered as underlying value drivers of digitalization?

Therefore, we analyze benefits of digitalization that have been identified in existing literature and derive to the underlying value drivers. We contribute to existing literature by analyzing and structuring existing literature to provide the basis for a detailed analysis of measurement approaches for digital value drivers. Furthermore, practitioners can benefit from our approach as we provide an identification of main benefits and propose value drivers to determine the gain of digital initiatives.

The remainder of the paper is organized as follows. After motivating our research and introducing the research question, we explain our research methodology. In section 2, we provide a structured literature review and synthesize the results of the literature review in section 3. In section 4, we derive conclusions, reveal limitations and give an outlook on future research.

2 Literature Review

This paper sticks to the well-established method for research synthesis of Cooper and Hedges [11] and adopts the changes towards the seven-step process of Cooper [12]. Accordingly, we formulate the scope including research objective and problem in the introduction section. In this section we outline the procedure of searching literature and define which information about each study is relevant to the previously described research objective. The selection of relevant studies based on their contribution and fit to the research problem is also illustrated. To integrate, condense and combine the results, we analyze the articles and develop an incorporating framework in section 3. Subsequently, the results are summarized and conclusions are drawn in the discussion section with regard to generalization and possible points of contact for further research. Finally, with this paper the results of the research are presented to public.

To ensure transparency and objectivity regarding the research sample selection, we identified relevant literature based on a keyword search of different data bases. As digitalization is a quite young research field, which is extensively discussed in research and practice, we included scientific literature as well as practice studies in our search.

Procedure: To identify relevant practice studies that cope with the value of digitalization initiatives, we draw on google search engine and used ‘digi*’ AND ‘value’ and ‘digi*’ AND ‘benefits’ as keywords. We focused on articles in English and German language. Furthermore, we searched white papers and studies from large management consultancies (e.g., McKinsey & Company, Accenture) and conducted a forward and backward search within the identified practice studies.

Hence, we gained a vast amount of results from our google search. Thus, we searched for publications by management consultancies and other white papers. After identifying the most relevant articles by screening the titles, we analyzed the introduction of the available data set. Thus, we identified 29 articles and studies that deal with the benefits and value of digitalization for companies.

To identify relevant scientific literature, we conducted a structured literature analysis based on established scientific databases that are relevant in the IS field. With new technologies and innovations like cloud computing, big data and many others establishing, the rules of competition have changed. But what is new with the phenomenon of digitalization compared to the usage of IT or digital technology that has been going on for years already? In this context, Gimpel and Röglinger [2] state, that “the new aspect of digitalization is not the usage of information technology per se but the speed of change and the world´s level of connectedness”. The miniaturization of increasingly powerful computing hardware leads to an omnipresence of technological devices. This is associated as Moore’s law and is considered to be the root cause or underlying driver of the digitalization phenomenon [2]. Additionally, this interpenetrating dissemination of IT combined with innovations like the internet enable all entities of an ecosystem to connect, which boosts an increase in value. Simultaneously to these technological developments, customers are increasingly willing to use technological devices. All in all, digitalization can be described as a situation in which different influence factors interact and thus the usage of digital technology is able to tremendously impact business practices and business models across almost all industries or even the whole ecosystem.

Hence, we searched for articles that cope with digitalization and the value that can be gained for a company due to digitalization. Thus, the keywords ‘digi*’ AND ‘benefits’ as well as ‘value’ in the title and the abstract of the articles were used. Furthermore, we limited the search to articles that were published after 2010, since we want to put new use and omnipresence of digital devices to the center of contemplation. With the release of the first iPhone in 2007 and the first iPad in 2010, there was an enormous increase of smart devices per person [13]. In 2010, the ratio of more than one smart device per person (calculated on the basis of the world’s population) was observed for the first time [13]. Hence, we chose 2010 as an adequate time limit for our analysis. Table 1 shows the combination of search terms in the selected databases.

Table 1. Selected Databases and Search Terms

Database	*Keywords*
AIS Electronic Library	‘digi*’ AND ‘benefits’, ‘digi*’ AND ‘value’, ‘digitalization’
EbscoHost	‘digi*’ AND ‘benefits’, ‘digi*’ AND ‘value’
IEEEXplore	‘digi*’ AND ‘benefits’, ‘digi*’ AND ‘value’

As digitalization is an extremely broad research field, many articles can be identified that somehow deal with digitalization. Thus, the scientific literature review generated a result of more than 300 articles with duplicates removed. To identify the articles that are relevant for our research topic, we first analyzed the titles of the articles whether they fit the focus of our manuscript to identify the value of digitalization for companies. All articles that obviously cope with another topic were excluded. In a second step, we analyzed the abstracts of the remaining articles and focused on the articles that deal with the value of digitalization for companies. After analyzing all articles, we gained a result of 27 articles which address the identification of the value of digitalization for companies. To complete the literature review, we conducted a forward and backward search recommended by Webster and Watson [14]. The identified articles were analyzed as previously described and if appropriate added to the selected sample. Finally, 31 articles were identified as relevant for further consideration.

Analyses: Concerning management and practice studies, beside almost all big players in the consulting industry, independent research institutes, as well as public institutions address digitalization in various studies. Even though many articles do not focus on a specific industry, most industries (e.g., media, banking, insurance, and manufacturing) are mentioned in the articles.

The influence of digitalization and the implications for companies is one of the major concerns in practice studies [4, 8–10]. Even though they focus on different aspects like the expectations of companies [10], influencing factors of digitalization on business and working processes or the effects of digitalization on a special industry, like production industry, the insurance industry, or German mid-sized companies they all agree that digitalization already has changed and will change many aspects of a company [6, 15, 16].

This digital transformation comes with several chances and challenges [2, 17, 18]. Therefore, Capgemini set up a study concerning the management practices and benefits of the digital transformation [19]. To accomplish successful digital transformation, organizational requirements need to change and classic organizational structures will no longer be adequate [20]. Thus, transformation management can decide about success or failure of a company in the digital age [2, 18, 21]. Reactions and requirements to overcome the new challenge are also widely discussed. Furthermore, the success factors and benefits of digitalization for companies are examined [1, 7, 18, 19]. Accenture conduct a survey among the Top 500 German companies and identify strategies that make the difference for the successful digital players [22].

Scientific literature on digitalization also discusses various topics. Currently, the focus of companies changes from developing an IT strategy towards integrating a ‘digital business strategy’ [3]. Digital business strategy sheds light on the possibilities and effects of digitalization on the firm. In general, it provides special attention on making explicit that the new digital technologies go beyond increasing efficiency and productivity towards competitive advantage and strategic differentiation [3]. Value creation is not limited to single products or services anymore. It expands opportunities to new dimensions that have not been accessible before [23]. Companies in future will not be successful because they once adopted a digital business strategy or business model. They will succeed due to flexibility in adapting to new circumstances and requirements [23]. As the modes of collaboration within and beyond ecosystems will change, companies need to adapt and increase flexibility [24, 25]. Most articles concerning digital business strategy develop theoretical models concerning the digital architecture, digital networks, platforms and processes [e.g. 23–27].

Besides digital business strategy, the combination of digital and physical components is discussed in literature. Yoo et al. [28] define the "carrying out of new combinations of digital and physical components to produce novel products" as digital innovation. According to Barrett et al. [29] "the economy [shifts] from a goods-based to a service-based economy" due to digitalization and digital innovation [30]. The integration of digital technologies in traditional products promises increased performance and experience [31]. Thus, the combination of digital and physical products is becoming a strategic topic for many companies as the gained flexibility creates novel market offerings and thus benefits [28, 30, 32]. To gain the value that comes with new market offerings, new ways of defining digital services are required as it differs from the traditional logic of services [33]. Furthermore, traditional innovation processes need to change due to the integration of digital technologies [31].

Besides discussing the influence of digital technologies on the strategy of a company, the integration of digital technologies in the operations of companies is a focus topic in literature. Matt et al. [34] claim that if the four transformational dimensions 'use of technologies', 'changes in value creation', 'structural changes', and 'financial aspects' are closely aligned, the potential benefits of digitalization can be realized. This "include[s] increases in sales or productivity, innovations in value creation, as well as novel forms of interaction with customers, among others" [34]. The integration of new technologies into operations can furthermore leverage higher organizational efficiency and thus increase savings in cost and time [35, 36].

Digitalization can furthermore help to improve the communication within and beyond the company [37–39]. By building innovation communities companies can enlarge their idea pools and thus gain tangible as well as intangible benefits [39]. Due to easy communication in corporate blogs or platform forums the performance of employees can increase due to knowledge spillovers [37, 38]. Nevertheless, technology needs to be aligned with the business goal to improve overall performance.

Besides literature that deals with digitalization in general, there are several studies that examine digitalization within specific industry sectors, like automotive industry, retail banking, media, and public sector [40–42]. Even though all articles discuss different aspects and industry specifics, they agree that new business models can create new value-added services [40]. Improved communication with the customer as well as smart data analysis can help to recognize customer needs [42] and thus improve customer experience and satisfaction [41]. Furthermore, due to virtualization of decision and operating processes and standardization, companies can achieve an increase of efficiency that leads to higher productivity and thus reduced costs [40, 41].

Although various topics have already been discussed, neither in scientific nor in practice literature we can find a structured overview or framework that can help companies to understand the benefits of digitalization. Thus, we will examine the benefits of digitalization and the underlying value drivers in more detail.

3 Deriving the Value of Digitalization

Despite many studies from business consultancies about implications and possible benefits of digitalization, this topic is still very vague for many companies. They often are not able to grasp this topic in terms of being able to set concrete organizational objectives. Therefore, this section condenses the benefits previously investigated from scientific and practice literature in order to derive the value drivers of digitalization.

To receive a more objective result, we aligned to a structured approach and discussed all results with other researchers. As a first step we carefully screened the 29 practice studies and the 31 scientific articles for benefits of digitalization. We gathered all mentioned aspects in a central database. After having identified a variety of benefits of digitalization, we clustered all benefits independently of each other to get a common understanding of the various terms and notions mentioned. Then we discussed the results within each other and with other researchers. This led us to a result of 38 kinds of benefits. We derived an appropriate wording for each kind of benefit. For example, customer centric, delight customers, customer behavior, customer loyalty, customer trust, citizen-centricity, customer satisfaction, client experience were subsumed to the benefit *customer experience*. Due to space restrictions, we only included the final wording.

Since the identified benefits of digitalization are diverse regarding granularity and sphere of impact, we categorize them to different levels of an information system. Since the different elements of an information system usually are organized in organizational layers [43–45], we refer to an established model by Buhl and Kaiser [45] for information and communication systems to allocate them to appropriate layers of organizational information systems. This model has been applied for categorization by other studies before [46, 47]. The model classifies an organization in four different intra-organizational layers and is based on the classification by Frank [48] and Winter and Fischer [49]: *Business Model*, *Business Processes*, *Application Systems & Services (Appl. Sys & Services)*, and *Infrastructure*. The layers are connected and increase in granularity from the lower to the upper ones. Furthermore, the model considers *Customers* as value driver of each organizational endeavor and supposes them as extra-organizational layer, which is however closely connected to the intra-organizational business model.

Infrastructure mainly contains hardware and networks of a company [49] and describes all kinds of technology that are used within a company. The benefits that can be observed on this layer are caused by technological advances due to digitalization. The *Appl. Sys & Services* layer includes all software, application, and data components [49]. As more and more services are offered online, companies need to deploy IT applications to accomplish their business processes. The benefits that can be achieved within this layer are on a technical operations level but can help the company to accomplish the overall goals. The *Business Processes* layer pictures the procedure of performing service delivery to achieve the desired business goals [49] and thus this level includes all benefits that result from improvements on an functional operations level due to digitalization. In contrary to the process layer, the *Business Model* depicts the organization from a strategic point of view [48, 49] and should be aligned with customer needs. Thus it connects the intra- and extra-organizational level. All strategic benefits that can be observed in literature are assigned to this layer. The *Customer* layer depicts an extra-organizational layer that refers to all interactions between the company and the customer. Thus benefits that result from the interaction with customers can be assigned to this layer. Table 2 gives an overview of the identified benefits. An overview of all references and a detailed assignment of references to the benefits can be found an extra online repository [50].

Table 2. Categorization of Digitalization Benefits

Customer	
relevance among customer	product and service quality
innovative products and services	customer experience
customer interaction convenience	customer tailored solution
drive customer behavior	customer conversion
Business Model	
enlarge customer pool	advance to new business fields
profitability	increased sales
increase returns	risk mitigation
expand to digital channels	cost reduction
competitive advantage	enable innovations
enhanced promotion	efficiency
new competitive business models	
Business Processes	
incr. productivity	process flexibility
reduced product time-to market	speed of service proposition
operational excellence	process automation
smart workflow integration	process improvement
gain external network synergies	
Appl. Sys & Services	
improved information base	use of customer data
new delivery model	use of internal data
knowledge management	customer insights
real-time information	
Infrastructure	
smart technologies	

Based on this investigation, we recognized in which areas digitalization particularly is supposed to lead to benefits. However, it still was not clear, how these benefits may pay off and how this can be appropriately measured. Furthermore, the benefits of digitalization are partially interlinked and mutually dependent. To depict the first idea of relationships between the identified benefits, we used deductive logic to relate the manifold vague digital benefits and to conclude on measureable value drivers of digitalization. In doing so, we gradually assigned the different kinds of benefits not only to the different intra- and extra-organizational layers, but also to particular levels of granularity. Therefore, we used logic trees on each organizational level which visualize the different levels of granularity. Benefits of similar granularity have been assigned to the same level and differing ones have been assigned to different levels. Furthermore, we incrementally connected benefits on a lower level of granularity (e.g., *speed of service proposition* or *real-time information*) to benefits on higher levels of granularity (e.g., *increased productivity* or *profitability*), since the ones on the lower level logically contribute to corresponding ones on the higher level. Consequently, we derived a model that depicts a top-down and bottom-up perspective on all identified extra- and intra-organizational benefits related to digitalization.

Since the benefit of digitalization is a very vague research topic with only few existing scientific research, the objective of this paper was to open the field of research by structuring and relating different benefits mentioned in literature in a first step, rather than to state one particular hypothesis that needs to be tested. By structuring the existing benefits with logic trees, we used a qualitative, deductive method to actually state several different hypothesis about the relationship of the single benefits. In doing so, we tried to minimize subjective judgment by conducting a discussion group of diverse scientists. We had a core team of three researchers who discussed their findings and suggestions in several rounds with up to 20 other researchers, including five professors and several PhD graduates. Nevertheless, continuation research is still necessary to proof the stated hypothesis. The resulting model for the benefits of digitalization including their linkages and corresponding areas is depicted in Figure 1.

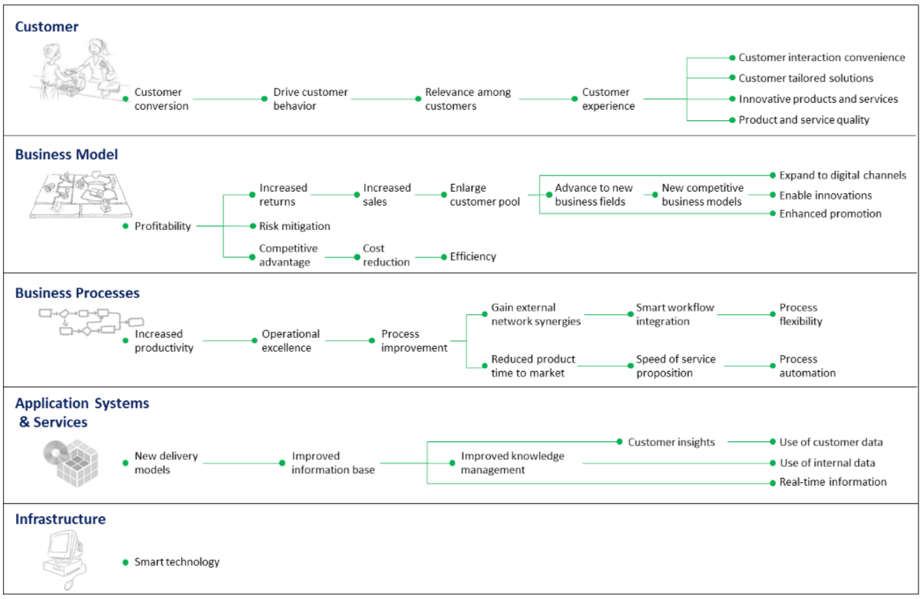

Figure 1. Logic Trees for the Digitalization Benefits on each Organizational Level

For all layers depicted in Figure 1, we exclusively used the benefits that were derived based on the analyzed literature and arranged them within logic trees. On the *Business Model* layer, Figure 1 shows the strategic benefits for an organization where, for instance, the *profitability* is influenced by three components: *increased returns*, *risk* *mitigation*, and *competitive advantage*. First, we observe higher *profitability* due to *increased returns* that can be caused by *increased sales*. Increased sales depend on an *enlarged customer pool* which can be generated by an *expansion to digital channels*, the *advance to new business fields*, and *enhanced promotion*. The advance to new business fields is enabled by *new competitive business models* that are based on digital *innovations.* Second, the *profitability* of a company can be influenced by risk. If improved *risk mitigation* strategies can be applied due to digitalization, profitability of a company can be increased. Third, profitability is influenced by the *competitive advantage* a company can achieve due to *cost reductions*, which in turn can be gained by improved *efficiency*. According to this example, the logic trees on the other organizational layers can be read similarly. Furthermore, the logic trees are not only connected within but also beyond the organizational layers.

4 Discussion

To enable a valid assessment of the target state of digitalization within a company, an appropriate measurement is required in future research. Therefore, we need to identify value drivers that can be measured to assess the status of digitalization. On the strategic level (*Business Model),* the overall profitability of the organization could be measured. As the overall profitability of a company is influenced by internal and external factors, one would not be able to obtain whether an increase in profitability would stem from an improved customer interaction (external factor) or an operational improvement (internal factor). Thus, we will not directly draw on the profitability to derive the overall contribution. However, as the *Business Model* layer constitutes the linkage between the intra- and the extra-organizational layer, the interfaces between Business Model & Customer as well as Business Model & Business Processes might offer a starting point for an appropriate measure. By measuring the consequences of digitalization at the intra- and the extra-organizational interfaces of the *Business Model* layer, an overall perspective on the status of digitalization can be gained. Hence, for each interface an appropriate value driver should be identified that (1) is able to depict the overall influence of digitalization on the intra- and extra-organizational layers and (2) can be influenced by the company. Thus, we choose the benefits on the highest granularity level that can be influenced by the company, i.e., as close to the root node of the logic trees as possible.

Intra-organizational perspective: The benefit on the highest granularity level from the intra-organizational perspective is competitive advantage. The competitive advantage of a company cannot easily be measured. Thus, cost reduction should be analyzed for its applicability as a measure for the intra-organizational perspective. Many companies use cost reductions to measure the success of initiatives that are supposed to increase internal competitiveness [51]. Nevertheless, cost reduction does not necessarily need to be the consequence of internal improvement. For example, production costs will decrease if less products are produced. In turn, less revenues can be achieved with less products to be sold, which will lead to an overall negative result. Thus, the sole measurement of cost reduction cannot cover particulars on success of digitalization. Thus, we examine *efficiency* as a value driver that can be measured. Efficiency is mainly driven by operational improvements of a company. In this paper, we consider efficiency from an economic perspective and hence suppose an activity to be efficient if there is no other way of performing a particular activity that leads to less cost, delivers the same results, upholds the same quality standards and is economically reasonable to invent. As efficiency, moreover, may be influenced by a company itself, we consider it to be an appropriate value driver for the intra-organizational perspective.

To assess efficiency within the organization established measures like maturity models or similar approaches can be used [52]. Thus, based on different maturity levels the status quo and target state of a company might be determined. A corresponding examination, however, is topic to further research.

Extra-organizational perspective: Within this perspective, there are many starting points for possible measures. For example, increased returns, increased sales, customer conversion and the size of the customer pool can quite easily be measured. However, those benefits are either not necessarily the consequence of external advancement or cannot be influenced directly by the company. Thus, we propose to choose *customer experience*, as this benefit is on the highest level of granularity that can be influenced by the company itself. While the other benefits like customer conversion oftentimes cannot be influenced from an internal point of view, customer experience can be directly changed with the help of appropriate projects.

A measure that might serve to determine a company's digital target state that maximizes the value driver customer experience is the Kano model [53]. This model measures customer experience through under and over fulfillment of customer expectations [54]. Based on a respectively designed questionnaire, a company could determine its customers' expectations, which might serve as a basis to determine the digital target state of the company. Another measure that could be used for assessing this perspective is the established American Customer Satisfaction Index [55]. A corresponding detailed examination is also in this case topic to further research.

Hence, *efficiency* and *customer experience* are identified as two of the main value drivers within digitalization that might be used as starting point to measure the value of digitalization and hence show the manifold fruits of digitalization. However, concrete measures as well as a reasonable process to assess the value of digitalization should be determined in future research.

5 Conclusion, Limitations and Outlook

As digitalization is on the rise, the competitive environment of companies in all different industries will change within the next years [1]. Thus, many companies set up digitalization initiatives to benefit from the promising prospects even though they lack a deeper understanding of the benefits digitalization can literally bring to their company. Furthermore, most companies are not able to assess their status quo as well as their target state concerning digitalization. To address the research question, we conducted a structured literature review within scientific and practice literature to identify the benefits of digitalization and to clarify the underlying value drivers. Thus, we identified 38 kinds of benefits of digitalization which can be categorized into the five areas of the model for organizational information and communication systems *Customer*, *Business Model*, *Business Processes, Application Systems & Services, and Infrastructure*. We used logic trees to relate the manifold vague digital benefits within each layer and to conclude on measureable value drivers of digitalization.

To enable an overall measurement, it is reasonable to consider the internal and the external perspective. Hence, we identified value drivers that enable the measurement at the interfaces between the intra- and extra-organizational perspectives. From the intra-organizational perspective efficiency enables to measure the influence of internal improvements. Measuring customer experience, furthermore, enables to measure digitalization progress from an external view. Each digitalization project should thus target to contribute to the company's profitability in terms of efficiency or customer experience or even both values. Thus, if a company decides to invest in digital initiatives, they should be assessed based on those drivers.

Despite the merits of this paper in terms of clarifying benefits and value drivers of digitalization, it is not without limitations. We base our literature review on scientific and practice literature. While scientific literature sticks to objective research goals and methods, practice literature might inhabit a bias as management consultancies want to position themselves as digitalization experts. Thus, they might exaggerate the positive effects and downplay the risks and challenges to gain new assignments. Nevertheless, management consultancies were able to gain deep insights into the real world application of digitalization during the last years. As the main focus of our research endeavor is to identify the key benefits and value of digitalization, we consider practice studies to be the most fertile source of information. Furthermore, we manually clustered and categorized the identified benefits to different kinds of benefits and layers of the organization. This might lead to subjectivity. However, we tried to reduce subjectivity as far as possible by drawing on a structured research procedure and by discussing our results with other researchers. Moreover, the developed categorization of benefits and the identified value drivers are a first approach to clarify the value of digitalization. However, we did not yet derive an empirical investigation of the underlying hypothesis. This is topic to further research. Furthermore, future research should feel encouraged to analyze different measurement methods for digital value drivers as well as establish a process for the valuation of digitalization projects.

Overall, our study contributes to existing knowledge and approaches the research question raised within this manuscript. Our manuscript can be equally beneficial for research and practice. On the one hand, the approach contributes to future research by analyzing and structuring existing literature and can thus provide the basis for a detailed analysis of measurement approaches for digital value drivers. Furthermore, our results support practice with the identification of the main benefits and value drivers of digitalization. Thus, they can make use of the categorization to determine the gain of their digital initiatives. Thus, all in all, the approach can help practitioners to get a better understanding of the benefits of digitalization, which might lower the hurdles that prevent companies from scaling up their digital effort.

Abstract. Rebound effects have been discussed in various disciplines. In the information and communication technology sector, this topic is still insufficiently studied. Basically, a rebound effect is a feedback mechanism, as a result of which savings from efficiency improvements are not or only partially realized. Due to the potential of cloud computing for efficiency improvements, not only in terms of energy efficiency, but also in terms of organizational resources in general, we describe rebound effects in this context by means of a systematic literature review and a case study. Our results provide a framework to categorize and identify potential rebound effects in cloud computing. The understanding of rebound effects and their influence on the various organizational resources (e.g., server hardware, human resources or IT know-how), is important for managers to sustainably decide for or against the adoption, integration and roll out of cloud computing services.

Keywords: Rebound Effects, Cloud Computing, Literature Analysis, Case Study, Conceptual Framework.

1 Introduction

In recent years, the cloud computing (CC) technology has emerged as a new computing paradigm and has gained increasing attention due to its remarkable advantages, e.g., reducing costs and complexity along with increasing flexibility [1, 2]. In its core, CC resorts to existing technologies like grid computing, virtualization and web services for the online delivery of scalable IT services, commonly on the basis of a pay-per-use pricing model [3]. However, when strategically outsourcing a supportive or even a core process into the cloud (so called “cloudsourcing”), it is mandatory that the management of the organization has a clear understanding of all influencing as well as influenced factors. One of these factors is the rebound effect, which diffuses alongside with the efficiency improvements of CC and which describes that expected savings resulting from these improvements cannot be realized, due to a growth in consumption of the underlying or different resources.

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Adelmeyer, M.; Walterbusch, M.; Biermanski, P.; Seifert, K.; Teuteberg, F. (2017): Rebound Effects in Cloud Computing: Towards a Conceptual Framework, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 499-513

Rebound effects have been discussed in various disciplines, e.g., psychology, but in the information and communication technology (ICT) sector this topic is still insufficiently investigated [4, 5]. Moore's law constitutes a commonly referenced example of rebound effects in the ICT field. It predicts that the microchip performance per cost unit doubles every 18 months, which makes ICT hardware widely affordable, but in turn leads to an increase of consumption [5, 6]. Existing literature on rebound effects in the context of CC mainly focuses on an energy saving perspective [7–9]. For example, Walnum and Andrae (2016) estimate that rebound effects possibly offset energy savings at the macro-level due to the increased amount of data transferred [8]. In the field of ICT, potential savings do not only result from energy efficiency improvements, but also from organizational resources, such as workforce [4]. Therefore, we expand the focus from a narrow energy saving perspective to efficiency improvements of general organizational resources in the context of CC. For example, if an organization outsources servers and corresponding storage into the cloud, the decreased costs as well as the enhanced provisioning of storage may lead employees to make use of the new storage facilities more extensively than before. This in turn would exhaust the expected savings, which consequently remain unrealized.

To avoid possible rebound effects that would absorb the resource-saving impact of CC, a basic understanding must be established [4]. With this in view, we conducted a systematic literature review focusing on the definition of rebound effects. Subsequently, we describe the phenomenon of rebound effects in CC by means of a case study, in which we accompany an organization during a typical outsourcing process into the cloud. Based on the findings, we provide a framework consisting of a definition of rebound effects in general (REGE) and rebound effects in CC (RECC), a conceptual model and a morphological analysis of RECC to identify, categorize and understand potential rebound effects in cloud computing. In practice, the final decision on the usage of CC services has a significant influence on the various organizational resources (e.g., server hardware, human resources or IT know-how). The understanding of surrounding factors such as the rebound effects is vitally important for decision makers to sustainably decide for or against the adoption, integration and roll out of CC services. From the scientific perspective, the framework constitutes a starting point for further investigation.

The corresponding research questions (RQs) we seek to answer are the following:

RQ1: How can rebound effects in cloud computing be conceptualized?

RQ2: Which organizational resources are potentially affected by rebound effects in cloudsourcing scenarios?

Before we answer these RQs, we outline our methodical approach and provide theoretical background on rebound effects in general. Second, we present a definition, a conceptual model and a morphological analysis concerning rebound effects in CC on the basis of a literature analysis and a case study approach. Finally, we discuss our research findings, line out implications for theory and practice and conclude with limitations as well as future research implications.

2 Research Methods

2.1 Systematic Literature Review

In order to identify and analyze relevant research on rebound effects, we carried out a systematic literature review according to vom Brocke et al. (2009) [10]. The systematic literature review provides the basis for the definition of REGE (cf. section 3) and consequently indirectly for the conceptual modelling and the morphological analysis of RECC (cf. section 4.1). In order to achieve high-quality results, we limited the search to the top 25 (out of 109) journals included in the AIS (2014) ranking, all A- and B-ranked journals and conferences according to the VHB (2008) ranking, as well as all A-ranked journals and conferences included in the WKWI (2008) ranking [11–13]. All the above meta-rankings of international information systems journals and conferences are widely accepted. Additionally, due to their diversified programs, we also considered the well-known conferences Americas Conference on Information Systems (AMCIS) and the Hawaii International Conference on System Sciences (HICSS) to be relevant.

For the queries, we defined the following search terms and phrases (rebound effect*, rebound-effect*, reboundeffect*, rebound mechanism*, rebound-mechanism*, reboundmechanism*, boomerang*). The wildcards used ensure the identification of related terms (e.g., ‘rebound effect’ or ‘rebound effects’ for ‘rebound effect*’). In this search, we deliberately left out the refining search term cloud computing, as the achieved results will naturally already contain the contributions in this field. With the listed search terms we searched the titles and abstracts of the previously mentioned publication organs and found only one paper. Since this initial search focused on IS publication organs, the implication by Gossart (2014) that the phenomenon of rebound effects is still largely unexplored in the field of ICT is verified [4]. Due to this result, we extended the initial search to the databases EBSCOhost, SpringerLink and Google Scholar, which led to a total of 2.325 results (EBSCOhost: 293, Google Scholar: 572, SpringerLink: 1.460). As these results are sorted by relevance in the corresponding databases, we focused on the first 100 results for each query in each database. After reading the titles and abstracts, we identified 54 relevant results (EBSCOhost: 21, Google Scholar: 16, SpringerLink: 17). A forward and/or backward search based on these results was not conducted since the initial literature search already distinctly focused on IS literature.

2.2 Case Study

The case study research method aims to study a single, contemporary phenomenon (e.g., an application, a technology or a decision) within its real-life context (e.g., in an organization) by investigating multiple sources of evidence (e.g., archival records and physical artifacts) over a logical time frame [14–19]. All these characteristics are especially important when the boundaries between phenomenon and context are not clearly evident [16, 19]. Case studies facilitate the understanding of the nature and complexity of the processes taking place [14, 17, 18]. Besides, they are particularly suitable for the investigation of information systems development, implementation and use within organizations [18, 20, 21].

As case studies can be distinguished by the research objective (descriptive, explorative, explanatory), research epistemology (positivist, interpretive, critical), research method (qualitative, qualitative/quantitative), case design (single, multiple) and unit of analysis (holistic, embedded) [20, 22], a variety of approaches exist to carry out case studies [15, 17, 18]. Our study generally follows the synthesized case research procedures by Dubé and Paré (2003), Gable (1994), Newell and Simon (1972) and Recker (2013), as depicted in Figure 1 [19, 22–24]. Instead of recommending specific case study methods, these procedures define fundamental elements and sort them in order to deduce theoretical statements [25].

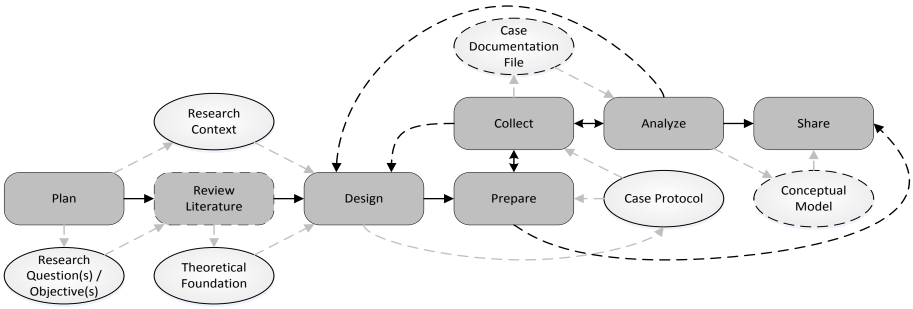

Figure 1. Synthesized case research procedure in accordance with Dubé and Paré (2003), Gable (1994), Newell and Simon (1972) and Recker (2013) [19, 22–24]

The single case study approach is particularly suitable for the investigation of previously unchallenged phenomena or issues at the beginning of theory generation. This is in line with our research objective to describe the emerging phenomenon of RECC (cf. section 1 & 2.1). A multiple case set-up, however, allows the researcher to test a theory [21, 22]. Therefore, this approach is appropriate when a theory has to be validated and a framework has to be evaluated. We try to explore the object of interest within its real-life context in an organization without defining any (in)dependent variables a priori [23, 26].

To be precise, we explore RECC at NOZ Medien, a media company in Northern Germany. NOZ Medien has more than 950 employees who are spread across nine locations. It has a daily readership of over half a million people. We have chosen NOZ Medien for our case study, since the decision makers confirmed their general interest in outsourcing processes into the cloud. Furthermore, top-level management assured full support but had not yet taken any steps towards "cloudsourcing". During the period from October 2013 until September 2014, we accompanied IT decision makers at NOZ Medien during a typical "cloudsourcing" process, which was predetermined by the company, from the (i) idea to outsource, (ii) as-is analysis, (iii) requirements definition, (iv) market analysis and (v) simulation to the point of (vi) transition or abortion. Since during the step 'transition or abortion' the IT decision makers at NOZ Medien came to the conclusion not to outsource the considered system into the cloud, the steps (vii) contract negotiations, (viii) migration, (ix) operation, (x) evaluation and (xi) optimization or discarding have not been run through. Given the fact that we factored in the possibility of cancellation of the outsourcing process when designing the case study and that we follow a conceptual approach for the definition of RECC, the impact on the conceptual framework is limited. In the present case study, the idea to outsource targets the email system at NOZ Medien. This system constitutes an autonomous unit inside the IT system landscape and is based on Microsoft Exchange 2007.

During the project steps conducted, we made use of several data collection methods in order to capture the contextual complexity and to obtain a substantial set of data [18]: (i) documentation (e.g., infrastructure plan), (ii) archival records (e.g., organization chart), (iii) interviews (e.g., with the IT decision makers) and (iv) physical artefacts (e.g., IT landscape); (v) direct observations were not included. These data are analyzed in a qualitative manner following an interpretive approach according to Myers (1997), who states that "interpretive studies generally attempt to understand phenomena through the meanings that people assign to them […]" and are "[…] aimed at producing an understanding of the context of the information system, and the process whereby the information system influences and is influenced by the context" [20, 27].

3 Rebound Effects in General

There is no uniform definition of the term rebound effect, it is rather discussed controversially [28, 29]. The primal characterization of this effect can basically be ascribed to Jevons (1865), who suggests that the efficiency improvement of coal-fired steam engines leads to a higher instead of a lower consumption of coal [30]. The reason for this is the reduction of the effective cost of coal realized through the higher efficiency [30, 31]. Sorrell et al. (2009) further distinguish between direct and indirect rebound effects, whereas economy-wide rebound effects reflect the sum of the two aforementioned [32]. The term rebound effect is not only used and discussed in disciplines related to sustainability but also in several others [32, 33], for example, in biology, physics, chemistry and psychology as well as in economic contexts, e.g., logistics. This highlights the variety of application areas on the one hand, and the multitude of existing rebound effects on the other. Gossart (2014), Plepys (2002) and Hilty et al. (2006) draw attention on the effects in the ICT sector [4, 6, 34]. They examine the existence of rebound effects in information and communication technology and their impact on the economy, whereas this topic still remains insufficiently explored in this area. Andrae (2013), Sedlacko et al. (2014) and Walnum and Andrae (2016) explore rebound effects in the context of energy savings in cloud computing [7–9].

Mathematically, rebound effects can most simply be described as the quotient of the difference between expected and realized savings (numerator), which is subject to an (unintended) alteration of the consumption of the resource regarded or different resources, and the expected savings (divisor) [35–37]:

$$Rebound\ effect\ (\%) = \frac{100*(expected\ savings - realized\ savings)}{expected\ savings}$$

Figure 2. Mathematical calculation of a rebound effect

In case the realized savings are smaller than the expected savings, this results in a positive rebound effect (percentage). If no savings can be realized, the efficiency improvement even results in a surplus of consumption (backfire); the rebound effect would then be greater than 100% (full exhaustion). Mathematically, in case more savings are realized than expected, also a negative percentage is possible.

Based on the systematic literature review, we build a concept matrix according to Webster & Watson (2002) in order to summarize how rebound effects are characterized [cf. http://bit.ly/RECCWI17] [38]. Out of the initial 54 results, 47 papers contained concepts characterizing rebound effects in several ways. In order to uncover and name the underlying concepts, we applied a conceptual content analysis approach when analyzing the literature [22], placing a strong focus on the general definition of rebound effects. In total, the following eight characterizing concepts of rebound effects in general were extracted from the identified literature: efficiency improvement; growth in consumption; direct/indirect; micro/macro level; offset; unintended; short-/long term; behavioral response.

The main cause for rebound effects is an efficiency improvement, which leads to a behavioral response, namely a (unintended) growth in consumption and an offset of the initial savings on a short- or a long term [31]. The scope of rebound effects can be distinguished between micro- (single actor) as well as macro-level (interaction of several actors) and further between direct (investment in the same resource or service) as well as indirect (investment in alternative/substituting resource(s) or service(s)) [31–33]. In summary,

A rebound effect describes the unrealized [(over)exhausted] saving of a resource in consequence of a (unintentional) growth in consumption, whereas the saving of this resource could have been expected and would have been possible based on the efficiency improvement concerning the use of this resource. A distinction is made between direct and indirect rebound effects, which affect the micro- as well as macro-level in the short- or long-term.

In the context of rebound effects, the commonly considered resource is energy in the form of, e.g., electricity or gasoline. In the following, the term resources will implicitly include any other forms of resources. Since energy is indirectly affected by the (efficient) use of time, time itself and as consequence workforce can also be seen as a resource [4, 5]. In addition to the main cause for rebound effects, namely an efficiency improvement, numerous secondary causes (also called “effects”) are discussed in literature, such as financial (caused by cost savings, e.g., income, reinvestment and market price effect), material (caused by the energy that is used for the production and provision of goods and services, e.g., embodied energy, consumption accumulation and new markets effect) or psychological effects (caused by increased demand as a result of moral justification, e.g., moral hazard, moral leaking and moral licensing effect) [31].

4 Rebound Effects in Cloud Computing

4.1 Definition and Conceptualization

The efficiency increase described in Moore's law concerning the increase of computational performance per cost unit leads in turn to a broad diffusion and a higher demand of the technology and consequently to an increase in energy consumption by ICT hardware [5, 6]. Due to its characteristics like resource pooling and virtualization, the cloud computing technology has the inherent potential for efficiency gains of resources, such as energy [8, 39].

Therefore, in a first step, the definition of rebound effects is transferred to CC. Starting point is the definition of REGE, which was derived based on the concept matrix resulting from the literature analysis (cf. section 3). Equally important is the de-facto definition for CC by Mell and Grance (2011), who define CC as "a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction" [40]. Furthermore, cloud computing can be distinguished between three service models (Software, Platform and Infrastructure as a Service) and different deployment models, such as private, community, public or hybrid clouds [40]. The results of the case study constitute another starting point for the definition of RECC. The cause for a REGE is an efficiency improvement. CC can lead to such efficiency improvements in various respects. In the following, one example for each of the five essential characteristics of CC [40] will be given: (i) on-demand self-service leads to time savings in the provision of computing capabilities; (ii) broad network access leads to independencies for using CC services via heterogeneous client platforms; (iii) resource pooling leads to savings in terms of maintenance, replacement and repair; (iv) rapid elasticity leads to a constant, appropriate performance; (v) measured service leads to a full control of costs.

The resource underlying a rebound effect can be of various natures: concerning REGE, the focus is generally put on the resource energy. In CC, the efficiency increase results from the use of cloud computing services, which in turn affects resources that are specific to the organization, e.g., liquid funds, working time and corresponding assets like hardware. Moreover, when evaluating a RECC, the overall corporate objectives (organizational perspective) have to be considered. Assuming that an organization outsources its servers into the cloud using Infrastructure as a Service (IaaS) in the form of virtualized resources from a CC provider, the servers used so far as well as the human resources, who administrated these servers (e.g., technicians and to some extent the former administrators), are no longer required. The residual value of the hardware and the monetized released working time, after deducting the costs for the CC service, can be interpreted as savings. Depending on the corporate objectives, these savings can or better should be used continuously. If the objectives comprise the steady growth of human resources [41], the investment of the residual value of the hardware as well as the transformation of the released working time into a new position, will mathematically lead to a positive rebound effect (exhaustion of the savings). However, only if these reinvestments are directly caused by or related to the adoption of CC services and diminish the realized savings in comparison to the expected savings, the result is a RECC. In case the investments are made based on the realized savings generated through the efficiency improvement of the adoption of CC, e.g., in order to increase production by means of new employees and production machinery, the savings were already realized and therefore do not result in a RECC. As long as the consumption of or investment in the same or (an) alternative resource(s) is in line with the corporate objectives, the rebound effect can be seen as positive from an organizational perspective. The situation would be different, however, if the corporate objectives comprised the gradual build-up of capital reserves and a high degree of automation. In this case, the said investments would mathematically still lead to a positive rebound effect, but as not in line with the corporate objectives, it would have to be assessed negatively from an organizational perspective.

Consequently, a RECC is depended on the context of an organization's intention or expectation. This interplay between the intentions or the expectations of an organization and the actual effect can be seen in Table 1.

Table 1. Rebound effects in cloud computing in the context of intention or expectation and effect in accordance with Hilty (2008) [41]

<table>
<tr><td></td><td></td><td colspan="2">intention or expectation</td></tr>
<tr><td></td><td></td><td>reduce input</td><td>increase output</td></tr>
<tr><td rowspan="3">effect</td><td rowspan="2">input does not fall</td><td>rebound effect in the narrow sense</td><td>intended growth</td></tr>
<tr><td colspan="2">rebound effect in the broad sense</td></tr>
<tr><td>output does not rise</td><td>saving of input</td><td>unintended stagnation</td></tr>
</table>

Depending on the point of view of an economic actor (private households, organizations, state), the intentions or expectations that cause rebound effects differ. Since an organization is generally interested in growth (increase in output), rebound effects in the narrow sense occur if an organization has the intention or expectation to accumulate savings (reduce input). Rebound effects in the broad sense arise under the intention of growth, leading to a disproportional resource consumption [41].

In addition, RECC can be distinguished between direct and indirect effects. For example, savings resulting from outsourcing a process into the cloud can directly be reinvested in the underlying resource saved or indirectly, e.g., in additional workforce managing the outsourced service. Furthermore, the effect level can be distinguished between micro (within the organization) and macro (outside the organization).

Based on the definition of REGE (cf. section 3) and the previous discussion, the following definition for RECC is derived:

A rebound effect in cloud computing describes the unrealized [(over)exhausted] saving of an organizational resource in consequence of a (unintentional) growth in consumption, whereas the savings could have been expected and would have been possible based on the efficiency improvement resulting from the use of cloud *computing services. The organizational assessment of the effect is depending on the corporate objectives. A distinction is made between direct and indirect cloud computing rebound effects, which affect the micro- as well as macro-level in the short- or long-term.*

Concerning RECC, the organizational context as well as internal decisions are focused, which are basically influenced by the corresponding corporate objectives. The conceptual model depicted in Figure 3, which is based on the literature analysis and the results of the case study, summarizes the components of a RECC.

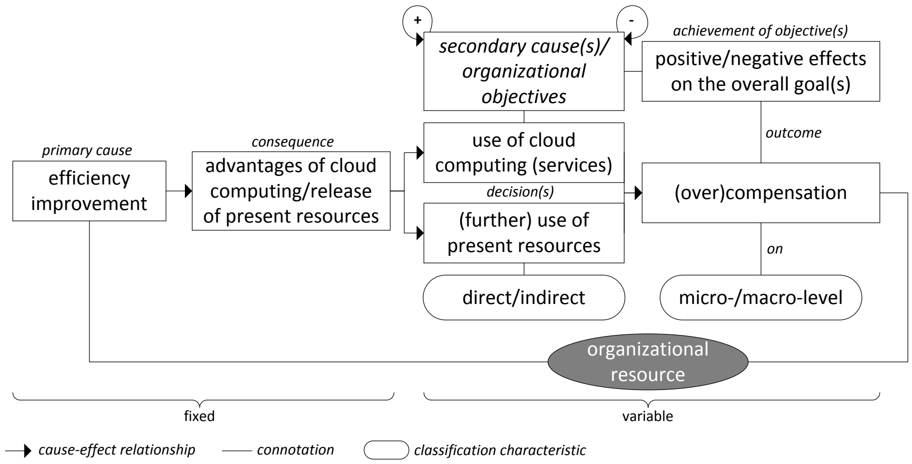

Figure 3. Conceptual model of a rebound effect in cloud computing

Finally, a morphological analysis has been conducted which combines the results of the concept matrix resulting from the literature analysis and the case study in order to investigate the “totality of relationships contained in multi-dimensional, usually non-quantifiable problem complexes”, in this case RECC [42] (cf. Table 2). The morphological analysis allows for the categorization of potential RECC, whereas the conceptual model primarily depicts connotations and causalities.

Table 2. Morphological analysis of rebound effects in cloud computing

<table>
<tr><td>cause and effect</td><td colspan="4">Saving (of an organizational resource) due to the use of a cloud computing service (IaaS, PaaS, SaaS), leading to an unintended effect on (other) organizational resources (growth in consumption)</td></tr>
<tr><td>(further) use of resources</td><td colspan="2">direct</td><td colspan="2">indirect</td></tr>
<tr><td>effect level</td><td colspan="2">micro</td><td colspan="2">macro</td></tr>
<tr><td>compensation</td><td>negative</td><td colspan="2">partially</td><td>backfire</td></tr>
<tr><td>period</td><td colspan="2">short-term</td><td colspan="2">long-term</td></tr>
<tr><td>assessment</td><td colspan="2">mathematical</td><td colspan="2">organizational (corporate objectives)</td></tr>
</table>

In summary, RECC are unrealized savings of an organizational resource caused by efficiency improvements, which arise from the migration to CC services as well as from the (unintended) effects on (other) organizational resources. Since the case study targets a SaaS solution and no distinction in existing literature on RECC could be identified, no further differentiation of RECC concerning service and deployment models could be made. Regarding the assessment of a RECC, a mathematical and an organizational viewpoint need to be distinguished. For example, it may be the case that a mathematically calculated partial compensation, thus a partial rebound effect, does not, only partially or disproportionately affect the corporate objectives. However, a mathematically calculated compensation can be negative (realization of more savings than expected), which can in turn lead to a disproportionate effect on the organizational goals, e.g., if the overall goal of an organization was a complete reinvestment or growth or to retain jobs.

4.2 Identification of Affected Resources

Since a REGE describes the efficiency improvement with respect to resources such as energy or the saving of these, organizational resources have been derived for the discussion of RECC. Basic IT-related resources, which are typically used in an organization, have been identified by means of a classification of accounts for industrial enterprises [43]. Due to the fact that this classification is directed towards the documentation and structuring of organizations' assets, it is well suited for our purpose. We concentrated on those basic resources that can directly or indirectly be influenced by changes in IT. For example, the outsourcing of servers might have a definable influence on the expenses for (external) maintenance; however, there are other effects, e.g., on expenses for advertising, that are difficult to assess. In order to expand the identified basic resources by special resources, that are also affected by CC, the three CC service models – Infrastructure (IaaS), Platform (PaaS) and Software as a Service (SaaS) – have been investigated [40]. Additionally, we held workshops with IT-management and conducted two expert interviews in May 2014 during the case study to identify potentially affected resources. Furthermore, the transcripts and the company's documentation (e.g., IT landscape, infrastructure plans, balance sheets) were analyzed qualitatively via inductive category development. Finally, all results have been aggregated (cf. Table 3).

Table 3. Organizational resources that are potentially (directly or indirectly) affected by changes in IT (in the short- or long-term)

Aggregated Category	**Organizational Resources**
IT related	employees, IT know-how, space, server software, energy, repair material, internal data and information, maintenance
Hardware & Systems	backup and recovery, server hardware, adjacent assistive systems, infrastructure and connection, air conditioning, devices and clients
General	money, customers and reputation, suppliers and partners, non-IT know-how

The categories and underlying organizational resources depicted in Table 3 are directly or indirectly affected by changes in IT, e.g., resulting from a possible cloudsourcing decision, and are therefore subject to potential RECC. For example, one expert states that migrating to the cloud would "save maintenance workload and costs". The major resource that is expected by the experts to be directly affected is money ("outsourcing to the cloud is way cheaper in comparison to an in-house solution"). If the expectation or intention regarding an organizational resource, in this case, to save money or maintenance, cannot or only partially be realized by an adoption of cloud services, this would lead to a rebound effect. Furthermore, depending on the organizational goals, resource saving potentials might be evaluated negatively from an organizational point of view. For example, the saving potential of workforce or rather employees contradicts the overall social goal of NOZ Medien to provide stability for employees and to safeguard jobs. Therefore, the experts at NOZ Medien explain that affected employees would be entrusted with other responsibilities in order to retain jobs and to prevent the loss of valuable IT know-how.

On the foundation of the organizational resources presented in Table 3 and specifically for the present case study at NOZ Medien, expected effects on organizational resources and goals resulting from a cloudsourcing decision were identified. In the case study, the existing email system is to be replaced by a user- or better to say mailbox-based service from a CC provider (SaaS). Therefore, the expected effects have only been derived and evaluated a priori. First, the corporate objectives at NOZ Medien were identified in an interview with the management and mapped against the organizational resources (e.g., the economic factor "the highest profit possible" is connected to the general organizational resource "money"). Second, expected effects on organizational resources were identified and evaluated together with the experts in workshops. The resulting analysis can be found in Table 4. As a result of the case study, effects have to be assessed depending on the organizational goal, as elucidated by the resource "employees".

Table 4. Expected effects of cloudsourcing on organizational resources at NOZ Medien

organizational goals	organizational resource (goal/expected effect)
"highest profit possible"	• money (+/+)
"continued growth of the company" & "provide a perspective and future for Employees" & "provide stability for employees and safeguard jobs"	• employees (+/-)
"efficiency and sensible use of resources"	• hardware & systems (-/-) • server software (-/-) • employees (-/-) • space (+/+) • energy (-/-) • maintenance (-/-) • money (+/+) • IT know-how (o/-)

5 Discussion and Conclusion

Potential RECC can arise in any area of an organization in which outsourcing into the cloud results in resource saving potentials. In contrast to the traditional view on rebound effects, which generally focuses on a narrow energy saving perspective [7–9], we expanded the focus and added an organizational perspective [41], in which the adoption process of a cloud service takes place. In this context, the intentions or expectations of organizations can lead to different assessments of rebound effects from a mathematical (compensation of the savings) in comparison to an organizational (compliance with the corporate objectives) perspective. Furthermore, rebound effects in CC do not necessarily arise from energy savings. Rather, the effects can be the results of savings of any organizational resource, which is subject to expected efficiency improvements in a cloudsourcing scenario (cf. RQ2).

The framework consisting of a REGE/RECC definition, a conceptual model, and a morphological analysis of RECC provides a foundation to identify, categorize and understand potential rebound effects in cloud computing (cf. RQ1). Furthermore, our results confirm the complex dependencies that are not always identifiable at first glance, which can involve many possible causes and manifestations of RECC. Consequently, there is an urgent need to research the existence and impact of RECC. In line with Gossart (2014), we argue that future research should focus on rebound effects in the ICT context in order to understand and mitigate the underlying causalities [4]. This broadened understanding can be very helpful when exploring the decision-making process as well as the involved influencing and influenced factors. Consequently, future research should also comprise the investigation of RECC in the short- as well as long-term. In order to accomplish this requirement, we provided a fundamental framework. For practice, the awareness of RECC can facilitate to (at least approximately) assess the impact of rebound effects even prior to outsourcing, since various organizational resources are significantly affected by a cloudsourcing decision. The awareness of factors surrounding such a decision is vital for making a sustainable judgement.

As any research endeavor, our findings also need to be viewed in the light of some limitations. First and foremost, the decision process for resource allocation underlying a rebound effect in an organization differs – at least to some extent – from other research areas of rebound effects cited. Unlike what is the case in, e.g., natural sciences, the decisions in organizations cannot always be fully predicted and do not necessarily follow general principles. Organizational decisions are mostly based on individual or community decisions and are limited by given budgets [6]. To consider this, these organizational goals were taken into account when developing the framework in accordance to Hilty (2008), who further differentiates between rebound effect perspectives of private households, enterprises and states [41].

The overall target of the paper is to present the results obtained from the systematic literature review as well as the case study.[1] Although case studies are considered to be an appropriate method to capture the richness of organizational contexts – in this case

[1] The case documentation file (cf. Figure 1) will be provided to interested readers.

of a German media company – the conclusions drawn cannot be unreservedly generalized [23]. Neither do we assert that the understanding of RECC would substitute a decision-making process for any given "cloudsourcing" project. Instead, the intention of our research is to arouse awareness that unintended rebound effects potentially exist in CC, which can affect organizational resources. By generalizing our results in the forms of definitions, a conceptual model as well as a morphological analysis of RECC, we already mitigate this limitation to some extent. Moreover, since the focus of the single case study was put on outsourcing an email system, further results may arise when investigating the outsourcing of other systems into the cloud. Therefore, rebound effects in different systems, application areas and organizations in the context of cloud computing or else in other ICT contexts are subject to future research. Especially regarding the various cloud service or deployment models, potential differences and unique characteristics concerning rebound effects need to be investigated.

Moreover, since NOZ Medien at the point of transition or abortion decided not to outsource the email system into the cloud, we have not been able to verify potential rebound effects by means of direct observation. Our study rather presents implications of RECC, however, they have only been derived a priori. Hence, our conceptual framework requires further validation and evaluation, for example via a multi case setting, to measure occurring RECC. Multiple case study setups allow for the testing of theories, whereas single case setups are preferable to identify and describe previously unchallenged or emerging phenomena, as executed in this study [22]. Furthermore, potential single case biases could be eliminated and multiple CC service models and the variety of factors influencing RECC could be investigated. To this point, our work provides the basis for future quantitative measurement of RECC. All in all, in order to improve the understanding of CC and all surrounding factors, we encourage researchers to extend the focus on technical advancements to take other influencing and influenced factors into account.

Acknowledgement

The authors thank all involved parties at NOZ Medien, especially Mr. Krum, Mr. Gödde, Mr. Gerdes and Mr. Granitza for their valuable insights, help and substantive support during the research process. Furthermore, the authors thank Mrs. Imhorst as well as the reviewers for their constructive feedback.

Abstract. Platform-as-a-service (PaaS) providers are increasingly engaged in nurturing vibrant ecosystems of independent software vendors (ISVs) by offering standardized services. However, cloud ecosystems have also been known for its fluctuation and high rates of desertion. A currently under-researched explanation for this low traction and high rates of fluctuation may lie in the fact that ISVs face considerable costs when joining and acting on a specific platform. If these costs are too high, they can rapidly outweigh the additional value generated by the ecosystem. This study therefore explains the role of different configurations of cost-inducing factors and resource benefits in influencing an ISV´s platform loyalty. By using a configurational approach based on fuzzy-set qualitative comparative analysis (FsQCA), we display complex interactional effects of cost and benefits as causal conditions on ISVs' intention to stay in the ecosystem and thus provide valuable insights for both practice as well as theory on platform ecosystems.

Keywords: PaaS, cloud, ISV, transaction costs, FsQCA

1 Introduction

The ubiquitous provision of on-demand computing resources via the internet sets cloud computing in the spotlight of practitioners and researchers [1]. The fastest growing segment of this on-demand service delivery phenomenon is the platform-as-a-service market (PaaS). PaaS refers to an on-demand programming environment for developers of software applications, which promises to make software development more efficient [2]. IT industry leaders like Amazon Web Service (AWS) or Salesforce provide a scalable cloud platform, i.e. an expandable code base, which offers a large amount of independent third-party developers' important resources such as computing power and software databases to enable the development of applications that extend the basic functionality of the platform [3]. Such applications can be vice versa offered as software-as-a-service (SaaS) on the platform provider´s marketplace. By the numbers, Salesforce´s cloud infrastructure consists of approximately 5.5 million apps and more than 4 billion transactions a day.

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Dellermann, D.; Jud, C.; Reck, F. (2017): Understanding Platform Loyalty in the Cloud: A Configurational View on ISV´s Costs and Benefits, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 514-528

This new logic of software development in the cloud has amplified the need for innovation from an ecosystem of third-party developers, called independent software vendors (ISVs) [4]. The focus of a PaaS provider is therefore to attract ISVs to join the ecosystem and facilitate innovation as well as the generation of complementary value propositions by offering standardized cloud services to an anonymous number of ISVs [5]. However, even famous examples like Microsoft´s cloud platform Azure show that it remains challenging to gain solid traction among ISVs. Furthermore, platform ecosystems have also been known for their fluctuation and high rates of desertion [6].

A currently under-researched explanation for disloyal behavior may lie in the fact that ISVs face considerable costs when joining and acting on a specific cloud platform. If these costs are too high, they can rapidly outweigh the additional value generated by the PaaS ecosystem [7] and induce ISVs' disloyal behavior and in its strongest manifestation the abandonment of a platform. Prior studies have mainly focused on the motivational factors and the relational rents that initially motivate ISVs to join an ecosystem [8, 9]. However, the costs associated with this choice and how particularly the interplay of the benefits and costs influence the decision to stay in a PaaS ecosystem has yet to receive research attention.

Previous studies that addressed this question were primarily focusing on a technological perspective and solely on the coordination costs related to platform dependencies [6] or the lock-in effects of cloud platforms. However, to provide a more holistic analysis of costs which affect sustainable traction among ISVs, also economic dimensions need to be included as entering service partnerships with a PaaS provider might induce a cost disadvantage relative to vertically integrated structures. However, managers are willing to accept certain costs if they expect superior returns and benefits [9,10].

We therefore propose that the interplay of transaction cost inducing hazards and resource-based benefits shape the decision of an ISV to stay loyal to a PaaS provider. As traditional regression-based net effect models are not capable to capture the complex interplay of different cost and benefit dimensions in shaping PaaS-related decision making, we apply configurational theory as theoretical lens and qualitative comparative analysis (QCA) as a way of analysis for understanding the complexities of PaaS ecosystems [11] and therefore address the following research question: *Which configurations of cost-inducing hazards and resource-based benefits maximize ISVs´ platform loyalty?*

To answer these questions, we analyze data from a survey of 42 ISVs on five leading cloud platforms by applying fuzzy set Qualitative Comparative Analysis (FsQCA) [12]. This case-oriented method enables us to analyze asymmetric and complex causal effects by extracting configurations that consistently lead to the platform loyalty [11, 13]. Our results reveal the role of cost-inducing hazards and resource benefits in influencing the loyalty of ISVs on certain cloud platforms. We therefore show that PaaS provider should balance such cost and benefit dimensions to gain solid traction among ISV and build sustainable ecosystems around their platform.

2 Conceptual Background

2.1. Platform Loyalty

A high number of complementary apps are central to the success of platform ecosystems [5]. Hence, PaaS providers are increasingly engaged in building vibrant ecosystems of ISVs around their platform [14]. For the long-term success and stability of a platform it is not only crucial to attract a large base of ISVs that produce high-quality applications but also to keep them loyal to the respective platform [15]. However, many platforms are plagued by high rates of platform desertion as ISVs stop developing applications [6], which represents the strongest manifestation of disloyalty. Further representations of disloyal behavior of ISVs might include factors like for instance showing reluctance to invest in the relation, stop curating existing applications on a specific platform or start multihoming [16]. Especially when ISVs change to rival platforms, the spillover of knowledge to competitors is a common threat to the PaaS provider that results from disloyal behavior [5]. Loyal behavior of a platform´s ISVs is a critical performance indicator. Furthermore, the ability of a PaaS provider to retain ISVs within their ecosystem is vital for success. Although previous work on developers´ loyalty on a platform in the B2C market also uses alternative explanations of platform loyalty [e.g. 17], we attempt to take an economic exchange lens, as such a perspective is especially important in the case of B2B applications. In this context, a PaaS provider should balance the effort required by the ISV to continue developing an application on the platform (i.e. cost-inducing factors) and the resource benefits offered to the ISV to stabilize the ecosystem and guarantee sustainability.

2.2 A Configurational Perspective on Platform-related Costs and Benefits

One core assumption of our study is that the influence of single factors on a specific outcome depends on the overall configuration of these factors rather than the net effects of each individual factor. Thereby, we abstain from conventional, rather reductionist variance models. Taking a configurational perspective on the conditions leading to platform loyalty is suitable for two reasons.

On the one hand, configurational approaches treat whole sets of elements as predictors rather than single variables [11]. These sets simultaneously explain the outcome of interest. Thus, one major advantage of configurational theory is its ability to explain synergetic and complementary effects [12]. This resonates well with current theoretical perspectives on the complexity of ecosystems as well as platform decisions [10]. For instance, ISVs are willing to accept cost if the benefits outweigh such. Hence, each variable in isolation may have a different effect on a decision than in combination with other elements.

On the other hand, configurations can display asymmetric relations between conditional and outcome variables rather than just symmetric ones [11]. So, configurational theory implies equifinality between different conditions and configurations [12]. Consequently, these conditions may either be sufficient or necessary causes of a dependent variable. According to both organizational [13] and information systems research [18] such notions possess superior accordance to organizational realities which are to a large part bounded to the larger context. As El-Sawy et al. [11] point out, this perspective thus particularly fits to explaining the ISV's decision to continue developing on a certain platform.

2.3. Research Framework

Fig. 1 illustrates the framework of our research. The framework comprises two facets of causal conditions for an ISV´s loyalty on a cloud platform. These two dimensions are theoretically grounded in TCT and the resource-based view. It therefore proposes that from the perspective of ISVs the configuration of four cost-inducing hazards (i.e. platform specificity; behavioral, market and technological uncertainty) and three resource benefits (i.e. technological, social and commercial capital) influences the intention of software vendors to stay in a certain PaaS arrangement.

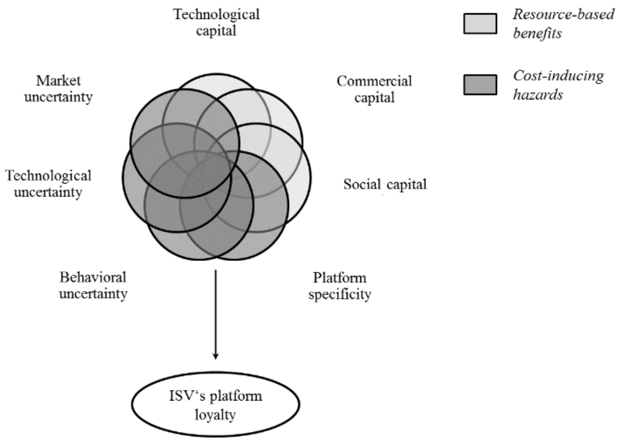

Figure 1. Research framework

The probably most prominent theoretical approach to explain boundary decisions associated with interfirm exchange (e.g. outsourcing decisions) is Transaction Cost Theory (TCT) [19 - 21]. TCT defines the costs of economic exchange (i.e. search and information costs; investments in social relations; opportunity costs) within the boundaries of a specific system (i.e. market or hierarchies) [22]. From TCT´s perspective developing applications on cloud platforms therefore might induce a cost disadvantage relative to vertically integrated structures of software development [7]. In the PaaS context, the required transactions for using an on-demand programming environment to develop software applications always create costs. According to TCT such costs mainly arise from two cost-inducing hazards: uncertainty and its sub-dimensions as well as specificity [23]. We therefore use these dimensions as cost predictors for platform loyalty.

Platform specificity: The specificity of a certain cloud platform represents the first hazard for ISVs. Platform specificity refers to the software migration between different PaaS providers [24] as well as the value of ISV´s assets within alternative PaaS relations [23]. For instance, cloud platforms require investments in relation-specific knowledge to participate in the ecosystem and capitalize from the access to complementary resources [20]. Apart from requirements to adapt software applications that are locked-in by specific APIs or for instance proprietary data storage implementations, high investments requirements create dependencies with the PaaS provider. This increases switching costs making it difficult for the ISVs to leave the actual cloud ecosystem and move to another platform [16].

Uncertainty represents the second cost-inducing hazard for ISVs. This TCT dimension is defined as the absence of complete information, which in turn leads to an ISV's inability to predict its surroundings accurately [25]. The uncertainty dimension can be subdivided in the volatility of market conditions (e.g. market, demand, and competitive environment), technological requirements (e.g. technological volatility) as well as the behavior (e.g. opportunism) of the PaaS provider [23].

Market uncertainty: Market conditions are crucial contextual conditions for ISVs. By developing complementary apps upon a platform, software vendors typically attempt to occupy a specific niche market [13]. Unpredictable user demand, substitute software products or changes in the competitive environment therefore increase the costs of ISVs.

Technological uncertainty: The second dimension of uncertainty in PaaS relations spans the difficulties to accurately predict the technological requirements. Particularly in the context of cloud platforms the quality of the service offering is hard to forecast. Furthermore, technological complexity and changes of specifications like for instance interfaces are frequently the most significant sources of uncertainty [7].

Behavioral uncertainty: Contrary to technological or market uncertainty, which is not directly related to the PaaS provider, behavioral uncertainty arises from the complexity of service performance evaluation. The platform provider for instance might follow its individual and act opportunistically [19]. ISVs therefore need to monitor the PaaS provider to detect opportunistic behavior like for instance exploiting resources or poaching in the ISV's niche [9].

From a resource-based perspective however, an ecosystem offers relational rents by providing the access to resources [26]. When ISVs decide to join an ecosystem, advantages or benefits need to be gained to make the commitment to a platform attractive [27, 28]. There are various forms of motives which drive ISVs to join and stay in an ecosystem. Most of them are related to getting access to a certain resource as technical or commercial resources. Kude et al. [9] grouped motives into three categories: technological capital, commercial capital and social capital.

Technological capital: By technological benefits we refer to access to technological resources that an ISV gains by joining a cloud ecosystem. These are for instance the PaaS provider's ability to supply integrated systems and its capability to innovate these systems [29]. First, the benefits from integrated systems arise for instance if the products and solutions offered by the ISVs offer only a small solution-space. Hence, this single solution gains value through the interoperability with a larger system of modules. Cloud ecosystems offer various technological resources like Applications Programming Interfaces (API), Software Development Kits (SDK) or Integrated Development Environments (IDE) [30]. Such resources allow the ISV to individually develop extending applications. Another benefit from the technological point of view is the availability of standards and technologies which are offered or hosted by the platform [9].

Commercial capital: Commercial capital refers to the PaaS provider´s or the whole cloud ecosystem´s marketing capabilities as well as its service and distribution networks. Especially, if ISVs have limited internal capabilities to heavily invest in marketing activities and to set up distribution networks, the access to such forms of commercial capital is crucial [31]. When partnering with huge platform providers like for instance Salesforce, ISVs can benefit from marketing and distribution capabilities to increase the awareness among many potential users by providing access to broad markets [32] or leverage highly visible cloud ecosystems to gain attention for own products. Distribution channels are for example AppStores. This kind of phenomenon also can be found in the domain of Enterprise Software where SAP or Microsoft offer respective features on their platforms. Using the possibilities of AppStores, ISVs can offer their solutions to end-users without the need to set up own distribution channels.

Social capital: Social capital refers to the PaaS provider´s reputation that is often aligned with the brand of this particular firm [32]. As ISVs are frequently unknown due to the limited reputation, customers might suspect the quality as well as reliability of their value propositions services. Nevertheless, such trustworthiness is a crucial topic in the software industry since the quality of SaaS offerings as well as the knowledge and experience of the vendor is difficult to assess a priori [9]. If a platform has reputation, e.g. AWS's reputation to produce and sell high-class products, ISVs may benefit from this reputation. A reputation can lead among others to a premium in prices. Furthermore, social benefits include the use of communities where ISVs can exchange information with other ISVs or ask for support in case of problems during the development of applications [17].

3 Research Methodology

3.1 Fuzzy-set QCA

Data analysis was done via FsQCA. This set-theoretic approach emphasizes the effects of the whole rather than its pieces. Hence, the method explicitly acknowledges that research cases are multidimensional. FsQCA thereby draws on measures of consistency and coverage to evaluate the predictive power of single configurations towards the outcome of interest. The first indicator, consistency, is analogous to correlation estimates in statistical methods. This value's meaning is the degree to which cases of a certain configuration agree in leading to a given outcome [12]. The second indicator, coverage, displays the degree to which a configuration accounts for the instances of an outcome. Hence, these values are analogous to R-square in regression analysis. FsQCA detects configurations with adequate consistency and coverage values in three steps which are: a) calibration, b) construction of truth tables, and c) truth table analysis [12].

Calibration represents the first step. This step is necessary because set-theoretic analysis is based on the degree of memberships of cases in a certain set of conditions (here, e.g. membership in the group of firms with high social capital). Thus, to obtain such so called fuzzy set membership scores all construct measures must be transformed to a scale ranging between 0 and 1 with 0 indicating full non-membership, 1 indicating full membership and 0.5 representing the crossover point [33]. Analogous to the calibration approach by Fiss [13], the observed maximum and minimum values within our sample for all variables specify full membership and full non-membership. The calculated scale midpoint (median of observed values) is the cross-over point. The fuzzy set memberships scores for each case were calculated via the calibration procedure in the FsQCA software program (version 2.5 [34]), with the three above mentioned values as calibration benchmarks.

The *construction and refinement of truth tables* represents the second step of analysis. In this context, a truth table is a matrix of all possible configurations of predictor conditions (in our case, 32 rows; in general, 2k, where k is the number of conditions observed [12]). Subsequently, the requirements of FsQCA demand a refinement of this truth table. The refinement procedure draws on two criteria to asses each possible configuration: frequency and consistency. The frequency criterion captures if and how many empirical cases exist which have a membership score of more than 0.5 and thus display membership in the configuration of interest more than non-membership. The standard threshold for frequency in medium-sized samples is 1 meaning that every configuration that exists in the empirical dataset will be part of the analysis [33]. The consistency criterion captures if a truth table row consistently leads to an outcome. This value should outreach .8, at least [12]. We choose a rather conservative threshold of .9 within this work.

In the third and final step, FsQCA analyzes the refined truth tables based on Boolean algebra, respectively counterfactual analysis, to be more specific. This step of analysis draws on the Quine-McCluskey algorithm which strips away factors that are inconsistently present or absent concerning the outcome [13]. By doing so, the algorithm excludes conditions that are no essential part of a sufficient configuration for the respective outcome. The result of this procedure encompasses two distinct solutions: the parsimonious solution and the intermediate solution. In the parsimonious solution, all simplifying assumptions derived from counterfactuals are included. In contrast, the intermediate solution only includes simplifying assumptions based on easy counterfactuals. Because of this dual algorithm, the intermediate solution necessarily represents a subset of the parsimonious solution, so that all conditions appearing in the parsimonious solution appear in the intermediate solution but not vice versa [12]. If a condition appears in the parsimonious solution, it passed a more thorough reduction procedure. In other words, the data provides particularly strong empirical evidence for the causality in this case. This condition thus displays a causal core of a configuration, while the periphery includes all conditions present in the intermediate solution [13].

3.2 Data Collection and Sample Description

Our sample consists of 750 firms equally distributed and randomly drawn among the ISVs of five market leading cloud platforms (i.e. Microsoft Azure, Oracle Cloud Platform, Amazon Web Services, SAP HANA, and Salesforce Force.com). There were two reasons for choosing exactly these platforms. First, all are instituted by established players and have shown an adequate amount of traction of their ISVs. Therefore, they can provide sufficient benefits for ISVs. Second, due to their high level of power imbalance they are perfectly suited for analyzing asymmetric third-party relationship and the corresponding costs related to that imbalance.

A web-crawling approach randomly collected sales contact data from the platforms´ app stores. This approach is congruent with previous surveys of third-party innovators [30]. Recipients were asked to forward the questionnaire to high-level executives (C-level; IT executives) as key informants who completed an online questionnaire containing the constructs of interest. We furthermore ensured confidentiality and anonymity to the participants.

In total, we obtained N=42 valid cases in which the data was complete. The resulting response rate of 5.6% is common in such settings. Non-response bias might still be an issue, so we compared responses of early and late respondents [35]. T-tests not reveal any significant differences ($p > 0.05$), hence we are confident to reject the presence of non-response bias in our study.

ISVs in our study were distributed among all five platforms (Microsoft Azure: 9; Oracle Cloud Platform: 4; Amazon Web Services: 2; SAP HANA: 9; and Salesforce Force.com: 18). Most of our respondents were high-level executives (C-level: 71.4%; BU executives: 19%). Participants in our sample indicated that they are highly experience in this topic (>10 years: 83.3%) and were experts in the context of our survey (95.2%).

3.3 Measurement Validation

To ensure validity we applied measures that were already developed and validated in prior studies in TCT [36 - 38]. For the benefit dimension, we developed scales based on the constructs of [9]. When necessary, we adapted scales slightly to the platform context. All items were rated on seven-point Likert scales. Through a pilot study with managers in the software industry, we pretested and refined our measurement instrument to ensure that each of them was clearly and unambiguously phrased.

Construct	Number of Items	MEAN	Standard Deviation	Loadings Range	Cronbach's Alpha	Composite Reliability	AVE
Outcome Variable							
Platform loyalty Adapted from [17]	3	5.65	1.36	.974	.941	.974	.949
Causal Conditions							
Platform specificity Adapted from [36]	4	4.99	1.41	.725-.931	.861	.907	.711
Market uncertainty Adapted from [37, 38]	4	4.61	1.62	.856-.952	.916	.941	.799
Technological uncertainty Adapted from [37, 38]	4	3.83	1.69	.785-.963	.925	.942	.804
Behavioral uncertainty Adapted from [37]	4	3.77	1.65	.848-.963	.894	.919	.743
Technological capital Following [9]	3	5.99	.97	.728-.954	.855	.900	.774
Commercial capital Following [9]	3	5.61	1.40	.796-.911	.834	.910	.751
Social capital Following [9]	3	5,62	1.36	.784-.941	.852	.912	.776

Table 1. Construct measures

We assessed reliability, convergent validity (see Table 1) to ensure that all values exceed the recommended threshold, supporting the notion of scale reliability. Furthermore, the AVE's square root exceed the shared variance between a single construct and all other constructs within model, reflecting discriminant validity [39]

We additionally conducted Harman's one-factor test [40] to assess for common method bias. The unrotated factor solution resulted in 5 factors explaining 80% of the variance (31 percent was the largest variance explained by one factor). Thus, common method bias is unlikely to be a problem.

4 Results

The results of the FsQCA reveal several patterns that explain how different configurations of cost-inducing hazards and resource-based benefits result in high or low levels of ISV´s loyalty. High levels of loyalty indicate a high intention to stay in the ecosystem while low loyalty indicates a high intention to leave. We extracted this pattern by comparing structures of different configurations [13]. Figure 2 shows the configurations resulting from FsQCA. Black circles indicate the presence of a condition, crossed-out circles indicate the absence of a condition, large circles indicate core condition, and small circles indicate peripheral conditions. Blank spaces indicate a condition may be either present or absent.

Figure 2. Solutions for high and low platform loyalty

4.1 Configurations for High Platform Loyalty

We identified five different configurations that result in a high intention of the ISV to stay, which underlines the equifinality of achieving a certain outcome. Consistency for configurations ranges from 0.91 to 0.99 representing the degree to which these configurations of causal conditions result in high platform loyalty. Raw coverage, which describes the importance of a certain configuration in explaining the intended outcome, range from 0.23 to 0.47. The overall solution consistency shows these five solutions can consistently result in high platform loyalty with 89%. The overall solution coverage indicates that the extent to which these seven configurations cover high likelihood of risk cases is 76%. We compared the five configurations that result in high platform loyalty to extract four strong patterns:

- **I.** In platform ecosystems that offer high benefits and low levels of behavioral and environmental uncertainty, ISVs have a high level of platform loyalty no matter if the amount of investment in platform-specific resources is high or low (1a).
- **II.** Technological capital is a necessary condition for ISVs to stay in an ecosystem. Its presence is required to create platform loyalty (1a,b,c,d,e).
- **III.** ISVs are willing to accept all forms of uncertainty as well to heavily invest in platform-specific resources when all three benefits are prevalent (1b,c).
- **IV.** If the ecosystem does not offer social and commercial capital to the ISV, the combination of technological capital and technological stability is required (1d,e).

4.2 Configurations for Low Platform Loyalty

Furthermore, we identified five distinctive configurations that exceed minimum consistency threshold and result in a low level of platform loyalty. Consistency for configurations ranges from 0.94 to 0.99. Raw coverage ranges from 0.32 to 0.46. These five solutions can consistently result in low platform loyalty with 94% and cover 69% of cases with this outcome. Comparing the five configurations reveals three further important patterns:

- **V.** In cases where technological uncertainty is high and ISVs are not provided with sufficient technological capital by the platform, their loyalty diminishes (1)
- **VI.** Especially when behavioral uncertainty is high and commercial capital is not provided by the ecosystem the ISVs´ loyalty to the ecosystem suffers (2; 3a,b,c).
- **VII.** Although technological capital is present, high behavioral uncertainty, market uncertainty and platform-specificity outweigh technological benefits resulting in a low level of platform loyalty (2).

4.3. The Role of Cost-inducing Hazards and Resource-based Benefits in Maximizing Platform Loyalty

Out of these seven patterns derived from the comparison of configurations that lead to high and low platform loyalty, we can reveal holistic insights of the interplay of cost-inducing factors and resource benefits in influencing the intention of a third-party developer to stay in the ecosystem or to leave it. Based on the commonalities among the pattern we identified three holistic findings to explain the loyalty of complementors.

First, technological capital is a necessary condition for ensuring platform loyalty among the ISV's. In all our sample cases, which displayed high levels of loyalty, the ISV perceived access to valuable technological resources which help it provide and innovate its systems and software products. The results strongly indicate that without the superiority of the technological capital provided via the ecosystem, gaining strong traction among ISVs is hardly likely. Thus, platform owners must ensure ISV's access to technological resources to ensure their loyalty.

Second, technological still does not suffice for predicting platform loyalty. In situations of high behavioral uncertainty, volatile market environments, highly specific needs of platform-related investments and the absence of further benefits like commercial and social capital, ISV may display low levels of loyalty even if they can access technological capital. Hence, the presence of technological capital is a necessary but not sufficient condition for high levels of platform loyalty.

Still, combinations of technological capital with other cost- or benefit-related factors prove to be collectively sufficient [33] for ISV's loyalty. Excluding the rather trivial solution 1a covering cases in which ISV perceiving high benefits with low hazards from this discussion, the results demonstrate two main paths to high platform loyalty (Patterns III and IV). One the one hand, the absence of technological uncertainty in combination with technological capital is sufficient for ISV's loyalty (solutions 1d,e). This finding highlights the importance of the appropriation of resources over access to them [41]. If technological specifications in the platform remain stable, profiting from accessed technological capital is much easier so that ISVs can obtain value from the ecosystem. On the other hand, in situations of high uncertainty and highly specific investments to the platform, technological capital does not suffice alone (solutions 1b,c). In these cases, ISV's loyalty is only secured, if they are also provided with commercial and social capital. Hence, in situations where profit from technological capital is not guaranteed, ISVs want further benefits from the ecosystem. As there are circumstances under which technological capital both alone and in combination with the other two benefits leads to high loyalty, these two paths are equifinal.

Third, in contrast to technological capital, commercial and social capital seem to be of different importance. The solution table for low platform loyalty demonstrates that for low levels of loyalty, commercial and social capital are absent. As a converse argument, the presence of both commercial and social capital is a sufficient condition for high platform loyalty. Hence, commercial and social capital can enhance technological capitals effects for platform loyalty but seem to be rather substitutable add-ons in the eyes of ISVs.

Fourth and finally, while cost-inducing hazards play a role in predicting ISV's loyalty towards an ecosystem, there is none which cannot be overcome by the provision of technological, commercial and social capital. Behavioral uncertainty seems to play a quite important role. In four of the five paths leading to low levels of loyalty, the ISV sees the platform owner as a key source of risk. This result highlights the outstanding importance of the platform owner in ensuring ISVs traction to the ecosystem. The other three hazards represent rather peripheral conditions which are partially interchangeable concerning their effect on platform loyalty. The permutations of the main solutions for high (1a,b,c,d,e) and low platform loyalty (3a,b,c) stem from different merely inconsistent combinations of these. So, these factors play rather minor roles in causally explaining platform loyalty.

5 Discussion and Conclusion

Our study describes the interplay of cost-inducing hazards and resource benefits of PaaS offerings in explaining platform loyalty. By comparing different configurations that result in high and low platform loyalty, we identified seven patterns that describe the role of cost-inducing hazards and resource benefits in shaping ISVs´ platform loyalty. By drawing on configurational theory and applying FsQCA we can provide a much more fine-grained perspective on the complex causality associated with our dependent variable, platform loyalty. In doing so, we contribute to theory on platform ecosystems and ISVs loyalty in various ways.

First, we introduce the concept of hazards related to transaction costs to this phenomenon and evaluate their role in weakening or strengthening ISVs loyalty. Thereby, we find that especially behavioral uncertainty serves as a key cause of low levels of loyalty while the other hazards play a rather peripheral role. Still, also behavioral uncertainty is accompanied by the absence of at least two of the resource benefits, so that only in combination with them behavioral uncertainty is a sufficient cause of disloyalty. These two insights advance theories on platform loyalty by a) outlining the platform owner's behavior as a key driver of platform-related costs in addition to previously identified cost drivers such as e.g. the management of technological dependencies [6] and b) indicating that while also highly loyal ISVs may face high levels of hazard and consequentially high transaction costs access to valuable resources outweighs these costs. Hence, our findings support a notion of ISVs loyalty to be driven by opportunity-seeking rather than risk-avoiding motives. This gives hints that the issue ISVs loyalty to platform ecosystems might hold important contextual differences compared to traditional business partnerships like for instance between outsourcing contractors [20, 21] or service providers and customers [42]. Further research might specify these differences and examine why these exist.

Second, drawing on configurational theory and applying FsQCA allows us to capture asymmetrical causal relationships and thus shed light on how the effects of distinct resource-based benefits on ISVs platform loyalty differ. Thereby, we provide a more differentiated view than previous studies [e.g. 3, 8, 9, 42] on how resource benefits motivate platform loyalty. Our analysis reveals that technological capital is a necessary condition for high loyalty, while commercial and social capital are collectively sufficient conditions. In other words, platform owners do not remain loyal if they do not perceive clear benefits on the technology side but were loyal in all the cases within our sample where all technological, commercial and social capital were high. These findings indicate a preference hierarchy of ISV. They may join and stay on the platform mainly with the goal of enhancing their own technological capabilities by the architectural features the software platform offers. If the platform's technological features are stable, the ISV will stay loyal even if cost-inducing hazards are high. Commercial and social capital are rather valued if such stability is not given and may partially compensate in this case. This fact challenges the findings of previous studies that were focusing on network effects as the main (and sometimes only) driver of platform traction [43, 44] We suppose future research on ecosystems to analyze why ISVs are rather technology-driven. Furthermore, it would be interesting to investigate if these perceptions and preferences match with value opportunities in ecosystems or rather indicate strategical "blind spots" of the ISVs which hinder them from benefiting more from commercial resources and network linkages gained through platform membership.

On the practical side, implications of our research show the impact of different influencing factors on if ISVs remain on a platform or leave. This is particularly important for offering cloud services like PaaS, which are rather addressing a mass market then providing customized service value proposition. We therefore provide insights on how such standardized PaaS offerings should balance cost-inducing hazards and benefits to gain solid traction among a huge number of anonymous ISVs. The different configurations derived from FsQCA may serve as a blueprint for PaaS providers in designing their ecosystems of third-party software development.

However, this work is not without limitations. Although FsQCA is particularly suitable for medium sample size (n=5-50) an increased sample size probably cloud enhance the insights and generalizability of our results. Second, we did not include platform characteristics in the analysis of our empirical data so far. However, the characteristics and the explicit value proposition of the single PaaS providers vary. For instance, SAP HANA´s in memory data base is a very specific service offering compared to the other platforms in our sample. We therefore intend to include such platform characteristics in the further progress of our study. Third, this study includes a potential selection bias as the respondents of the survey that are still on the platform might over represent loyal ISVs. To proceed this study, attempt should therefore point towards gathering data from ISVs, who already left the platform, to gain more robust results.

Abstract. E-commerce based companies rely on the effective use of the information systems used to support their processes. Accordingly, managers place a great emphasis on the success of projects to introduce such systems. However, research increasingly suggests that project success may not be as objective as one would assume or hope. Quite contrary, as our work will show, project success is often constructed by the stakeholders involved in the project. Extending prior research, we investigate how different groups of stakeholders construct their own perception of project success and how these different perceptions influence each other. Through our work, we provide management with insights into threats to a reliable project management approach for critical IS projects and identify a few major drivers that need to be accounted for to make sure that such critical projects really are successful.

Keywords: Renewal Project, Enterprise System, Project Success, Case Study, Subjectivity of Success

1 Introduction

Issues with backend enterprise systems (ES) can have a critical impact on business performance. In particular, e-commerce based companies suffer from an ineffective usage of backend ES and might struggle to cope with competition. A prominent example for the effect of such issues on once prosperous businesses is the Otto Group, a large German distance retailer [1]. Due to under-investments, the technology base of the Otto Group had become outdated and scattered. For instance, 130 different ES were used to support the frontend services the customers interacted with. This led to complicated and delayed technological changes and made internal processes inefficient. In turn, the inefficient processes and the high complexity of the backend ES affected the number of available products online and the lapse rate at Otto Group. In sum, Otto has failed to reign in that toxic complexity and to manage a successful renewal project.

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Cases like this sparked our interest in the reasons for successful ES renewal projects. We were able to select a multi-channel fashion retailer in Central Europe as our case site. In particular, we were enabled to analyze a renewal project [2] for a Product Information Management System (PIMS) in the e-commerce department of a multi-channel retailer. IS project success research in general, which is relevant for this type of project analysis, can be subdivided into two main streams. In the first stream, researchers are assessing project management success by the 'Iron Triangle' of a project's cost, time, and quality [3, 4]. Thereby, researchers aim to identify indicators that enable projects to reduce costs and time and increase the quality of the resulting product. The second stream focusses on the success of the project's product [5]. More recently, these aspects have been combined and resultant customer satisfaction [6] has become the focus. Prior research with a specific focus on ES implementation and renewal projects has been based on the assumption that such projects are essentially disruptive and lead to changes to the technology as well as the work environment and the task [7]. However, we have found evidence in our exploratory case study that even scheduled events that have no influence on the task can cause significant disruptions and adaptation efforts. As project success can also be considered as socially constructed and perceived [8], the investigation of the discrepancy between perceived success and the reality is necessary to come to a real understanding of project success. Thus, we aim to explain the diversion between perceived and actual success of an ES renewal project. We applied the critical realism perspective to identify the mechanisms behind the development of such a diversion. For our research, this is the appropriate approach, because it allows to focus on establishing causality [9]. On this basis, we formulate the following research question: *How and why is there a discrepancy between end-users' perceived and real ES renewal project success?*

We aim to provide an overview of the mechanisms that are behind the different perceptions of the renewal project. This will result in a type II theory [10] and several relevant practical implications. In the following section, we provide a brief overview on the theoretical background of our research. We discuss the methodology of our explanatory, longitudinal single case study in section three, before presenting and discussing our findings in section four and section five, respectively. Finally, we conclude our research by summarizing the key results, discussing the limitations and contributions of our study, and providing an outlook on future research.

2 Theoretical Background

There is a lot of research about IS projects and system success as well as failure [8, 11–13]. However, there is no agreed definition of IS project success in general [5]. In part, this is attributable to the multiple facets of project success. As success is a multi-dimensional construct, it is subjective and depends on perceptions [5]. A distinction between overall project success and project management success is an important step in the analysis process for determining whether a project should be considered a success or a failure [14]. Project management success is often measured as adherence to planning in the form of the 'Iron Triangle' of time, budget, and quality. The Iron Triangle is popular in research [3, 15] and in practice [5]. On the other hand, there is also the product related dimension of the project outcome, which can be coined product success [5]. As an example, we look at the definition by Basten, Joosten and Mellis [6]. In their definition, the adherence to planning in the form of the Iron Triangle is the definition of project management success. Product success is defined as the effect of the product in terms of organizational benefits or customer satisfaction. Overall project success is determined as the successful combination of these two success dimensions.

Research on IS project success is generally based on the measurement of IS product success [16, 17]. The wide range of criteria for the measurement of product success, make it an ambiguous measure. Aspects directly related to IS products can be used for an assessment based on system performance, for instance, perceived usefulness, information quality, and system quality (e.g. ease of use) [18] or system reliability [15]. A more general approach to IS project success in the past focused on the combination of project management and a successful product [3]. However, the perception of information system failure or success is largely stakeholder-dependent [19]. IS project success is, therefore, socially constructed and perceived [8]. This understanding has given rise to a performative perspective on IS project success [8]. A performative perspective is based on the identification of actors and their relational effects in the networks of IS projects. Actors in a project network value different aspects of an implemented IS or of a project differently. Consequently, the actors measure and evaluate IS project success differently. This aspect is crucially related to organizational sensemaking. Organizational sensemaking is focused on determining what an event means for members of an organization [20]. Sensemaking is based on the idea of retrospectively making sense of events [20] such as a renewal project. During the course of such a project, sensemaking in a group can be influenced by the social dynamics in the group of affected people. For instance, it is a crucial characteristic of a good team that members show a great deal of synergy and loyalty to each other and to their leader [21, 22]. However, these are also factors, which can lead to groupthink [21]. In particular, hierarchical groupthink, which originates in the desire of individuals to please their leader by agreement in opinion, can have a strong influence on the assessment of project success. Especially, since employees' sensemaking can be strongly influenced by a management's narrative [22]. For instance, employees (i.e. end-users) develop a reliable system [23] to cope with perceived adversity, which might be caused by technological glitches in their work environment. Whether overcoming the situation as a group can give them a collective mind and feeling of success is the subject of further research.

3 Methodology

To answer the aforementioned research question, we decided to analyze one case company longitudinally with a single case study approach. We reviewed the transition and change of end-users' expectations in the organizational context of the e-commerce subunit, which is the unit of analysis. Thereby, we aim to explain the deviation of perceived project success over time. This single instant serves as a starting point for the search for an explanation [24]. In combination with insights from the literature, this holistic view allows us to develop the explanation [10] presented at the end of this paper.

3.1 Case Description

We acquired a project for the analysis of the renewal and adaptation of an ES. During the course of the single case study, we analyzed the development of perceived and real ES renewal project success. As case company, we selected a multi-channel fashion retailer with a sizable online shop, which is located in Central Europe. Thereby, the e-commerce department (in the following referred to as FASHION) and its Product Information Management System (PIMS) were at the center of our research. A PIMS allows to centrally manage all information required to market and sell products on distribution channels such as FASHION's online shop and marketplaces. FASHION is a department of two managers, content managers, and supporting technicians. FASHION's deputy department head characterizes his business unit in the following way: *"I see us as a hub which compresses the product information and provides access to sales channels [for other departments in the company]." Due* to changing requirements, FASHION regularly undergoes changes of its e-commerce platform. At the center of the change process, the new PIMS release was supposed to significantly improve PIMS overall and the Web-Client version in particular. The release was supposed to update the software to the originally contracted level, since this version had not been ready for renewal for the original project. Changes in roles or assigned tasks were not planned. At the time, FASHION had a lead and a deputy technician who were responsible for the online-shop system and PIMS, which were the relevant IS for e-commerce. The deputy technician had started his new job a month before the introduction of the new release.

There were 84 recorded users of the PIMS Web-client, which include the department heads, their deputies, the content management team, and users in various purchasing departments. We only evaluate the PIMS Web-Client, which is a content management system for product information, classification in the structure of the online-shop, and management of product images. Content managers focus on texting and classification of products. Texting and classifying a product took on average 7-8 minutes before the renewal project. Up to 50 articles had to be processed by a content manager per day. FASHION employs two teams of four content managers and two interns. The other employees in the purchasing department mainly search and read in the PIMS. Team leads in the content management team use a Master client version of the PIMS, which allows them to assign work packages of texting and classification work to team members. Two months after the renewal of the new release of the PIMS, one of the two remained team lead for the texting group and the other became head of a newly created product image production team.

3.2 Data Collection

We used several data collection methods during the case study. Our data collection included 22 *semi-structured interviews*, *participant observation*, and *document analyses*. Semi-structured interviews are defined as interviews in which pre-formulated questions are used, but not strictly adhered. New questions can emerge during the conversation [25]. We interviewed different user types, such as content managers, team leaders, managers, and employees of the technical support. The multi-level analysis in our research made it necessary to include different user categories for the analysis of the specific ES [26]. Thereby, we aimed to get an integrated view of user adaptation and developing experiences of the renewal initiative by interviewing a carefully selected set of people over the course of the renewal project for eight months. We interviewed as many individual users of the PIMS as necessary to get an understanding of the typical user role in FASHION. Interviews with management focused on the department head and his deputy who were responsible for the PIMS project. Technology support included the positions responsible for the e-commerce related IT services and those responsible for the particular IS project. The first author conducted the interviews in person, recorded and transcribed them. The interviews lasted typically between 45 to 60 minutes. Before an interview, we provided some information to the interviewees regarding the interviewer, the background and purpose of the study, and the anonymity and use of gathered data [27]. We conducted the semi-structured interviews at three points of time: (1) before the start of the project, (2) shortly after the renewal, and (3) after employees had settled in with the new system (see Figure 1). This time frame was chosen because researchers suggest a gap of one month between perception of a new system and usage measurement [28]. If the gap is longer, it might be motivated by factors that the researcher cannot control. However, if it is shorter, the gap may not give adequate time for adjustment in the perception process of individuals and their use of a new system [28].

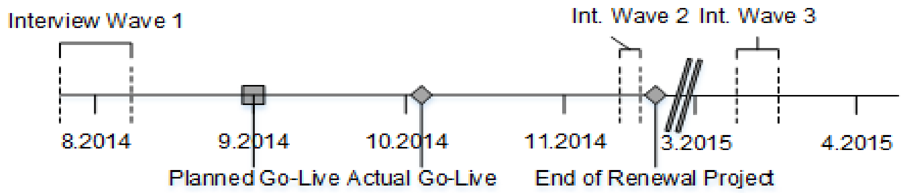

Figure 1. Data collection plan at FASHION

The first interview series started with an assessment of the system's version at the time and with an assessment of the typical adaptation of users with regard to the system. Furthermore, we asked for users' and managements' expectations regarding the introduction of a new PIMS release. In the second wave, we interviewed a content manager, the team leaders, a manager, and the technicians to assess their evaluation of the project and the actual progress made. This second round of six interviews, included questions whether the expectations were met by the new release. It also included questions about the user adaptation and the adaptation process necessary to deal with the new system shortly after its introduction.

Only the deputy department head could be interviewed during the mid-term sessions because of the ramifications of the busy holiday season. A content manager is the second missing interviewee interviewed before the project, as he had voluntarily dropped out of the company in the meantime. The third round of in total eight interviews included a final round of questions whether the expectations were met and questions regarding the adaptation. We asked users about the amount and kind of organizational support that they received in each round (see Table 1).

Table 1. List of Interviewees at FASHION

Interviewees	*Total # of Persons*	*Interviews Wave 1*	*Interviews Wave 2*	*Interviews Wave 3*
Content Managers	3	2	1	2
Team Leaders	2	2	2	2
Lead Technician	1	1	1	1
Deputy Technician	1	1	1	1
Deputy Department Head	1	1	1	1
Department Head	1	1	-	1
Totals	**9**	**8**	**6**	**8**

When possible, we used *participant observation* to gain a practical understanding of their interactions with the software. This aspect was supported by the previous role of the main researcher on this project, who had been an intern in the e-commerce department as a student. *Document analyses* were mainly part of the initial analysis during and after the first round of interviews and helped to understand the organizational structure, IT infrastructure, and IT architecture. In addition, we documented the rules and procedures of data collection in a case protocol to ensure rigor in data collection. Furthermore, a case study data base was used which contained the interview transcripts, field notes, collected documents, coded data, and the coding scheme [24, 29]. The data was organized based on Spradley's suggestions [30]. This organization allows separating objective facts in the condensed and expanded account and subjective interpretations in the analysis account and fieldwork journal.

3.3 Data Analysis

The unit of analysis of the case study is the work system of FASHION. For coding and tracking the qualitative data from the field, we used AtlasTI and followed an inductive coding approach. Inductive coding is appropriate in our research context as it allows to abstract themes, which are mentioned by interviewees on a reoccurring basis. We started with open coding of the interview transcripts. These open codes are descriptive and merely allow a categorization of constructs identified in the interview transcripts. We intensively compared and contrasted the developed categories with each other. In a second phase, we conducted axial coding to refine the interpretation of the categories and properties. At this stage, we also controlled for a possible researchers' bias in the categorization process by crosschecking the categorizations of the codes with an independent student assistant's categorization of a sample of three examples for each category. The categorization was very similar.

We used a critical-realism (CR) as the epistemological perspective for the analysis of our gathered data. CR distinguishes between a transitive and intransitive domain. The intransitive domain consists of the elements such as events and the causal powers in the ontological domain of the actual and the real that the researcher attempts to understand [31]. The transitive domain contains the observations, knowledge or theories about the independent world of the intransitive domain. A perfect match between theories and reality is not likely, and theories are fallible. Intransitive elements do not change over time, however, the theories about them do and presumably become less fallible [9]. Thus, this research approach is ideal for the analysis for complex interactions and consecutive smaller events [9], such as the forming of perceptions of project success in iterative steps.

Specifically, we followed the principles for conducting the CR research in IS by Wynn and Williams [9] for our data analysis. The first principle is the detailed explication of events through the abstraction of individual's experiences, as the foundation of causal analysis. This step is crucial for understanding the PIMS and FASHION as an organization. Second, we explained the structure and the contexts of these events. For instance, this involved the analysis of the sequence of the flow of information inside of FASHION. Third, in the process of retroduction we identified the hypothetical causal mechanisms, which could explain the specific occurrence of these events [9, 32]. Fourth, we evaluated with empirical corroboration whether the hypothesized mechanisms illustrate reality correctly, elucidate the events better than other mechanisms and are appropriate explanations with a high degree of causal power by referring to our obtained data [9]. This was executed by constantly referring back to our transcripts and the documents. Finally, we employed triangulation, mainly to emphasizes the necessity to use more than one source of evidence, that is in our case the combination of different interviewees insights with our observations and document analysis to find an appropriate causal explanation for the different perceptions of reality [9]. The resultant contributions of a CR study can be classified as type II theory [10], which provides explanations for the occurrence of a phenomenon in a social system [9].

4 Findings

At first, we are going to outline characteristics of the interviewees and the stakeholder groups relevant to the case study. All people interviewed knew PIMS since its launch in the firm in August 2013 and had several years of experience inside the firm. The content managers were working in a rather small team that was the innovative "new" group in the company. Management had been familiar with the PIMS since its introduction and had been in the business area for two to three years. The in-house technicians were relatively new to the area and the technology. The head technician had joined the firm half a year before the migration project, while the deputy technician joined just one month before the start of the renewal project. As head technician, he was responsible for planning and organizing the renewal project. However, his background had been more in e-shop-systems. There was a multitude of ongoing projects at the same time inside FASHION. His only in-house technical support was the new deputy technician, who had worked with the PIMS at a previous employer. But he had to familiarize himself with the renewal project and its scale.

Initially, the new release of the PIMS had been purchased. However, it had not been ready for the initial implementation. Management had made the decision to implement the old release with some upgrades, which were ready at the time, and to create a hybrid version. The organization was still incorporating that change, as the head technician noted*: "Just recently, we were at a user group meeting of the software producer. Based on their project status classification, we just finished the renewal phase and are currently entering stabilization. However, the new release will* *disrupt that phase."* The project team for the introduction of the new release included the deputy department head, the head technician, and the deputy technician. A contract for the new release was signed in April 2014, which also included the move to a new service partner. The deputy department head gathered 23 end-user requirements, i.e. their expectations for the release of PIMS's Web-Client version in meetings in April and May 2014. Table 2 presents the four main requirements of this list as assessed by the head technician after the end of the project. These four common themes of expected changes emerged during the first round of interviews with content managers: First, the users expected an adaptation of the user interface for the product classification process. This included a change from a slow drag and drop process of individual product classifications, up to 20 at a time, to a simultaneous selection out of a list of characteristics. Second, an improved semantic search was required for the Web-client. Third, seamless navigation between product, variant, and article level in the PIMS Web-client also featured in the interviews. Fourth, product images should be available on all presentation layers in the system. The department head had the following expectations: *"[Whenever the new release is migrated and running], we will start by introducing a new design of the content management process. This will be a project of another five days [...]."* This process has not been implemented to date, October 2016. Management's expectations were in clear divergence to the technicians' expectations. Both technicians mainly expected benefits for handling of the technology and background changes. Besides, they planned a 1:1 migration to the new service provider.

Table 2. Main requirements for PIMS assessed after project completion

Main Requirements	*Status at Project's End*
Seamless navigation of system levels (product, variant, article)	Done
Integration of a spelling check	Testing
Automatic classification of products	To Do
Product images visible on all presentation layers in the system	In evaluation

Subsequently, the two technicians and the renewal partner prepared technical changes for the actual project. The migration of the entire data for the PIMS to the new hosting and general service provider was planned for the end of August 2014 and the planned go-live was on the 1st of September 2014. Separate hosting and service partners characterized the previous set-up. A renewal of the new release involved a service partner, who hosts and provides maintenance services out of one hand. An attempt to go-live on the 1st of September was made. Soon after this go-live, users from the content management team experienced such a lack of system performance and data quality that the attempt was abandoned. The new release was deemed not ready and FASHION reverted to the old set-up for the rest of the month. A new attempt to go-live was made at the beginning of October. Even at this point, users soon experienced a severe lack of performance and responsiveness. The service partner had underestimated the server capacity necessary to run the old PIMS implementation. In-house technicians began to learn that the original data model was incorrect for the design of the standard software. It lacked stability and had a slower performance than planned as it was used as a calculation tool for stock levels and other data, which was against the original design brief of the standard software. The head technician summed up the situation in the following way: *„The guys [from the first implementation partner] just screwed up a little. They were not capable of implementing a PIMS, at least of this scale."* Despite many separate efforts by the new service partner and the in-house technicians, a lack of performance persisted. Several data exports and imports were redesigned to reduce the workload for the PIMS. Ultimately, the stability of the system improved with a sequence of hot-fixes and bug fixes that were issued by the software producer and the service partner. Thus, it was possible to overcome the worst part of stability and performance issues within the first two weeks of the new release. The deputy technician stated: *"At the moment, we are happy that the system runs in an identical version on the new platform."*

It is evident, that end-user expectations were not confirmed positively. When asked about the share of expectations that were met, a content manager stated: *„About 30 to 35%. [...]. Expected was 60% of fulfillment of requirements."* Hence, she subsumed: *"The product has improved a little."* The newly assigned team leader for content management commented: *"Currently, I would say that performance-wise we are back on the level of the old version of the PIMS."* Furthermore, it was noted that *"the new classification approach with drop-down lists takes longer now."* This was due to a lack of performance of the hardware with the new hosting partner. Thus, a goal of the renewal was initially missed. While management acknowledged these problems, the deputy department head had the following impression: *"You can feel it, they [the users] are also satisfied. Some of the things that have changed are things that they wanted. […] 30% of requirements were ready with the first version after the release. We are currently implementing another 20% of our requirements and the other 50% are extra goodies. They will follow later."*

A great variety of perceptions persisted to the end of the project. For instance, one content manager stated that she felt like only 20% of the requirements were actually met. Independently, the interviewed content managers and team leads stated similar figures. In an interview with the head technician after completion, it turned out that he had never been aware of the list of requirements from the workshop. Just one of the 23 requirements on the list was met over the duration of the project. Eight requirements were classified as a planned "To Do" by the lead technician, two more were being worked on or planned, while the rest of twelve requirements was not understood or seen as conflicting by him. A content manager subsumed that "*the performance after the introduction of the new release and the management of the transition issues is just back to the way it used to be with the old release […]*."

This perception of the overall progress did not square with management's perception. The managers felt that employees focused too much on the negatives and the deputy department head stated: *"The new release is still about 20 to 30% slower than the old release. Many employees focus on this downside during conversations."* His perception of the fulfillment of the initially gathered requirements was fundamentally different and more positive: *"I would presume that 50 to 60% of the requirements on our list have been met by now."* The attitude towards problems, which were raised by content managers, was clear: *"'Yes, everything was better in the past'. Yes, the change was not easy, it has brought additional workload, it also brought certain restrictions, but it was just necessary, […]."* The department head expressed a new idea of the initial project's focus: *"We are closer to the standard. We have almost 100% of the standard. This was the top priority."* This was a fundamental change to the beginning of renewal project when users were asked to formulate a list of requirements during the workshop. This raised user expectations, which were slowly crushed as the project progressed. The department head was aware of this, but did not inform the content managers or purchasing department end-users: *"[…] we did not ask for intensive feedback, because we implemented very little from the long list of requirements because we changed a lot in the backend instead. [...], we can invest more in features and usability [when the backend of the system is stable]."* This decision was made because the department head had been aware of the issues during the migration process: *"[…] after the introduction of the new release, we had catastrophic system performance."* Nevertheless, the department head was of the impression that individual performance had increased substantively: *"We have an increase of 30% in productivity and speed compared to the previous release."* Considering everything, he specified: *"I am convinced that we have a "Ferrari" [i.e., PIMS] that we cannot use appropriately."* All the while also stating: *"That is just not a perfect system and we probably expect too much of it."*

Yet, technicians' perception of the overall project was different at the end of the initial renewal phase. The deputy technician acknowledged: *"We carry a huge load of requirements that were not met previously. There are plans, but neither the time nor the ability to create To-Do's to actually assess and implement the desired changes."* However, some parts of the transition were also perceived to be a success as it was possible to reduce the time needed for data imports and exports for the PIMS by about 50%. In part, this can also be attributed to changes in the hardware of the hosting partner. The technician was of the impression that this new speed in reaction motivated some users: *"The system pretends to help me, that's cool."*

During the course of the renewal project, many new projects and issues had overridden what the technicians wanted to achieve regarding their preparation of technology. The head technician's description of his interaction regarding the management of IT projects with FASHION's management illustrates the discrepancy in thinking: *"Management certainly listens, however it is unclear whether they truly understand and take note when necessary. Our department head admitted to me that we probably addressed too many issues at once. Overload will lead to failures. […]".* When the head technician perceived these issues during the migration process, he made the momentous decision to scale down the project. The project complexity was reduced by focusing on the main migration: "*In the end, everything had to be rushed because our management had communicated a deadline inside our organization. […] It is my belief that internal policy created an expectation inside the organization which resulted in pressure and eventually lead to friction losses."* End-users were not clearly informed, which allowed the different expectations to linger.

5 Discussion

We identified several mechanisms that can help us to explain the evolving perceptions of end-users. An important mechanism, which influenced end-users' perceptions was the **narrative of success**, the focus in management's communication on motivating employees by showing them that they are successful and taking part in something meaningful for FASHION and the multi-channel retailer as a whole. All interviewed content managers perceived the new release as an opportunity to improve their work and its outcomes, and fundamentally believed in this narrative of success. As strong e-commerce growth required many rapid changes, they had developed a common culture of trial and error, which they all ascribed to themselves. This mechanism is closely linked to the insight that success and particularly project success is socially constructed and perceived by different stakeholders [5, 8] and can be linked to organizational culture [33]. The specific aspect of narratives of success has also been raised in previous research on IS projects [13, 34].

Furthermore, employees in FASHION's e-commerce department show a great deal of synergy and loyalty to each other, as well as to the department head. These are the aforementioned characteristics of a good team [21, 22]. However, in this situation, the mechanism of **hierarchical groupthink** was present on the basis of belief in the e-commerce department's narrative of success. The following quote of the department head illustrates his power in setting an agenda: *"We have spent the last three quarters with very intense discussions and got a lot of scolding: Everything was better before [with the system before PIMS]. I have heard [this] so often, but all have to agree to it or have to engage with it, because there is no alternative. Now everyone agrees with it."* Janis [35] provided six criteria to identify and determine a situation of groupthink: 1.) *Little or no consideration of alternate plans:* Management at FASHION did not have a back-up plan for a failed migration or further technical issues. For instance, downtimes were seen as a given. 2.) *Risk is not assessed:* Management and Technicians at FASHION did not assess the risk for the operations of the difficult migration that they planned. Subsequently, the migration and go-live of the new release failed. If people raised issues, it was stated that the project simply "had to be done in this way". 3.) *No review is taken of rejected plans:* There was just one option: The execution of the initial plan. This was further enforced by commercial arrangements for the release change, which had been designed by management inflexibly to save money. The failure of the first renewal attempt for the new release occurred, because the software of the new release had not been ready. 4.) *Advice from outsiders is not sought*: Management did not feel able to fund a specification project by technical experts from a consultancy. *5.) Facts that support the plan are acknowledged, facts that do not support the plan are ignored:* This was observed in management's attitude to end-users input regarding project success. From management's point of view end-users simply focused too much on the negative. 6.) *Contingency plans are not created:* There was no alternative plan created for the renewal project and the implemented solution. The technology is a *'Ferrari'* and simply not used properly. The described groupthink had the effect that content managers bought in to this assessment and that significantly influenced, how they made sense of the renewal project.

As aforementioned, there were four different levels of information: technicians, managers, content managers, and purchasing department end-users, who were not informed about the particularities of the project. These different groups had different sensemaking experiences. This is due to the different points in time at which they received their inputs. At first, the technicians became aware of the issues with the initial implementation. This was crucial for other parties' sensemaking. As the management was made aware of the technological issues, the deputy department head commented: *"If you turn one stone, you have to turn them all."* This meant scope creep and a more comprehensive change then initially anticipated, but also a change of priorities. As a consequence, the aforementioned list of requirements remained unknown to the lead in-house technician till one of the researchers presented it to him after the end of the project. The end-users realized a dawning failure based on the results they perceived in their daily work. A content manager commented: *"It became evident during the run of the project that our [the content management] team's wishes […] were difficult to implement."* The content management team reacted with not focusing on the wishes and expectations anymore. This can be described as the mechanism of **inherent fatalism** of end-users. Instead, they realized that the renewal project was a threat for their productivity. Overcoming the threat and the difficult phase was therefore a great success. According to a team lead, the new attitude to the project became: *"It simply had to be done."* She described their experience with the adversity as a *"state of war"*. She went on to say: *„It is a positive experience to go through such difficult periods. It is an opportunity to grow personally and to see what you are capable of."* We interpret the described personal growth and experience of performing against the odds as the seed for the perception of success that end-users reported. This appears to be at the heart of their sensemaking process. It overshadows the project and its original purpose over time. The other team lead stated in the third rounds of interviews: *"I do not know [how many requirements were met]. I have no idea. [...] You get used to situations and if something is suddenly missing from the tools that you use, you find other ways. […] Whenever you get used to something you stop questioning it. Hence, I do not know what can be improved at the moment."* The hallmark of success in such a scenario became reaching the previous level of performance and they abandoned the goal of renewal. As a group, the users at FASHION developed a reliable system, similar to those described in the literature [23], to cope with the adversity that they perceived because of the technological glitches in their work environment. Overcoming the situation as a group also gave them a collective mind and a collective feeling of success. This finding adds to previous research which has identified the importance of organizational culture for IS project success in general [33]. Aspects of inherent fatalism as a mindset, its antecedents, and its consequences have featured in previous research. For instance, research on perceived organizational support and psychological contracts of employees with their employer [36] has investigated conditions that might lead to inherent fatalism on the part of the employees. Part of the process to readily accept the situation in the workplace is the rationalization process of individual end-users. More specifically, motivated reasoning [37, 38], which is the reliance on a biased set of cognitive processes, is likely to be important for explaining end-users ability to focus on the aspects under their control. The end-users could have been motivated to avoid a reasoning that would stain the embraced narrative of success of FASHION. As a consequence, such an approach allows them to remain motivated to work [39] at FASHION. The organization relied on the described combination of mechanisms, which has its roots in the instilled organizational narrative of dynamism and success, to motivate users to overcome the problems in daily use. As a result, the deputy department head believed that all people involved were satisfied and summarized: *"The users found ways to deal with the performance problems."*

6 Conclusion

A CR approach enabled us to develop a better nascent theory for the understanding of various perceptions and evaluations of success of IS projects in organizations. Our explanation of the link between the mechanisms identified above is the main contribution of our study. We use them to explain the discrepancy between end-users' perception and real renewal project success: For *end-users*, the perceived success of overcoming the adversity of the renewal project was a good match with the overall groupthink, and the predominant organizational narrative. They perceived themselves as the group of people that was working in a dynamic market environment and as those who successfully struggle with its dynamism. Overall, their sensemaking of the situation had a fit with FASHION's organizational narrative. From this, we draw the conclusion that overcoming the adversity of a project's ramifications is a big factor in the perception of successful projects by end-users. This creates a feeling of unity and resolve in good teams. The greater purpose of being part of something interesting (a growing and dynamic business – fitting the organizational narrative) is also an important aspect. For *management*, the resilience of end-users, who are motivated in such a way, is crucial to ensure relative success to their adjusted objectives. As observed in our case, managers seem to adapt their level of perceived success based on the information they receive from the technicians, who are closest to the matter at hand, but are not necessarily aware about the overall story that has been told by management about the project they are working on. Thus, there is a wider disconnection in the sensemaking of individuals in an organization about the success of a project. As long as management dominates the perception of the business environment and end-users buy into the derived organizational narrative, it is likely to influence the sensemaking process of end-users. In our case, this means that the adversity of the initially *planned* technological change is seen as inevitable on the level of end-users. End-users seem to consider the greater cause inherent in the organizational narrative and respond with a fatalistic and resilient attitude and form a reliable system, which allows them to cope with the adversity related to technology project in their organization. For *technicians*, this means that their sensemaking is constrained by time pressure and in our case the inevitable lack of experience with the PIMS. In this situation, they had to make sense on the fly. Furthermore, they did not feel empowered to manage relationships with end-users and expectation management on their own. Overall, this led to the described situation in which the perception of the business environment and the resulting organizational narrative dominated the perception of a project's success. We think that this theoretical understanding is generalizable as the organizational narrative, which informs perception, is likely to depend on the organizational environment.

A possible limitation of a single case study is always generalizability. We deem a single case as appropriate for exploratory research and aim to challenge generalizability of our results on the basis of multiple cases in future research. It is a practical implication of this paper that managers should make sure that they actively nominate someone, who plays the role of a devil's advocate [22] to manage the expectations related to a synchronized plan. This will alleviate the problem of groupthink based on a similar perception of the environment and the resulting organizational narrative. In our particular case, the common believe led to a lowering of expectations which allowed to reinterpret failure as success in meeting adjusted expectations. This is a benevolent outcome. It is also possible, that the organizational narrative further aggravates end-users. A narrative told to motivate employees can ring hollow if it is not backed up by reality. Thus, management and technicians should communicate more directly and more transparently with end-users about the underlying technology. Even if they do not understand the technology in detail, they are likely to welcome the gesture of inclusion and the possibility to participate. In a different environment as in our case, users can resort to adverse behavior such as user resistance [40, 41]. The circumstances of this can be at the center of future research.

Abstract. Shared understanding facilitates the implementation of IS and can help to prevent unintended consequences. However, research is hitherto not precise on the kind of knowledge such understanding needs to capture. Taking an activity theory perspective, this paper theorizes that shared understanding needs to cover knowledge, experiences and perspectives on the contested activity systems the HIS is implemented in. Analyzing the data of an in-depth case study, it is found that issues emerging during the rollout can be traced back to a lack of shared understanding about the affected activity systems, particularly to insufficient shared understanding about the instrument-mediated relationships between contradictory motives, rules and the evolved division of labor. These findings are synthesized in a framework on critical aspects of shared understanding. This framework offers a coherent explanation for the rise of unintended consequences and enhances our learning of shared understanding in IS implementation.

Weeger, A.; Ott-Schwenk, A. (2017): What Teams Need to Be Clear about - an Activity Theoretical Perspective on Shared Understanding in Health IS Implementation, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 544-558

1 Introduction

Society expects a great deal from health information technology (IT), particularly concerning quality, safety, and efficiency of healthcare [1]. Imagine a hospital implementing a health information system (HIS) to fulfill these expectations. Its management follows the advice of text books and clarifies the problems the IS should tackle, builds consensus, considers various options, chooses an IS that meets its needs, plans implementation carefully, continually involves stakeholders and maintains strong commitment [2, 3]. Nonetheless, after the rollout, unintended consequences such as workflow challenges and resistance arise leading the intended outcomes untapped.

The literature reveals that this scenario is not unique, but that HIS implementation regularly disappoints users and stakeholders [2]. Implementing information systems (IS) that meet the difficulties of the healthcare domain and its various stakeholders is thus a major challenge [4], particularly since HIS must account for numerous social and technical factors that originate in a complex and evolving environment [2, 5]. In this regard, shared understanding enables interdisciplinary teams to implement IS effectively [6, 7]. Such shared understanding involves the recognition of diverse perspectives, resolution of differences in meaning and an agreement on the socio-technical requirements and the role of the IS within the activities it is employed [8].

However, research has to date not precisely worked out the kind of knowledge and experiences that need to be covered by shared understanding, which enables teams to efficiently implement IS and to avoid unintended consequences [8]. To guide design and implementation of HIS that are better able to meet expectations and thus improve HIS implementation outcomes, it is valuable to gain deeper understanding of the aspects of healthcare activities that shared understanding needs to cover. Consequently, this paper aims to contribute to our knowledge by exposing and classifying socio-cultural characteristics of healthcare activities and the various perspectives of stakeholders that need to be recognized and aligned during HIS implementation. Thus, we put forth following research question: *What are crucial aspects of healthcare activities that need to be covered by shared understanding during HIS implementation to avoid unintended consequences?*

To approach this question, we conducted an interpretative case study of an HIS implementation in a large German hospital. Grounded in Activity Theory (AT), we developed initial assumptions about aspects of healthcare activities that need to be recognized, shared, and considered during IS implementation. AT informed our understanding of the elements and complexities of collective activities, the significance of diverse perspectives and the role of HIS as a mediating instrument. The assumptions derived from AT did not only guide data collection and analysis, they were also constantly refined during this process. By means of iteratively interpreting data and refining the theoretical concepts, we could develop a coherent explanation of the rise of unintended consequences that emerged during and after the rollout of the HIS. These explanations then informed the development of a framework, which points to crucial aspects that need to be covered by shared understanding to avoid such problems. Before we lay out our theoretical stance, we briefly point up the complexities of HIS implementation and introduce the concept of shared understanding.

2 Theoretical Foundation

Stability and reliability are pivotal in healthcare settings [9]. IS implementation should thus carefully manage change to healthcare activities, which are increasingly complex, contested, highly hierarchical, and multidisciplinary in nature [9-11]. Concerning this matter, prior research identified that embedding generic HIS as "one size fits it all" is reasonably difficult [12, 13]. Rather, the design and functionalities of HIS and evolved practices need to be wisely adapted [10, 14], such that the HIS fits with the socio-organizational context. These adjustments need to span the complete implementation process [15]. Consequently, several literature reviews have identified management and user involvement as critical measures for the design and implementation of HIS [2, 16].

Users, managers and IT professionals need to be aware of individual knowledge that is crucial for the design and implementation of HIS such as knowledge on the capabilities and limitations of the HIS as well as perspectives regarding necessary adjustments to work practices [16]. Aligning HIS and established work practices successfully is thus contingent on shared understanding.

2.1 Shared Understanding

Shared understanding is commonly defined as "the overlap of understanding and concepts among group members" [17] and refers to the extent to which a basic understanding of a common subject matter exists [6]. The common subject matter in IS implementation is the creation and adaptation of an IS that is well aligned with existing and emerging practices [6, 18-20]. As our research focuses on HIS implementation, we define shared understanding here as overlapping mental representations of knowledge and experience that allows people involved in HIS implementation to form joint explanations and expectations of the HIS and how it affects healthcare activities.

It is assumed that an understanding of reality is primarily constructed in the mind of the individual by organizing and combining new experiences with existing experiences and knowledge [21]. Thus, there are multiple constructions of reality and "there is no objectively, right understanding on a certain object of interest that matches reality, but rather different conceptualizations that may 'fit' reality better or worse" [8]. However, research on shared understanding clearly shows that combining and aligning individual understandings of IT professionals and their stakeholders is important for successful IS implementation projects [see e.g. 6, 18, 19, 20, 22-24].

Shared understanding does not imply that people involved in IS implementation simply accumulate individual conceptualizations of reality. Rather, they need to share their perspectives, negotiate meanings, and agree on a mental representation they want to follow [8]. Moreover, it is assumed that teams hold several mental representations, which are usually framed as task- and team-related models and either cover knowledge on the task, the way the task is approached or the team [8, 25]. Besides these rather broad categories, IS research has hitherto barely worked out the detailed kind of task-related knowledge and experiences that are crucial for effective IS implementation [8].

Though prior research reveals that insufficient fit between the HIS and the socio-organizational context contributes to HIS implementation failures [14], the kind of knowledge about healthcare activities that needs to be enacted remains unclear. AT provides concepts to analyze collective IS-mediated activities and to approach this gap. AT exposes the interrelations of the constituents of work activities and thus illuminates the socio-organizational context. Hence, AT should help us to understand what needs to be recognized, shared, and considered during IS implementation, particularly concerning the role of the HIS within these activities. Below we offer a brief introduction to AT.

2.2 Activity Theory

Although AT is still rather unfamiliar in IS research, it has emerged as an important theory for understanding change of IS-mediated work activity [26]. AT relates the different conceptions of human activities and the material, mental, and social resources through which they are enacted [27, 28]. To frame these relations, AT introduces the activity system as analytical unit that covers how diverse actors work together [28].

The triangular activity system comprises the mutual aim of the activity (the *object*), all the people who are directed towards the object (the *subjects*), cognitive and materialized *instruments* used in activity to realize the outcome more efficiently, explicit and implicit *rules* that govern the work, the way tasks are distributed (the *division of labor*) and the wider *community* of practitioners that revolve and evolve around the object [29-32]. Instruments, rules, and the division of labor empower actors with experience and skills collected in the past, relate the subjects to the community and determine the possibilities and boundaries of their actions [21, 29, 30, 33].

The object as a key concept of AT refers to a physical or cognitive entity that is under construction, moving from a ‘problem space’ to a result or an outcome [28, 31]. As the “true carrier of motives of the collective activity systems”, the object takes shape and acquires its value by being transformed by multiple members of an activity system. Thus, the object is an enduring purpose of the activity and determines individual goals and actions through which, in turn, it may be achieved [31].

Though object-relatedness is a key characteristic of human activity [34], it is not free of contradictions. People frequently perceive difficulties in constructing a connection between the goals of their individual actions and the motive of the collective activity [34]. These problems stem from the multi-voided and contradictory nature of human activities [31]. AT views activity systems as an accumulation of multiple perspectives, traditions and interests, where the division of labor creates different positions of the participants and the instruments, rules, and conventions carry multiple layers and strands of history [35]. Such contradictions are exemplified by diverse perspectives on the patient who may be considered as a person to be helped or as a source of revenue. Likewise, HIS as one of multiple instruments employed in healthcare activities can be viewed as a resource to provide better healthcare or to generate higher revenues.

Such contradictions within activity systems cannot be observed directly, they can only be identified through their manifestations [36] such as tensions, disturbances, and breakdowns that destabilize activities and reveal inefficiencies [31, 37]. Moreover, contradictions are also viewed as driving change. Building on these ideas, we conceptualize IS implementation as a process of reconfiguring activity systems to resolve contradictions or mitigate tensions. IS implementation projects are thus only successful, when tensions, disturbances, and breakdowns could have been reduced.

Modifying elements in activity systems also bears the risk of new or amplified contradictions that may surface as unintended consequences. To avoid the rise of unintended consequences, these contradictions need to be identified, considered and proactively approached by means of adequate strategies and measures such as purposeful adaptations to the IS and other cultural historical elements of the activity.

2.3 Summary and Initial Assumptions

Literature shows that effective design and implementation of IS is contingent on shared understanding [see e.g. 6, 19, 20, 23, 24]. However, prior research is not precise on the kind of task-related knowledge, experiences, and perspectives shared understanding needs to cover [8]. Building on the concepts of AT, we assume that the design and implementation of IS not only requires knowledge of individual actions and interactions with the IS, but also of the joint activity the IS mediates. IT professionals, users and stakeholders thus need to share their individual knowledge and perspectives on the system of instruments employed in collective activities and rather invisible aspects such as rules and the division of labor as well as the strands of history they carry.

An understanding that combines divergent conceptions of the historically evolved and contested activity systems, their elements, and interrelations is expected to enable IT professionals and users to identify contradictions and to agree on the role of the HIS within these systems. Such shared understanding will enable them to anticipate and avoid unintended consequences during and after rollout. Vice versa, we expect that significant obstructions of work activities indicate that the people involved in IS design and implementation based their actions on insufficient shared understanding of the contested activity systems. Thus, they were not able to anticipate novel or amplified contradictions and resulting tensions as reflected by unintended consequences.

3 Methods

To identify the aspects of healthcare activities that need to be captured by shared understanding, we decided to take an interpretative perspective and to conduct a single, in-depth case study [38-40]. An interpretive lens acknowledges that people create their own subjective and inter-subjective meanings as they interact with the world [38]. Case studies are capable to provide an ample description and analysis of these perspectives [40]. Thus, the case study approach fits well with exploring crucial aspects of healthcare activities that need to be recognized, considered, and shared in this specific context.

In line with Eisenhardt's [41] recommendation for case study research, we framed our research question in the light of prior research. Moreover, we engaged in an iterative process of considering theoretical concepts from extant literature, developing assumptions about the characteristics of shared understandings, comparing the patterns identified with our theoretical deliberations and enhancing our theoretical perspective [39]. Below, we introduce the case, and describe data collection and analysis in detail.

3.1 Research Case

In 2011, a large teaching hospital in Germany with approx. 9,000 employees in 17 clinics and 40 specialist departments started an initiative to gradually implement an IS for care documentation (henceforth CareDoc) at almost all intensive-care stations such as the internal medicine, the gynecological clinic, and the psychiatric clinic. Replacing the former paper-based nursing documentation instrument, CareDoc was intended to enable the wards to comply with external requirements, such as increasing the efficiency of day-to-day clinical activities and optimizing reimbursement. From an AT perspective, the paper-based instrument should be replaced to resolve tensions between the abilities of the hitherto employed instruments and evolving aspects of the object of healthcare activities, particularly efficient provision of healthcare services.

The paper-based care documentation is ward-specific and essentially a large piece of paper. This instrument is used to document basic patient data such as demographics and vital parameters, medications, treatment, and nursing reports. CareDoc replicates and extends these functions as it, for instance, also enables users to enter orders and to manage schedules. Moreover, CareDoc provides interfaces to the hospital's central information system used to manage master patient data and accounting processes.

Responsible for most medical documentation (i.e., data entry), the nurses at the ward are the key-users of CareDoc and thus particularly relevant during requirements-elicitation. This fact is also reflected by the project team responsible for the adaptation and implementation of CareDoc at the wards. The team was led by an IT project manager and supported by two IT professionals and three nurses. The nurses were relieved of their day-to-day activities at different wards to a varying degree (25-75 %).

Depending on the specialization of the clinic, the vendor of CareDoc provided several basic templates that reflect best practices from other hospitals. In the early phase of the project, the project team involved various users, whose task was to learn how the templates need to be aligned with standard processes at the clinics and their wards. The resulting customized templates reflect approx. 80% of the functionalities needed in all clinics. The remaining 20% were identified as ward-specific and were added as customization prior to the rollout at the wards. The customizations were predominantly informed by the nurses. To gather the requirements, a standard implementing procedure was adopted for every ward. First, the project team and the staff at the ward, particularly the nurses, jointly created a specification document that reflects ward-specific requirements. The project team then customized CareDoc accordingly. Two weeks before the rollout of CareDoc on the ward, the users were trained to use the adapted version of CareDoc. During the rollout phase, which lasted about 14 days, members of the project team helped ward staff to implement CareDoc within their day-to-day work and to fix emerging issues. The rollout strategy, particularly the selection of CareDoc and the basic template development, included key success factors noted in the literature: selection of adequate technology, senior leadership, and continuous consultation of key-users during all project phases [2, 3]. Thus, this case gives us the opportunity to identify aspects of healthcare activities that are not easily recognized by best-practice measures, but are critical for avoiding unintended consequences.

3.2 Data Collection and Analysis

Data was collected between 11/15 and 03/16 at the addictive disorders ward of the psychiatric clinic. The addictive disorders ward was chosen for two reasons. First, from 2012 to 2015, CareDoc was already rolled out at nine other intensive-care wards. Thus, the project team has gained significant experience and benchmarks concerning the adaptation and implementation of CareDoc. Moreover, they have already refined the templates so that they sufficiently cover most standard requirements. Second, the nurses at this ward were particularly engaged during the requirements elicitation and unanimously agreed on the general requirements so that little problems were expected.

We took the role of an 'outsider researcher' during ward-specific requirements-collection, customization, and rollout. We triangulated data sources (i.e., interviewed key-users and project team members, talked to and observed nurses and physicians, and reviewed documents) to safeguard reliability and credibility of the data [39, 42, 43].

Table 1. Formal Interviews (approx. 9.5 hours)

Interviewee	*Interviews (total length)*	*Documentation*
PT01 (Project Manager., IT professional)	2 (45 min.)	Notes/memorized report
PT02 (Project Team, IT professional)	3 (90 min.)	Notes/memorized report
PT03 (Project Team, nursing background)	1 (40 min.)	Verbatim report
PT04 (Project Team, nursing background)	2 (50 min.)	Notes/memorized report
PT05 (Project Team, nursing background)	2 (50 min.)	Notes/memorized report
NU01 (Nurse at the ward)	3 (110 min.)	Verbatim report
NU02 (Nurse at the ward)	3 (70 min.)	Verbatim report
M01 (Ward Mngr., line manager of nurses)	3 (100 min.)	Verbatim report

The formal interviews were set up as semi-structured conversations [40]. The interview guideline contained open questions about the interviewees' knowledge and experiences on the affected activities and the role of CareDoc within. The interviews covered all available project members as well as involved key-users as assigned by management (Table 1) and aimed at exposing the knowledge, experiences, and perspectives the key-users and project team members shared. During the interviews, we gathered data on their conceptions of the healthcare activities, knowledge, and experiences regarding conventions and tools that are related to care documentation and that govern actions and interactions between the people involved. The formal interviews were recorded and transcribed whenever possible. Some of the interviewees felt uncomfortable with the recordings. However, during these interviews a comprehensive number of notes was taken and a report based on these notes was prepared immediately after the interviews.

To identify emerging issues and to collect data on the tensions within the activity systems that may cause these issues, one researcher was on-site during rollout (5 days, 9 hours per day) and observed nurses' use of CareDoc, related outcomes and problems that significantly obstructed work activities. In addition, we conducted a vast number of informal conversations with nurses, physicians, and the members of the project team to gain understanding on the issues we have observed and on underlying tensions. These casual conversations and observations were instantly recorded in the case diary.

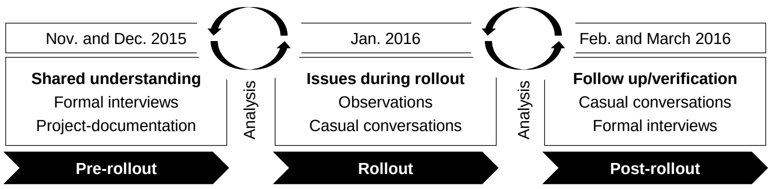

Figure 1. Iterative process of data collection and analysis

In accordance with the principles of interpretative research, data collection and data analysis occurred in a mode of continuous interplay, such that we were always open and willing to modify our initial assumptions (see Figure 1). One researcher constantly coded the data. The other researcher cross-checked the coding to ensure inter-rater reliability. Once agreement on the coding was reached, we compared, analyzed, interpreted and discussed emerging patterns as a team effort [42]. Whenever our interpretations differed, we went back to the data, theory, and/or the field and discussed the findings until we came up with an interpretation that was plausible for both authors [39]. Data collection lasted until all inconsistencies and gaps were resolved.

Aimed to understand which conceptions of the activities the IT project team and the nurses as key-users share, the first analysis cycle was conducted between the pre-rollout and the rollout phase. After coding the data on the individual conceptions of the work activity (i.e., open coding) [42], the resulting codes were analyzed and categories formed. The categories could have been assigned to an activity system component (e.g., subject or rule) or to a relationship between multiple components (e.g., relation between actors and implicit rules). Next, we compared the findings in each category to identify similarities, connections, and patterns between the individual conceptions.

During the second major cycle of data analysis, we focused on issues that emerged during the rollout and potential tensions between CareDoc and the healthcare activities. To do so, we coded data from the rollout-phase in search for aspects of the activity system that have previously not been shared as well as pointers to underlying tensions. Again, we created categorical codes, compared the resulting codes with the activity system components and assigned them to one of the activity system codes.

Finally, we analyzed the coded data and created a conceptual matrix [42]. For each problem that emerged, the matrix encompassed the aspects of the activity system that were covered by the shared understanding before the rollout as well as our AT-analysis of tensions within the activity system developed in the second cycle. This matrix allowed us to generate an overview of relevant data and to analyze how the emerging problems relate to aspects of the activities of nurses that were not covered by the shared understanding that guided adaptation and implementation of CareDoc.

4 Findings

The rollout strategy, including key success factors as noted in the literature [2, 3] helped to adapt CareDoc such that it enables nurses to document relevant data and to comply with standards. Moreover, CareDoc provides management and clinicians data better in quality (i.e., reimbursement and diagnosis). However, we also observed unintended consequences that emerged during and after rollout. These issues mitigated efficiency gains considerably and provoked resistance. Below, we analyze how these issues can be traced back to insufficient shared understanding of the activities affected by the HIS. We briefly present three of the most apparent unanticipated issues, illustrate the tensions and underlying contradictions, and analyze the aspects that were not covered by the shared understanding, which was developed during requirements elicitation and customization of CareDoc. Table 2 provides a summary of these findings.

Table 2. Summary of findings: contents of shared understanding (SU)

Aspects that were covered by SU	*Aspects that were not covered by SU*
Expected individual performance gains (e.g., documentation, reimbursement)	Contradictory perspectives (e.g., caring for patients vs. documentation quality and costs)
People/occupational groups involved in the activities that are affected by CareDoc	The historically evolved contradictory role of the community (e.g., volunteers and trainees)
The form and function of the formal paper-based documentation instruments and resulting technical requirements regarding types of data-fields, forms, reports, etc.	Additional, ward-specific enhancements of the formal instruments, their role as governance mechanism (e.g., reminder, overview), and the limitations of CareDoc (providing overview)
Legal requirements on healthcare activities (e.g., transparency, authentication, and medication handling)	Interpretation and evolved (contradictory) implementation of rules as reflected by norms, the instruments, and the division of labor

The first vignette refers to the coevolution of the instruments and other aspects of healthcare activities such as handover of tasks and performing medication in cases of emergency. The formal official paper-based documentation templates did not enable nurses to get a quick overview of all vital parameters, medication, and observations of the patients at the ward. To work around these shortcomings, over the years, nurses created and gradually refined 'monitoring sheets' for every patient at the ward. These letter-sized sheets hung at the board, enabled nurses to keep track of patients (e.g., in case of emergency and during shift handovers) and offered great flexibility. Data such as vital parameters, adapted dosages or important events were recorded on these sheets before typically trainees or voluntaries updated the formal documentation.

During requirements elicitation, it was decided to replace the monitoring sheets with CareDoc reports. Recording and analyzing data directly in CareDoc should reduce errors and enable early access to care documentation. However, the reports offered were not able to occupy the role of the monitoring sheets sufficiently: the report must be manually activated, is only accessible via the small monitors at the wards and does thus not offer a quick overview. For instance, NU02 stated that *"the monitoring sheets enabled us to overview patients much more easily […] which is quite important at a closed psychiatric ward."* Moreover, the reports did not occupy the function of a to-do list and reminder in the way as the monitoring sheets did. In consequence, shift handover was considerably obstructed and nurses' willingness to utilize CareDoc decreased.

Though the tensions between the adapted set of instruments and the nurses began to surface early, the project team, ward mgmt., and physicians were not able to understand why nurses requested to keep the monitoring sheets until the rollout. Particularly physicians, who presume timely and accurate data, advocated to use the CareDoc reports. This indicates that the project team did not thoroughly consider the role of the monitoring sheets as an important mediator between the actions and interactions of the nurses. Thus, these neglected the historically collected skills that enable nurses to deal with specifics at the wards (e.g., adapting medication, keeping track of patients).

The second vignette concerns medication management at the ward. Legally, nurses are only allowed to administer drugs as prescribed by a physician. Since physicians are frequently not available at the addictive disorders ward of the psychiatric clinic on short notice, however, nurses are in the need to adapt the dosage on their own and get authorization retrospectively (e.g., in case of an acute delirium or when symptoms like restlessness or shivering appear). This well-practiced shift in the division of labor has become an accepted norm at the wards. Since they feel less comfortable setting the dosages without consulting a nurse, physicians even asked if it *"is possible to calculate the optimal dosage within CareDoc*" (observation note).

Though, physicians, nurses, and IT professionals discussed the need for dynamic dosing intervals, customized related forms accordingly and agreed that the dosage could not be 'calculated', their shared understanding did not enable them to anticipate that CareDoc considerably restricts the flexibility as given by the paper-based instrument. These historically evolved aspects of the medication activity, particularly the tension between the way tasks are distributed in case of emergency and the legal requirements, were not uncovered during requirements engineering. Neither the nurses shared their knowledge and experiences regarding these aspects, nor did the IT project team point out that CareDoc will increase transparency due to time stamps of physicians' authorization of medication and nurses' administration of medication and thus, most likely, limits flexibility regarding medication handling at the ward.

Only during the rollout, the nurses recognized that CareDoc does not allow them to adapt the administration of medications on short notice or to enter up physicians' authorization after administering adapted medication without causing legal problems and –at worst– risking adverse personal consequences. Awareness of these problems negatively impacted nurses' attitude towards CareDoc. This even caused some of them to resist using the system until it was clarified how to deal with medication management in cases of emergency.

The third vignette reflects how gradual changes to the object of healthcare affected the division of labor. During the last years, cost pressures, and workload significantly increased at the wards, which stressed the need to gain efficiency. Therefore, the way tasks are distributed was continuously adapted. Amongst others, volunteers and trainees are increasingly asked to measure and document vital parameters. Legally, this must be supervised and authorized by a certified nurse, who also signs the documentation. In practice, however, nurses have not the time to accompany the volunteers and trainees and thus only sign the documentation afterwards.

Due to an IT policy, volunteers do not possess a user account that is required to perform documentation in CareDoc. Thus, after the rollout of the IS, documentation of vital parameters was limited to nurses and trainees. This obstructed the evolved mode of task distribution and increased nurses' documentation effort considerably. Since they either need to record vital parameter on their own or must sign recordings of trainees, they had less time to care for patients, which is usually the true motive of their activity (*"we spend too much time at the computer and have less time for the patients"*, NU01). Moreover, some of the nurses did not want to key in data they have not collected (*"I will not key in data that I have not measured"*, NU03).

Data collected prior to the rollout reveals that nurses and IT professionals did not share knowledge concerning the nature, history, and significance of the mode of task distribution at the wards and how CareDoc enforces conflicting legal requirements. During requirements elicitation, IT professionals and nurses did not consider how CareDoc could amplify tensions between legal requirements and the division of labor. Thus, neither IT professionals could anticipate that the characteristics of the IT tool would destabilize established ways of doing, nor ward management could clarify roles and responsibilities and thus take measures to mitigate or resolve these tensions.

5 Discussion

The paper-based instrument was found to limit the efficiency of healthcare activities (e.g., documentation quality, reimbursement). These tensions should be resolved by an HIS. Selection of an adequate system, senior leadership and user involvement enabled the project team to adapt the HIS so much that it covers most requirements, particularly those that concern the interactions of individuals with the system. However, as with similar HIS implementation initiatives reported in prior literature [2], the replacement of the legacy tools provoked unintended consequences. These were not anticipated, although the people involved could build upon benchmark data from nine rollouts prior to the addictive disorders ward and templates that are based on best practices from other hospitals. Case study data reveals that IT professionals and stakeholders failed to create shared understanding on critical aspects of the socio-technical environment the HIS is embedded in. The framework presented below summarizes and classifies these.

5.1 Crucial Aspects of Healthcare Activities

The unintended consequences we have observed indicate that users, managers, and IT professionals had difficulties to share –often– tacit knowledge and experiences related to three characteristics of their collective healthcare activities, particularly those that go beyond individual requirements. Accordingly, they struggled to anticipate how these aspects relate to the novel HIS, particularly how contradictions within the activity systems are mitigated or amplified by HIS implementation. In Figure 2 these aspects are classified (1-3) and located in a triangular activity system diagram (1-3).

The first aspect reflects that healthcare activities are characterized by contrasting objectives (aspect 1). Data reveals that the way the legacy tool and the IS account for different perspectives on the object of the collective activity was hardly considered (e.g., maintaining monitoring sheets vs. entering data directly in the HIS and using the reports). We found that exposing the contested nature of the activities and bearing in mind how the instruments account for divergent motives and thus how they impact the relationship between professional groups is critical. Creating shared understanding on this aspect would have most-likely enabled actors to anticipate and avoid the issues.

Second, patient care is characterized by a tension between the need for stability and sensitivity for variation [9]. This tension is also reflected in the historically evolved division of labor, which provides stability but needs to be sensitive to variation (e.g., in case of an emergency). Employed instruments need to account for these evolved and diverse modes of task distribution (aspect 2). Thus, actors must ensure that the HIS can govern routines and variations like their predecessors did or adapt the division of labor accordingly (e.g., task distribution between nurses, trainees, and volunteers).

Third, healthcare is highly influenced by regulation and traditional hierarchies [9]. However, evolved practices may contradict these conventions. Since HIS are often designed to comply with formal rules, they have the potential to amplify these contradictions. Hence, people engaged in IS implementation need to recognize, share, and consider explicit and implicit rules that govern actions and interactions between the subject and the community and clarify the role of the HIS within (aspect 3).

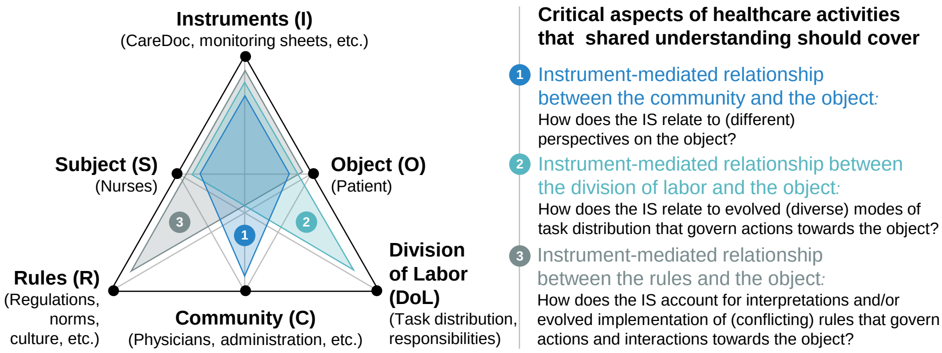

Figure 2. Aspects of healthcare activities that should be covered by shared understanding

The framework can help practitioners to more carefully consider the complex mediating relationships between instruments, rules, and the division of labor, facilitate the creation of shared understanding on the role of the HIS within and enables them to resolve contradictions without amplifying existing or creating novel ones.

Though awareness of the critical aspects will help, practitioners need to bear in mind that learning about an activity is at large inherent to the participation in an activity [44]. Thus, creating shared understanding might require IT professionals to participate in activities that are or may be affected by the HIS. This will most-likely enable them to better illuminate the aspects identified here, to anticipate emerging issues and to develop corrective actions. Practitioners might employ strategies such as cooperative prototyping, where users and IT professionals are involved [45]. Mutual prototyping may raise issues and shifts questions from subject-object interactions towards the rather invisible IS-mediated aspects of collective activities. Moreover, best-practices and approaches like the "MindMerger" [8] could benefit from methods that put an emphasis on the collective nature of human activity such as "expansive visibilization" does [31].

5.2 Limitations

Although this research offers a coherent explanation for the rise of unintended consequences after IS implementation in a complex setting, some limitations need to be acknowledged. First, the empirical data analyzed in this research stem from a single in-depth case study. Thus, it has to be shown if the activity theoretical perspective on shared understanding also explains outcomes in other settings. Second, data about early phases of the project could only be collected retrospectively, particularly regarding the design of the standard templates. Third, the timeframe for data collection was restricted. Thus, the rise of additional unintended consequences after data collection cannot be ruled out. Fourth, the number of interviews conducted is limited, some of the interviewees did not feel comfortable with recordings and only one researcher could monitor the rollout. Fifth, only the three most significant issues that emerged during and after rollout are reported in this paper. Though the analysis of the other outcomes support the conclusions drawn, the theoretical concepts still need to demonstrate their empirical validity [46]. Further research employing multiple and longitudinal case studies in other settings or quantitative studies that operationalize and test the theoretical statements may increase the confidence in the mechanisms identified here.

6 Conclusion

We know that effective design and implementation of HIS is contingent on shared understanding [see e.g. 6, 19, 20, 23, 24]. However, our learning on the kind of task-related knowledge and perspectives that need to be shared is limited. Our research contributes to this gap by providing a theoretically grounded framework that captures crucial aspects of healthcare activities that should be recognized, shared, and considered during HIS implementation projects. Moreover, we contribute to prior research by increasing our understanding on the socio-organizational aspects HIS must fit with [14]. We reveal that the people involved in HIS implementation need to create shared understanding about socio-organizational aspects that are not necessarily exposed using best-practice approaches. Following AT, the people involved need to recognize that HIS occupies positions within complex, collective, and historically evolving activity systems [35]. To resolve contradictions within these systems without provoking novel ones, the multiple perspectives and traditions that are carried by its actors, its artefacts, rules, and conventions need to be recognized, shared and aligned.

Abstract. Bei der Umsetzung der digitalen Transformation bewegt sich das IT-Management in Krankenhäusern in einem Spannungsfeld aus historisch-kulturellen Vorbedingungen und den besonderen Herausforderungen wissensintensiver Expertenorganisation. Um zu untersuchen, wie professionell das IT-Management vor diesem Hintergrund ist, wurde in der vorliegenden Studie der Professionalisierungsgrad des IT-Managements als Beschreibungsgröße vorgeschlagen. Darüber hinaus wurden Ausprägungen der IT-Governance und des IT-Entrepreneurships als mögliche Determinanten des Professionalisierungsgrades konzeptionalisiert. Ein entsprechend aufgestelltes, hypothesengeleitetes Untersuchungsmodell wurde anhand der Daten von 164 CIOs deutscher Krankenhäuser überprüft. Die Ergebnisse der Studie deuten auf Professionalisierungspotenziale des IT-Managements im strategischen und evaluierenden Bereich hin. Etablierte Kommunikationskanäle zwischen CIO und Krankenhausleitung sowie eine ausgewiesene IT-Budgetverantwortungen wirkten sich positiv auf den Professionalisierungsgrad aus. Zudem Das agierte das IT-Management umso professioneller, je stärker der IT-Entrepreneurship auf organisatorischer und individueller Ebene ausgeprägt war. Die Ergebnisse können den theoretischen Erkenntnisstand über die Wirkungsweise von IT-Governance und IT-Entrepreneurship erweitern und auf ähnliche, wissensintensive Expertenorganisationen übertragen werden.

Keywords: IT-Management, Krankenhaus, CIO, Governance, Entrepreneurship

(Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 559-573

1 Einleitung

Die digitale Transformation birgt vielfältige Potenziale für eine Effizienz- und Qualitätssteigerung der Gesundheitsversorgung [1]. Zentrale Akteure innerhalb des Versorgungsgeschehens sind Krankenhäuser, die alleine im Jahr 2014 etwa neunzehn Milliarden Gesundheitsdienstleistungen erbracht haben [2]. Die Digitalisierung der hierfür notwendigen krankenhausinternen Abläufe soll die Planung und Koordination der Behandlung effizienter gestalten, die Informationstransparenz klinischer Prozesse erhöhen und den Zugang zu medizinischem Wissen vereinfachen [3]. Die Digitalisierungsmaßnahmen reichen dabei von der Dokumentation des Behandlungsverlaufs, über die Befundanforderung und -rückmeldung, bis hin zum Aufbau von entscheidungsunterstützenden Systemen, Wissensdatenbanken und der elektronischen Patientenakte (EPA) [4]. Bei der Durchführung entsprechender Maßnahmen bewegt sich das zuständige IT-Management der Krankenhäuser in einem Spannungsfeld aus historisch-kulturellen Vorbedingungen und gesetzlichen sowie ökonomischen Rahmenbedingungen.

Krankenhäuser sind, historisch bedingt, durch linienförmige Organisationsstrukturen und starre Hierarchien geprägt [5]. Abstimmungen über interdisziplinäre, abteilungsübergreifende Abläufe, welche ein primäres Betätigungsfeld des IT-Managements darstellen [6], finden zumeist nur auf oberster Hierarchieebene, zwischen der ärztlichen, pflegerischen und kaufmännischen Krankenhausleitung (KHL), statt [7]. Hinzu kommt, dass die vorherrschende berufsständische Autonomie, insbesondere des ärztlichen Bereichs, zu Zieldivergenzen und einer Vermischung von zentralen und dezentralen Entscheidungen führen kann [5]. Entsprechend können IT-Vorhaben in Krankenhäusern selten per Mandat durchgesetzt werden, sondern sind auf langfristige Abstimmungsprozesse angewiesen [8,9]. Vor diesem Hintergrund steht das IT-Management vor der Herausforderung, hochkomplexe und wissensbasierte Behandlungsprozesse in geeigneter Form informationstechnologisch zu unterstützen [10]. Hierbei wird der Erwartungsdruck durch den exponentiell steigenden, medizinischen Wissenszuwachs zusätzlich erhöht [11]. Bei der Integration entsprechender Anwendungen sieht sich das IT-Management nicht selten mit veralteten, heterogenen Systemen konfrontiert [12]. Eine weitere krankenhausspezifische Herausforderung ergibt sich aus den diversen gesetzlichen Vorgaben und Normen (bspw. Basel II, Medizinprodukte-Gesetz), welche die Etablierung eines umfassenden Risikomanagements erfordern [13] und somit in ihrer Umsetzung umfangreiche personelle und finanzielle Ressourcen binden können. Schließlich herrscht in der Krankenhauslandschaft ein zunehmender Wettbewerb und ökonomischer Druck [5], wodurch sich konkrete Erwartungen an das IT-Management ergeben. So sollen einerseits Effizienzreserven identifiziert und ausgeschöpft werden (z.B. die Vermeidung von Doppeluntersuchungen), andererseits steht die IT als potenzieller Kostenfaktor selber auf dem Prüfstand [12].

Die beschriebenen Rahmenbedingungen stellen das IT-Management der Krankenhäuser vor ein Dilemma: Zum einen erfordern die vielfältigen, teilweise divergierenden Herausforderungen weitreichende Handlungsfreiräume auf operativer, taktischer und strategischer Ebene [10], auf der anderen Seite können insbesondere historisch, kulturell und ökonomisch bedingte Restriktionen diese Freiräume begrenzen [5].

Über die Handlungsfähigkeit des IT-Managements von Krankenhäusern, im Sinne von planenden, steuernden und überwachenden Aktivitäten [10], existieren bis dato keine empirisch fundierten Erkenntnisse. Vielmehr wird dieser Forschungsgegenstand bisher nur randläufig in Studien zur IT-Adoption und zur IT-Governance betrachtet [1,4,9,14,15]. In der vorliegenden Arbeit wird zur Beschreibung des Umfangs und des Formalisierungsgrades des IT-Managements der *Professionalisierungsgrad* als konzeptionelle Beschreibungsgröße vorgeschlagen. Die Studie folgt weiterhin der Annahme, dass Ausprägungen der IT-Governance und des IT-Entrepreneurships mögliche Einflussgrößen auf den Professionalisierungsgrad darstellen. Entsprechend wurde vor dem Hintergrund des krankenhausspezifischen Kontextes ein hypothesengeleitetetes Untersuchungsmodell entwickelt, auf Basis dessen folgende Forschungsfragen beantwortet werden sollen: (1.) Wie ausgeprägt ist der Professionalisierungsgrad des IT-Managements in den deutschen Krankenhäusern und (2.) inwiefern beeinflusst die Ausprägung der IT-Governance und des IT-Entrepreneurships den Professionalisierungsgrad?

Durch die Betrachtung der Krankenhäuser, welche stellvertretend für Expertenorganisationen besondere Anforderungen an das IT-Management stellen, soll die Beantwortung der Forschungsfragen das theoretische Verständnis über die Wirkungsweise von IT-Governance und IT-Entrepreneurship erweitern. Auf der anderen Seite sollen die Ergebnisse praktische Hinweise liefern, wie das IT-Management im Hinblick auf die Herausforderung der digitalen Transformation in den Krankenhäusern professionalisiert werden kann.

2 Konzeptionelle Entwicklung des Untersuchungsmodells

2.1 Professionalisierungsgrad des IT-Managements

Das IT-Management umfasst alle planerischen, steuernden und überwachenden Aktivitäten, welche im Bezug auf die IT-Ressourcen eines Unternehmens auf strategischer, taktischer und operativer Ebene durchgeführt werden [10]. Nach Weill [16] handelt es sich bei diesen Aktivitäten um die Durchführung IT-bezogener Entscheidungen. Der *Professionalisierungsgrad* des IT-Managements kann über den Umfang und den Formalisierungsgrad der durchgeführten IT-Managementhandlungen definiert werden [10,17]. Professionalität im IT-Management hat demnach eine *quantitative* und eine *qualitative* Dimension.

Zur Definition der quantitativen Dimension können normative Ansätze herangezogen werden [10,18]. Eine zentrale Aufgabe des strategischen IT-Managements ist die Entwicklung einer, mit der Krankenhausstrategie korrespondierenden IT-Strategie [10]. Idealerweise wird die IT-Strategie in eine Finanz- und Investitionsplanung und in ein längerfristiges Projektportfolio überführt [19]. Um den Beitrag der IT zur Erreichung der Unternehmensziele darstellen zu können, erfolgt weiterhin eine strategische Überwachung, bspw. in Form gezielter Evaluationen [10]. Auf taktischer Ebene umfasst das IT-Management alle Aktivitäten, die zur Überführung der IT-Strategie in erfolgreiche IT-Projekte notwendig sind [10]. Hierbei ergeben sich insbesondere Aufgaben rund um die Analyse, Auswahl, Spezifikation, Einführung und Evaluation neuer Systeme [18]. Die Aktivitäten des operativen IT-Managements beziehen sich schließlich auf den erfolgreichen Betrieb aller IT-Komponenten, welche an den klinischen und administrativen Krankenhausabläufen beteiligt sind (Infrastruktur und Netzwerke, Applikationsbetreuung und -wartung, Help- bzw. Servicedesk, etc.) [10].

Die qualitative Dimension des Professionalisierungsgrades kann darüber definiert werden, inwiefern die einzelnen Handlungsweisen formalisiert bzw. standardisiert nach festgelegten Vorgehensweisen durchgeführt werden [12]. Durch die Formalisierung können die IT-Managementaktivitäten einerseits fortlaufend optimiert werden, indem sie an Best-Practice Lösungen ausgerichtet werden [9]. Andererseits ermöglicht die formalisierte Durchführung eine Orientierung der IT-Managementhandlungen an der Unternehmensstrategie [12]. Für die Formalisierung der Managementhandlungen werden in Krankenhäusern sowohl industrielle IT-Governance-Rahmenwerke (bspw. COBIT® oder ITIL®), als auch eigenentwickelte, bzw. generisch entstandene Rahmenwerke genutzt [9].

2.2 IT-Governance

IT-Governance schafft die Rahmenbedingungen für einen zielorientierten Betrieb der unternehmenseigenen IT-Ressourcen [16,20]. Gegenüber dem IT-Management befasst sich IT-Governance nicht mit der Durchführung IT-bezogener Entscheidungen, sondern mit den hierfür notwendigen Befugnissen und Verantwortlichkeiten [16]. IT-Governancemechanismen lassen sich in Strukturen, Prozesse und relationale Ansätze unterteilen [22]. Vor dem Hintergrund der krankenhausspezifischen Vor- und Rahmenbedingungen (vgl. Kap. 1) und im Hinblick auf den Professionalisierungsgrad des IT-Managements erscheinen insbesondere die *hierarchische Positionierung*, das *strategische IT-Alignment* und eine *ausgewiesene IT-Budgetverantwortung* des CIOs bzw. der IT-Abteilung relevante IT-Governancemechanismen darzustellen.

In Krankenhäusern werden abteilungs- und einrichtungsübergreifende Digitalisierungsmaßnahmen vorrangig auf oberen Hierarchiestufen abgestimmt, da sie über die bereichsbezogenen Entscheidungsräume des ärztlichen, pflegerischen und administrativen Bereichs hinausgehen [5,7]. Entsprechend kann eine hohe hierarchische Positionierung des CIOs (bspw. als Mitglied der KHL) die notwendigen Handlungsfreiräume, insbesondere für krankenhausweite Digitalisierungsprojekte, schaffen [9,23,24].

Neben der hierarchischen Einordnung wird die ganzheitlich Plan- und Steuerbarkeit der IT auch von der Ausprägung des strategischen IT-Alignments determiniert [9,10]. Unter IT-Alignment kann die wechselseitige Abstimmung von Strategien, Architekturen, Prozessen sowie Leistungen zwischen IT und (klinischen) Fachabteilungen verstanden werden [19,26]. In Krankenhäusern hat das IT-Alignment in den vergangenen Jahren verstärkt an Bedeutung gewonnen, da sich das Wirkungsfeld des IT-Managements mit zunehmenden informationstechnologischen Potenzialen von dem rein administrativen Funktionsbereich auf den medizinischen und pflegerischen Bereich ausweitet [1,4,10]. Die Synchronisierung von IT und Unternehmensstrategie kann sich zum einen in der Intensität des strategischen Austausches zwischen CIO und KHL und zum anderen in einer, mit der Krankenhausstrategie korrespondierenden IT-Strategie manifestieren [19,26]. Schließlich kann vermutet werden, dass eine ausgewiesene IT-Budgetverantwortung auf Seiten des CIOs bzw. der IT-Abteilung den Professionalisierungsgrad des IT-Managements erhöht, da hierdurch vermutlich langwierige investitionsbezogene Abstimmungsprozesse zwischen den Fachabteilungen verringert werden können [8].

Ausgehend von diesen Vorüberlegungen wird folgende Hypothese aufgestellt:

H1. Je ausgeprägter die IT-Governance, desto höher ist der Professionalisierungsgrad des IT-Managements in den Krankenhäusern.

2.3 IT-Entrepreneurship

Entrepreneurship beschreibt die Neugründung von Organisationen als Reaktion auf identifizierte Marktpotenziale und als Ausdruck spezifischer Gründerpersönlickeiten [27]. Jüngere Definitionen verstehen unter Entrepreneurship das unternehmerische Denken und Handeln innerhalb bestehender Organisation und beziehen sich dabei sowohl auf die Ausprägungen der Organisationskultur [28], als auch auf persönliche Eigenschaften der Organisationsmitglieder [29]. In der vorliegenden Studie wird zwischen *IT-Entrepreneurship-Kultur* und *IT-Entrepreneurship-Persönlichkeit* unterschieden.

Organisationen mit einer hohen IT-Entrepreneurship-Kultur erkennen und erschließen innovative, IT-bezogene Marktpotenziale im Vergleich zu ihren Mitbewerbern vergleichsweise frühzeitig als strategische Wettbewerbsvorteile [28]. Kennzeichnende Merkmale einer IT-Entrepreneurship-Kultur sind eine visionäre und innovative Grundausrichtung, eine vergleichsweise hohe organisatorische Flexibilität und eine Unternehmensleitung, die aktiv den Einsatz innovativer Technologien fördert [28,30]. Eine ausgeprägte IT-Entrepreneurship-Kultur kann sich in Krankenhäusern auf verschiedene Weise positiv auf den Professionalisierungsgrad des IT-Managements auswirken. Zum einen ist die Durchführung strategischer Managementaktivitäten in hohem Maße von der Unterstützung durch die KHL abhängig [8,14]. Andererseits profitiert sowohl die Implementierung als auch der operative Betrieb neuer IT-Lösungen von einer innovativen Grundhaltung und flexiblen Organisationsstrukturen, da hierdurch die Neugestaltung klinischer Arbeitsabläufe nicht nur ermöglicht, sondern im besten Fall auch aktiv von den klinischen Endanwendern eingefordert wird [8,15].

IT-Entrepreneurship-Persönlichkeiten zeichnen sich durch unternehmerisches Denken und Handeln hinsichtlich innovativer IT-Lösungen aus, womit sie nicht selten auch mangelnde Entscheidungsbefugnisse auf mittleren und unteren Hierarchiestufen ausgleichen [27,29]. Eigenschaften von IT-Entrepreneurship-Persönlichkeiten sind eine vergleichsweise hohe Risikobereitschaft, eine eigenständige und proaktive Vorgehensweise sowie eine hohe Partizipationsbereitschaft gegenüber IT-Anwendern [29,31]. In Krankenhäusern kann eine ausgeprägte IT-Entrepreneurship-Persönlichkeit des CIOs den Professionalisierungsgrad des IT-Managements auf verschiedene Weise positiv beeinflussen. Auf der einen Seite können risikoaffine und proaktiv agierende Persönlichkeiten vorherrschende Entscheidungsrestriktionen (vgl. Kap. 1) überwinden und somit zu einem innovativem IT-Betrieb beitragen [29-31]. Auf der anderen Seite kann das IT-Management vermutlich insbesondere in Expertenorganisationen wie Krankenhäusern von einem partizipativen bzw. anwenderorientierten Führungsstil des CIOs profitierten [8,15]. Dies zeigt sich exemplarisch an der Herausforderung, die oftmals hochkomplexen, wissensintensiven medizinischen Behandlungsprozesse in geeigneter Form durch IT zu unterstützen [6]. Gerade klinische Entscheidungen gelten aufgrund des Zusammenspiels von medizinischem Erfahrungswissen, individuellen Patientendaten und medizinischer Evidenzlage als schwer standardisierbar [11]. Entsprechend bedarf es für die Identifikation innovative IT-Lösungen, welche den Klinikern die aktuelle und relevante medizinische Evidenz störungsfrei im Kontext des jeweiligen Behandlungsgeschehens zur Verfügung stellen sollen, nicht nur eine proaktive und risikoaffine Persönlichkeit, sondern auch eine enge Zusammenarbeit zwischen IT-Management und klinischen Experten [6,10,14,18].

Ausgehend von diesen Vorüberlegungen wird folgende Hypothese aufgestellt:

H2. Je ausgeprägter der IT-Entrepreneurship, desto höher ist der Professionalisierungsgrad des IT-Managements in den Krankenhäusern.

2.4 Untersuchungsmodell

Zur Strukturierung des Forschungsvorhabens wurden die konzeptionellen Vorüberlegungen in ein hypothesengeleitetes Untersuchungsmodell überführt (Abb. 1). Die drei zentralen Beschreibungsgrößen des Modells wurden zweistufig angeordnet, da im Hinblick auf den Professionalisierungsgrad des IT-Managements von einem unabhängigen bzw. einem, sich reziprok ergänzendem Einfluss der IT-Governance und des IT-Entrepreneurships ausgegangen wurde. Neben den vorab konzeptionalisierten Beschreibungsgrößen umfasst das Modell Kontrollvariablen als konfundierende Merkmale.

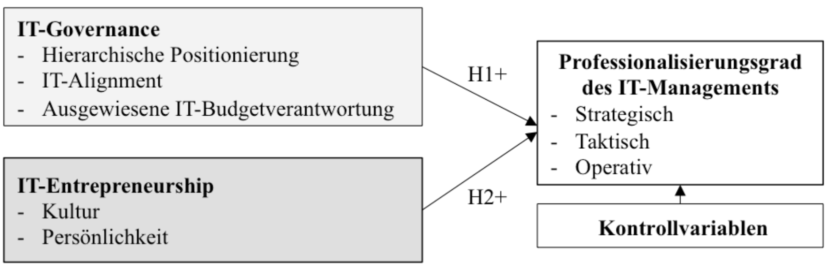

Abbildung 1: Untersuchungsmodell

3 Methode

3.1 Operationalisierung und Datenerhebung

Zur Beantwortung der Forschungsfragen wurde in Anlehnung an Köbler et al. [32] eine empirische Querschnittsuntersuchung als Datenerhebungsmethode ausgewählt. Der hierbei genutzte Fragebogen wurde in mehreren Schritten entwickelt.

In einem ersten, konzeptionellen Schritt wurden die Items für den Fragebogen aus der Literatur abgeleitet [9,10,12,16,18,22,27–31,33–35]. In einem zweiten Schritt wurden die identifizierten Items gemeinsam mit zwei CIOs auf die Übertragbarkeit auf deutsche Krankenhäuser überprüft und teilweise angepasst. Schließlich wurde der Fragebogen in einem Online-Erhebungstool umgesetzt und zwei Pretests unterzogen, in welchen die inhaltliche und technische Plausibilität überprüft wurde. An den Pretests beteiligte sich eine heterogene Gruppe aus vier zusätzlichen CIOs und sechs Wissenschaftlern. Insgesamt wurden 35 Items für die Überprüfung des Untersuchungsmodells entwickelt (vgl. Tab. 2).

Professionalisierungsgrad des IT-Managements: Die quantitative Dimension des Professionalisierungsgrades wurde in Anlehnung an Winter et al. [10] über die Anzahl der durchgeführten IT-Managementaktivitäten operationalisiert. Die qualitative Dimension wurde in Anlehnung an Schlegel et al. [12] über den Formalisierungsgrad der IT-Managementaktivitäten erfasst.

IT-Governance: In Orientierung an vergleichbare Studien [33,36] wurde die Ausprägung der IT-Governance sowohl über organisatorische, als auch über individuelle Eigenschaften operationalisiert. Um die hierarchische Einordnung des IT-Betriebes zu erfassen, wurde gefragt, ob der CIO Mitglied der KHL ist und ob die IT-Abteilung als Stabsstelle fungiert. Das strategische IT-Alignment wurde operationalisiert, indem zum einen die Intensität der strategischen Kommunikation zwischen CIO und KHL und zum anderen das Vorhandensein einer, mit der Krankenhausstrategie korrespondierenden IT-Strategie abgefragt wurden. Schließlich wurde erhoben, ob der CIO bzw. die IT-Abteilung über ein ausgewiesenes IT-Budget verfügen.

IT-Entrepreneurship: Zur Operationalisierung der IT-Entrepreneurship-Kultur wurden in Anlehnung an Bradley et al. [30] drei Items entwickelt, mit denen der Unterstützungsgrad durch die KHL, die Flexibilität der Organisationstruktur und die visionäre Ausrichtung innerhalb des Krankenhauses eingeschätzt werden konnten. Die IT-Entrepreneurship-Persönlichkeit wurde ebenfalls über drei Items operationalisiert, mit denen die proaktive Handlungsweise, die Risikoaffinität und die Partizipationsbereitschaft des CIOs erfasst wurden [31].

Kontrollvariablen: Insgesamt wurden sechs Kontrollvariablen als konfundierende Größen erfasst. Dies waren auf organisatorischer Ebene der Status eines Verbundkrankenhauses, der Status eines Universitätskrankenhauses, die Größe (Bettenzahl) sowie die Trägerschaft des Krankenhauses. Diese Merkmale wurden als positive Einflussgrößen auf die IT-Adoption von Krankenhäusern identifiziert [1,4,37] weshalb vermutet wurde, dass sie auch mit dem Professionalisierungsgrad des IT-Managements zusammenhängen können. Auf Ebene des CIOs wurde in Anlehnung an Smith et al. [36] die Betriebszugehörigkeit des CIOs (in Jahren) sowie in Anlehnung an Burke et al. [38] der akademische Grad (Hochschulabschluss) erhoben. So wurde davon ausgegangen, dass die Erfahrung und Beständigkeit einer Position, sowie die Qualifikation den Professionalisierungsgrad beeinflussen können.

Der Link zu dem Online-Fragebogen wurde in der Feldphase an 1284 CIOs deutscher Krankenhäuser verschickt. Die E-Mailadressen wurden in einer vorgeschalteten Internet- und Telefonrecherche erfasst. Die recherchierten CIOs waren insgesamt für 1675 Krankenhäuser zuständig. Von 305 Krankenhäusern konnten keine Adresse ermittelt werden, da entweder die Position des CIOs nicht existierte, die IT Organisation extern durchgeführt wurde oder in der Recherche keine Auskunft gegeben wurde. Der Erhebungszeitraum erstreckte sich von Februar bis April 2016. In diesem Zeitraum wurden drei Nachfassaktionen durchgeführt.

3.2 Stichprobe

Insgesamt nahmen 188 CIOs an der Umfrage teil, von denen nach einer Vollständigkeits- und Plausibilitätsprüfung 24 Bögen aussortiert wurden. Die verbliebenen 164 auswertbaren Datensätze entsprachen einer Rücklaufquote von 12,8%. In der finalen Stichprobe waren 45,1% der Teilnehmer für mehr als ein Krankenhaus zuständig, sodass die teilnehmenden CIOs insgesamt 397 Krankenhäuser betreuten ($\overline{x}$=2,4; SD=4,6). Die durchschnittliche Betriebszugehörigkeit der CIOs lag bei 11,7 Jahren (SD=7,9). Über einen Hochschulabschluss verfügten 58,5%. Zur Überprüfung der Repräsentativität wurde die Stichprobe in Anlehnung an Köbler et al. [32] nach Größe und Trägerschaft segmentiert und mit der Population deutscher Krankenhäuser verglichen [2] (vgl. Tab.1). Gegenüber der Grundgesamtheit waren kleinere Krankenhäuser mit weniger als 200 Betten leicht unterrepräsentiert und mittlere und größere Krankenhäuser entsprechend überrepräsentiert. Hinsichtlich der Trägerschaft waren private Einrichtungen unterrepräsentiert und öffentliche- sowie freigemeinnützige Krankenhäuser überrepräsentiert.

Tabelle 1: Gegenüberstellung von Stichprobe und Population [2]

Trägerschaft	*unter 200 Betten*	*200 bis 799 Betten*	*800 Betten und mehr*	*Stichprobe*	*Population*
Öffentlich	21,4%	58,9%	19,6%	34,1%	29,7%
Privat	63,2%	26,3%	10,5%	11,6%	35,1%
Frei / Gemeinnützig	44,9%	55,1%	0,0%	54,3%	35,1%
Studienstichprobe	39,0%	53,0%	7,9%	100,0%	
N	64	87	13	164	
Population	56,2%	39,1%	4,7%	100,0%	
N	1113	774	93		1980

In Tabelle 2 werden die deskriptiven Statistiken der Items dargestellt, welche für die Operationalisierung der Beschreibungsgrößen im Untersuchungsmodell genutzt wurden.

Tabelle 2: Deskriptive Statistiken (WB=Wertebereich; n=164)

	Items	WB	$\overline{x}$	SD
strat. IT-Mgmt	Strategische Überwachung (gezielter Evaluationen inkl. Kennzahlenerhebung)[1]	1-3	1,37	0,67
	Erstellung eines Projektportfolios (für ca. 12 Jahre) [1]	1-3	1,55	0,69
	Entwicklung einer mit der Krankenhausstrategie korresp. IT-Strategie[1]	1-3	1,58	0,73
	Strategische Steuerung in Form der Priorisierung und Initiierung von Projekten[1]	1-3	1,76	0,68

[3] 0=„Nein“; 1=„Ja“
[4] 1=„Stimme überhaupt nicht zu“; 2=„Stimme eher nicht zu“; 3=„Stimme eher zu“; 4=„Stimme voll und ganz zu“

3.3 Datenanalyse

Um die Annahmen des Untersuchungsmodells zu überprüfen, wurde eine multiple Regressionsanalyse mit SPSS23® durchgeführt. Multiple Regressionsanalysen eignen sich als hypothesenprüfende Verfahren, da sie den Einfluss mehrerer unabhängiger Variablen (Prädiktoren) auf eine abhängige Variable (Kriterium) testen [39].

Als Kriterium diente der *Professionalisierungsgrad des IT-Managements*. Zur Quantifizierung des Professionalisierungsgrades wurde ein gewichteter Summenscore gebildet, indem pro durchgeführte IT-Managementaktivität ein Punkt und pro formalisiert durchgeführter IT-Managementaktivität 1,5 Punkte vergeben wurden.[1] Der gewichtete Summenscore wurde skaliert, sodass der Professionalisierungsgrad des IT-Managements in einem Wertebereich von 0 bis 100 Punkten lag.

Um das Untersuchungsmodell zu überprüfen, wurden fünf Merkmale zur Beschreibung der IT-Governance[2], zwei Merkmale zur Beschreibung des IT-Entrepreneurships sowie sechs Kontrollvariablen als konfundierende Größen in das Modell eingeschlossen (vgl. Kap. 3.1). Zur Quantifizierung der *IT-Entrepreneurships-Kultur* und *-Persönlichkeit* wurden Summenscores gebildet, indem jeweils der Zustimmungsgrad zu den drei aufgestellten Aussagen (vgl. Tab. 2) aufaddiert wurde.

Für die statistischen Analysen wurden fehlende Werte durch Mittelwerte ersetzt. Zur Überprüfung der Modellvoraussetzungen wurde auf Homoskedastizität sowie auf Normalverteilung der Residuen getestet. Zur Prüfung auf Multikollinearität wurden Toleranzwerte sowie der Variance Inflation Factor (VIF) berechnet [39]. Zudem wurden die signifikant in dem Modell verbliebenen Prädiktoren korreliert.

4 Ergebnisse

Von maximal 100 Punkten, die für den Professionalisierungsgrad des IT-Managements erreicht werden konnten, erzielten die befragten Einrichtungen durchschnittlich 42 (SD=14; n=164). Der niedrigste Wert lag bei 15, der höchste bei 100 Punkten. Nur knapp jedes fünfte teilnehmende Krankenhaus erreichte einen Wert über 50 (19,5%; n=164). Strategische IT-Managementaktivitäten wurden gegenüber operativen und taktischen Managementaktivitäten vergleichsweise selten durchgeführt. Dies galt insbesondere für die strategische Überwachung, aber bspw. auch für die Entwicklung von längerfristigen IT-Projektportfolios und für die IT-Strategieplanung (vgl. Tab. 2). Sowohl im strategischen, als auch im taktischen und operativen Bereich wurden evaluierende bzw. überwachende IT-Managementhandlungen im Gegensatz zu planenden und ausführenden Aktivtäten seltener durchgeführt (vgl. Tab. 2).

In Tabelle 3 werden die Koeffizienten der Prädiktoren im Regressionsmodell, gegliedert in Anlehnung an die Operationalisierung der Beschreibungsgrößen (vgl. Kap. 3.1), dargestellt. Von den 13 Prädiktoren, welche in das Modell eingeschlossen wurden, ergaben sich neun signifikante Beta-Koeffizienten (vgl. Tab. 3). Zusammengenommen erklärten die eingeschlossenen Prädiktoren 47,0% der Varianz des Professionalisierungsgrades (korr. R^2). Drei der fünf überprüften IT-Governancemerkmale zeigten einen signifikant positiven Einfluss auf den Professionalisierungsgrad. Ebenfalls wirkte sich die IT-Entrepreneurship-Kultur und -Persönlichkeit signifikant posi-

[1] Die moderierende Gewichtung folgt der Annahme, dass formalisiert durchgeführte Managementaktivitäten im Hinblick auf den Professionalisierungsgrad nicht zwangsläufig doppelt so hoch gewertet werden können, wie ad-hoc durchgeführten Aktivitäten, da die Aktivität an sich der wesentliche Aspekt ist.

[2] Die Variable “CIO ist Mitglied der KHL“ wurde aufgrund der ungleichen Verteilung der Merkmalsausprägungen (5% zu 95%) aus der Regressionsanalyse herausgenommen.

tiv auf den Professionalisierungsgrad aus. Auch der Status eines Universitätsklinikums und der des Verbundkrankenhauses zeigten einen signifikant positiven Einfluss.

Die Residuen waren normalverteilt und Homoskedastizität lag nicht vor, sodass die Modellvoraussetzungen erfüllt waren. Die errechneten Korrelationsstatistiken gaben keine Hinweise auf Multikollinearität (vgl. Tab. 3). In Tabelle 4 werden die Korrelationen der signifikanten Prädiktoren in Form einer Korrelationsmatrix dargestellt. Die Korrelation der Prädiktoren weisen auf schwache, positive Korrelationen zwischen einzelnen Prädiktoren hin, wobei die „Intensität der strategischen Kommunikation" mit drei signifikanten Korrelationskoeffizienten am häufigsten korrelierte (vgl. Tab. 4).

Tabelle 3. Koeffizienten der Prädiktoren im Regressionsmodell (n=164)

Prädiktor	*Beta*	*Sig.*	*Toleranz*	*VIF*
Intensität der strat. Kommunikation	0,205	0,002	0,798	1,254

5 Diskussion

Ein professionell agierendes IT-Management gilt als Dreh- und Angelpunkt für eine erfolgreiche Umsetzung der digitalen Transformation [4,10,19,32]. Vor diesem Hintergrund erscheint es umso bemerkenswerter, dass bis dato keine empirisch fundierten Erkenntnisse darüber existieren, wie professionell das IT-Management in Krankenhäusern tatsächlich ist und wodurch der Professionalisierungsgrad determiniert wird. Um diese Forschungslücke zu schließen, wurde in der vorliegenden Studie ein hypothesengeleitetes Untersuchungsmodell entwickelt und anhand der Daten von 164 CIOs überprüft.

Die Ergebnisse der Studie deuten auf diverse Professionalisierungspotenziale des IT-Managements hin. So müsste ein Großteil der befragten Krankenhäuser die IT-Strategieplanung intensivieren und entsprechende IT-Vorhaben konsequent in adäquate Finanz- und Investitionsplanungen sowie in längerfristige Projektportfolios überführen, wenn Digitalisierungspotenziale proaktiv genutzt werden sollen [10,19]. Zudem müsste der Einsatz von Evaluierungsmaßnahmen wie bspw. Systemanalysen, Anwenderbefragungen oder IT-Benchmarks verstärkt fokussiert werden, damit der Digitalisierungsfortschritt fortlaufend überwacht und sein Wertbeitrag transparent dargestellt werden kann [9,10,13].

Bei entsprechenden Professionalisierungsbemühungen sieht sich das IT-Management der Krankenhäuser mit unterschiedlichen Herausforderungen konfrontiert [5,7-9,12-14]. Vor diesem Hintergrund wurde die Annahme getroffen, dass eine ausgeprägte IT-Governance sowie ein hoher IT-Entrepreneurship den Professionalisierungsgrad positiv beeinflussen. Die Ergebnisse der Studie konnten diese Annahmen weitestgehend bestätigen. So scheint sich der intensive Austausch zwischen CIO und KHL positiv auf den Professionalisierungsgrad des IT-Managements auszuwirken. Dies gilt auch für eine ausgewiesene IT-Budgetverantwortung des CIOs bzw. der IT-Abteilung. Der Einfluss der hierarchischen Positionierung des CIOs konnte aus methodischen Gründen nicht überprüft werden. Jedoch zeigten die Ergebnisse, dass das IT-Management in den meisten Krankenhäusern auf mittleren und unteren Hierarchiestufen eingeordnet ist. Die Wirkungsweise der betrachteten IT-Governancemechanismen sollten im Zusammenhang mit dem ebenfalls betrachteten IT-Entrepreneurship interpretiert werden. So deuten die Ergebnisse darauf hin, dass der Professionalisierungsgrad des IT-Managements durch eine ausgeprägte Unterstützung der KHL positiv beeinflusst wird. Darüber hinaus scheint ein professionell agierendes IT-Management mit einer visionären Grundhaltung und flexiblen Organisationsstrukturen einherzugehen. Schließlich zeigten die Ergebnisse, dass sich eine ausgeprägte Entrepreneurship-Persönlichkeit des CIOs positiv auf den Professionalisierungsgrad des IT-Managements auswirkt. So kann vermutet werden, dass CIOs auf mittleren und unteren Hierarchiestufen mangelnde Entscheidungsbefugnisse durch unternehmerisches Denken und Handeln ausgleichen [27,29]. Darüber hinaus scheint das IT-Management insbesondere in wissensintensiven Expertenorganisationen wie Krankenhäusern von einem anwenderorientierten Führungsstil des CIOs zu profitieren [8,15].

Die vorliegende Studie liefert erste Hinweise auf wesentliche Begleitumstände und Vorbedingungen eines professionellen IT-Managements. Hierdurch erhalten Krankenhäuser empirisch fundierte Hinweise für eine erfolgreiche Umsetzung der digitalen Transformation. Insbesondere die Rolle einer ausgeprägten Entrepreneurship-Persönlichkeit des CIOs kann einen Ansatz für weitergehende Forschungsarbeiten liefern. In einem ersten Schritt könnte eine reliable und valide Operationalisierung des Konstrukts, bspw. durch faktoranalytische Verfahren fokussiert werden. Weiterhin könnten Folgestudien die Wechselwirkung von IT-Governance und IT-Entrepreneurship durch Interaktionstests näher spezifizieren. Auch wäre es von Interesse, die IT-Performance der Krankenhäuser in einem erweiterten, mehrstufigen Untersuchungsmodell als zusätzliche Zielgröße zu berücksichtigen. Die IT-Performance könnte dabei über die IT-Unterstützung klinischer Prozesse operationalisiert werden. Schließlich könnte die Übertragbarkeit der Ergebnisse auf andere Betätigungsfelder des IT-Managements, insbesondere auf das Feld wissensintensiver Expertenorganisationen (z.B. Hochschulen) überprüft werden.

6 Limitation

Bei der Interpretation der Studienergebnisse müssen mehrere Limitationen berücksichtigt werden. Zum einen steht die betrachtete Stichprobe nicht repräsentativ für die Grundgesamtheit der deutschen Krankenhäuser. Kleinere und nicht private Einrichtungen waren unterrepräsentiert. Die Faktoren zur Beschreibung des Professionalisierungsgrades und des Entrepreneurships wurden zwar inhaltlich validiert, jedoch nicht auf Reliabilität überprüft. Die vorgenommene, moderierende Gewichtung folgte zudem ausschließlich inhaltlichen Erwägungen. Weiterhin wurde die IT-Governance größtenteils über binäre Merkmale operationalisiert. Zukünftige Ansätze sollten hier, komplementär zur Operationalisierung von IT-Entrepreneurship, validierte Item-Skalen nutzen. Zwischen den einzelnen Prädiktoren zeigten sich schwache, jedoch signifikante positive Korrelationen. Obwohl dies die Interpretierbarkeit der Ergebnisse im Hinblick auf die zusätzlich berechneten Multikollinearitätstatistiken nicht schwächt, sollten zukünftige Ansätze eine überschneidungsfreie Operationalisierung adressieren. Auch aus der Nutzung des gewählten Analyseverfahrens ergeben sich Limitationen. Regressionsanalysen eignen sich insbesondere für die Überprüfung prozesshafter Modelle mit einseitigen Abhängigkeiten zwischen den Merkmalen. Diese kausalen Beziehungen spiegeln die Realität des betrachteten Untersuchungsfeldes jedoch nur bedingt wider, da sich IT-Governance und das IT-Management vermutlich rekursive beeinflussen. Schließlich berücksichtigt das Modell keine Strukturbrüche zwischen den individuellen Merkmalen des CIOs und den Merkmalen der Organisation. Zukünftige Ansätze sollten daher auf komplexere Analyseverfahren, wie bspw. Mehrebenenmodelle oder Strukturgleichungsverfahren zurückgreifen.

Introducing Archetype Theory to Information Systems Research: A Literature Review and Call for Future Research

Raphael D. Schilling, M. Kazem Haki, and Stephan Aier

University of St. Gallen, Institute of Information Management, St. Gallen, Switzerland
{raphael.schilling,kazem.haki,stephan.aier}@unisg.ch

Abstract. Studying organizational configurations on the one hand and the dynamics of organizational change on the other hand are dominant topics of interest in the information systems (IS) discipline. Studies in each of these research streams take advantage of various well-established theoretical lenses from reference disciplines such as management science. In this study, we take a closer look at archetype theory, which combines these two research streams and which eventually provides a dynamic perspective on organizational configurations. Through a literature review, this study provides a comprehensive understanding of archetype theory (i.e., its constitutive constructs and assumptions) as well as on its application in studying dynamics of configurations. In introducing archetype theory to IS research, we discuss the explanatory power of the respective theory for investigating IS phenomena as well as the methodological and theoretical implications of employing the theory in IS research.

Keywords: Archetype Theory, Literature Review, Change, Configuration

1 Introduction

Investigating configurations has long been central to management research [1-3] as well as to information systems (IS) research [4, 5]. Respective studies seek for patterns, classifications, and sets of structures that differ in their fundamental characteristics and that are effective under different circumstances [e.g., 3, 6]. Such configurations have been researched for IS governance [e.g., 4, 7, 8], ERP implementation [e.g., 9, 10], inter-organizational IS [e.g., 11], among others. However, as fast-moving change has become the natural mode of organizational life [12], the existing *static and deterministic view* on configurations would not appropriately account for the dynamics of change in a turbulent environment [6]. Consequently, configurations should also be examined from the *perspective of change* as they emerge from the dyadic, dynamic interactions between organizations and their ever-changing environment [6, 13].

In the extant IS literature, scholars dominantly examined *either* configurations [e.g., 4, 5, 7, 11], *or* dynamics of change [e.g., 14, 15-17]. As the use of proper theoretical lenses guides scholars in both theory building and theory testing in IS research [18-23],

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Schilling, R.D.; Haki, M.K.; Aier, S. (2017): Introducing Archetype Theory to Information Systems Research: A Literature Review and Call for Future Research, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 574-588

in this study we promote the use of archetype theory as a purposeful theoretical lens to *simultaneously* study configurations and dynamics, i.e., the configurations that result from dynamics of change. Compared to other frequently used reference theories in IS, such as institutional theory [24, 25], *archetype theory* has not gained recognition in IS research.

After generating their theory on the information technology (IT) function in organizations, Guillemette and Paré [26] in the discussion of their resulted insights state that the lens of archetype theory guides theory-driven investigation of configurations and their inherent dynamics, thus opens new avenues for studying various IS phenomena. As such, with the goal of introducing archetype theory to IS research and commencing preliminary discussions on its implications in IS research, in this study we seek for (i) providing a comprehensive understanding of archetype theory and its underlying analytical constructs and assumptions, and (ii) reviewing how and for which purposes extant research has applied archetype theory. Therefore, compared to existing reviews in management research that focus on archetypes in, for instance, professional service firms [27, 28] and sports organizations [29], the focus of our review is the theory itself and its applications. To this end, our study uncovers the explanatory power of archetype theory in investigating a wide range of IS phenomena, since it caters an in-depth and profound understanding of the underlying mechanisms of change as well as the configurations resulting from change. Finally, we discuss methodological and theoretical implications of employing archetype theory for IS research.

2 Archetype Theory

The identification of optimal configurations and their dynamics have long been the focus of research in management studies [30]. Research on this topic evolved through three schools of thought, namely gradualist, contingency, and structural adjustment paradigms [31]. During the development of the classical management theories in 1950s, academia believed in "one best way" to structure organizations [32]. The *gradualist paradigm* consequently propagates evolutionary approaches [33], similar to Darwin's model of evolution and is reflected in, for instance, lifecycle and maturity model metaphors. Due to neglecting the context in which configurations are embedded, this initial understanding was challenged by other theorists [41], focusing on the contextual factors, which ultimately lead to the *contingency paradigm*. The latter brings a central argument to the forefront of configuration research: "the external circumstances that produce particular organizational designs, and the idea that there is an appropriate linkage between the external, the internal, and performance" [32, p. 400]. Later, institutional theory adds to the contingency paradigm by revising the linkage of internal and external contingencies and performance through a stronger focus on institutional pressures [32]. As such, organizations are understood as reflections or responses to rules, beliefs, and conventions in their surrounding environment [34]. However, organizations have been evolving differently, even when exposed to the very same institutional pressures [35]. Theories of the *structural adjustment paradigm* thus focus on the dynamics of organizational adaptation and explain the movement between different organizational configurations in the same organizational context. In this paradigm, configuration theory has been influential in taking punctuated equilibrium assumptions (i.e., necessity of ongoing fit between contingency factors and configuration parameters) and in considering a significant number of contingencies resulting in rich descriptions of optimal configurations [36]. Configuration theory posits that configurations can be determined through typologies, taxonomies, and archetypes [27]. As the notion of archetype in configuration theory tries to not only consider optimal configurations but also the underpinning mechanisms that bring about these configurations, it has further been recognized as archetype theory[1]. This theory comprises two key aspects: (i) the *exploration of organizational archetypes* as well as (ii) the *analysis of change*. The following sub-sections describe these aspects in detail.

2.1 Exploration of Organizational Archetypes

Greenwood, Hinings, and Laughlin [35, 38, 39] elaborated the concept of optimal configurations through the notion of archetype and archetype theory respectively. According to archetype theory, an archetype comprises the twin concepts of *interpretative scheme* and *structural arrangement*:

The *interpretative scheme* describes an organization's conception on what it should be doing, how it should be doing, and how it should be judged. This conception is shaped by the prevailing set of ideas, beliefs, and values [38]. The *structural arrangement* implements and reinforces the ideas, beliefs, and values through establishing organizational structures and processes that reflect the respective beliefs and values [38]. Thus, there is a strong interrelation between the interpretative scheme and the structural arrangement as they reinforce each other.

In an ideal case, organizations will evolve towards a situation of organizational *coherence*, where the structural arrangement and the interpretative scheme represent an "appropriate design for adequate performance" [38, p. 295]. As such, in the coherence situation, interpretive scheme and structural arrangement are in line with each other and represent a specific archetype. However, neither do all organizations change in the same way nor will all of them reach a level of high performance. Thus, the analysis of change is an integral part of archetype theory, for which the concept of *change tracks* has been applied.

2.2 Analysis of Change

The identification of archetypes is a preparatory step for the explanation of change. By the identification of the archetype, an organization is situated in one of the following *positions* [38]:

1. *Archetype coherence*, where the interpretative scheme and structural arrangement match and thus reflect and reinforce each other.

[1] Theorists introduced archetype theory both as a subordinate of configuration theory [27] and as a synonym of configuration theory [37].

2. *Embryonic archetype coherence,* where some design elements are discordant as interpretative scheme and structural arrangement do not perfectly match.
3. *Schizoid incoherence*, where organizations show the presence of two different archetypes at the same time and thus competing interpretative schemes and structural arrangements.

To explain the actual change process, archetype theory outlines the movement of organizations along the abovementioned positions through the concept of *tracks* [38]:

1. *Track A - Inertia:* Most organizations will stick to one archetype for a lengthy period of time. This track describes a situation of archetype coherence with incremental changes, where only slight structural adjustments within a particular archetype can be observed.
2. *Track B - Aborted excursion:* Here, organizations shift from a position of archetype coherence towards an embryonic archetype coherence and back to archetype coherence.
3. *Track C - Reorientation:* Describes the typical transformation situation, where organizations move from an archetype to another. This includes fundamental changes in both the structural arrangement and interpretative scheme.
4. *Track D - Unresolved excursion:* Describes a failed change process. The organization is trapped between two competing archetypes.

Relying on archetype theory's focus as well as on its well-defined constructs and relations, it has a considerable potential to help scholars understand the dynamics of change and its resultant configurations (i.e., archetypes) in IS research. The concept of organizational coherence considers both, tangible artifacts such as structures and processes but also intangibles such as values and beliefs. It also acknowledges the role of dynamics of change by defining multiple change tracks. Therefore, it is worthwhile analyzing how archetype theory has already been applied and, more specifically, how configurations and change have been examined through this theory in the extant literature.

3 Research Method

Despite its potential, archetype theory has not gained much attention in IS research yet [31]. We therefore opt for a literature review, which is considered suitable to identify potential implications for prospective research [40]. This section describes how we identified and analyzed the relevant literature.

3.1 Literature Selection and Review Process

In order to identify prior research relevant to archetype theory, we searched for articles, containing "archetype theory"[2] in either the title, abstract, or keywords. To extract high-quality contributions, we limited our search process on scientific databases to peer-reviewed, scholarly journals (with no limitation on the publication date and the type of journal) and excluded other types of publications (e.g., books, projects, conference proceedings). We identified the related articles by scanning Business Source Premier as well as ProQuest scientific databases. The goal was to cover a wide range of research disciplines, including IS. Not surprisingly, we did not find any journal article in IS, we thus extended the search process and further included AIS-supported conference articles in IS, which were retrieved from the AIS Electronic Library.

We subsequently went carefully through the abstracts of all articles and excluded those that were not relevant (see **Table 1**).

Table 1. Search and selection process of the literature review

Database	Business Source Premier	ProQuest	AIS Electronic Library
Search Term	"archetype+theory" IN title OR abstract OR keywords		"archetype+theory"
Filter	Only look for scholarly journals		none
# of articles found *(total: 42)*	7	34	1
# of articles excluded and reasons for exclusion *(total: 26)*	• Article has no relation to archetype theory according to abstract (10 articles) • Article is referring to "jungian archetype theory", which is different than the archetype theory in management science (9 articles) • Article is a book review (1 article) • Article is written in other languages than English (1 article) • Article is a seminal article on archetype theory (5 articles)		
# of articles considered for review *(total: 16)*	16 application articles that employed archetype theory as a theoretical lens in investigating their phenomena of interest.		

We also differentiated seminal articles (contributing to the seminal assumptions and constructs of archetype theory) from application articles (applying assumptions and constructs of archetype theory to their phenomenon of interest). Seminal articles are used for the construction of the analysis framework, which is described in the following section. We used the analysis framework to code the application articles to gain insights on how scholars applied archetype theory in their respective research.

[2] It is noteworthy that we did not search for the term "archetype" alone or other relevant terms such as "configuration" and "gestalt" [41]. This is due to the focus and scope of our research in reviewing archetype theory itself and its applications, not in identifying the derived archetypes or configurations in the extant research.

3.2 Analysis Framework

Following the guidelines of Webster and Watson [40] and Fettke [42], we developed an analysis framework to guide literature analysis. This analysis framework comprises the *constructs* of archetype theory (as introduced in Section 2) as well as further components to gain insights on how archetype theory has been *applied*. The constitutive components of the analysis framework are:

Use of the theory: Archetype theory can be used to explore archetypes and/or to analyze change. We classified, whether new archetypes are explored and whether changes are analyzed based on archetype theory. This helps us gain insight into the purposes archetype theory is dominantly used for.

Exploration of the archetype: This component of the analysis framework aims at identifying how archetypes have been described. We therefore extracted all the proposed archetypes along with the respective interpretive scheme and structural arrangement of each archetype.

Change: Explaining the dynamics of change is one of the fundamental premises of archetype theory. Therefore, this component of the analysis framework captures the core findings of articles on change, particularly with regard to different types of change tracks.

Research method: In order to capture the dynamics of archetypes, researchers need to employ appropriate methods to investigate structural arrangements and, even more challenging, interpretive schemes. This will support future research in selecting appropriate research methods. Therefore, in the analysis framework, the employed research methods are classified into conceptual, quantitative, and qualitative methods and the corresponding techniques have been captured.

Level of analysis: With this component of the analysis framework, we aim at understanding whether archetype theory is more suited for any particular level of analysis. We distinguish between department (e.g., financial department), organization (e.g., a particular company), industry (e.g., law advisors), and sector (e.g., professional service firms) levels of analysis.

Complementary theory: If archetype theory is used in combination with any other theory, such observations are noted down in this component of the analysis framework. This helps us understand relevant theories that can be used as complementary to archetype theory.

After developing the analysis framework, we coded the extracted articles based on the analysis framework[3].

---

[3] The summary of the coding is available for download under http://bit.ly/2f4cJPn

4 Results

The analysis of the extant literature resulted in identifying 16 articles in which archetype theory has been employed [27-29, 31, 43-54][4]. This section presents the major findings of our review in line with the previously introduced analysis framework.

As shown in **Table 2**, the reviewed articles proposed different archetypes. However, some pairs of comparable archetypes (e.g., bureaucratic and managerial archetypes) are frequently used in different articles and only about half of the articles proposed new or substantially modified existing archetypes. Therefore, the identified archetypes are representative for similar situations and can be re-used in other studies. Further, according to the use of the theory, 13 of the articles are concerned with the analysis of change. The latter is an indication that although identification of archetypes is a considerable contribution per se, they are mainly used to better understand the dynamics of change in organizations. We have also observed that at least two different archetypes are identified in each of the reviewed articles. This observation is related to the fact that change is mainly associated with a movement between archetypes.

Table 2. Purpose of theory use and employed research methods in the reviewed articles

Category			**Reference**	**# of articles**[5]
Purpose of theory use	*Exploration of Archetypes*	Managed Professional Partnership / Managed Professional Business	[43, 44]	2
		Bureaucratic / Managerial	[45-47]	3
		Kitchen Table Boardroom / Executive Office	[29, 49, 50]	3
		Others	[27, 28, 31, 48, 51-54]	8
	Analysis of change		[31, 43-54]	13
Research Method	*Conceptual*	Literature Analysis	[27-29]	3
	Qualitative	Semi-Structured Interviews	[31, 45-48, 50, 51, 53, 54]	9
		Secondary Source Analysis	[31, 45-48, 50, 52, 53]	8
		Meeting Observation	[48, 54]	2
	Quantitative		[43, 44]	2

4.1 Organizational Archetypes

By comparing the archetypes investigated in the reviewed articles, we were able to identify patterns of how archetypes are typically described. It is out of scope of this

[4] Literature analysis uncovers 5 *seminal* articles of archetype theory [35, 38, 39, 55, 56], which are used to develop our analysis framework. The derived analysis framework is used to analyze 16 *application* articles.

[5] The same article may be assigned to multiple categories. For instance, Haki & Legner [31] applied qualitative research through semi-structured interviews and secondary source analysis.

article to describe each particular archetype in detail[6]. We rather aimed at explaining how archetypes have been described in the reviewed articles to eventually synthesize how archetype theory can actually be applied. In line with the analysis framework, we distinguish between the structural arrangement and the interpretive scheme of archetypes.

Structural Arrangement: In order to describe the structural arrangement, the work of Cooper et al. [55] is often a starting point in the reviewed articles [44, 46, 54, 55]. Cooper et al. posit that structural arrangement can be defined through both *structures* and *systems*. *Structures* are generally classified by considering the degree of differentiation and integration. Differentiation has been identified through, for instance, considering the level of specialization amongst teams [28] or through the range of different disciplines within organizational entities [48]. Integration is considered to be expressed by the location of the decision power [49], the information flow [55], and the degree of commonly applied rules and procedures. *Systems*, here mainly to be understood as processes, are generally classified into strategic control, marketing control, financial control, and operating control. Reviewed articles propose to measure strategic control through, for example, the degree of strategic freedom of different organizational entities [43, 44]. Marketing and financial control can be observed by the tolerance regarding financial and marking targets [43], compensation systems, and systems for performance appraisal [46]. Operating control finally may be expressed by the degree of centralization of control and information systems [46].

Interpretative scheme: Less consistent are the descriptions used for the interpretative scheme. This is due to the fact that intangibles (such as values and beliefs) are much more difficult to define and measure than tangibles (such as an organization's structure). For instance, in order to distinguish between "partnership" and "managed" archetypes, authors looked at the perceived purpose of an organization, also described as an organization's "raison d'être" [54]. For partnership, this is often the exchange of knowledge with peers, whereas for managed organizations this would be the increase of productivity [43, 44]. As another example, for sport organizations, differentiation has been made between their degree of professionalism in terms of their target definition (e.g., sport as a leisure activity vs. sport as a profession) [29]. Other scholars also differentiated different interpretive schemes along the underlying principles when taking decisions, for example regulation-oriented versus efficiency-oriented decision making principles [45, 46].

4.2 Change

Since the concept of change tracks is an integral part of archetype theory, prior to our review we expected that the articles to take up and refer to this concept [38]. Surprisingly, we identified only few articles [49, 54, 55] that explicitly distinguish between change tracks as explained in Section 2. Instead, Liguori [47], for example, employs a rather basic construct of change tracks and distinguishes between incremental and radical changes. Incremental changes are considered as modifications

[6] Brock [57] provides detail specifications of the identified archetypes in the literature.

of the structural arrangements only, whereas radical changes also involve changes in the interpretative scheme. This conception is confirmed by the other authors, highlighting the crucial role of the interpretative scheme in change processes [44, 46]. It is noteworthy that Kirkpatrick & Ackroyd [52] demonstrate, how change does not necessarily lead to a new archetype but may also be reflected in an adjustment within the current archetype. Therefore, change can be examined through both adjustment within an archetype and movement between different archetypes.

Further, instead of focusing on the change process as such, authors were interested in understanding why and how a change process is initiated. Authors understand change of the archetype as a reaction to environmental and contextual pressures, which are filtered by organizations through an internal process of interpretation and attribution of meanings [47, 52]. Frequently given examples for such pressures are globalization [28, 44, 52], (de-)regulation/change in government policy [28, 44, 52], change in client needs [44], technological progress [52], as well as capacity for action in terms of both technical and managerial/leadership capabilities [47].

4.3 Research Method, Level of Analysis, and Complementary Theories

In this section we describe the employed research methods in the reviewed articles followed by a discussion of the level of analysis and complementary theories. The majority of the reviewed articles employed *qualitative* research methods and case study research in particular (see **Table 2**).

In case studies, semi-structured interviews, and the review of secondary sources, such as documents, reports, presentations, and media articles were common to identify archetypes and/or changes among archetypes. Indicators for the structural arrangement were, for example, the degree of integration expressed by the decision power of the headquarter [28]. The interpretative scheme was, for example, assessed by capturing the underlying principles during the decision making process [46, 47]. In addition, two articles identified the observation of meetings as an appropriate technique to extract values and decision making processes [48, 54].

Change was identified in two different ways: Either by comparing different cases at a single point in time, or by carrying out longitudinal case studies. The decision for either of the two options is thereby depending on the underlying research question. Liguori [47], for example, was interested in why similar organizations react differently to the same kind of change, whereas Carter and Mueller [48] were interested in the change process of one organization between two archetypes. This implies that whenever the dynamics of change of one particular organization are of interest, longitudinal studies are more appropriate.

Conceptual research was only conducted in articles focusing on rather abstract research topics such as ideal types of governance [27] or synthesis on archetypes described by the other authors [29].

Concerning *quantitative* methods, only two articles applied archetype theory through a quantitative research design [43, 44]. Both articles aimed at examining change of archetypes in different groups of professions (architects and law firms). To this end, they did so by taking two already defined archetypes and assigned the organizations to one of them based on the answers received in a questionnaire.

The reviewed articles investigated archetypes and change, on different *levels of analysis*. Three articles focused on the department level, for instance, the departments of local government and change in the accounting system [45-47]. Two articles focused on single companies and were classified as research on the level of organization [31, 48]. The majority of the reviewed articles examined archetypes and change on the industry level. Two conceptual articles also focused on the sector of legal advisors and auditors [27, 28].

Besides the employed research methods and the level of analysis, we were also interested in identifying *theories* that were used complementary to archetype theory. We consider configuration theory (more precisely, the typology and taxonomy aspects) as well as agency theory to be relevant, because they were used in the reviewed articles to facilitate exploration of archetypes and explanation of change in archetypes. Harlacher und Reihlen [27] employed configuration theory to identify governance taxonomies and compared them with existing archetypes in the literature. Pinnington [44] employed agency theory to better explain change in archetypes. The use of agency theory helped Pinnington [44] explain changes in the decision making system (structural arrangement) for cases, where the ownership of organizations has changed [44]. According to agency theory, control mechanisms are intensified in cases, where the ownership and the management of the same organization are separated (e.g., shareholder vs manager). This may lead to a change in archetypes because not only the structures but also the values are changed.

5 Discussion

This article starts with the premise that the study of configurations should account for the underlying change mechanisms that bring about the creation or emergence of the respective configurations. As such, the simultaneous study of change and configurations results in profound insights on the dynamics of configurations, their development in a series of change events, and eventually gives meaning to their aspects and specifications.

IS scholars have been striving to explain change and proposed a variety of approaches to identify optimal configurations. To this end, various theoretical lenses have been employed to study change (e.g., evolutionary/Darwinian approach) and optimal configurations (e.g., contingency theory). Relying on the constitutive constructs and theoretical premises of archetype theory, this theory provides a theoretically sound basis to not only explain changes but also to explore configurations. Therefore, it can be employed in studying various IS phenomena in which identifying configurations and explaining the underlying change mechanisms are central. To elaborate the employment of the archetype theory and its contributions in prospective IS research, we provide two exemplary implications on both research streams namely, optimal configurations and change:

The study of optimal configurations is quite dominant in, for instance, IT governance. As pointed out in a literature review on IT governance by Brown and Grant [58], the extant literature has been dominated by either configurations of IT governance [7, 59, 60] — introducing centralized, decentralized, and federal governance modes — or by contingency factors influencing IT governance structure [8]. Nevertheless, existing studies mainly prescribe optimal IT governance structures while the underlying mechanisms that bring about these structures remain obscure. Therefore, the promoted lens of archetype theory proposes a dynamic, non-deterministic approach to explain how and why different IT governance structures arise. It also brings up the possibility of establishing different IT governance structures under the same organizational contingencies and further explains how this non-deterministic process is as such. Moreover, concerning the change stream of research, extant research gives rise to the nature of IS change so that change is not solely or even mainly incremental and cumulative, but rather is episodic and punctuated [61, 62]. These studies mainly lay emphasis on explaining change mechanisms while the emerged configurations form this dynamic process is of outmost interest for different IS phenomena. As such, the explored relation between change processes and the emerged configurations can not only give rigorous meaning to the dynamics of configurations and their occurrence, but also explore typological configurations that can be observed in different contexts and situations. Therefore, the use of archetype theory can systematically guide prospective IS research to not only explain the nature of change but also explore configurations.

To apply archetype theory in IS research, our review motivates longitudinal case studies to rigorously reflect dynamics of configurations over time. We encourage mixed-methods research to not only explore configuration but also to confirm their generalizability in a larger extent. Our review confirms applicability of archetype theory on different levels of analysis. Therefore, we not only see value in applying archetype theory on a more granular level, where local variants of organizational specialties may be considered, but also in studies that concern multiple levels of analysis. Finally, our review reveals that, owing to its explanatory power, the theoretical constructs of archetype theory can be synthesized with other theories (e.g., agency theory) to be used as complementary lenses in providing thorough explanations of IS phenomena.

Our literature review is limited to publications in scholarly journals and AIS conference proceedings. This is a limitation in terms of coverage of relevant research (e.g., conference proceedings in other disciplines). However, this restriction ensures a certain quality level of the reviewed articles while including conference-level contributions from IS. Our study reveals that archetype theory has not gained much attention in IS literature (only one article, [31]). Therefore, our review provides insights on how this theory can be applied in prospective IS research.

6 Conclusion

While spotlighting the necessity of simultaneous investigation of configurations and change, this study contributes to the existing body of IS knowledge through introducing archetype theory as a new theoretical lens, which guides IS scholars in such investigations. Through a literature review, this study carefully extracts theoretical constructs of archetype theory and investigates why, how, with which approaches, and through which methods archetype theory has been applied in the extant literature.

The concept of archetype provides a basis to systematically describe configurations in terms of their structural arrangement as well as the values and beliefs that reinforce these arrangements. The theoretical assumptions on change in archetype theory also provides a rich explanation on the dynamics of configurations. As such, this theory helps IS scholars elaborate on change not only through demonstrating movements among different archetypes, but also through indicating adjustments within an archetype.

Abstract. Cyber-physical systems (CPSs) are service systems that connect a product's physical and computational elements through telecommunication networks. Typically, the processes in CPSs are executed on this physical and computational infrastructure. As the developing of new CPS is costly, testing and validating a CPS's design at an early stage of development is desirable in order to avoid potential bad investments. The high development and potentially high hardware costs, however, make it difficult to create a full CPS prototype only for testing. This work uses Trkman's critical success factors of business process management (BPM) as a theoretical lens and identifies "technical-feasibility fit" as an additional complementary success factor. Based on these factors, we develop a method for creating CPS testbeds that allow testing of CPSs at lower costs at an early stage of the development. We demonstrate the method's application by a case in which we develop a testbed for an electric vehicle charging service.

1 Introduction

Service is the value created in relational interaction processes [1] that connect a company to several "collaborators" [2, p. 492] such as partners, employees, and suppliers. All entities together form the *service system*, which VARGO and LUSCH defined as a dynamic configuration of four types of resources, i.e., people, technologies, organization, and information [3]. *Service Development* refers to a firm's approach to creating new service offerings and has been described as a cyclical process that includes various planning and implementation activities at the progressive stages of "Design", "Analysis", "Development", and "Launch" [4]. Notably, a service development project can also return to earlier stages if later planning and development activities require modifications of the service concept. Against this background, service development requires that service concepts are tested repeatedly for their business value and for their operational feasibility [5]. For instance, shortly after initial idea generation, firms typically evaluate the service concept ideas through a "screening" [6]. However, the individual development stage activities related to the design of the service, processes, and the actual system require more exhaustive testing [4]. Business value embodied in, e.g., profitability, growth and reward potential, as well as competitive advantage [6, 7] is typically assessed using conventional qualitative and quantitative market research techniques like surveys, focus groups, one-on-one interviews and conjoint analysis [8].

In contrast, the testing of the operational feasibility of a service concept requires to look deeply into the service system's value creation processes as well as the technological and informational resources they use. "Prototyping" is one approach to achieve rapid customer-centric service experimentation [9]. In this context, it is an important question how *service prototyping* can be used to "materialize an integrated set of service system components, such as the people, the process, the technology, and the physical evidence" [10, p. 137]. According to OSTROM et al., prototyping has not received sufficient attention in service research, and thus, they feature service prototyping in their recent list of important service research areas [10].

Especially in the domain of cyber-physical systems (CPSs), technology components are of particular significance. Typically, CPSs connect (remote) computational and physical entities, e.g., sensors and actuators, via global computational networks [11]. In this context, *prototyping* is highly important for this type of service system because of the requirement that complex technical infrastructures have to be built at early stages of the service development—even before the progress and the processes can be fully tested.

Against this backdrop, the present paper addresses the following research question: *How can service prototyping materialize the process and technology components of cyber-physical systems?* The contribution of this paper lies in the design of a method for creating CPS testbeds. We intend to improve CPS service development by facilitating prototyping and testing for operational feasibility at early stages of the development process and at reasonable costs.

The development of the method is informed through the theory of *task-technology fit (TTF),* a theoretical lens that has been applied previously in business process management (BPM) [12, 13]. The TTF theory helps to assess whether certain technologies are appropriate to a given process. Therefore, this paper also seeks to synthesize research on prototyping in service development and research on success factors in BPM, which have so far been considered only separately.

The remainder of this article is structured as follows: The next section gives background on the testing of CPS with regard to the process perspective and success factors. Then we explain our research approach, followed by the method and a demonstration of its application in a project that develops a service for electric vehicle (EV) charging. The evaluation section provides first evidence of the method's usefulness. A discussion of our results follows, and the final section concludes the article.

2 Research Background

2.1 Challenges in Testing CPS

CPSs are specific service systems including networked computational systems that are partly embedded into physical objects [11]. Sensors and actuators connect the physical and digital worlds. An ever-growing number of CPSs, which have become ubiquitous in every-day life, generate a vast amount of data, with typical applications ranging from smart grids [14], physical infrastructures in transportation [15], traffic and process control to automotive and medical systems [16].

CPSs are complex systems with complex processes that typically run on expensive hardware. In particular, the embedding of physical components requires higher standards for reliability and safety as system failures can result in severe damages, e.g., of the environment [17]. Embedded systems such as driving assistance or brake control are examples of CPSs integrated in every-day systems, whose failures can result in serious consequences for the public. Moreover, the behavior of CPSs cannot always be predicted.

While traditional end-to-end business processes are implemented within or across a few application systems, processes in CPSs add another layer of complexity. In effect, parts of the business logic are shifted into these embedded systems [18]. From the business perspective, addressing the challenges posed by the nature of CPSs requires considerable investment. Failing in the latter stages of the development due to miss-specified processes that are unable to execute within and across the CPS can be costly, so guarding against such situations is critical for managing and executing business processes.

2.2 Process-Focus in Service Design and Testing

Testing CPS for operational feasibility is of great importance throughout the various stages of service development [5]. Prototyping has been discussed as a promising ap-

-proach to achieve a balance between receiving early insight on the feasibility and the costs associated with the testing activities [10]. The key intellectual challenge in service prototyping is to achieve an integrated service experimentation that materializes all relevant components of the service systems in a way so that the service stakeholder can make sense of the service and make reasonable decisions about the progress of the development project [9]. The scope of this paper has been set to processes and technology, which are the most significant components of CPS service systems.

The BPM literature has put forth constructs, models, and theories that help to study the relationship between processes and technology. Notably, in an attempt to identify critical success factors (CSFs) for BPM, TRKMAN demands "continuous improvement efforts" for BPM and two types of "fit" for business processes [12, p. 126]. The "fit between business environment and business processes" has been explained by the *contingency theory* [19], which in essence states that there exists no universal or "best way" to manage an organization. Instead, achieving an appropriate organization is contingent to various internal and external constraints. Accordingly, business processes have to be designed so that they meet the constraints of the process environment. The "fit between business processes and technology" [12, p. 127] has been explained through *task-technology fit (TTF)*—a theory that identifies that a positive impact of information technology (IT) investments on organizational performance is subject to matching IT and business processes.

The need for "dynamic improvement" of business processes is justified by the theory of *dynamic capabilities*, which postulates that organizations need to address changing environments through the ability to integrate, build, and reconfigure internal and external competences. Therefore, business processes need to be reviewed for both types of fit continuously.

We focus on TTF, which provides means to study the CPS's *process* and *technology* service components in conjunction. While testing in software development projects already accounts for about one third of development cost [20], the testing and validation of the distributed and embedded components of a CPS is even more complex and costly [21] and thus underlines the importance of a proper TTF.

3 Research Approach

To approach the problem of testing the operational feasibility of a service concept in the context of a CPS throughout different stages of the service development process, we perform two research activities: At first, we aim at the derivation of a framework for critical success factors in BPM from the extant literature. This step is required to examine and categorize different state-of-the-art CSFs to identify the gap and motivate the extension of the framework with an additional CSF of testing the operational feasibility of the service concept. The second strand of our research deals with the development of a method that is capable of closing the identified gap.

Table 1. Research Steps

#	Step	Activities	Outcomes
1	*Analyze CSFs*	Investigate extant CSFs Align CSFs and BPM Analyze applicability in use case scenario	Framework Identified gap
2	*Propose Extension*	Propose testbedding as an extension to the TTF	Motivation Proposed extension
3	*Method Design*	Design the method Apecify activities	Method instantiation
4	*Demonstration*	Demonstrate the extension Iterative execution Adopt continuous improvement	Evaluation

Table 1 summarizes the steps undertaken in this research and the generated outcomes. In the first step, we identify relevant CSFs in the extant literature (see CSFs labelled with [*] in Table 2). Taking the specific requirements imposed on service testing in the CPS context, we propose the extension of the general framework of success factors in BPM with an additional CSF (see CSF_{2+} in Table 2). We then design the method suitable for ensuring and warranting that the chosen technology set for the service at hand aligns with the corresponding business processes. Finally, we complement the demonstration of the method with a discussion of the proposed approach against related testing procedures.

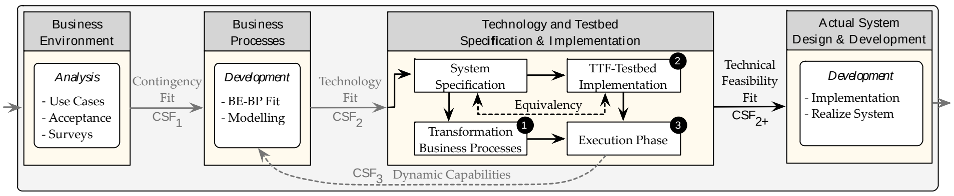
4 A Method for Creating CPS Testbeds

Against the backdrop of high risks associated with business processes relying on CPSs, we enhance TRKMAN's model of CSFs [12] by an additional CSF that follows the TTF. We introduce the specification and implementation of a testbed as means of ensuring the *technical feasibility fit* between the chosen technology set and the business processes (cf. Figure 1). In effect, a testbed combines virtual, simulated, and physical components into a configurable experimental setup for testing [23]. In an ideal world, the behavior and properties of the testbed are equivalent to ones of the specified service system. Thus, we use the term *testbed equivalency*.

Our work aims at achieving an optimal TTF with a technology ensemble feasible to execute the business processes, while treating the remaining activities required to address further CSFs as a *black box*. Assessing the TTF can be expensive, which is especially true for distributed processes that run on heterogeneous and specialized hardware. Prototype development with a testbed combines the benefits of early testing and validation with cost savings, because the actual hardware roll-out can be postponed until the testbed has been used to validate the correct execution of all involved (business) processes. Hence, prototyping can "reduce the chances of costly new service failures" [10, p. 137].

Testbeds have to correctly imitate the execution of the business processes, and thus, require a precise specification of the target system's behavior. We therefore limit the scope to business processes that use standardized and established technologies, techniques and protocols, so that the behavior of the system can be anticipated.



4.1 Steps of the Method

Figure 1. Embedding of Testbedding into the Framework of CSFs for BPM

Figure 1 locates the proposed *technology and testbed specification and implementation* within the process and framework of CSFs in BPM. The activity blends in after CSF_1 and CSF_2 have been achieved through the contingency and technology fits. At this point, the business processes have been modelled and formalized. Based on the business processes and underlying standards, a set of technologies, i.e. software and hardware components, has been chosen. The testbed method consists of three steps: First, the resulting business processes must be *transformed (1)* into a state-based representation. Simultaneously, the *testbed implementation (2)* is performed. The testbed equivalency to the actual system must be assured through the equivalency of the testbed specification to the system specification. Subsequently, the implemented and configured testbed is put to use in the *execution phase* (3) by executing the transformed business processes from step (2).

(1) Transformation of Business Processes into a State-based Representation: Business processes are typically represented as models and the Event-driven Process Chain (EPC) and Business Process Model and Notation (BPMN) are arguably the most prominent graphical process modeling languages in both, academia and practice. To ensure correct process execution and *soundness*, one needs to transform the EPC or BPMN models into a *state-based* representation. The utilization of a state-based representation allows to precisely comprehend the current state of the process and check every state transition for compliance. In this context, *Petri nets* are recommendable [24] which is justified by the large existing body of knowledge on formal validation of Petri nets [25]. Moreover, for the actual transformation, one can make use of existing and well-tried methods for *model-to-model transformation* to convert the business processes into Petri nets. The mapping itself is straightforward: "*tasks* are modeled by *transitions*, *conditions* are modeled by *places*, and *cases* are modeled by *tokens*." [26, p. 15]. A *marking* can be understood as a snapshot that reflects the Petri net's state at a certain point in time. In order to make the state transitions of the resulting Petri net transparent, the individual states must be represented in such a way that they are *observable*. This approach is similar to *lean manufacturing* or *Andon systems* where certain situations are signaled. Several options are conceivable for providing such an output like displays, acoustic signals, and light-emitting diodes (LEDs). Once a suitable and observable state representation has been decided upon (e.g., LEDs), a coherent mapping of the individual Petri net markings, i.e., states, must be developed. A naïve solution is to assign an individual LED to each place on the Petri net, which would visualize the presence of a token at the corresponding place. However, the number of places in the resulting Petri net can be large for complex business processes. This can be mitigated by using different states of the same signal emitter to code the marking, e.g., using multi-colored LEDs and modes like *on/off* or *blinking/pulsing* in different intervals. A display can also be attached that can be used to output the state as well as accompanying information such as enabled transitions or a history of states, which can be used for *backtracking* purposes to achieve full coverage of the process.

(2) Testbed Implementation: Based on the results of the TTF assessment, a testbed has to be specified that ensures *equivalency* to the technology set intended for the implementation of the productive IT infrastructure. Due to heterogeneity in required capabilities among various use cases and domains, the hardware selection process needs to be considered individually. However, a careful evaluation of the underlying task-technology fit is mandatory to provide a tangible basis for choosing suitable hardware components for the intended testbed. Naturally, the selected hardware should be capable to imitate the actual productive component of the CPS.

Important activities in this development stage include the assessment and comparison of different hardware and software vendors and sources, as well as their compatibility. Active support and maintenance should be taken into account as well. The decision regarding a suitable means for the output depends on many factors like the total number of devices in the testbed, the processes' complexity, and the degree of concurrency. Depending on which output mean(s) is/are chosen, a formal mapping and representation of the different states must be defined. Finally, the testbed device(s) is/are assembled and programmed so that it can emulate the intended business processes.

(3) Execution Phase: The set of business processes to be tested should be compiled beforehand and in accordance with the testbed specification. The resulting *test suite* is then processed by executing the different processes in the testbed environment. In the spirit of *continuous improvement*, the processes are executed iteratively within the testbed. If an abnormality is experienced during the execution phase, this information is recorded and re-evaluated in an iterative manner in a subsequent execution round. Each execution of the processes in the testbed environment provides feedback to the specification phase until the result meets the acceptance criteria. In some cases, the testbed might also prove that a given business process is unfeasible for real-world execution. This information flow and the subsequent addressing of defects results in a demonstrated *technical feasibility* of the technology—given the assumption that the testbed and the final system are equivalent when the processes are emulated. This additional step that contemplates the initial TTF constitutes an additional CSF: *Technical Feasibility Fit*. Once the "sweet spot" in terms of robustness has been reached, the replacement of the testbed with the actual production system is approached.

5 Demonstration

5.1 Project Setting: EV Charging Infrastructure

We applied the testbed method in the domain of EV charging. EVs are charged using charging points, which combine electrical and computational components. The CPS at hand comprises a charging infrastructure of networked charging points and an information system (IS) that, among other tasks, controls the individual charging points, authorizes users to unlock a charging point and charge their vehicles, and handles the billing of charging transactions.

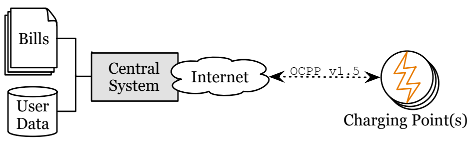


Figure 2. Central System and Charging Points

In particular, the processes for controlling the charging infrastructure, which comprises the *charging points* and a corresponding *central system* (see Figure 2), have been formalized in the *Open Charge Point Protocol (OCPP)*. The OCPP represents a *de facto standard* and protocol for the communication between the central system and the individual charging points [27]. The communication is realized by sending OCPP-based SOAP requests over HTTP. According to the OCPP, charging points can be in one of four states and different messages are used to either initiate or communicate a change of the state as visualized in Figure 3. For instance, an *expired reservation* is to be detected by the charging station itself which will then change its status to *available* whereas a request to *cancel a reservation* is sent by the central system to a specific charging station.

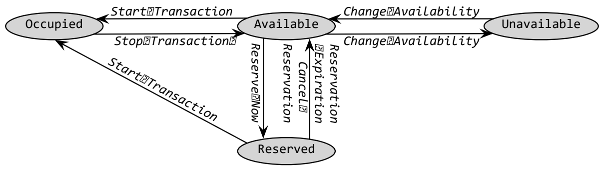

Figure 3. Transition System of a Charging Point According to the *OCPP v1.5*

5.2 Method Application

We perform the three aforementioned steps of the method (cf. Figure 1):

(1) Transformation of Business Processes into a State-based Representation: As the testbed is supposed to ensure that the business processes and the real world are compatible, a transformation into a state-based representation is performed. This is realized by transforming the individual BPMN models into a Petri net representation. In our case, we transformed the business processes that have been specified for the central system and a charging station (cf. Figure 2). To make the different states "experiencable" and observable, we relied on signaling using LED states to represent the states of the charging point:

$$\text{State} \equiv \{[\text{LED}_{\text{red}} = x_1], [\text{LED}_{\text{yellow}} = x_2], [\text{LED}_{\text{green}} = x_3]\},\ x_i \in \{\text{off}, \text{on}, \text{pulse}, \text{blink}\} \quad (1)$$

Figure 4 illustrates how the individual states of the *BPMN model* are mapped to a *Petri net* and specific *LED states*. Each marking of the resulting Petri net corresponds to a unique LED allocation.

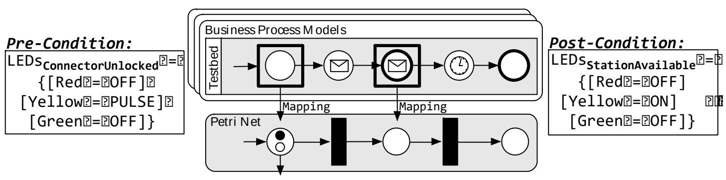

Figure 4. *Mapping* of BPMN to *Petri Net* and *LED States*

(2) Testbed Implementation: The architecture of charging stations mandates several functional requirements for the testbed implementations: reading of NFC cards, mobile

Internet connectivity, and exchange of messages with the central system based on OCPP v1.5. The publicly available Web Service Description Language (WSDL)[1] files were used for the specification and software development for the testbed and the corresponding central system. We then engineered a testbed device to resemble a charging station for the testbedding.

LEDs indicate the state of charging station as in Figure 3 (i.e., idle, reserved, out-of-business, connector (un-)locked, charging, charging finished. In addition to the LED signals, the transition sequences are logged and shown on a display. Because of its low cost, versatility, broad support, and active community, a *RaspberryPi* Model B[2] served as the basis for the development of the testbed .

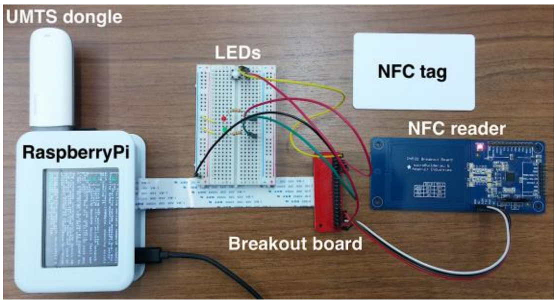

Figure 5. The *Testbed* Devices

Figure 5 shows the testbed device imitating a charging station including a near field communication (NFC) reader and the connected LEDs. The device itself is mounted in a plastic housing and also features a touchscreen display. The device connects to the Internet via universal mobile telecommunications system (UMTS) or wireless local area network (WLAN). Finally, the previously developed software was deployed on the testbed device.

(3) Testbed Execution: After specifying the mappings between the states of the business process and the states of the LEDs, the testbed is used to execute the processes. A continuous improvement cycle is included in the execution. All methods in the standard were tested against a OCPP-compliant central system. Correct business process execution is evaluated for each execution round by observing the specific outputs—that is, the messages and LED states—and comparing them to the expected output. In order to comprehend the correct execution for each state, the processes can be executed step-wise (comparable to debugging a software implementation). Traces of the execution of the business processes are logged for later analysis.

The testbed allowed us to test different processes that could otherwise not have been tested by typical means of simulation. The ability to test a transaction from the start to the finish by holding a NFC tag in front of the reader of the testbed device helped us to come up with a robust solution. Errors found in an early stage could

already be ad-

[1] OCPP v1.5 WSDL - http://www.openchargealliance.org/?q=node/9

[2] RaspberryPi Model B - https://www.raspberrypi.org/products/model-b/

dressed within the next iteration (cf. CSF_3). Throughout the development phase, the testbed was used to validate the correct execution according to the OCPP. Thus, all components comprising an EV-charging infrastructure could be executed and tested in a realistic setting.

6 Discussion

6.1 Contributions to the Practice of New CPS Development

We proposed to extend the task-technology-fit perspective towards the testing of technical feasibility in the development of new CPSs, which led to the identification of "Technical Feasibility" as an *additional* critical success factor (CSF) for such projects. Motivated by the observation of OSTROM et al. that the question how service prototyping can "materialize an integrated set of service system components" [10, p. 137] has not been sufficiently addressed by service research, this paper provides an illustrative example of creating a testbed to check a CPS's technical feasibility at an early stage of service development. The testbed mimics the CPS and allows to check the CPS's business processes for technical feasibility and correct execution. We believe that this paper contributes meaningfully to the practice of new CPS development, because it shows a way to test a CPS before implementing the "real" technical components of the CPS to the full extent. Especially in highly standardized environments, our approach may enable service, product and IT engineers to align their designs not only with the business envi- ronment but also with the enabling hardware. From a managerial perspective, taking the CSF of "Technical Feasibility Fit" carefully into account can mitigate the risk and thereby the cost of erroneous specifications that would surface late in the development process. A testbed mimics the specified system and makes it accessible through a hands-on method, which enables developers to detect such erroneous specifications earlier. In regard to the demonstrated EV-charging infrastructure testbed, announced revisions of the OCPP will be addressed. The IS at hand implements business processes that have to be executed consistently across a fleet of heterogeneous charging points (e.g., different vendors, models, and revisions). Inter-compatibility can be assured using the presented method.

6.2 Contributions to Service Research

When proposing a new method, there is a need to demonstrate its "worthiness" against the existing body of knowledge. We therefore subsequently review the extant literature to demonstrate that this research creates novel scientific knowledge if transferred to contexts other than its originating one. We consider service testing in four streams in the academic literature, viz., (a) *product-service systems*, (b) *cyber-physical systems*, (c) *service marketing* and (d) *service blueprinting* as part of *service engineering*.

Cyber-physical Systems: service testing in CPS literature is mainly interpreted from a computer science point-of-view as the problem to prove the security, privacy, reliability, or resilience at the intersection of embedded computing components and cyber infrastructures [28, 29]. Thus, researchers suggest to rep- resent CPSs using formal specifications, which facilitate the adoption of formal verification techniques [29] as testing means. Formal specifications naturally focus on a CPS's physical and computational aspects.

While the CPS literature addresses interactions between physical and com- putational components only, our work also includes human interactions with physical components during the assessment of technical feasibility. Therefore, unlike the prevalent literature on testing in CPS, our work considers the entire service system comprising of people, technology, organization and information if all the CSFs are taken into account during service development.

Product-service Systems: PSS originates from manufacturing and industrial engineering with a focus on how to develop marketable customer solutions that involve physical components. PSS endeavors are often based on conventional product design processes. The properties relevant for "testing" include product-related quality issues as well as specific economic and environmental benefits of PSS [30]. While many successful PSS implementations have been reported—such as the Electrolux case study of in-flight services [31]—testing is mentioned rarely. Testing PSS primarily focuses on the physical PSS components and provides ways to step-wisely develop service concepts during iterative product design cycles [32].

Service Marketing: the prevalent metrics for assessing service concepts in service marketing relate to financial performance, anticipated market impact [33] or anticipated customer satisfaction [34]. Related to the latter, recent publications suggest techniques that strive to make a future customer's service experiencable at an early stage of service development, such as the customer journey, touchpoint approaches, and storytelling [8]. Roleplaying, design scenarios, story- boards, desktop walk-through, and service staging extend this list [35]. Addition- ally, visualizing techniques such as flow-charting, service blueprints, and process- chain-network diagrams are frequently suggested [36]. "Prototyping", however, has been widely neglected in the service marketing literature [37]. BOWERS early assumed the root-cause in arising cost for people and equipment if one wanted "to create a whole process just for testing" [38]. In the CPS setting, testing procedures from service marketing are not capable of addressing technical feasibility within a service as proposed in this study.

Service Blueprinting: the concept service blueprinting, originally proposed by SHOSTACK, is widely used in practice to analyze and design customer interaction in service systems [39]. The service blueprint depicts the division and visibility of a service system's work, structured by the actors (customers and providers) and stages (front-stage and back-stage) [40]. Blueprinting has been reported to be beneficial in new service development, management and control of existing service processes, and customer preferences monitoring (see [41]). It explicitly shows the physical evidence that is seen by the customer during various stages of service delivery. While testing back-stage activities by means of a service blueprint comes closest to what our method intends to achieve, blueprinting focuses on the non-IT components of the service system. This is why we also failed to find guidance to our problem of testing a CPS's technical feasibility in this stream of literature.

6.3 Limitations

In this paper, we proposed an enhancement to the CSFs for BPM in the context of developing new services that are enacted using CPSs. Currently, the scope of the testbed method is very limited as it is only applicable if the system behavior can be anticipated or if it is prescribed by a standard. In absence of established and validated standards, a sound testbed specification that is equivalent to the original technology is almost impossible to achieve. Therefore, future research must explicate for which scenarios the approach is suitable as our findings are derived from a very specific use case that basically dictates the technology to be used and thus cannot be generalized. Furthermore, the scope of this research is on technical feasibility. Future research should also focus on an economic evaluation of the testbed method, i.e., introduce key performance indicators that give evidence on cost savings, improved quality of business processes, and gains for the latter phases in CPS development.

7 Conclusion

High development costs make it difficult to create a full CPS prototype only for testing. However, testing is important to ensure the operational feasibility of the CPS design at an early development stage. Our work applied and extended task-technology fit in order to develop a method for creating CPS testbeds. A testbed allows to validate the correct execution of business processes while also providing evidence on the interaction of customers with the physical components. Our major contribution lays in the identification of the technological feasibility as an additional critical success factor in new CPS development, which, if considered carefully, can help to mitigate the risks of premature failure and may save costs of the CPS development and testing. We incorporated technical feasibility into a method for creating testbeds that is applicable when the behavior of the system is prescribed in standards. This method proved to be useful for our purposes in developing a new CPS for EV charging.

Abstract. Training service provider is a crucial factor for high-quality service delivery. Due to the rise of new devices, reviving Virtual Reality (VR) offer great opportunities to overcome current training challenges. As various new interaction and visualization systems push into market, guidance on how to design VR-based training systems is necessary. The presented use case is based on technicians in technical customer services (TCS) who tackle increasing complexity of machines. We fill the research gap of design knowledge by (1) analyzing the domain in a multi-method approach to elicit meta-requirements, (2) proposing design principles, and (3) instantiating them in a prototype. The interaction of the user with the training system was identified as key aspect to foster learning. We follow a design science research approach (DSR) combing the build-phase with agile evaluation cycles obtaining focus groups and demonstration with a prototype.

(2017): How Machines are Serviced - Design of a Virtual Reality-based Training System for Technical Customer Services, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 604-618

1 Introduction

Due to the high range of tasks [1] combined with the increasing complexity of machines [2], service technicians processes of technical customer services (TCS) are complex entities. Thus, training technicians is a crucial factor for high-quality service delivery. It is common to train the relevant skills directly on the job which is time consuming and expensive as the service is completed slower or error costs for mistakes arise. Another option is the use of training facilities but they involve travel expenses, running costs for the facility and time for traveling.

Existing literature proposes the use of Virtual Reality (VR) as it provides a virtualized simulation that suits training purposes well. In addition, the immersion or presence effect of VR enhances the transfer of learned processes to the real world [3]. As VR technology is known for several years some prototypes are presented in literature (e.g. [4]) but the broad usage was, due to their costs, rather limited. With new technology and, especially, new interaction systems the usage in a larger context gets possible, which is why we revive the discussion and propose to use VR while building new training systems. Based on the example of TCS, this allows us to train the service provider (technicians) and generate a better understanding of machines with lower costs than training on the job or training facilities would provide.

The paper makes use of the design science research paradigm and follows its four step approach: (1) for analysis we used a multi-method approach to elicit requirements. (2) Based on them we derived design principles and instantiated the system. (3) We evaluated the artefact multiple times through focus groups during the development and a demonstration (formative), and (4) diffused our insights, which is done with this contribution. The core of this work is the blueprint of a VR-based training system that is based on the elicited requirements and design principles. So, further similar systems can be built analogously to our instantiation. Gregor and Hevner [5] argue that the instantiation itself contributes to the knowledge base.

The paper is structured as follows: First, we introduce the related work of VR in the next section. In section 3, we introduce our research approach. Next, we present the artefact design comprising the meta-requirements, design principles and the instantiation. We conclude by discussing novelty, practical relevance, theoretical contributions, and limitation as well as giving an outlook for future work.

2 Related Work

Virtual reality and so called head mounted displays (HMD) have a long history [6–8]. Up to the last 2-3 years most research made technical possibilities of HMD subject to discussion; only few business-related questions and use cases were discussed [9]. This was due to the fact of high cost of the first HMD systems.

On the basis of new technological developments (e.g. such as the announcement of Oculus Rift) new opportunities arise. New devices are being developed to enhance usability for the user [10]. The three principles of VR *immersion*, *interaction*, and *user* *involvement* with the environment, offers a very high potential in education by making learning more motivating and engaging [10].

Most of the research relates to medical training systems (e.g [10–13]), but also maintenance and service have been discussed (e.g. [14–19]). An example is the work of Rahimian at al. [21] who reports the use of VR for the professional training of architecture, engineering or construction specialists. The authors focus on visualization technologies to foster innovation in engineering [20]. However, the investigation of user interactions with the devices have rarely been discussed as it was not possible with the technologies so far. A close to reality training scenario could be realized only by combining the VR visualization with interaction and tracking of hands to model work steps. This is where our work starts.

Freina and Ott (2015) investigated in their state of the art of VR education several aspects for the main motivation of VR usage: it is mainly used for scenarios that "cannot be accessed physically". This limit may be due to time problems, physical inaccessibility, limits because of a dangerous situation or ethic problems [10]. In line with the authors, we started our research because of the need of maintain objects on machines that are physical inaccessible or just accessible for one technician and not the trainer. An example is the training scenario in the tank of an agricultural machine which is described in the instantiation section.

Guidance for the design of VR systems is suggested by several authors. For instance, Wann [21] took up design principles from a psychological perspective. Further, Chaturvedi et al. [22] propose core properties for building virtual worlds. Kohler et al. [23] suggest key principles such as usability, sociability, pragmatic and collaborative to build virtual worlds. Finally, Sutcliffe and Gault [24] investigated criteria for successful virtual reality applications that are suitable to be basis for design principles. All of them discussed the design in context to older virtual reality devices. Thus, we founded our design principles on them but expanded them to new aspects of new hardware and enhanced interaction components.

3 Research Approach

We follow a design science research (DSR) approach [25–27] as it is generally accepted for service systems engineering (SSE) [28]. Based upon their study about the state of the art in SSE, Böhmann et al. [28] argue, that the complex socio-technical context of service systems restricts the opportunities for meaningful laboratory-style research. Hence, they propose that research needs to be embedded within a service system in a real-world scenario and call for the design of novel service systems. In line with the authors, our approach continuously involves experts from TCS as well as observations of real-world process scenarios. We investigated the four phases analysis, design, evaluation and diffusion. By contributing our work we spread our insights (diffusion); the other three phases (analysis, design, evaluation) are shown in Figure 1.

Once the relevant business problem was defined, according to Hevner [29], attributes of the pursued future system have to be investigated and defined. These attributes are usually referred to as *meta-requirements* [30] because they reflect generic requirements that should be met by the future system (cf. section 4.1). The meta-requirements were elicited from the analysis of the real-world scenario (workshops, process analysis, expert interviews, benefit analysis).

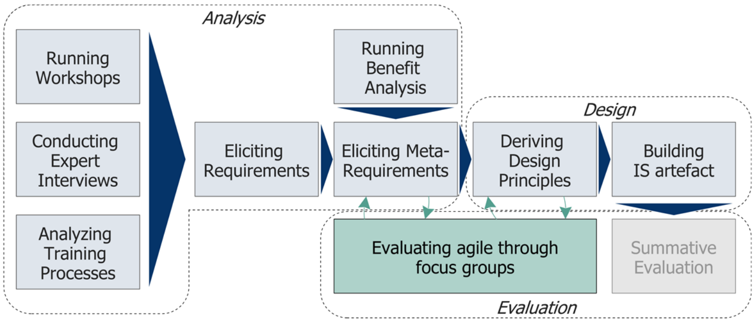

Figure 1. Research Approach

Although VR has a long scientific history, practitioners only have few experiences and just a brief idea about its usage in their specific scenario. This is why we chose to conduct a multi-method approach (workshops, expert interviews, process analysis, benefit analysis), on the one hand, to explorative analyze the domain and combine the different points of view and, on the other hand, calibrate and validate our work [31]. Next, an information system needs to be designed that meets the identified meta-requirements. Therefore, we proposed *design principles* (DPs) that describe how the new system should be built in order to fulfill the identified meta-requirements (cf. section 4.2). Finally, the IT artefact was instantiated (cf. section 4.3).

Since the evaluation of design artefacts and design theories is a central and critical part of DSR [27, 32], we combined the build-phase with several evaluation phases. How to go about choosing and designing an appropriate evaluation approach is a very significant but under-addressed issue in extant DSR literature [33]. Hence, Venable et al. [33] propose a framework for developing an appropriate evaluation strategy. Following their argumentation, our evaluation strategy is human-risk & effectiveness-oriented, due to the novelty of VR in practice. As a result, we have to evaluate our artefact early in a naturalistic setting, conducting formative and summative evaluations [33]. For implementing the evaluation strategy, we made use of agile software development [34] to rapidly develop and evaluate the software continuously (formative evaluation with focus group). So, we were able to validate the applicability to real world problems. The final summative evaluation is not part of this paper (thus, indicated in grey in Figure 1).

3.1 Requirement Collection and Analysis

User Workshops. The collection of requirements started with user workshops (first workshops). The goal was twofold. First, we wanted to get everyone's ideas on how a VR-based training system might look like (brainstorming session). Second, we wanted to collect an initial set of requirements we could start with (collection session). In order to get a broader understanding and minimize bias, we prepared the same workshop twice in two companies of different size and field. Both are part of the machinery and plant engineering sector with a major focus on TCS. The reason of splitting the workshops to different companies with different sizes was to get a company-, sector- and size-independent view. Overall, we had 13 participants from the group of technicians (user), service instructors and the management board.

For the collection of the requirements, which is the relevant part for this paper, we concluded the brainstorming session with an introduction about VR technology, its features, limitations and expectations. Afterwards, we answered everyone's questions before we asked them to write down requirements they have on a VR-based training system on paper cards. Those were put on a poster and consolidated (in case that requirements are mentioned multiple times). When everyone finished the collecting, we discussed the idea connected to every requirement. After everyone was clear, we asked them to rate every requirement (benefit analysis) on a three-tier scale ranging from 1 (very important) over 2 (important) to 3 (not that important). To minimize social influence and further specify the requirements, we asked every participant in the following interviews, as they were done with the same participants, individually what the most important requirements are.

Interviews with Practitioners. We used a semi-structured interview with eight questions separated into a general part and a requirement-specific part. In the general part, we asked questions about demographical information, their experience with VR before we started the workshop, and the general assessment of the technology. The questions were chosen to get an idea about the current situation and the attitude of the interviewee towards VR. Within the requirement-specific part, we asked the interviewee to name the two most important requirements from the workshop and about potential showstoppers that prevent people from using a VR-based training system. To sum up, the interviewee was asked to describe how training is conducted in their company, what challenges they face with the current approach and, finally, whether they think that VR might be beneficial. Regarding the documentation and the analysis procedure of the interview transcripts, the recording technique consisted of a digital record and afterwards a full text transcription and a content analysis [35].

Process Analysis. Besides the use of workshops (including interviews and benefit analysis) the current situation in training was of major importance. Therefore, we attended in multiple trainings in both companies and analyzed how technicians are taught and what role TCS processes play. Making use of shadowing [31] we participated with two IS researchers, tried to minimize our influence and documented the training itself. Afterwards, the transcripts were analyzed regarding the setting and the TCS processes to derive requirements or validate the known requirements.

Meta-Requirements. In order to generate a manageable list out of all mentioned requirements, to start implementing with, we first clustered them using open coding [35]. This was done to ensure that different aspect implied in the requirements are included. Among every clustered group, we chose the requirements that were rated highest in the benefit analysis. For the software implementation three groups were excluded as they target organizational aspects that are not relevant for the software or aspects that are not in focus of a training system. The process of generating meta-requirements was done by a researcher team of three information system researchers. Afterwards, the meta-requirements were discussed with the focus group (as described in 3.3 and appendix A). The remaining list form the (evaluated) meta-requirements that are discussed in the following.

3.2 Implementation

Starting with the elicited meta-requirements, the aforementioned team of information systems researchers derived design principles that support the design of the system. Those were based on a literature study, including papers that explicitly state design principles for Virtual Reality. Based on them the system is likely to fulfill the initial requirements. The derivation itself was executed in iterations to refine and revise the principles over and over again. When the team was convinced the meta-requirements were discussed with the focus group (as described in 3.3 and appendix A) and, thereby, evaluated to cover the most important aspects. Afterwards, the system was implemented in cooperation between the information system researchers and visual technology experts. All features were implemented in an agile approach with integration of the focus group multiple times (evaluating multiple versions of the system). The result of the implementation is described in section 4.3 and gives insights into the VR-based training system.

3.3 Evaluation

Following a human risk & effectiveness evaluation strategy, we conducted several formative evaluation cycles and a final summative evaluation [33]. For the evaluation of the meta-requirements (second workshop) and the design principles (third workshop), in each case we used discussions in form of focus groups [36, 37]. The focus group meetings were conducted in 2015 (For details about the participants see Appendix A). Different types of participants and at least two of every type were invited; on the one hand, to get different point of views, on the other hand, to have people with homogenous background to get a free-flowing conversation [36]:

1. Representing the TCS and, hence, user and customer perspective from practice, three attendees from a medium-sized service provider for air-conditioning technology and three participants from a large agricultural technology manufacturer with own TCS attended.
2. For gaining insights from a technological perspective, two IT practitioners and two visual technology researcher with expertise in implementing VR participated.
3. To bridge the technological and service view, three IS researcher specialized in service science were invited and took up the role as leader of the open discussion.
4. For the design of the content and targeted communication of information, two researchers with specialty in education and media psychology were invited.

So, with the focus group meetings, we were able to evaluate the functional design and usefulness of the VR-based training system in the business context of TCS.

4 Artefact Design

Within this section, we present the design process of our IS artefact. To specify the real world problem, we start with the meta-requirements that were generated. Based on them design principles are presented that deal as foundation of the implementation of our VR-based training system. Additionally, we give details about how our system was designed and how the design principles influenced it.

4.1 Meta-Requirements

Through the multi method-approach, we generated an overall of 69 requirements structured into seven cluster. The clustered groups were named *generating*, *content*, *interaction*, *usage*, *organization*, *output* and *general*. The groups *output*, *organization* and *usage* were excluded as they do not have a training focus but rather an organizational focus. The group *output* contains requirements concerning additional output variants of the system that might be needed in organizations but not for training. The second group *organization* targets organizational aspects that are not relevant for implementation. Finally, the third group *usage* aims at scenarios where the system might be usable besides training. With the remaining four groups 14 meta-requirements are selected that were ranked highest. They are described in the following:

- **MR1: Include CAD-data.** Usually for every machine the manufacturing company owns construction data (named Computer-Aided Design). This three-dimensional model of the machine is designed by engineers for construction purpose, before the machine itself is built. As those CAD-models (mostly) are an accurate representation of the machine, they should be the source VR builds the representation on.
- **MR2: Recording of guided trainings.** The VR-based training system should be based on a guided training that leads the trainee through the process. The trainer should be able to record or prepare trainings on his own.
- **MR3: Highlighting of parts.** As complex machines consist of several parts, the selection and highlighting of parts is beneficial to understand what parts exist and how they are installed.
- **MR4: Assembly of parts.** The system needs to simulate the assembly of parts of the machine to enable the trainee to understand which parts belong to the machine and to see parts lying underneath others.
- **MR5: Disassembly of parts.** Analogously, the disassembly of parts must be included as well to enable maintenance or repair processes.
- **MR6: Movement of parts.** While (dis-)assembling, the trainee should be able to move, rotate and inspect the parts to see and understand the details.
- **MR7: Validated interaction.** To ensure that trainees are learning the correct order on how to (dis-)assemble parts of the machine, the system needs to validate whether the interaction with the parts is possible.
- **MR8: Meta information on parts.** When inspecting or moving the parts, the system should include meta information about the part such as the name or part number.

- **MR9: Variants of machines.** As machines often exist in different variants (e.g. for different markets), the system should include information about different parts and in which variants they are used.
- **MR10: Machine parameters.** The training system should include settings and machine parameters of parts or the machine itself, as they might be crucial for the maintenance and repair.
- **MR11: Tool information.** For certain parts tools are needed (e.g. for fixing or configuring). The training system should include information about tools needed.
- **MR12: Intuitiveness.** For the training the usability plays a major role. The trainee needs fast and easy access to the system without a long training phase for the interaction with the training system itself.
- **MR13: Motivating.** On top of fast and easy interaction, the system needs to be pleasurable to use and motivating. This improves learning performance and trainee's intention to use.
- **MR14: Realistic.** Finally, the system needs to be as realistic as possible to encourage transfer of knowledge acquired in the system to a real world scenario.

Summary. Overall, we elicited 14 meta-requirements based on workshops, expert interviews and benefit analysis. In particular, the interaction with the service object (to simulate a real service scenario) is of major importance (MR3 – MR7). This is why, we explicitly focused on interaction design within our design principles in the next section.

4.2 Design Principles

Starting with the meta-requirements, we derived design principles that support the design of the training system. They are described in the following:

- **DP1: Use existing construction data.** As described, construction data for machine exist in the companies. Thus, the first design principle is to build the system on top of the construction data and integrate various data formats to allow applicability in different companies (as they might use different software for CAD). In addition to the fulfilment of MR1, another minor requirement for easy maintenance of the system benefits when the system is built on top of existing systems and software (compatible to user's domain as proposed by [24] and sustain user-created content (ES3 by [22])).
- **DP2: Integrate process data.** With the need for guided training, the reuse of already existing training processes is suggested and contributes to the principle sustain user-created content (ES3 by [22]). So, the system should be built on top of process models as main representation as they are well understood and explored in literature and practice. This would fulfill MR2 and MR7 (as the interaction can be validated by the process).
- **DP3: Integrate additional parts information.** As there are some requirements concerning information on parts, the system needs to include textual or medial information. So, when the trainee is facing or moving the particular part of the machine it is possible the learn more about it. Thus, the trainee can learn what exactly

the particular part is about. The information ranges from meta information through variants of the machine the part is used in, and parameters of the part to tools that might be needed for the particular part. This fulfills MR8-MR11. The design principle was not present in literature about VR design principles [21–24]. However, it was explicitly asked by the technicians in the workshops and by the education and media psychology researchers in the focus group evaluation.

- **DP4: Carefully design parts interaction.** As different interaction with parts of the machine is needed, this becomes a main aspect of the system. For the training system the interaction is the key feature that enables trainees to understand and learn. Thus, special attention about the way of interacting with the system is crucial (in line with principle 1 by [21] and the usability principle by [23]). The design principle contributes to MR3-MR6.
- **DP5: Reduce interaction possibilities.** Finally, recent interaction systems in VR offer a wide range of pattern (such as controller-based, hand-based, voice-based etc.). However, from the requirements and gained experience the last design principle is, to limit the actually used interaction with the system to one primary approach. This ensures that users are not overwhelmed by different concepts, patterns and interaction approaches. Consequently, this simplifies the familiarization of users with the system. From our point of view, we encourage the usage of hand-recognition-based interaction as it appears to be the most natural way to interact with the system (in line with [24] and [23]). Thus, it fulfills MR12-MR14 as it improves the system's usability, motivation to use and, when hand-recognition is used, the realism of the system.

Summary. Overall, we derived five key design principles. Each of them contributes to at least one meta-requirement. Table 1 summarizes all five design principles and their relation to the meta-requirements and literature.

Table 1. Design Principles

DP	Description	MR	Literature
1	Use existing construction data	1	[24][22]
2	Integrate process data	2,7	[22]
3	Integrate additional parts information	8-11	
4	Carefully design parts interaction	3-6	[21][23]
5	Reduce interaction possibilities	12-14	[24][23]

4.3 Instantiation

The system components (see Figure 2, numbered from 1-3) of the VR-based training system are primarily based on Oculus Rift DK2 (see 1) as a display and tracking device. The tracking captures orientation and position of the head relative to the Oculus Camera. Thus, the interaction in VR are precise and the visualization immersive. For further user interaction, a Leap Motion controller (see 3) is mounted in front of the Oculus head mounted display (HMD). The Leap Motion is a high frame per second hand tracking camera device and gives the opportunity to display hand and motion fluid into the visual experience of the user. To enhance the hand interaction area, a new 30-degree angle mount (see 2) was built to shift the hand area down and support a more natural hand input environment (fulfilling DP4). For the rendering and visual input, a high end gaming computer is needed to realize the necessary power for the experience.

For the visualization pipeline, an own linear learning authoring tool was developed that combined the CAD data (fulfilling DP1) with processes (fulfilling DP2) and results in an immersive VR learning experience. The authoring tool allows using CAD data without ever preprocessing it for the VR environment. On the one hand, the data is not visually optimized to display in VR, but on the other hand, a fast and cost efficient way to create new learning scenarios without touching the CAD data is a big advantage in the creation of lessons.

Figure 2. Hardware component setup

Figure 3. User hand avatar

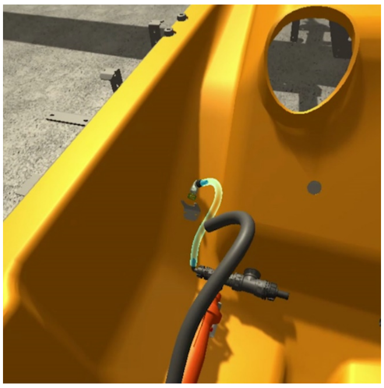

Figure 4. Placing components

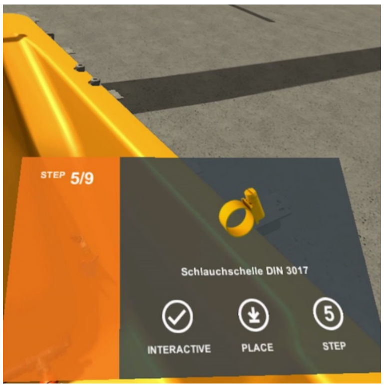

Figure 5. User manual and menu

In the VR-based training system, the whole interface and interaction techniques are mapped to hand gestures and hand movement (see Figure 3). Complex finger tasks are simplified to give the user a better control and robust recognition. The learning tasks are more oriented towards the knowledge transfer than learning certain hand movements (see Figure 4) (fulfilling DP4 and DP5). Additionally, we built a user manual and menu interface (see Figure 5) that comes up as soon as the system detects the inside of the users hand. So, the interaction is twofold: with the out-/upper side of the hand the user can interact with the simulation and on the in-/inner side he or she gets an interface with additional information (fulfilling DP3).

The system is designed for standing users with approximately 2x2m interaction space. Due to the need of a high end gaming computer and the amount of components it is best used in an (mostly) immobile setup.

5 Conclusion, Discussion and Outlook

Conclusion. The effective use of Virtual Reality (VR) offers great opportunities to overcome current challenges in the domain of TCS. Due to the complexity of service systems engineering [28], guidance on how to design service support systems is necessary. To overcome this complexity and fill the research gap of design knowledge on VR-based training systems, we followed a DSR approach within this paper through, first, exploring the domain and eliciting meta-requirements (step 1), and second, deriving design principles continuously working in an interdisciplinary team of practitioners and researchers (step 2). The key feature was the design of the interaction with the service object, as it was the major requirement (to simulate a real service scenario).

Discussion. Before we started the project on VR, our main expectation was that for users the most important requirements would concern the acceptance of the VR device itself. We thought of motion sickness, refusal of wearing the device on the head or problems with spectacle wearers. Surprisingly, the most important requirements we found was about the interaction with the system. So, for our users the VR itself seems to be acceptable straight away as major companies (e.g. Facebook, Sony, HTC) are pushing into market. So, users get more and more in contact with the technology and used to the idea of virtual worlds. We experienced broad interest through all companies and individuals we talked to. Most of them mentioned deployment scenarios in their own processes that might be useful (e.g. constructors (teaching order of assembly), engineers (visualizing unbuilt machines), farmers (introduction and commissioning to tractors)). We further found scenarios that are not trainable without VR, due to danger-related (e.g. the repair of running wheel gears; to build an understanding about what happens when certain gears are damaged) or size-related reasons (e.g. the repair of parts inside of a tank of a spraying machine that is just the size of one person).

Not only because of the broad interest, one main aspect we found was that integration of potential users in development is very crucial. New technologies are connected to a learning process on both sides, developer and user, which is why they have to talk about possibilities and see what works for them and what does not. This is how we came up with integrating a gesture interaction component to offer the hand-based interaction as it was the most natural option for users.

Finally, the VR-based training is suitable at least to teach scenarios that are not trainable otherwise. Whether it might help in other scenarios as well and improve the training is a research question that arose during the project for further investigation.

Novelty and Practical Relevance. We address a real-world problem consisting of need for TCS support through training systems that teach complex machines. At the same time, since recent VR is still an emerging technology, little knowledge about the design of training systems exist. Both from the point of practice and from theory, a transfer of the proposed design knowledge to other user groups or even customers offer new subjects of research. Thus, we formulated the design principles to be as generic and applicable as possible to other user groups and sectors. With our instantiation we demonstrated how to build a VR-based training system using recent hardware (Oculus Rift DK2 and Leap Motion). Hence, cost-efficient training with commercial VR technology is possible, which is of major relevance for small and medium sized companies.

Theoretical Contribution. Regarding the theoretical contribution, this research work contributes to the methodological knowledge base of IS Design and service systems engineering, and builds upon existing methods of DSR and the design of service systems. In DSR, a theoretical contribution is usually regarded to be in form of prescribing how a specific solution can be designed in order to solve a relevant real-world problem; often presented in form of design principles [38, 39] that guide the implementation of specific instantiations. Gregor and Hevner [5] argue that the instantiation itself contributes to the knowledge base as the demonstration of a novel artefact can be a research contribution that embodies design yet to be articulated, formalized, and fully understood. Prescriptive knowledge can be generated through (1) inventing new solutions for new problems, (2) improving and thereby developing new solutions for existing problems, or (3) adopting known solutions to solve new problems [5]. We position our work as a new solution, a VR-based training system, to solve an existing problem consisting of complex machines that needs to be serviced by TCS. We build our work on the knowledge base of Virtual Reality Design Principles. However, for the field of technical customer service the integration of additional service related information and the design of the interaction with the service object is crucial. Thus, we enhanced the known principles with our study. Therefore, we explored the problem domain and formulated meta-requirements that represent the conditions that should be met by a VR trainings solution. Additionally, we contribute to the IS research knowledge base by instantiating the evaluation strategy proposed by Venable et al. [33] in combination with agile software development as enhancement of the classic DSR approach. Hence, with our work, developed in a transdisciplinary team obtaining IS research, service science, education and media psychology as well as practitioners from service providers, manufacturers and IT companies, we meet a research gap and the claim for evidence-based design research [28].

Limitations and Outlook. We discussed our work with experts from two different sectors in order to transfer the design principles to other sectors. However, researchers are welcome to evaluate the applicability and potentially needed adoption separately as the VR-based training system has a wide area of possible applications. Based on the results of the benefit analysis, we focused on an excerpt of all collected requirements and the evaluation of the VR-based training system with technicians. Hence, (1) the transfer of additional requirements have to be investigated further. (2) We have not conducted a summative evaluation regarding the economic benefit and the training success yet. Thus, the next step of our research is the evaluation of our instantiation in form of a field test [40] in the TCS of the agricultural technology company and the service provider for air-conditioning technology. Thereby, an experiment that allows conclusions about the training effect is needed. To sum up, our approach can be considered as VR with new hardware that might lead research to specify new business models or training options.

Multi-Channel Choice in Retail Banking Services: Exploring the Role of Service Characteristics

Abstract. Companies are moving towards omni-channel management offering all products and services on all channels. Yet, some of these investments might be obsolete as certain products are associated with certain channels. At this point, service companies are still left behind as past research focused on product categories and it remains unclear if the results are transferrable to services. Our study addresses this gap by analyzing the influence of service characteristics on channel choice. We tested our research model by surveying 2,000 banking customers in Germany on their past channel choices for five financial services. The results show that complex services with a high value are rather purchased in a branch than the online channel. Thereby, demographics and behavior-related constructs are important control variables. The results improve the understanding of channel choice behavior in a multi-channel context for services and provide guidance for practitioners to right-channel IT investments.

Keywords: Multi-Channel Choice, Omni-Channel Management, Service Characteristics, Retail Banking Services, Multinomial Logistic Regression

1 Introduction

Recent research suggests that companies are moving from a multi-channel to an omni-channel management which seems to be the next generation of channel management [1]. Omni-channel management comes with several advantages: It allows customers to seamlessly shift between channels and use them simultaneously, and it improves the user experience [1]. To move from multi- to omni-channel capabilities, serious IT investments are required. For example, Commerzbank, the second largest bank in Germany, is investing more than 200 million Euro into their multi-channel banking platform to make services accessible on all channels [2]. Thereby, it is debatable whether all products and services have to be offered on each channel (omni-channel), or whether certain products and services are more suitable to particular channels than others (multi-channel). For instance, Gupta et al. [3] find that search goods are more likely to be purchased online, whereas experience goods are more likely to be purchased offline.

13th International Conference on Wirtschaftsinformatik,

Hummel, D.; Schacht, S.; Maedche, A. (2017): Multi-Channel Choice in Retail Banking Services: Exploring the Role of Service Characteristics, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 619-633

In general, the role of product categories on user's multi-channel choice is well established in retailing (e.g. [3, 4]). Yet, it is unclear if the results are transferrable to services. While products are tangible, exchangeable, tradable and preservable, services typically fulfill the opposite of characteristics: Intangible, heterogeneous, inseparable and perishable [5]. Yet, there is no commonly shared definition of services [5], and bundles of products and services further complicate the differentiation. Nevertheless, most multi-channel studies have focused on clearly defined products (such as books) and services (e.g. [6–8]). Gupta et al. [3] examine the role of product categories for three products and one service. They find varying significances of price search intentions on channel switching behavior for the different product categories. Similarly, Gensler et al. [7] find different results for two product categories in retail banking that could not be explained theoretically. In particular for financial services, they suggest to examine the role of service categories in greater detail in future research. Also other researchers suggest to research the role of product categories on channel choice [9]. Thereby, it is important to note that product *categories* are "all the products offering the same general functionality" [10] whereas product *characteristics* are features of a product like color, weight, price, etc. Services can also be categorized along characteristics and be grouped into service categories. Thus, we aim to answer the following research question:

Do service characteristics influence user's channel choice across all stages of the buying process in the context of a multi-channel environment in financial services?

To address this question, we build on the multi-channel literature from peer-reviewed papers which report channel behavior in a multi-channel context. Based on the literature, we developed a research model and surveyed banking customers in Germany on their past channel choices for five financial services. Due to the mixed results regarding the effects of demographics on individuals' channel choice, we additionally controlled for several demographic characteristics and experiences.

The contribution of this work is manifold as we consider service characteristics of five different financial services across four different stages of the buying process. Moreover, we study different channels using a strong empirical foundation of 2,000 banking customers. In addition, we focus on the users' demographics and the often neglected importance of service characteristics on channel choice. Our research also comes with implications for practitioners: Following an omni-channel strategy of providing all products and services on all channels without a clear objective can result in waste of scarce resources. Instead, managers should carefully balance which products and services are offered on which channel. Our study is to be distinguished from other studies as it addresses channel choices of purchases rather than tasks (e.g. [11]) and it is conducted in a multi- and not a single-channel environment.

The remainder of this paper is organized as follows: Chapter 2 recaps the related work. In chapter 3, we describe the constructs and hypotheses to answer our research question. Chapter 4 outlines the data collection and the applied research methodology. In chapter 5, we summarize the results of our research and discuss them in more detail in chapter 6. Finally, we conclude our research in chapter 7.

2 Related work

Some studies consider product categories as a determinant of channel choice (e.g. [3, 7, 12, 13]). For an overview, we provide a summary of 10 studies in Table 2. Several insights can be derived from the analysis: Almost all studies note that product categories and characteristics have an influence on user's channel choice (e.g. [7, 13]), customer segments (e.g. [14, 6]), and customer value (e.g. [4]). Only partially, product categories seem to have no impact as, for instance, Maity and Dass [12] could not find an influence of the product type on information search. Further, the related work reveals that researchers developed various characteristics to classify categories, namely complexity, perceived risk, purchase frequency, search/experience goods, etc. In addition, it becomes apparent from the analysis that many different channels and product categories have been examined, but hardly any services. Focusing on services, Table 1 displays studies from the context of financial services. The comparison shows that service characteristics are only one covariate of channel choice and that there is a broader picture behind channel choices in a multi-channel environment. Beyond the service characteristics, the stage of the buying process, the channel characteristics, and the demographics influence user's channel choice. For instance, Gensler et al. [7] suggest that the stage of the buying process has a moderating impact on channel choice, and many other researchers also included several stages in their studies (e.g. [3, 15, 16]). This paper addresses all aspects except for the already well-studied channel characteristics such as price, risk or convenience (e.g. [17]).

Table 1. Related work on multi-channel choices in financial services

Source	*Channels (among others)*	*Several stages*	*Channel Charact.*	*Demo-graphics*	*Service Charact.*	*Services*
[18]	Branch, Internet, phone	-	X	X	X	1; 5-8
[19]	Branch, Internet	X	X	X	-	-
[20]	Branch, Internet, ATM	-	X	-	-	-
[16]	Branch, Internet	X	X	X	X	6
[21]	Branch, Internet, phone	X	-	X	-	1-4; 6; 8
[7]	Branch, Internet, phone	X	X	X	-	1; 2

1: Checking account; 2: Securities account; 3: Credit; 4: Savings account; 5: Retirement provision; 6: Mortgage; 7: Insurance; 8: Investments

In financial services, only Black et al. [18] and Frambach et al. [16] considered the service characteristics. The former study is an explorative, qualitative work that yielded valuable insights into channel choices in services but that, to the best of our knowledge, has not yet been validated by practice. The latter study is an empirical analysis but only includes one service (mortgage) and thus it does not allow for comparisons between different services. Other studies of channel choice in financial services do not account for service characteristics (e.g. [19–21]). Overall, we can derive from the related work that product and service characteristics influence user's channel choice.

Table 2. Subset of related work on product categories in a multi-channel context

Study	*Channel*	*Categories*	*Results*
[18]	1, 2, 3	Financial products	- Type of financial product a key influencer for channel selection - Product description along complexity and perceived risk
[15]	1, 2, 4, 5, 7	10 broad categories	- Different channels used for searching different product categories - Assessment of shopping attributes differs for product categories and channels - Categorized along purchase frequency, durability and degree of entertainment
[22]	1, 2, 4	Fashion	- Product-channel associations (e.g. store for personal items; Internet for functional repeat purchases)
[13]	1, 2, 4	11 categories	- Hypothesized about products-channel-associations; investigated channel migration along product type - Results show that product categories generally influence customer's channel choice
[3]	1, 2	Flight tickets, books, wine, stereo systems	- Drivers and inhibitors of channel switching differ across product categories - Categorization along search and experience goods - Search goods more likely to be purchased online, whereas experience goods more likely offline
[6]	2, 3, 4	Household and personal products	- Multichannel behavior across product categories; categories influence of consumer segments - Classification along complexity, purchase frequency and tangibility - Covariates of multichannel shopping (i.e. channel choice) differ across product categories
[7]	1, 2, 3, 6	Checking account, brokerage account	- Results indicate that effects of channel choice attributes could differ between product categories - Assumption that product categories might explain differences and suggest to undertake further research
[23]	1, 2, 4	Furniture, appliances, music, books, etc.	- Generally, significant relation between product categories and cross-channel free-riding behavior - Free-riding behavior differs across respective product categories
[12]	1, 2, 5	Airline tickets, food delivery	- Product type moderates effect of media richness on perceived fit, satisfaction, and channel choice - No support for the moderating effect of product type on information search
[14]	1, 2, 3	Mobile solutions (telecomm.)	- Replication of [6]; perceived product complexity determines affiliation to certain customer segments - Covariates of multichannel shopping differ across categories
[24]	1, 2	Apparel, consumer electronics	- Product category affects usage of on- vs. offline channels in each stage - Shoppers more involved with a category use Internet (maybe due to increased purchase frequency)

1: Store/branch; 2: Internet; 3: Telephone/Call Center; 4: Catalog; 5: Mobile; 6: ATM; 7: Other

3 Development of constructs and hypotheses

After scanning existing literature on the effects of the most common service characteristics, we realized that there is quite some research in the field of products, but only few results on services. Thus, based on the related work, we formulate a set of hypotheses that can be tested for services rather than products. We focus our hypotheses on the two main banking channels that are also apparent from the related work section: the branch and the online channel.

3.1 Service complexity

Service complexity is a well-known construct to characterize a service. The construct is adapted from product complexity and is defined as "the extent to which the consumer perceives a service to be difficult to understand or use" [22:112]. Complexity of products is addressed by several researchers (e.g. [14, 6, 16, 18]). Black et al. [18] recognize the importance of complexity of financial products on channel choice. Even advanced Internet users in their focus groups had strong reservations for purchasing complex services online, and they preferred to go to the store [18]. Frambach et al. [16] also study service complexity and find that people prefer the offline channel for complex services. They argue that customers need help in their decision making and thus opt for the branch. Finally, Konus et al. [6] find that the Internet is too complex for shopping, whereas this finding could not be supported in a replication study [14].

Hypothesis 1 (H1): For services with a high complexity, customers prefer the branch, while for services with a low complexity, they prefer the online channel.

3.2 Service value

Service value describes the monetary value of a service purchased. Service value is closely associated with perceived risk, because when the involved sums are high, then there is a greater probability of making a bad decision [26]. Burke [15] supports this finding by stating that customers are more likely to visit the store when looking for expensive and infrequently purchased goods. Service value also impacts the number of channels used. Heitz-Spahn [23] argues that customers engage in more searching when the product or service is expensive and thus automatically use more channels. Sullivan and Thomas [13] find that channel choice varies by the total amount of money spent.

Hypothesis 2 (H2): For services with a high value, customers prefer the branch, while for services with a low value, they prefer the online channel.

3.3 Service purchase frequency

Purchase frequency describes the "total number of purchase occasions" [12:16]. Purchase frequency has been studied in the context of product categories by various researchers (e.g. [13, 15, 23, 27]). Customers tend to choose the store when purchasing goods infrequently, because they need advice from knowledgeable sales people [15]. Sullivan and Thomas [13] find a relationship between channel choice and purchase frequency as customers which use the Internet and the catalog buy more frequently than customers which choose the store.

Hypothesis 3 (H3): For services with a high purchase frequency, customers prefer the online channel, while for services with a low purchase frequency, they prefer the branch.

3.4 Service usage frequency

To our knowledge, service usage frequency has not been studied in the context of multi-channel choices. Gensler et al. [7] suggest studying usage frequency to explain differences between financial products. For our research, we interpret service usage frequency as the frequency a customer is using or interacting with the service after its purchase. A comparable way of looking at usage frequency is the product return behavior of customers. Several researchers have shown that the more often customers return products, the more likely they use a digital channel and vice versa (e.g. [28]).

Hypothesis 4 (H4): For services with a high usage frequency, customers prefer the online channel, while for services with a low usage frequency, they prefer the branch.

3.5 Stage-channel associations

Finally, we study stage-channel associations. Stage-channel associations “exist when consumers associate a certain stage of the buying process with a particular channel” [5:989]. Thereby, stages represent the various phases of the buying process. Channels, like the branch or the Internet, are the contact points that customers employ for information, contracting, and use. For example, the Internet is often associated with the search stage, while the store is associated with the purchase stage [8]. Other researchers find similar stage-channel associations (e.g. [15, 22, 27]), but it is unclear if they also exist in the context of services.

Hypothesis 5 (H5): The buying process stage has a moderating impact on users’ channel choice as the information stage is associated with the online channel while the purchase stage is associated with the branch.

3.6 Demographics, Internet usage and Internet experience

The influences of demographics on channel choice in a multi-channel environment are questionable. Some researchers argue that there is no relationship between demographics and channel choice (e.g. [6, 21]). Older studies, however, find that age [18, 29, 30], income [18], education [29], and gender [30] influence individuals’ channel choice. Thereby, young, male customers with high income and education favor the Internet. Therefore, we control our data for demographical differences.

Beyond demographics, we also control for the influence of behavior-related constructs (e.g. Internet experience, Internet usage, online banking usage, etc.) on channel choice. It is not surprising that Internet experience favors the channel choice of the Internet channel (e.g. [16]). Yet, we have found no other studies that consider the effect of online banking usage and mobile banking usage on channel choice in a multi-channel environment. In addition, no other study considered the effect of low experiences on online banking in a multi-channel context.

The hypotheses introduced above are integrated in a research model (see Figure 1).

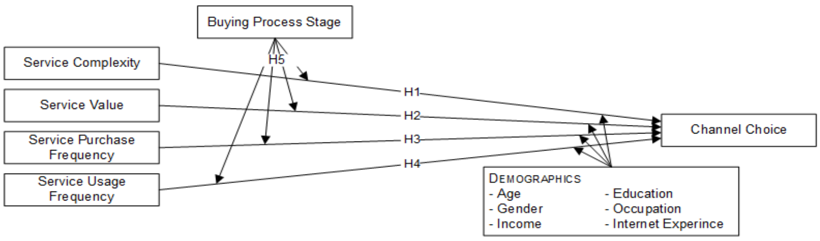

Figure 1. Research model

4 Research methodology

4.1 Data collection

To test our hypotheses, we build on a dataset that was collected and analyzed by Graupner et al. [31]. The authors employed a market research firm that conducted a survey among 2,012 German retail banking customers from May to June 2015. The survey was hosted online and assessed the actual past channel choice for different financial services. Intentionally, customers without Internet access were excluded from this study as they are not able to use the online channel of this study. The financial services under observation were credit, checking account, savings account, securities account, and retirement provision and each service is represented at least 300 times in our survey. Although theory of planned behavior states that behavioral intentions are antecedents for actual behavior [32], asking for actual behavior is advantageous over intentions to use a channel as intended behavior may not result in actual behavior. The survey covered seven different channels that are the most common ones in German retail banking: branch, online, mobile, telephone, postal, family and friends, and other. For the definitions of the respective channels see Hoehle et al. [33]. Family and friends are not a banking channel per se but a way to inform oneself or to receive counseling. We have chosen the sector of financial services for our study as it offers a wide range of services to compare and as multiple channels are already available since decades [33].

Table 3 displays the demographics. The sample of our data collection comprises more men than women with an average age of 42 years. 29% of the respondents report an average income between 1,500€ and 2,499€ per month and 70% are employed. The sample is representative for the German Internet population of 2015.

Table 3. Demographics

Attribute		*Total*	*%*	*Attribute*		*Total*	*%*
Gender	Male	1,066	53%	**Income**	< 1,500€	521	26%
	Female	946	47%		1,500-2,499€	590	29%
Age	18-29	410	20%		2,500-3,499€	502	25%
	30-39	550	27%		> 3,500€	399	20%
	40-49	405	20%	**Education**	In training	190	9%
	50-59	370	18%		Working	1,405	70%
	>60	277	14%		Not working	417	21%

4.2 Measurement of dependent variable

The dependent variable is the channel choice of the customer for the information, counseling, contracting, and usage stage for the respective financial service. During the information stage, customers search for information (e.g. by scanning the website) while during the counseling stage they are actively seeking advice from a person, for instance in the branch or in the online channel (e.g. video chat with an advisor). For the contracting and usage stage see Gensler et al. [7]. In the survey, the respondents specified the chosen channel for one service in each stage of the purchasing process. Channel choice is a categorical variable as there is no hierarchy between the channels.

Table 4 illustrates the channel choices across the different stages of the buying process. It displays that the branch and the online channel are by far the most often chosen channels in our data set as they cover 70% of all choices. Thus, we will focus our results and the subsequent discussion on these two channels.

Table 4. Channel Choices across different stages of the buying process

Channel	*Information*	*Counseling*	*Contracting*	*Usage*[*]	*Total choices*
Branch	755 (38%)	1,038 (52%)	1,183 (59%)	437 (20%)	3,413 (35%)
Online	939 (47%)	546 (27%)	633 (31%)	719 (33%)	2,837 (35%)
Mobile	34 (2%)	22 (1%)	16 (1%)	40 (2%)	112 (1%)
Phone	20 (1%)	54 (3%)	34 (2%)	127 (6%)	235 (3%)
Postal	25 (1%)	15 (1%)	59 (3%)	127 (6%)	226 (3%)
Friends	157 (8%)	99 (5%)	n/a	n/a	256 (3%)
Other	82 (4%)	53 (3%)	87 (4%)	17 (1%)	239 (3%)
None	n/a	185 (9%)	n/a	684 (32%)	869 (11%)

[*] Multiple answers possible

4.3 Measurement of independent variables

The independent variables are the service characteristics of service complexity, value, usage frequency and purchase frequency. The assessment of the independent variables was not conducted by the survey participants themselves. Instead, the values were gathered by asking ten employees of different seniority and from different departments of a large German commercial bank for their expert assessment. This approach was used to reach an objective and transferrable evaluation of the respective financial services. An evaluation by the survey participants might have caused a social desirability bias towards rating their own choice (i.e. financial service) as particularly difficult and complex to manage. The bank employees were given a short questionnaire where they had to specify the service characteristics for each financial service on a 5-Point-Likert scale ranging from 5 ("very high") to 1 ("very low"). The inter-rater reliability of their judgements was low and explanations could solve all disagreements. For the analysis, the average of the different responses was used for each characteristic rather than the most frequent entry of the assessment to allow for more fine-grained differences in the evaluation of the respective dimensions.

4.4 Data analysis

Based on the related work, we assume that customers are influenced in their channel choice during the different stages of the buying process based on service complexity, value, usage frequency and purchase frequency. In addition, the stage is hypothesized to have an effect on the dependent variable. Thus, the channel choice is expressed by the following formula (1):

$$CC_{c,s,t} = \alpha_{c,s,t} + \beta_{c,s,t} \times Complex + \gamma_{c,s,t} \times Value + \delta_{c,s,t} \times Use_{frequ} + \eta_{c,s,t} \times Purch_{frequ} + \chi_s \times Stage \quad (1)$$

whereas,	$CC_{c,s,t}$	Channel choice of customer c for service s in stage t
	$\alpha_{c,s,t}$	Constant for channel c for service s in stage t
	$\beta_{c,s,t}$	Factor for service complexity for channel c for service s in stage t
	$\gamma_{c,s,t}$	Factor for service value for channel c for service s in stage t
	$\delta_{c,s,t}$	Factor for service purchase frequency for channel c for service s in stage t
	$\eta_{c,s,t}$	Factor for service usage frequency for channel c for service s in stage t
	χ_s	Factor for stage of the purchasing process for service s

As the dependent variable is a nominal variable, we used a multinomial logistic regression (MLR) method to calculate the research model. Thereby, we employed the statistical software R and especially the nnet package that can be used for Feed-Forward Neural Networks and Multinomial Log-Linear Models. The MLR is an extension of the binary logistic regression by estimating separate binary models for each category. In the end, only N-1 binary logistic regression models are displayed as one category serves as a reference and each binary model estimates the effect in comparison to this reference category (in our case the online channel).

5 Results

First, Table 5 shows the dimensions of service characteristics. For example, the securities account and the retirement provision are rated much more complex than the checking or savings account. Moreover, checking and savings account are purchased and used more often than the retirement provision.

Second, we examined the distribution of the channel choices. Figure 2 shows the relative amount of the channel choices across the four stages of the buying process. The graphs are similar in their structure. Most customers inform themselves online with a range of 33% (retirement provision) to 54% (checking account) of the customers. The branch is used equally or less often at this stage. A major shift occurs in the counseling stage when more customers visit the branch. For all financial services, the branch is predominant (between 48% and 56%). Only for the checking account, the difference between the online channel and the branch is small (9%).

Table 5. Dimensions of service characteristics

Service	*Complexity*	*Value*	*Purchase frequency*	*Usage frequency*
Credit	3.1	3.9	2.6	2.6
Checking account	1.5	2.0	5.0	3.6
Savings account	1.7	2.6	2.5	2.5
Securities account	3.9	3.7	3.0	2.7
Retirement provision	4.1	3.6	2.0	2.0

1=Very low; 2=Low; 3=Medium; 4=High; 5= Very high

Also in the contracting stage, most customers prefer the branch over other channels. The difference is particularly visible when studying the retirement provision as only 18% of the customers used the online channel to purchase the credit compared with 63% using the branch. Finally, most customers again use the online channel for the after-sales stage. Yet, here the data scatters from 37% (retirement provision) to 66% (checking account).

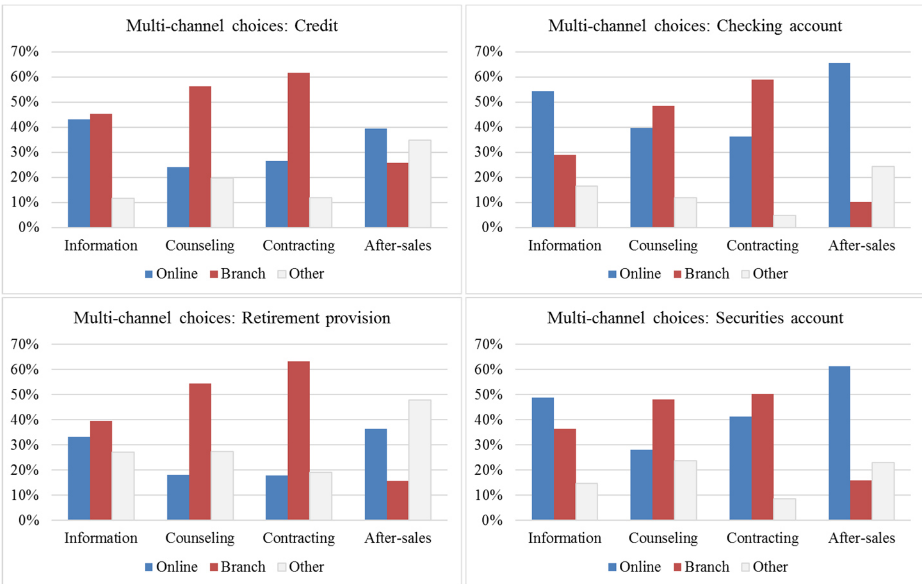

Figure 2. Channel choices of different financial services across stages of the buying process

In a next step, we analyzed whether the above mentioned differences, especially in the contracting and the after-sales stage, are significant or within ranges that can still be explained by coincidence. Table 6 displays the results of the MLR. Although the complete results are displayed, we only discuss the branch and the online channel.

The results show that the channel choice is significantly different in the branch and the online channel in the contracting stage (all characteristics significant) and the after-sales stage (only complexity and value significant). For instance, value of services yield in a different channel choice for the branch ($p<0.01$) compared with the online channel in the contracting stage. Further, complexity leads to a different channel choice between branch ($p<0.04$) and the online channel in the after-sales stage. The direction of the effects are consistent across all stages. Complexity and usage frequency always carry a negative sign, while the effect for value and purchase frequency is positive. We find more significant differences for other channels. Yet, the results for them are not reliable due to small case numbers (see Table 4).

Moreover, we estimate the effect of the stage of the purchasing process on the channel choice. Again, we used a MLR for the analysis and the results are shown in Table 6. There exists a relationship between the stage of the buying process and the chosen channel as the channel choice is significantly different for the branch and the online channel. Together with Table 4, we can state the online channel is associated with the information and after-sales stage, while the branch is associated with the counseling and the contracting stage.

Effects of buying process stage on channel choice. p-values in brackets. Values in bold are significant at the 5% level
1: Family and Friends

When controlling for demographics and behavior-related constructs, all demographics are significant at least in one stage, e.g. age (counseling and contracting stage), gender (all stages) or education (all stages except for counseling stage). This implies, for example, that women are using the branch significantly more often than men across all stages of the buying process. In addition, education is influential as customers with higher education are more likely to choose the online channel and they are less likely to draw upon counseling. On the other hand, channel choices seem to be almost independent of income and occupation. A similar picture arises from behavior-related constructs, where online banking usage and low experiences with the online banking are significant in all stages, whereas Internet usage is only significant in the information and contracting stage. It is evident that customers having low experiences with online banking are more inclined to avoid the online channel. The opposite holds true for online banking usage.

6 Discussion

We started from the question whether service characteristics influence channel choices. Our results show that the channel choice between the branch and the online channel is significantly different for the constructs of complexity, value, and usage frequency in the contracting and the after-sales stage. They are not significant in the first two stages. Thus, we can partly accept H1, H2, H3 and H4 as complexity and value influence channel choices in the last two stages while purchase frequency and usage frequency are only significant in one stage.

1: Family and Friends

H5 is fully supported as there is a significant effect of the stage on the channel choice. In addition, demographics and behavior-related constructs moderate the influence on channel choice, e.g. as males and customers with higher education favor the Internet channel. Thereby, our results confirm the idea that the channel choice is dependent on the purchased services and its characteristics.

Hence, our research is in line with prior studies on product categories which showed that the type of product or service influences the channel choice (e.g. [7, 13]). We agree with Black et al. [18] that banking customers rarely choose the online channel for complex services and we can confirm the findings of Burke [15] that customers prefer the store for expensive goods. Additionally, we can confirm the findings of other researchers (e.g. [15, 27, 8]) that certain stages are associated with certain channels. Finally, we find a significant influence of demographics on channel choice and thus disagree with some researchers (e.g. [6, 21]) in this regard.

7 Summary and conclusion

This work studies the influence of service characteristics on channel choice. Based on previous literature, we developed a research model including four service characteristics, and tested it across five financial services in the retail banking industry in Germany. Our results show that channel choices for the branch and the online channel are significantly different for the service characteristics during the contracting and the after-sales stage. Additionally, there is a relationship between the stage of the buying process and the channel chosen. In general, our results are in line with prior studies that examined product characteristics. Practitioners can use the results to determine which of their services to offer on which channel. We suggest digitizing less complex services with a low value, especially in the contracting stage. Further, practitioners can use stage-channel associations to tailor the channels according to customers' preferred contact points in each stage of the buying process.

However, this paper has some limitations. First, the channel choices are retrospective and only allow for a limited view on how customers purchase services in the future. Additionally, many banks did not offer all services online so that banking customers did not have a free choice across all channels. Second, the assessment of the service characteristics was performed by banking professionals (more objective but more distant from channel choices) and not the users (more subjective but more relatable to channel choices) themselves. It is debatable which assessment yields more meaningful results. Third, we neglected the channel characteristics that might have an influence on channel choices, too. Fourth, customers without Internet access were excluded as the survey was conducted online. Despite a high internet user penetration in Germany, this might create a bias towards the online channel. Finally, the paper only addresses the retail banking sector in Germany and the results might not be transferable to product-service bundles, other industries, or countries.

Thus, future research might replicate our study in other service industries (e.g. telecommunications, consulting or education) or other countries (e.g. United States or Austria). Moreover, the interesting results on demographics could be taken into account in future studies.

Digital Nudging: Altering User Behavior in Digital Environments

Tobias Mirsch[1], Christiane Lehrer[1], Reinhard Jung[1]

[1] University of St. Gallen, Institute of Information Management, St. Gallen, Switzerland
{tobias.mirsch,christiane.lehrer,reinhard.jung}@unisg.ch

Abstract. Individuals make increasingly more decisions on screens, such as those on websites or mobile apps. However, the nature of screens and the vast amount of information available online make individuals particularly prone to deficient decisions. Digital nudging is an approach based on insights from behavioral economics that applies user interface (UI) design elements to affect the choices of users in digital environments. UI design elements include graphic design, specific content, wording or small features. To date, little is known about the psychological mechanisms that underlie digital nudging. To address this research gap, we conducted a systematic literature review and provide a comprehensive overview of relevant psychological effects and exemplary nudges in the physical and digital sphere. These insights serve as a valuable basis for researchers and practitioners that aim to study or design information systems and interventions that assist user decision making on screens.

Keywords: Digital Nudging, Choice Architecture, Behavioral Economics, Human-Computer Interaction, User Interface Design

1 Introduction

Human decision making is imperfect. Research in psychology and behavioral economics has shown that individuals are influenced by various psychological effects during their decision making – consciously or unconsciously [1]. In fact, decisions are highly context-dependent; that is, they are influenced by the choice environment [2]. The reliance on heuristics and the influence of psychological effects such as social norms lead individuals to make predictable mistakes and often decide to their own detriment. Against this background, Thaler and Sunstein introduced the concept of libertarian paternalism as an approach to deliberately design choice environments to affect human behavior while respecting individual freedom of choice. Libertarian paternalism aims at helping individuals make better decisions in their own interest [2]. Choice environments can be designed using so-called nudges, which are relatively minor changes to decision environments. Nudges either attempt to overcome or use specific psychological effects to guide individuals towards a predefined choice option. Nudges refer to "any aspect of the choice architecture that alters individuals' behavior in a predictable way without forbidding any options or significantly changing their

13th International Conference on Wirtschaftsinformatik,
February 12-15, 2017, St. Gallen, Switzerland

Mirsch, T.; Lehrer, C.; Jung, R. (2017): Digital Nudging: Altering User Behavior in Digital Environments, in Leimeister, J.M.; Brenner, W. (Hrsg.): Proceedings der 13. Internationalen Tagung Wirtschaftsinformatik (WI 2017), St. Gallen, S. 634-648

economic incentives” [2, p. 6]. Designing choice environments through the purposeful implementation of nudges is called nudging. A prominent example for nudging in the physical sphere is the change of cafeteria design to guide students towards a healthier diet without eliminating unhealthy foods from the menu. This is achieved by positioning healthy food options at eye level, thus making them easier to reach compared to unhealthy options [2]. In research, various disciplines, such as medicine [e.g., 3], psychology [e.g., 4], and different areas from sociology [e.g., 5] have dealt with the concept of nudging. The literature mainly discusses the application of nudging in the development of policies [e.g., 6], encouraging environmentally friendly behavior [e.g., 7], and promoting healthy lifestyles [e.g., 8]. In practice, nudging has been picked up by a number of companies and governments, which increasingly try to influence individuals’ choices [9].

The concept of nudging is increasingly gaining relevance in the digital sphere, as nowadays more and more decisions are taken on screens, such as websites or mobile apps, ranging from the choice of a travel destination to purchases of all types to the right life partner, insurance, or investment. However, in the digital environment, individuals are particularly prone to making deficient decisions. Due to the vast amount of information available on the Internet, individuals often fail to process all the relevant details to reach an optimal choice. Instead, individuals often make decisions on screens in a hasty and automated manner [10]. In this context, nudging can be an effective tool to guide users’ decision making. Compared to physical contexts, digital environments provide several advantages for nudging: the implementation of digital nudges is easier, faster and cheaper; moreover, the Internet provides specific functionalities, like user tracking, which allows personalization of nudges presented to users, making them potentially more effective [11].

While nudging has gained momentum in various fields of research as well as in practice, digital nudging has not gained much attention by information systems (IS) scholars. Against this background, we present digital nudging as a relevant and fruitful research area for IS research and for human-computer interaction (HCI) research in particular. However, prior HCI research has used behavioral economics concepts that focused mainly on a few selected heuristics and biases, such as the endowment effect, loss aversion [e.g., 12], or the status quo bias [e.g., 13]. In behavioral economics, Benartzi and Lehrer [10], and in IS, Weinmann et al. [11] extend the nudging concept to the digital context. Weinmann et al. [11] define digital nudges as user interface (UI) design elements that affect choices and propose a five-step process for developing nudges in online decision environments (see figure 1).

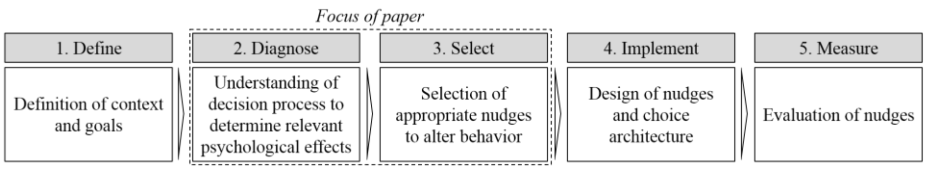

Figure 1. Nudging Development Process [11]

In the present paper, we heed the call of Weinmann et al. [11] for further research to gain a sound understanding of the mechanisms that underlie nudging. To achieve this research goal, we conducted a systematic literature review encompassing research from different disciplines. As a result, we provide an overview of relevant psychological effects that have been discussed in relation to nudging. Moreover, we present examples of digital nudges to illustrate possible approaches in practice. Thereby we address the second and third steps of the nudging development process, i.e., "Diagnose" and "Select". Based on these steps, concrete nudges and choice architecture can be developed ("Implement") and tested in lab experiments or in real world settings ("Measure"). With regard to the first step ("Define"), we do not limit our literature review, as well as the nudges presented, to a specific digital context, but provide a broad range of possible application areas.

The contribution of this paper is twofold. First, from a research perspective, we present digital nudging as a relevant and promising research area in the IS, particularly the HCI domain. In this paper, we provide an overview of the body of knowledge regarding relevant psychological effects that underlie nudges in the physical context. Thus, we illuminate the theoretical mechanisms that may also be at play in digital nudging. The psychological effects and nudges presented provide a valuable basis for behavioral researchers who aim to transfer them to the digital context and empirically examine their effects on user behavior. Moreover, our findings can guide design-oriented researchers when designing IS and interventions that assist users in making self-beneficial choices. Second, for practitioners, the concept of digital nudging provides new stimuli for UI and user experience (UX) design. A deeper understanding of the psychological effects at play in human decision making and behavior helps UI designers intentionally develop theoretically based nudges. By doing so, they can either make use of a specific psychological effect to reach a certain goal (e.g., increase sales or transaction speed) or counteract its influence. The exemplary digital nudges provide initial ideas as to how they may be implemented. Moreover, as all UI design decisions influence user behavior, UI designers can use the knowledge about the effects to verify if the current choice environment of their IT artefacts nudges users in the intended way or not.

This paper proceeds as follows. First, we present the theoretical background of behavioral economics, nudging, and HCI. Subsequently, the methodology of the literature review and the results are presented. The paper concludes with a summary, limitations, and proposals for further research.

2 Theoretical Background

2.1 Behavioral Economics and Nudging

Traditionally, economics views the human being as homo economicus, whose decision making is fundamentally rational. However, this view disregards behavioral studies of cognitive and social psychology that have empirically shown that humans do not always behave and decide rationally [2]. Behavioral economics combines psychology and economics to investigate and model human behavior with consideration for cognitive limitations and complications. Thereby, “behavioral economics increases the explanatory power of economics by providing it with more realistic psychological foundations” [14, p. 1].

According to dual process theories, dominant in the field of social psychology, individuals use different cognitive systems to assess information during the decision making process: on the one hand, there is intuitive System 1, which is fast, automatic, effortless and emotionally charged; and on the other hand, there is reason-based System 2, which is slower, effortful and deliberately controlled [15]. Most empirical studies in the field have concluded that everyday activities are mainly driven by System 1, making human decision making prone to heuristics and biases [15, 16]. Heuristics, i.e., simple rules of thumb, facilitate and accelerate the decision making process by reducing the amount of information processed. Moreover, the external environment, or choice context, is an important parameter in the decision making process [e.g., 17]. For example, different contexts may alter the assessment of trade-offs or comparisons between different options.

Nudging is a concept based on insights from behavioral economics aiming to alter environments in a way that would increase the likelihood of certain behaviors. A nudge is a simple intervention within the choice architecture to steer individuals by addressing specific psychological effects to make use of or overcome them. What differentiates nudges from other forms of intervention is that they are designed to preserve full freedom of choice [2]. Nudges are, for example, notifications that inform individuals of their calorie intake, nutrition labels on food or the automatic enrollment in a pension plan with an opt-out option [18]. Stipulating a certain diet or exercise or enrolling someone without an opt-out option would not be considered a nudge. Transferred to the digital context, digital nudging refers to the "use of user-interface design elements to guide people's choices or influence users' inputs in online decision environments" [11, p. 3]. These UI design elements include graphical design, specific content, wording or small features (e.g., product ratings) [11].

2.2 UI Design in the HCI Domain

Research in the field of HCI studies and designs interfaces facilitating the interaction between users and IT artefacts, such as websites, applications, or devices. UI design aims at maximizing the usability and UX [19]. The usability of an IT artefact refers to its ease of use and efficiency. UX can be associated with various meanings, ranging from “traditional usability to beauty, hedonic, affective or experiential aspects of technology use” [20, p. 91]. According to Hassenzahl and Tractinsky, “UX is about technology that fulfils more than just instrumental needs in a way that acknowledges its use as a subjective, situated, complex and dynamic encounter” [20, p. 95]. It can be described as a consequence of the internal state of the user, including, for example, needs, motivation, expectations, or feelings.

HCI scholars have provided various principles and guidelines for good UI design [e.g., 21, 22]. Those guidelines are based on a sound understanding of individuals’ behavior and needs and acknowledge demographic diversity as a starting point for the design process (e.g., IFIP reference model [23]). Due to the heterogeneity and changes in how humans interact with IT artefacts, UI design principles do not represent ultimate laws for design. In fact, HCI research continuously tries to advance its approaches to improve interfaces and experiences in relation to technological and user development. In doing so, HCI research often leans on insights from other fields, such as ethnography or even phenomenological philosophy [24]. We claim that behavioral economic insights and the concept of nudging are inspirations for HCI research. First, research is informed by a real-world phenomenon: the imperfection of human decision making and how relatively simple it could be addressed with digital nudges. Second, through this approach, the gap between theory and practice can be bridged by providing a first analysis. Third, it can represent an approach to discover and develop new theories as well as empirical methods or an understanding of how different approaches may complement each other. Overall, a basis for further discussion of underlying issues or support to draw conclusions from experiments with empirical results can be established. Through this approach, HCI researchers may be able to provide UI designers with insights and guidelines to increase performance or user satisfaction and lower error rates [25].

3 Literature Review on Nudging

3.1 Systematic Literature Review

To provide a comprehensive overview of the existing research on nudging, the underlying psychological effects as well as related areas, such as libertarian paternalism and behavioral economics in the digital context, we conducted a literature review in April 2016. Following the methodology proposed by vom Brocke et al. [26], we performed a search spanning multidisciplinary databases providing access to academic journals and conference proceedings. We conducted four searches by applying relevant phrases (see table 1) in the fields title, keywords, and abstract.

Table 1. Results of the literature review

Search Phrase / *Database*	*Nudging / Nudge*	*Choice Architecture*	*Libertarian Paternalism*	*Behavioral Economics AND Online*
ScienceDirect	506	1232	14	13
EbscoHost	167	652	46	4
AISeL	1	21	0	2
Unfiltered results	673	1884	60	19
Sum of relevant articles	65			

From these results, we excluded duplicates and articles not published in journals or conferences. Afterwards, we screened the articles to evaluate if they contributed to this paper. During this process, we excluded articles not topic-related, for example, articles about improving ozone modelling using observational nudging in a prognostic meteorological model or articles about the impact of nudging coefficient for the initialization on the atmospheric flow field and the photochemical ozone concentration. In a last step, we selected those articles that report on concrete nudges or/and psychological effects. For example, some articles just reported on the acceptance of nudging in society but did not elaborate on the underlying psychology or exhibit examples. After this evaluation, we considered 65 articles to be relevant for this work. Table 1 provides a detailed overview of the results.

3.2 Identified Psychological Effects and Nudges

Through the literature review, we identified a total of 20 psychological effects in the context of libertarian paternalism and nudging. Most articles described the underlying psychological effects and the associated nudges as well as a concrete application or illustrated example. However, some papers only reported psychological effects without providing examples of nudges, while others reported nudges without touching upon underlying psychological effects. In the latter case, we complemented the described nudges with the psychological effects based on gained expertise and insights. Table 2 provides an overview of the identified psychological effects based on the literature review. The frequency of appearance is higher than the number of identified papers because many papers referred to more than one psychological effect.

Table 2. Psychological effects extracted from literature

Academic literature has mainly discussed nudging in relation to promoting healthy and environmentally friendly behavior. With regard to health, the authors discuss and empirically investigate nudges that influence food choices through framing effects such as labels, which indicate the healthiness of food [e.g., 30, 47, 48], or the positioning of healthy food options in an easily accessible way in cafeterias and/or increased visibility [e.g., 41, 53, 54]. With regard to environmentally friendly behavior, research examined nudges using social norms, such as messages that refer to the mass by stating, for example, that 70% of customers purchased at least one ecological product [5]. Furthermore, research discussed nudges based on loss aversion (e.g., subsidizing less polluting or taxing polluting travel options) [66] and anchoring and adjustment (e.g., setting reference points to evaluate eco-friendliness) [35].

The following section describes the identified psychological effects and the associated examples of nudges in more detail. Additionally, we provide examples of possible approaches for nudges in digital contexts. For this purpose, we selected well-known websites. Still, we do not claim that the examples of digital nudges are the result of a purposeful implementation by the UI designers based on the nudging concept. Nevertheless, they carry psychological effects and can be observed as nudges. These examples mainly serve to illustrate how digital nudges may appear in practice. Before providing a detailed description of every psychological effect, it must be mentioned that they partly overlap [2]. Additionally, as highlighted by Thaler and Sunstein, nudges rarely ground on only one specific psychological effect but rather on the interplay of a few different effects [2]. Furthermore, due to the length restrictions of this paper, we focused on the most frequently mentioned psychological effects (i.e., framing, status quo bias, social norms, loss aversion, anchoring & adjustment, hyperbolic discounting, decoupling, priming, and availability heuristic).

Framing. Tversky and Kahneman describe the term framing as the act of designing a decision frame in a way that the "decision-maker's conception of the acts, outcomes, and contingencies associated with a particular choice" [82, p. 453] is governed through psychological principles. By this means, shifts and outcomes of decisions are more predictable and probabilities are altered. Framing refers to a controlled presentation of a decision problem considering different framing methods regarding one decision problem. In this paper, we follow this definition but focus specifically on accentuation, orientation, and presentation of decision problems. A vivid example retrieved through the literature review shows how to reduce accidents on curvy roads by painting a series of white stripes on the streets (horizontal to the driving direction). The stripes alter the perception of speed for drivers – the driven speed was perceived as faster than it really was. Therefore, the drivers intuitively slowed down, and accidents were reduced [43]. In this example, the perception of speed was framed through a targeted accentuation and different (perceived) presentation of the environment, which altered the probability to reduce the speed. In the digital context, a practical application example can be observed on Amazon.com. On the product pages, Amazon accentuates product-related items. In doing so, the choice architecture is intervened by pulling the attention of the user to related articles. This accentuation may trigger an additional purchase, which was originally not planned by the user.

Status Quo Bias. The status quo bias describes the strong tendency of individuals to remain with the status quo as the disadvantages of leaving the current state loom larger than the advantages associated with a change. Kahneman et al. see the status quo bias as a manifestation of an asymmetry of value called loss aversion, that is, "the disutility of giving up an object is greater than the utility associated with acquiring it"

[83, p. 194]. A prominent example is the Austrian organ donor system, which automatically registers every citizen as an organ donor, while in other countries the opposite is the case. In Austria, individuals need to actively decide against organ donation, which positively influenced the participation [58]. In the digital context, many examples can be found where companies set defaults on their websites, such as insurance options on travel websites or delivery options on e-commerce sites. Another example are online configuration tools for cars (e.g., Tesla.com). The car configurator on the Tesla website is a practical application example for nudging, where a nudge in the form of default settings is implemented. When configuring a model, certain packages and options are chosen by default. This procedure is also applied for software products (e.g., pre-selected installation options).

Social Norms. Social norms influence human behavior and can be described as "rules and standards that are understood by members of a group and that guide and/or constrain social behavior without the force of laws" [84, p. 152]. Social norms emerge from "interaction with others; they may or may not be stated explicitly, and any sanctions for deviating from them come from social networks, not the legal system." [84, p. 152]. Moreover, individuals tend to orient towards the behavior of others, searching for social proof when unable to determine the appropriate mode of behavior in a given situation. An example for the application of social norms in nudging is the "most of us wear seatbelts" campaign in the USA in 2002 and 2003 by the Montana Department of Transportation, which aimed to promote safe driving behavior [85]. Amazon's product recommendation systems exhibit an example for calling upon social proof. On the page of a specific product, a recommendation for further products is given, based on what items were bought by other customers ("Customers Who Bought This Item Also Bought"). The group of other customers set a certain standard or a rule for the purchase of a specific product, which the single customer may follow, taking into account the information possessed by others.

Loss Aversion. The psychological principle of loss aversion assumes that losses and disadvantages have greater impact on preferences than gains and advantages [83]. Price benefits can be used to subsidize environmentally friendly options while taxing less environmentally friendly ones [66]. Examples for nudges on Booking.com can be found on the result page of an applied search for a hotel. There, statements such as "Booked 36 times today", "-45% TODAY!", "8 people are looking right now", or "In high demand!" are implemented to trigger the user to not "lose" the offer she found. By giving information about the popularity or limitation, these statements may shorten the purchase decision.

Anchoring and Adjustment. When individuals lack information, they tend to assess or estimate it by using an individual starting point. This initial starting point is either given by the decision frame or the result of a more or less accurate calculation. Consequently, different starting points result in different estimates and are biased toward the considered starting values. Tversky and Kahneman [86] describe this as anchoring and adjustment. For example, the European Energy Label provides information about the energy class and water consumption as well as energy consumption. These labels are used for home electronics, such as washing machines, televisions, or fridges [42]. The exhibited values provide a reference point (anchor) and may serve for users as a tool for comparison between different choice options. Both online and offline retailers often give different (price) options for a product. Apple, for example, offers the iPhone 6s Plus in three capacity options with different prices. The options are displayed at the same moment, while the lowest and the highest price options serve as anchors. This may lead the user to assess the median option relative to the given reference points (prices) influencing her price perception.

Hyperbolic Discounting. According to the concept of hyperbolic discounting, individuals behave inconsistently in terms of time [87]. They value the present and the near-present stronger than the future. Therefore, individuals prefer options with present effects, even though future effects may be greater or better. Rewards such as direct cash payments, vouchers, or price subsidies may serve as nudges to nudge the user toward the better, yet future, choice or action. These nudges have been implemented to promote healthy activities or discourage unhealthy ones [76]. An example for the application in the online sphere can be observed on the website of Europcar, which uses immediate rewards. The result page of Europcar's rental car search displays the prices, where two prices are given for each result. One price saves 9% on the booking if the customer not only books the car but also pays online. This incentive nudges users toward immediate purchase by providing a financial benefit.

Decoupling. When individuals make a decision, they consider the costs of their choice, but this may not be straightforward. According to Prelec and Lowenstein [88], it is more difficult to evaluate the costs of purchases paid by credit card in contrast to cash, as the payment is decoupled from the consumption. As a result, the perceived costs of the decision decrease. This phenomenon is called decoupling [89]. An approach to overcoming decoupling is the disclosure of costs or effects of decisions. The disclosure of environmental costs with energy use or the full costs of credit cards help individuals to understand future costs in the current decision situation and may help to optimize individuals' choices [18]. Media Markt, Europe's market leading retailer for consumer electronics, offers financing and deferred payment for products on its German website. By this means, the retailer wants to decouple the purchase from the actual payment to lower the decision barrier and make purchase more likely.

Priming. Individuals can be prepared for a situation where a decision takes place. Before the decision is made, specific topics, moods, questions, or information can be introduced, for example, by visualizing the consequences of a decision. An example for priming is the nudge of eliciting intentions, such as "Do you plan to vote?" or "Do you plan to vaccinate your child?", before actions or decisions are taken [18]. Priming can be described as the preparation of individuals for the decision moment by gently leading them to the decision. The priming effect can also overlap with framing and other psychological principles [2]. As a result of our search for illustrative examples of priming in the online domain, we identified the Instagram account of Air France as a tool to prime users for a decision. The exhibited pictures prime the users by visualizing consequences or possible outcomes of a decision – in this case, emotional pictures of travelling and destinations. The pictures may nudge the user toward a specific destination or the decision to travel in general.

Availability Heuristic. Individuals tend to judge probabilities of events based on the ease at which they can be recalled. Easily available and often or regularly occurring events are perceived as more likely than less present events, independent from real probabilities [86]. Media campaigns, for example, can induce the imagination that specific risks are more frequent by exhibiting examples of real cases with fatal outcomes (e.g., deaths caused by smoking, plane crashes). Those visual and frequently displayed cases can alter the judgement of individuals toward vulnerability and increased sensitivity to the specific event [90]. Online banner campaigns are a vivid example of a practical implication of a digital nudge making use of the availability heuristic. In the Google Display Network, advertisers can make campaigns available to users by displaying their campaign on the specific ad spaces. Through tracking the user, they can show the ads repeatedly. In the decision moment, their campaign is at the forefront of their mind, and thus, easily available for the users. This may nudge them toward the option of the advertising firm.

4 Conclusion, Limitations, and Further Research

Given the high proliferation of technology in everyday life, more and more purchases as well as life decisions are made on screens. In digital contexts, users often engage in fast and automated decision making, making them prone to making deficient decisions. Against this background, we presented digital nudging as an effective tool to guide the users' decisions by implementing purposefully designed UI design elements. While nudging has been widely discussed outside the IS and HCI domain, little is known about the psychological mechanisms that underlie digital nudging. To address this research gap, we conducted a systematic literature review and identified twenty psychological effects that were investigated in the physical context and that may be transferred to digital environments. In this paper, we presented nine effects in detail as well as exemplary nudges in the physical and digital spheres.

Our research has several implications for theory and practice. First, by presenting the concept of digital nudging, we aim to encourage both researchers and practitioners to incorporate it into their work leveraging the insights into decision making processes and approaches to alter it. It is our intention to inspire behavioral and design-oriented researchers to conduct further research on the effectiveness of digital nudging and thereby advance this increasingly relevant concept. Moreover, we aim to provide new stimuli to practitioners in private and public organizations to create effective UI that benefit both users and organizations. Second, the identified psychological effects and exemplary nudges contribute to HCI research. While HCI scholars are well aware of human psychology and cognitive science, these new insights enhance the theoretical basis of UI and UX design and can be used in design processes and guidelines. Design-oriented researchers can apply psychological effects and nudges when designing IT artefacts to either leverage or counteract the influence of specific psychological effects. Positioning nudges effectively on UI can increase the usability and UX of IT artefacts. Third, for practitioners, the identified psychological effects and exemplary nudges enhance the understanding of decision making and cognitive heuristics and biases at play. UI designers can use these insights to design nudges, i.e., simple interventions for a specific use context and goal. As digital nudges are small changes to an existing UI, their implementation is relatively fast and cheap. Moreover, interventions designed based on empirically validated theory may be more effective compared to a trial-and-error approach, which is often used in practice. Furthermore, our findings help practitioners to better assess whether implemented choice environments serve the intended purpose or steer the user toward an unintended behavior.

The main limitation of this work is that the examples of digital nudges were chosen based on the authors' observation of the websites. We were not able to assess whether the UI design elements were the result of a deliberate nudging development process. Furthermore, as mentioned in the literature, psychological effects partly overlap. Consequently, some of the illustrated nudging examples also overlap, and thus, the underlying psychological effects cannot be clearly differentiated.

Digital nudging unlocks a plethora of further research opportunities. As stated in the introduction, this paper addresses the second and third steps of the nudging development process. Design-oriented researchers could focus on the later steps by designing, implementing and evaluating the effectiveness of digital nudges through lab or real world experiments. From a behavioral research perspective, it would be valuable to investigate the psychological effects in digital contexts to determine whether they show similar predictable effects as in physical contexts. Moreover, it appears promising to examine the effects of specific digital nudges on individuals' decision making, in different digital contexts (e.g., PC, mobile devices, digital signage), as well as to consider different user characteristics. The results may allow for tailoring digital nudges to individual users by leveraging user data and targeting technologies, depending on their current use context and their characteristics.

Terrorbekämpfung mithilfe sozialer Medien – ein explorativer Einblick am Beispiel von Twitter

Christian Reuter, Katja Pätsch, und Elena Runft

Universität Siegen, Institut für Wirtschaftsinformatik, Siegen, Deutschland
christian.reuter@uni-siegen.de

Abstract. Das Internet und insbesondere soziale Medien werden bekanntermaßen nicht nur zu vermeintlich guten Zwecken genutzt. So findet die Rekrutierung neuer Mitglieder und die Verbreitung von Ideologien des Terrorismus ebenfalls über dieses Medium statt. Aber auch die Terrorismusbekämpfung bedient sich gleicher Werkzeuge. Die Art und Weise dieser Gegenmaßnahmen sowie die Vorgehensweisen sollen in diesem Artikel thematisiert werden. Im ersten Teil wird der Forschungsstand zusammengefasst. Der zweite Teil stellt eine explorative empirische Studie der Terrorismusbekämpfung in sozialen Medien, insbesondere in Twitter, dar. Verschiedene, möglichst charakteristische Formen werden in diesem Rahmen am Beispiel von Twitter strukturiert. Ziel ist es, sich diesem hochrelevanten Gebiet mit dem Ziel von Frieden und Sicherheit aus Perspektive der Wirtschaftsinformatik zu nähern und weiteren Forschungsarbeiten in diesem Gebiet als Grundlage und Ausgangspunkt dienen zu können.

Keywords: Soziale Medien, Twitter, Terrorismus, Krisenmanagement

1 Einleitung

Die Anschläge in Paris 2015 und in Belgien 2016, um zwei aktuelle Beispiele zu nennen, forderten nicht nur viele Opfer, sondern hatten auch weitreichende politische Folgen. Der sich zu den Anschlägen bekennende sogenannte Islamische Staat (IS) nutzt insbesondere soziale Medien auf eine professionale Art und Weise zur Rekrutierung neuer Kämpfer und zur Werbung für ihre Ideologie [1]. Aber auch aktive Gegner dieses Terrorismus nutzen die gleichen Kanäle zur Terrorbekämpfung. Soziale Medien spielen auf beiden Seiten eine große Rolle. Deren Nutzung durch Unternehmen [2], aber auch durch terroristische Organisationen wurde in der Forschung bereits betrachtet (siehe Kapitel 2). Die Terrorbekämpfung im Web 2.0 hat allerdings wissenschaftlich noch vergleichsweise weniger Beachtung gefunden. Obwohl beispielsweise das Hacker Netzwerk *Anonymous* dem IS den virtuellen Krieg androhte, wurden die daraus resultierenden Folgen wenig in den Medien rezipiert.

Wir fragen uns, wie wird auf die Propaganda der Terroristen geantwortet? Twitter eignet sich nicht zuletzt aufgrund der Zugriffsmöglichkeiten gut, um eine derartige Analyse durchzuführen. Deshalb untersuchen wir in dieser Arbeit, von welcher kompakte Auszüge bereits als Poster-Beitrag veröffentlicht wurden [3], Tweets und Twitter-Accounts im Hinblick auf Anti-Terrormaßnahmen. Hierzu werden wir zunächst den Stand der Forschung zu Terrorismus und sozialen Medien darlegen (Kap. 2). Anschließend erläutern wir unsere Methodik, gefolgt von der qualitativen Analyse der Inhalte (Kap. 3). Schließlich diskutieren wir unsere Ergebnisse (Kap. 4), um ein Fazit aus unseren Erkenntnissen ziehen zu können (Kap. 5).

2 Stand der Forschung: Terrorismus, Propaganda und deren Bekämpfung in sozialen Medien

Dieses Kapitel beschäftigt sich mit dem aktuellen Stand der Forschung bezüglich der Relevanz der sozialen Medien im Zusammenhang mit terroristischer Propaganda sowie existierenden Forschungsergebnissen zu möglichen Gegenmaßnahmen.

Verbreitung terroristischer Propaganda in sozialen Medien. In vielen Arbeiten zu Terrororganisationen und sozialen Medien werden allgemein terroristische Organisationen, aber meist konkret der sogenannte Islamische Staat (IS, ISIS, ISIL, DEASH) thematisiert. So versuchen auch wir allgemein von allen Terrororganisationen zu sprechen, spezifizieren uns aber auch auf den IS, da die aktuelle Situation dies einfordert. Medien, unter anderem die TV-Berichterstattung, spielen im Terrorismus eine große Rolle: „Einen Teil der Verantwortung für die zu beobachtenden Panikreaktionen der Menschen tragen die Medien“ [4]. Einer US-repräsentativen Studie gemäß fördert Angst Vorsorgemaßnahmen; Zorn verhindert sie [5]. Christoph [6] argumentiert: „Ohne ein Bekennerschreiben, ein Abschiedsvideo des Attentäters oder ein letztes Posting im sozialen Netzwerk wäre ein Bombenanschlag nichts als ein Kapitalverbrechen. Durch die terroristische Kommunikationsstrategie wird das Verbrechen erst zum terroristischen Akt“. Terroristen sind jedoch „nicht mehr auf Medienmacher angewiesen, sie sind selbst zum Agens in diesem Spiel geworden“ [6]. Und das nicht ohne Grund: „Terrorismus kann […] nur dann Bedeutung besitzen, wenn er auch auf einer medialen Ebene […] sinnhaft gemacht wird“ [6]. Soziale Medien bieten demnach „den Vorteil der Immersion, das heißt der Verschmelzung von Medium und Botschaft. Die Glaubwürdigkeit terroristischer Narrationen wird so gestärkt, indem sie über vermeintlich seriöse Portale wie YouTube verbreitet werden“ [6]. So entsteht das Gefühl, „der Terrorist sei *einer von uns*, indem er die selben Kommunikationskanäle (‚-waffen‘) nutzt wie der Rezipient selbst“ [6].

Doch nicht nur YouTube dient der Verbreitung: In den vergangenen Jahren ist Twitter zur beliebtesten Internetplattform von Terroristen geworden [7]. Neer und O’Toole [8] haben die Nutzung sozialer Medien durch ISIS untersucht und betonen, dass soziale Medien (insbesondere Twitter) als strategisches Werkzeug genutzt wird, um junge Dschihadisten, Ba'ath Beamte und Frauen für ihre Gewaltüberzeugungen zu begeistern. Klausen et al. [9] betonen, dass die britische Terroristengruppe al-Muhajiroun ihr internationales Netzwerk von YouTube-Kanälen für Propaganda und die Darstellung von gewalthaltigen Inhalten sehr durchdacht ausnutzt. Weinmann und Jost [10] erläutern die Nutzung von Facebook, Twitter und YouTube durch Terrororganisationen zur Rekrutierung und Propaganda: Soziale Medien erleichtern es, Gleichgesinnte zu finden und deren Inhalte zu konsumieren. Gleichzeitig können Terroristen in sozialen Medien auch eine quasi endlose Menge potentieller Mitglieder adressieren, die sonst nicht den Weg in die geschlossenen Foren finden würden. Gemäß der Studie waren zu Beginn Foren die wichtigsten Kontaktpunkte für Mitglieder, Interessenten und Neueinsteiger. Deren Nutzung wurde durch polizeiliche Überwachung erschwert, ebenso gerieten sie in das Fadenkreuz von Nachrichtendiensten, die die Seiten angriffen und stilllegten. Daraufhin wendeten sich immer mehr internetaffine Terroristen den sozialen Netzwerken zu [10]. Dennoch existieren die Foren weiterhin parallel, denn dort debattiert der harte Kern der Community „generelle Entwicklungen in der Szene, führt Diskussionen über ideologische und theologische Fragen und konsumiert Autopropaganda“ [10].

Mehr um den Inhalt geht es bei Zelin [11]: Alle Medien des IS sind auf Arabisch veröffentlicht und nur ein kleiner Anteil ist in andere Sprachen übersetzt. Nach Archetti [12] trägt Online-Propaganda aber nicht nur zur Rekrutierung bei: Ein Dschihad-Video anzusehen könnte sogar die Entschlossenheit von Terrorgegnern erhöhen – folglich eine entgegengesetzte Wirkung. Trotz dieses Zwiespalts gilt: Jede Aufmerksamkeit ist essenziell. Während manche mit Abneigung auf die Videos reagieren, lassen sich andere davon inspirieren – und genau das will der IS erreichen [13].

Die Propagandaziele, in deren Verbreitung sozialen Medien eine Schlüsselkompetenz zugeschrieben wird, reichen von externen Absichten wie der Verbreitung von Angst, bis zu internen wie der Schaffung emotionaler Verbundenheit mit der Zielgruppe [14]. Die Strategie der IS-Mitglieder ist es, durch Posts potenzielle Anhänger aus der ganzen Welt anzuwerben und globale Terrorzellen zu schaffen. Greene [15] thematisiert die taktischen Vorgehensweisen*:* Eine beliebte Taktik zum Verbreiten von ISIS-Propaganda über soziale Medien sind „Twitter-Bomben“, die die beliebtesten Hashtags der Woche nutzen und sie in IS-verwandten Beiträgen verwenden, wodurch ein größeres Publikum erreicht wird [15]. Damit erreicht der IS Personen, die für gewöhnlich nicht an Propagandamaterial interessiert sind und nur zufällig auf die terroristischen Tweets stößt. Ein weiterer Trick zur schnellen Verbreitung ist das gegenseitige Folgen auf Twitter [16]. Meinungsfreiheit, liberale oder unzureichende Inhaltskontrolle auf Twitter begünstigen terroristische Absichten.

Bekämpfung terroristischer Propaganda in sozialen Medien. Einen neuen Blickwinkel auf terroristische Aktionen im Internet eröffnet Gartenstein-Ross [17]: Er gesteht dem IS die erfolgreiche Nutzung von beispielsweise Twitter zu, aber macht gleichzeitig darauf aufmerksam, dass der IS völlig auf den Erfolg dieser Propaganda angewiesen ist und daher eine Schwächung der IS-Kommunikationsstrategie angepeilt werden sollte. Seine Lösungsansätze sind hierfür das Gründen einer kleinen und flinken Einheit speziell zur Widerlegung IS geladener Propaganda [17]. Denn in puncto Glaubwürdigkeit sieht Gartenstein-Ross eine Schwachstelle: Ein Grund, warum IS Nachrichten verwundbar sind, ist, dass Teile davon nicht wahr sind und dadurch der IS beträchtlichen Schaden bezüglich der Wahrnehmung seiner Glaubwürdigkeit riskiert [17]. Ein weiterer Aspekt ist die Professionalität im Umgang mit sozialen Medien. Die sprachlichen Fähigkeiten der Mitglieder (die Statements und Videos in europäische Sprachen übersetzen) [18] tragen zur Verständniserleichterung bei.

Mit generellen Maßnahmen und Strategien zur Terrorbekämpfung beschäftigt sich Turk [19]. Demnach sind die Vereinigten Staaten die wichtigste Weltmacht und Marktführer in der Technologie der Anti-Terror-Entwicklung. Dagegen fokussieren sich Jeberson und Sharma [20] auf die gezielte Ermittlung möglicher Methoden zur Identifizierung Terrorverdächtiger in sozialen Netzwerken. Cheong und Lee [21] beschreiben, dass in Verbindung mit intelligenten Data-Mining-, Visualisierungs- und Filtermethoden diese Daten in einer Wissensbasis gesammelt werden könnten, die für Entscheidungsträger und Behörden von großem Nutzen für schnelle Reaktion und Überwachung während eines solchen Szenarios werden könnten. Sutton et al. [22] thematisieren darüber hinaus den Einsatz von *Backchannels* als einer besonderen Form des Data-Minings zur Informationsgewinnung. Weinmann und Jost [10] erläutern, dass „die Analyse terroristischer Onlinekommunikation, wie sie auf den entsprechenden Social Media-Seiten quasi offen einsehbar ist, [kann] uns viel über die Denkweise von Terroristen, ihre Motivation, ihre Pläne und Ängste verraten“ könne. Statt einer strengeren Zensur radikaler Inhalte sollen demnach „terroristische Kommunikationsstrategien durch einen Mix aus technischen (Hacking) und vor allem psychologischen (Gegenpropaganda) Mitteln“ [10] gestört werden. Hussain und Saltman [23] betonen, dass die generelle Zensur sogar kontraproduktiv sein kann und regen zu positiven Maßnahmen wie den Ausbau von Inhalten gegen den Extremismus an. Ebenfalls folgert Gartenstein-Ross [17], dass die Schwächung der strategischen Kommunikationskampagne des IS ein bedeutsamer Sieg wäre. Aber (glaubwürdige) Gegenpropaganda stammt nicht nur aus dem Ausland: Unter dem Stichwort „Anti IS Humor“ erläutert Al-Rawi [24], dass nach der Veröffentlichung eines ISIS-Videos mit religiösem Gesang Hunderte von arabischen YouTubern begannen, es in lustige Tanzclips zu verwandeln. Darüber ist eine Fokussierung auf Präventivmaßnahmen, auch in Kombination mit (offline) Aufkläraktionen in Schulen, Universitäten oder Gefängnissen, möglich [25].

Die bisherigen Erkenntnisse zur Gegenpropaganda liefern einen Ausgangspunkt für unsere Analyse. Wir explorieren Gegenpropaganda zur Terrorismusbekämpfung und versuchen diese zu systematisieren. In vielen Arbeiten liegt der Fokus auf der Rekrutierung neuer Mitglieder. Bilder und Videos sollen daher die jugendlichen Nutzer von Twitter durch ihre schnelle und einfache Konsumierung beeinflussen. Wir untersuchen und analysieren im Folgenden Gegenmaßnahmen am Beispiel von Twitter.

3 Explorative Studie der Terrorismusbekämpfung in Twitter

Im folgenden Kapitel wird zunächst die verwendete Methodik der Studie beschrieben, um anschließend die resultierenden Kategorien (I) Aufklärung, (II) Parodie/Satire und (III) Hacking hinsichtlich markanter Phänomene zu analysieren.

Methodik. Unsere Analyse fokussiert auf Gegenpropaganda in Tweets und vergleichen Aussagen der Terroristen mit denen von beispielsweise der US-Regierung oder den Medienberichten. Für die Analyse wurde eine qualitative Inhaltsanalyse angewendet. Hierfür war die Verkleinerung des Datenmaterials von Twitter nötig, sodass die Menge qualitativ handhabbar wurde [26]. Auf Twitter finden sich zahlreiche Accounts und Hashtags, die sich dem Kampf gegen den Terror widmeten.

Begonnen wurde die Recherche auf dem Account der US-Regierung @ThinkAgain_DOS, welche versucht, die Propaganda der terroristischen Organisationen aufzudecken. Von diesem Account wurden viele Hashtags wie #FreeTheWorld oder #VivaSAA gefunden, die der Terrorismusbekämpfung dienen. Dazu gehören #ThinkAgainTurnAway, #Daesh, #DaeshLiesExposed, #alleyesonISIS, #IstandwithSyria, #FreeTheWorld, #Syria, #ISIS, #trollingday, #trollingisis, #isismovies, #ISIL, #NotInOurName, #No2ISIS, #OpIceISIS und viele mehr. Außerdem konnten über die Twitter-Funktionalität (Vorschlag) mehrere User mit ähnlichen Interessen gefunden werden, z.B. @OYEQF, @QuilliamF, @Sil3nceBl4ck, @AnonymousMedia, @AntiTerrorismTR, @Active_Change_F. Das in jenen Accounts und Hashtags vom 1. bis 31. März 2016 identifizierbare Material wurde gesammelt und gespeichert.

Account/Hashtag	**Intention**	**Methode**
@ThinkAgain_DOS	Aufklärung	Verbreitung und Kommentierung aktueller Veröffentlichungen zum Thema
@AverageMohamed	Aufklärung	Informationsverbreitung mithilfe von Cartoons
@Operation_ISIL	Hacking	Aufruf durch Hashtags, auffällige Accounts zu melden
@isis_karaoke	Parodie / Satire	Posten von Fotos von IS-Kämpfern mit Zeilen aus bekannten Pop-Songs unter dem Motto „dropping songs, not bombs“
#TrollingISIS bzw. #TrollingDay	Parodie / Satire	Posten modifizierter, verhöhnender ISIS Bilder
#ISISChan bzw. ISIS_Chan	Parodie / Satire	Google-Bombe: Ergebnisse der Bildersuche zu „ISIS“ mit Darstellungen des Anime-Mädchens mit grünen Haaren im schwarzen Dschihadisten-Outfit mit einer Melone
#ISISCrappyCollageGrandPrix	Parodie / Satire	japanische Photoshop und Hashtag Kampagne zur Verhöhnung von IS-Kämpfern

Tabelle 1: Übersicht über ausgewählte Accounts und Hashtags, deren Intention und Vorgehen

Wir verdichteten das gefilterte Material, indem mithilfe von Open Coding [27] Kategorien erstellt wurden, aus denen wir schließlich spezifische Beispiele auswählten und exemplarisch analysierten. Eine Limitation ist die damit nicht erreichte Repräsentativität; diese war jedoch auch nicht das Ziel dieser Arbeit. Es geht hier nicht um die Bestätigung von vorab festgelegten Hypothesen, sondern um die Entwicklung von Hypothesen und Theorien aus dem Material [27]. Weiterhin können Bias-Effekte aufgrund des explorativen Vorgehens mit Identifikation markanter Merkmale nicht ausgeschlossen werden. Überdies wurden englische Tweets untersucht – somit fokussiert die Arbeit Wirkungen und Aktivitäten im englischsprachigen Raum.

Insgesamt ließen sich die gefundenen Posts, Hashtags und Accounts drei (nicht immer vollständig trennscharfen) Kategorien zuordnen: (I) Aufklärung, (II) Parodie/Satire und (III) Hacking. Diese basieren auf den im Codierungsprozess entstandenen und später verdichteten Unterkategorien (Presse, Bilder, Trolling, Anime, Grand Prix, Verulkung). Im Folgenden sollen die Hauptkategorien untersucht und jeweils exemplarische Beispiele daraus analysiert werden. Wir versuchen aus der Masse markante Phänomene herauszuarbeiten, was jedoch nicht immer gelingt. Beispielsweise sind in der Kategorie des Hackings Accounts und Trends schnelllebig und austauschbar. Sie ähneln sich so stark, dass kaum markante Unterschiede festgestellt werden können.

Kategorie I: Aufklärung. Unter Aufklärung verstehen wir die Versuche, der terroristischen Propaganda mit Logik zu antworten, um sie so außer Kraft zu setzten. Laut Duden ist es eine „völlige Klärung“ im Sinne einer „Darlegung, die über bisher unbekannte Zusammenhänge aufklärt“. Interessant sind die beiden Accounts @ThinkAgain_DOS und @AverageMohamed, da sie das gleiche Ziel haben, aber sehr verschieden arbeiten. @ThinkAgain_DOS sollte als offizieller US-Regierungs-Account zur Terrorbekämpfung auf Twitter eine Vorreiterrolle einnehmen. @AverageMohamed dagegen bekämpft den Terror, indem er versucht, mit Cartoons Informationen zu verbreiten. Die praktische Zielgruppe, die es zu untersuchen gilt, sind demnach die Accounts @ThinkAgain_DOS und @AverageMohamed, deren Aktivitäten der Aufklärung der Allgemeinheit sowie potenziellen IS-Anhängern gelten.

Abbildung 1: Tweet von @ThinkAgain_DOS

Abbildung 2: Tweet von @syrmukhabarat

Eine bekannte Methode stellt die Verbreitung und Kommentierung aktueller Veröffentlichungen zum Thema dar. Im @ThinkAgain_DOS Tweet (02.03.2016) verbreiten und kommentieren sie einen Artikel der Zeitung *The Independent* (Abbildung 1), der einen weiterführenden Link zu einem Bericht über britische Imame enthält, die sich im Irak über den Kampf gegen die ISIS informieren. Dies geschieht in der Hoffnung, dass die Imame ihre Eindrücke aus dem Irak zu Hause verbreiten und so der weiteren Radikalisierung entgegenwirken können. Wir sehen, dass die Maßnahme, auf die gesetzt wird, die Aufklärung über die tatsächlichen Gegebenheiten in IS

Gebieten innerhalb der sozialen Medien ist. @Selbyist hat auf den Tweet geantwortet: „*This will need thorough investigation. I don't trust that rag Independent, and who's paying for this, George fucking Soros?*” (02.03.2016). Dadurch wird zum einen „Independent“ als Quelle, der er/sie nicht vertraut, kritisiert und nach der Finanzierung gefragt. Hier erkennt man, dass Aufklärung nur über Medienberichte zur Glaubwürdigkeit nicht ausreicht.
